hostname on page 4387
prefix-delegation on page 4388

address <*ipv6 address*> lifetime

Use the **address lifetime** command to specify an Internet Protocol version 6 (IPv6) address is manually bound to a single Dynamic Host Control Protocol version 6 (DHCPv6) client, identified by its client ID (DUID). Use the **no** form of this command to remove the IPv6 address association from the host client. Variations of this command include:

address <*ipv6 address*> **lifetime** <*valid lifetime*> <*preferred lifetime*>
address <*ipv6 address*> **lifetime** <*valid lifetime*> **infinite**
address <*ipv6 address*> **lifetime infinite** <*preferred lifetime*>
address <*ipv6 address*> **lifetime infinite infinite**
address named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime** <*valid lifetime*> <*preferred lifetime*>
address named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime** <*valid lifetime*> **infinite**
address named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime infinite** <*preferred lifetime*>
address named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime infinite infinite**

Syntax Description

<*ipv6 address*>	Specifies the IPv6 address to assign to the single DHCPv6 client. There is no prefix length associated with this address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
named-prefix	Optional. Specifies that the address is constructed using the value defined in the named prefix.
<*prefix name*>	Specifies the name of the variable that holds the service provider assigned value for the IPv6 address prefix. The IPv6 prefix cannot be a link-local address.
<*ipv6 prefix/prefix-length*>	Specifies the numerical value and length of the IPv6 address prefix. The prefix value is specified in colon hexadecimal format (**X:X::X/<Z>**), for example: **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
<*valid lifetime*>	Specifies the valid lifetime of the IPv6 address. This value must be longer than the preferred lifetime value. Valid lifetime range is **0** to **4294967295** seconds. By default, the valid lifetime value is set to **2592000** seconds.
<*preferred lifetime*>	Specifies the preferred lifetime of the IPv6 address. This value must be shorter than the valid lifetime. Valid preferred lifetime range is **0** to **4294967295** seconds. By default, the preferred lifetime value is set to **604800** seconds.
infinite	Specifies that the IPv6 address does not age. This parameter can be used instead of either the valid lifetime or preferred lifetime value.

Default Values

By default, no IPv6 address is bound to a client.

Command History

Release R10.1.0	Command was introduced.
Release R10.9.0	Command was expanded to include the **named-prefix** parameter.

Functional Notes

Multiple IPv6 addresses (up to 50) can be entered for a single DUID using multiple instances of this command.

Usage Examples

The following example specifies that the IPv6 address **2001:DB8::1**, with infinite valid and preferred lifetimes, is assigned to the DHCPv6 host client **F2A4C9**:

(config-dhcpv6)**#host client-identifier F2A4C9**
(config-dhcpv6-host)**#address 2001:DB8::1 lifetime infinite infinite**

host client-identifier

Use the **host client-identifier** command to create a Dynamic Host Control Protocol version 6 (DHCPv6) host entry within the DHCPv6 Host Configuration mode. This command creates a host entry in the host server pool and specifies the manual binding of a set of information to a single client as identified by a DHCPv6 client ID (DUID). Use the **no** form of this command to remove the host client ID (DUID) from the host server pool. Variations of this command include:

host client-identifier <*client DUID*>
host client-identifier <*client DUID*> <*IAID*>

Syntax Description

<*client DUID*>	Specifies the DUID of the client to be matched as a DHCPv6 host. The DUID is expressed as a hexadecimal value.
<*IAID*>	Optional. Specifies a hexadecimal value that represents the IAID expected in the DHCPv6 client request.

Default Values

By default, no host DUID is specified.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

The value specified by this command is used to allow a single device, or interface, to match the DHCPv6 server pool host.

Usage Examples

The following example creates a DHCPv6 host DUID of **F2A4C9** in the DHCPv6 Host Configuration mode:

(config-dhcpv6)**#host client-identifier F2A4C9**
(config-dhcpv6-host)**#host client-identifier F2A4C8**

hostname

Use the **hostname** command to specify the manual binding of a host name or fully qualified domain name (FQDN) to the specified Dynamic Host Control Protocol version 6 (DHCPv6) client. Use the **no** form of this command to remove the host name or FQDN from the client. Variations of this command include:

hostname <*partial fqdn*>
hostname fqdn <*fqdn*>

Syntax Description

<*partial fqdn*>	Specifies the DHCPv6 client's host portion of its FQDN without a specified zone.
fqdn <*fqdn*>	Specifies the DHCPv6 client's entire FQDN.

Default Values

By default, no host names are specified.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example specifies an FQDN for the DHCPv6 client **F2A4C9**:

(config-dhcpv6)**#host client-identifier F2A4C9**
(config-dhcpv6-host)**#hostname fqdn host.company.com**

prefix-delegation

Use the **prefix-delegation** command to enable Internet Protocol version 6 (IPv6) address prefix delegation from the Dynamic Host Control Protocol version 6 (DHCPv6) server to a single DHCPv6 client, identified by its client ID (DUID . Use the **no** form of this command to disable IPv6 address prefix delegation. Variations of this command include:

prefix-delegation *<ipv6 prefix/prefix-length>*
prefix-delegation *<ipv6 prefix/prefix-length>* **lifetime** *<valid lifetime> <preferred lifetime>*
prefix-delegation *<ipv6 prefix/prefix-length>* **lifetime** *<valid lifetime>* **infinite**
prefix-delegation *<ipv6 prefix/prefix-length>* **lifetime infinite** *<preferred lifetime>*
prefix-delegation *<ipv6 prefix/prefix-length>* **lifetime infinite infinite**
prefix-delegation named-prefix *<prefix name> <ipv6 prefix/prefix-length>*
prefix-delegation named-prefix *<prefix name> <ipv6 prefix/prefix-length>* **lifetime** *<valid lifetime> <preferred lifetime>*
prefix-delegation named-prefix *<prefix name> <ipv6 prefix/prefix-length>* **lifetime** *<valid lifetime>* **infinite**
prefix-delegation named-prefix *<prefix name> <ipv6 prefix/prefix-length>* **lifetime infinite** *<preferred lifetime>*
prefix-delegation named-prefix *<prefix name> <ipv6 prefix/prefix-length>* **lifetime infinite infinite**

Syntax Description

<ipv6 prefix/prefix-length>	Specifies the numerical value and length of the IPv6 address prefix. The prefix value is specified in colon hexadecimal format (**X:X::X/<Z>**), for example: **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
named-prefix *<prefix name>*	Optional. Specifies that the address is constructed using the value defined in the named prefix and the name of the variable that holds the service provider assigned value for the IPv6 address prefix. The IPv6 prefix cannot be a link-local address. If a named prefix is used, the lifetime values are determined by the named prefix's configuration and do not need to be specified with this command.
lifetime	Optional. Specifies the lifetime of the IPv6 address prefix in the DHCPv6 server pool.
<valid lifetime>	Specifies the value of the valid lifetime for the IPv6 address prefix. This value must be greater than the preferred lifetime value. Valid lifetime range is **0** to **4294967295** seconds, with a default value of **2592000** seconds.
<preferred lifetime>	Specifies the preferred lifetime for the IPv6 address prefix. This value must be less than the valid lifetime value. Valid preferred lifetime range is **0** to **4294967295** seconds, with a default value of **604800** seconds.
infinite	Specifies that the prefix does not age.

Default Values

By default, no IPv6 address prefixes are specified or sent to the DHCPv6 client. By default, when using a named prefix with this command, the default lifetime values are those assigned by the delegating DHCPv6 server.

Command History

Release R11.1.0	Command was introduced.

Usage Examples

The following example enables IPv6 address prefix delegation for requesting DHCPv6 clients served by the server pool. This IPv6 address prefix is configured with **infinite** valid and preferred lifetimes.

```
(config-dhcpv6)#host client-identifier F2A4C9
(config-dhcpv6-host)#prefix-delegation 2001:DB8:3F::/64 infinite infinite
```

SERVICES COMMAND SETS

This section includes the following command sets:

COUNTER PROFILE CONFIGURATION COMMAND SET

The Counter Profile Configuration Command Set allows you to modify a profile for a counter. The profile can then be used to define the behavior of one or more dynamic counters. Dynamic counters allow you to set up a counter that monitors traffic as it is transmitted to, or received by any interface. In addition to the interface to be monitored, the virtual local area network (VLAN), VLAN priority bit, and color of the traffic can be specified.

Counter profiles are created and configured using the counter-profile command from the Global Configuration mode as follows:

```
>enable
#configure terminal
(config)#counter-profile 0/1
(config-count-prof 0/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76

All other commands for this command set are described in this section in alphabetical order.

color

Use the **color** command to include color marking in the selected counter profile. Use the **no** form of this command to remove color marking from the selected counter profile. Variations of this command include:

color green
color red
color yellow

Syntax Description

green	Marks packets that comply with CIR/CBS as green.
red	Marks packets that violate CIR/CBS and EIR/EBS as red.
yellow	Marks packets that violate CIR/CBS but comply with EIR/EBS as yellow.

Default Values

No default values are necessary for this command.

Command History

Release R10.11.0	Command was introduced.

Usage Examples

The following example marks packets that comply with CIR as ‘green’:

(config)**#counter-profile 0/1**
(config-count-prof 0/1)**#color green**

Technology Review

Color parameters represent bandwidth profiles. There are four basic profiles:

- CIR is the average rate up to which Service Frames are delivered. Service Frames are always sent at the User-to-Network (UNI) speed.
- Committed Burst Size (CBS) is the maximum number of bytes allowed for incoming Service Frames to still be CIR compliant.
- EIR is the average rate up to which excess Service Frames (frames whose average rate is greater than CIR) are admitted into the network.
- Excess Burst Size (EBS) is the maximum number of bytes allowed for incoming Service Frames to be EIR complaint.

A service frame is green if it is compliant with CIR/CBS of the bandwidth profile. A service frame is yellow if it is greater than the CIR/CBS of the profile, but less than the EIR/EBS. A service Frame is ‘Red’ if it is not compliant with either the CIR/CBS or EIR/EBS.

Green service frames are delivered per the performance objective and not generally discarded because they are in profile. Yellow service frames are out of profile, but are not typically discarded unless network conditions (for example, congestion) prevents delivery. Red service frames are out of profile and immediately discarded.

pbit <*number*>

Use the **pbit** command to include the virtual local area network (VLAN) priority bit in the matching criteria for the counter profile. Use the **no** form of this command to remove the VLAN priority bit from the matching critera.

Syntax Description

<*number*>	Specifies the value of the VLAN priority bit to be used for the matching criteria for the counter profile. Valid range is **0** to **7**.

Default Values

By default, the VLAN priority is not included in the matching criteria for counter profiles.

Command History

Release R10.11.0	Command was introduced.

Usage Examples

The following example adds VLAN priority **3** to the matching criteria for the counter profile:

(config)**#counter-profile 0/1**
(config-count-prof 0/1)**#pbit 3**

vlan

Use the **vlan** command to include the virtual local area network identifier (VLAN ID) to the matching criteria for the counter profile. Use the **no** form of this command to remove the VLAN ID from the matching criteria. Variations of this command include:

vlan <*vlan id*>
vlan none

Syntax Description

<*vlan id*>	Specifies the VLAN ID to include in the matching criteria for the counter profile. Valid range is **0** to **4094**.
none	Specifies that only untagged traffic is included in the matching criteria for the counter profile.

Default Values

By default, VLAN IDs are not included in the matching criteria for counter profiles.

Command History

Release R10.11.0	Command was introduced.

Usage Examples

The following example includes only untagged traffic in the matching criteria for the counter profile:

(config)**#counter-profile 0/1**
(config-count-prof 0/1)**#vlan none**

DESKTOP AUDITING LOCAL POLICY COMMAND SET

Desktop auditing is an AOS feature that uses Dynamic Host Configuration Protocol (DHCP) in conjunction with the Microsoft® Network Access Protection (NAP) Protocol to monitor the health of client computers connected to a NetVanta network. The two protocols work together to ensure that systems connected to the network are using appropriate corporate policies, such as appropriate firewall settings, antivirus settings, and other client health information. This information is exchanged between clients and servers in statement of health (SoH) and statement of health response (SoHR) messages.

Desktop auditing is configured on AOS products by enabling the feature and by optionally configuring filters to limit the output of the collected NAP information. These optional filters allow you to see who the policy violators are. When desktop auditing is enabled, the AOS product collects DHCP information, such as the medium access control (MAC) and IP addresses, virtual local area network (VLAN) ID, host name, and source port, as well as the MAC and IP addresses of the server and the date and time of the last DHCP information update. The NAP information collected by desktop auditing includes the client's OS version and service pack, processor architecture, firewall name and state, antivirus name and state, antispyware name and state, automatic update configuration, security update information, and the NAP state (enabled or disabled) of both the server and the client.

Desktop auditing local policies determine when a NAP client may be a violator by collecting NAP information for the connected clients and comparing them to the configured policies. It is possible to monitor clients' firewall states, antivirus states, antispyware states, auto-update states, and security update statuses using these policies. If no desktop auditing policies are configured, then, by default, desktop auditing monitors all NAP information for each client.

For more information about configuring desktop auditing, refer to the *Configuring Desktop Auditing in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Desktop auditing should be enabled on the AOS device before configuring the desktop auditing local policy. Desktop auditing is enabled using the command *desktop-auditing dhcp on page 1257*. To create a desktop auditing local policy and enter the policy's configuration mode, enter the **desktop-auditing local-policy** command from the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#desktop-auditing local-policy
(desktop-audit-policy)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the section listed below:

do on page 81
exit on page 83

All other commands in this command set are described in this section in alphabetical order:

anti-spyware current

Use the **anti-spyware current** command to define the local desktop auditing policy to monitor clients' antispyware status. If the antispyware is inactive, disabled, or not up-to-date, the client is a violator and its statistics will be collected. Using the **no** form of this command removes antispyware monitoring from the policy.

Syntax Description

No subcommands.

Default Values

By default, desktop monitoring local policies monitor all NAP information for each client.

Command History

Release 17.8	Command was introduced.

Usage Examples

The following example specifies that the local policy will monitor clients' antispyware status:

(config)**#desktop-auditing local-policy**
(desktop-audit-policy)**#anti-spyware current**

anti-virus current

Use the **anti-virus current** command to define the local desktop auditing policy to monitor clients' antivirus status. If the antivirus is inactive, disabled, or not up-to-date, the client is a violator and its statistics will be collected. Using the **no** form of this command removes antivirus monitoring from the policy.

Syntax Description

No subcommands.

Default Values

By default, desktop monitoring local policies monitor all NAP information for each client.

Command History

Release 17.8	Command was introduced.

Usage Examples

The following example specifies that the local policy will monitor clients' antivirus status:

(config)**#desktop-auditing local-policy**
(desktop-audit-policy)**#anti-virus current**

auto-update current

Use the **auto-update current** command to define the local desktop auditing policy to monitor clients' auto-update status. If the auto-updates are not configured to check for updates, download them, and install them automatically, then the client is a violator and its statistics will be collected. Using the **no** form of this command removes auto-update monitoring from the policy.

Syntax Description

No subcommands.

Default Values

By default, desktop monitoring local policies monitor all NAP information for each client.

Command History

Release 17.8	Command was introduced.

Usage Examples

The following example specifies that the local policy will monitor clients' auto-update status:

(config)**#desktop-auditing local-policy**
(desktop-audit-policy)**#auto-update current**

firewall enable

Use the **firewall enable** command to define the local desktop auditing policy to monitor clients' firewall states. If the firewall is disabled or inactive, the client is a violator and its statistics will be collected. Using the **no** form of this command removes firewall monitoring from the policy.

Syntax Description

No subcommands.

Default Values

By default, desktop monitoring local policies monitor all NAP information for each client.

Command History

Release 17.8	Command was introduced.

Usage Examples

The following example specifies that the local policy will monitor clients' firewall states:

(config)**#desktop-auditing local-policy**
(desktop-audit-policy)**#firewall enable**

security-update current

Use the **security-update current** command to define the local desktop auditing policy to monitor clients' security update status. If security updates are not current, the client is a violator and its statistics will be collected. Using the **no** form of this command removes security update monitoring from the policy.

Syntax Description

No subcommands.

Default Values

By default, desktop monitoring local policies monitor all NAP information for each client.

Command History

Release 17.8	Command was introduced.

Usage Examples

The following example specifies that the local policy will monitor clients' security update status:

(config)**#desktop-auditing local-policy**
(desktop-audit-policy)**#security-update current**

DYNAMIC COUNTER CONFIGURATION COMMAND SET

The Dynamic Counter Configuration Command Set allows you to create a dynamic counter. Dynamic counters are used to monitor traffic as it is transmitted to, or received from any interface. After a dynamic counter is created, it is assigned an interface to monitor and a counter profile that defines the matching criteria for traffic to monitor on the interface. For example, the counter profile can be configured to monitor any green traffic being received on a particular VLAN from a specified EFM bonding group, or it can be configured to monitor red traffic on a particular VLAN being discarded by the policer.

Dynamic counters are created and configured using the dynamic-counter command from the Global Configuration mode as follows:

```
>enable
#configure terminal
(config)#dynamic-counter 0/1
(config-dyn-count 0/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

set counter-profile <slot/index> on page 4403
set interface <interface> on page 4404

set counter-profile <*slot/index*>

Use the **set counter-profile** command to assign a specific counter profile to the dynamic counter. The counter profile is used to specify additional matching criteria for counting packets on the interface. Use the **no** form of this command to remove counter profile from the dynamic counter. Variations of this command include:

set counter-profile <*slot/index*> **exclude**
set counter-profile <*slot/index*> **include**

Syntax Description

<*slot/index*>	Specifies the index of the counter profile to assign to the dynamic counter in the format <*slot/index*>.
exclude	Specifies that the dynamic counter will count packets that do not match the counter profile.
include	Specifies that the dynamic counter will count packets that match the counter profile.

Default Values

No default values are necessary for this command.

Command History

Release R10.11.0	Command was introduced.

Functional Notes

A counter profile provides additional filtering capabilities to dynamic counters. Only one counter profile can be attached to each dynamic counter; however, a single counter profile can be attached to more than one dynamic counter.

Usage Examples

The following example specifies that the dynamic counter will count packets on the interface that match the criteria specified in counter profile **0/1**:

(config)**#dynamic-counter 0/1**
(config-dyn-count 0/1)**#set counter-profile 0/1 include**

set interface <*interface*>

Use the **set interface** command to specify an interface to be monitored by the dynamic counter. Use the **no** form of this command to remove the dynamic counter from the interface. Variations of this command include:

set interface <*interface*> **queue** <*queue*> **[congestion-drop | dqueue | enqueue]**
set interface <*interface*> **rx**
set interface <*interface*> **tx**

Syntax Description

<*interface*>	Specify an interface to be monitored by the dynamic counter in the format <*interface type [slot/port	slot/port.subinterface id	interface id	interface id.subinterface id	ap	ap/radio	ap/radio.vap]*>. For example, for a Gigabit Ethernet interface, use **gigabit-ethernet 0/1**; for an EFM group, use **efm-group 0/1**.
queue <*queue*>	Specifies that queue statistics for the specified queue will be collected by the dynamic counter. Valid range is **0** to **n**.
congestion-drop	Specifies that packets chosen by the congestion manager to be dropped rather than enqueued are counted.
dequeued	Specifies that packets that have successfully left the queue to be sent on the interface are counted.
enqueued	Specifes that packets that have entered the queue are counted.
rx	Specifies that packets recieved by the specified interface are counted.
dx	Specifies that packets transmitted by the specified interface are counted.

Default Values

No default values are necessary for this command.

Command History

Release R10.11.0	Command was introduced.

Usage Examples

The following example specifies that the dynamic counter will count packets received by Gigabit Ethernet interface **0/1**:

(config)**#dynamic-counter 0/1**
(config-dyn-count 0/1)**#set interface gigabit-ethernet 0/1 rx**

ETHERNET OAM CFM COMMAND SET

Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) is a type of service management for wide area network (WAN) Ethernet networks over an entire Ethernet service instance. Ethernet OAM CFM provides maintenance and monitoring within multiple network domains and different domain levels, and is specifically concerned with detecting faults over the service instance. Using a system of messages and notifications within the service domain, CFM can discover Ethernet service instance connection paths, locate and verify faults in the connection, isolate any discovered faults, give notification of discovered faults, and assist in fault recovery.

CFM operates between maintenance domains (MDs), MD levels, maintenance intermediate points (MIPs), and maintenance endpoints (MEPs). MDs are administrator domains of switches and routers, created for the purpose of managing a WAN network. Each MD is nested in a hierarchy, and these hierarchies create MD levels. Each level is specific to the MD, as each level is made up of a different MD along the service instance. These levels are created by the beginning and termination of MDs using MIPs and MEPs. MIPs are maintenance points within the MD, and MEPs are maintenance points that terminate the domain.

Ethernet OAM CFM in AOS deals specifically with MEPs in the AOS product. MEPs terminate Layer 2 traffic and are typically routers that convert Layer 2 traffic into a Layer 3 interface. CFM detects service connectivity problems by sending continuity check messages (CCMs) between MEPs, by sending path trace messages (Ethernet traceroute) between MEPs, and by sending loopback messages (Ethernet ping) between MEPs.

The Ethernet OAM CFM command set describes the commands needed for configuring MDs, maintenance associations (MAs), and MEPs. To enable Ethernet OAM CFM functionality, enter the command *ethernet cfm on page 1273* from the Global Configuration mode prompt as follows:

```
>enable
#configure terminal
(config)#ethernet cfm
(config)#
```

Once Ethernet OAM CFM is enabled, you must create a maintenance domain using the **ethernet cfm domain** <*name*> **level** <*level*> command (refer to *ethernet cfm domain on page 1274*). This command is entered from the Global Configuration mode prompt, and enters the maintenance domain configuration. Enter the command as follows:

```
>enable
#configure terminal
(config)#ethernet cfm domain domain1 level 6
(config-ecfm-domain)#
```

After entering the MD Configuration mode, you can access the MA Configuration mode, the MEP Configuration mode, and the Interface Configuration mode. The following command set describes commands common to all CFM Configuration modes, as well as those specific to maintenance association (MA), MEP, or Interface configurations. For more information regarding Ethernet OAM CFM and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
exit on page 83
interface on page 84

The following commands are MD configuration commands:

association <name> on page 4407
remote-mep hold-time <minutes> on page 4408

The **association** <*name*> command, as described in the MD configuration command section, creates an MA and enters the MA Configuration mode. The following commands are MA configuration commands:

ccm interval on page 4409
component <component> vlan on page 4410
mep-validation on page 4412
remote-mep <mep id> on page 4414

The **component** command, as described in the MA configuration command section, creates a component and enters the Component Configuration mode. The following commands are component configuration commands:

mp-sender-id on page 4415

Ethernet OAM CFM can also be configured at the interface level. CFM must be enabled and an MEP must be created at the interface level using the commands *ethernet-cfm down on page 2174* and *ethernet-cfm mep on page 2175* from the Ethernet or Ethernet subinterfaces. Once CFM is enabled and the MEP is created at the interface level, the MEP can be configured using the following commands:

alarm-priority-level on page 4416
alarm timers <alarm time> <reset time> on page 4418
ccm-enabled on page 4419
mep-enabled on page 4420
priority <value> on page 4421
snmp-trap fault alarm on page 4422

association *<name>*

Use the **association** command to create, enable, and enter the configuration of an Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) maintenance association (MA). Use the **no** form of this command to remove the association and its association maintenance endpoints (MEPs).

Syntax Description

<name>	Specifies the name of the MA. Names can be up to 42 characters in length.

Default Values

By default, no MAs exist.

Command History

Release 17.4	Command was introduced.

Functional Notes

For more information regarding Ethernet OAM CFM and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables and creates MA **association1** from the Maintenance Domain (MD) Configuration mode, and enters the MA Configuration mode:

```
(config)#ethernet cfm domain domain1 level 6
(config-ecfm-domain)#association association1
(config-ecfm-assoc)#
```

remote-mep hold-time <*minutes*>

Use the **remote-mep hold-time** command to specify the length of time an associated maintenance endpoint (MEP) remains in the maintenance domain's (MD's) remote MEP database after the MEP has entered a failed state. Use the **no** form of this command to return to the default value.

Syntax Description

<*minutes*>	Specifies the length of time the associated MEP remains in the MD's MEP database after the MEP has failed. Range is **1** to **65535** minutes.

Default Values

By default, MEPs remain in the MD's MEP database for **100** minutes.

Command History

Release 17.4	Command was introduced.

Functional Notes

Each MEP that is created is associated with a particular MD. The MDs maintain an MEP database of remote MEPs, listing all configured and associated remote MEPs within the system. When a remote MEP fails, it can be removed from this database after a specified amount of time. When the remote MEP entry is purged, any errors logged relating to the remote MEP are also purged.

For more information regarding Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that remote MEP entries are purged from the MD's remote MEP database after **60** minutes:

```
(config)#ethernet cfm domain domain1 level 6
(config-ecfm-domain)#remote-mep hold-time 60
(config-ecfm-domain)#
```

ccm interval

Use the **ccm interval** command to specify how frequently maintenance endpoints (MEPs) of this association send continuity check messages (CCMs). Use the **no** form of this command to return to the default value. Variations of this command include:

ccm interval 100ms
ccm interval 1s
ccm interval 10s
ccm interval 1m
ccm interval 10m

Syntax Description

100ms	Specifies the interval as 100 milliseconds.
1s	Specifies the interval as 1 second.
10s	Specifies the interval as 10 seconds.
1m	Specifies the interval as 1 minute.
10m	Specifies the interval as 10 minutes.

Default Values

By default, the continuity check message (CCM) interval is set to **1** second.

Command History

Release 17.4	Command was introduced.

Functional Notes

For more information regarding Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example sets the CCM interval to **1** minute:

```
(config-ecfm-domain)#association association1
(config-ecfm-assoc)#ccm interval 1m
(config-ecfm-assoc)#
```

component <*component*> vlan

Use the **component vlan** command to create a set of virtual local area networks (VLANs) as a fixed group on a particular component and assign these VLANs to be protected by the maintenance association (MA) on this component. The command also enters the Component Configuration mode. The **no** form of this command removes the component definition from the association. Variations of this command include:

component <*component*> **vlan none**
component <*component*> **vlan** <*vlan id*>

Syntax Description

<*component*>	Specifies the component to be added to the MA. Components are specified in the form <*component type [slot/port]*>. For example, for an Ethernet component, use **eth 0/1**. To discover available components, enter **component ?** at the prompt.
vlan none	Specifies that this MA component is not attached to a virtual local area network (VLAN).
vlan <*vlan id*>	Specifies to which VLAN this MA component is attached. VLAN IDs range from **1** to **4094**.

Default Values

By default, no component is defined.

Command History

Release 17.4	Command was introduced.
Release A5.01	Command was expanded to include the Gigabit Ethernet component.

Functional Notes

At least one component must be added to each MA. The components and VLANs are associated so that the VLANs are protected by the MA to which the component belongs. The first VLAN ID listed is the primary VLAN ID for the entry being created.

A component must be configured on a VLAN before you can configure its associated maintenance endpoint (MEP).

For more information regarding Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures an **Ethernet** component that is associated with **vlan 5**, and enters the Component Configuration mode:

(config-ecfm-domain)**#association association1**
(config-ecfm-assoc)**#component ethernet 0/1 vlan 5**
(config-ecfm-ma-comp)#

mep-validation

Use the **mep-validation** command to specify whether or not maintenance endpoints (MEPs) use a comparison between their continuity check message (CCM) database (received CCMs) and their list of configured remote MEPs (that should be sending CCMs) to generate an alarm when a mismatch is discovered. The **no** form of this command disables MEP validation. Variations of this command include:

mep-validation
mep-validation start-delay *<delay>*

Syntax Description

start-delay *<delay>*	Optional. Specifies a delay (in seconds) that the MEP will wait before enforcing MEP validation. Delay range is **1** to **65535** seconds.

Default Values

By default, MEP validation is enabled with a delay of **30** seconds.

Command History

Release 17.4	Command was introduced.

Functional Notes

The MEP validation is used to compare an MEP's list of received CCMs with a list of MEPs that should be sending CCMs. When MEP validation is enabled, an alarm is sent when a mismatch is discovered. By default, each MEP validates their MEP list, and all CCMs received must correspond to preconfigured remote MEPs in the maintenance association (MA).

Disabling validation (using the **no** form of the command), or changing the start delay, can be useful when creating a domain association or when troubleshooting. Disabling validation in these circumstances prevents unnecessary alarms and warnings. For example, if you wish to allow the unit to dynamically learn its remote MEPs rather than manually entering them, disabling validation allows you to do that without generating unnecessary alarms.

For more information regarding Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example disables MEP validation:

(config-ecfm-domain)**#association association1**
(config-ecfm-assoc)**#no mep-validation**
(config-ecfm-assoc)#

The following example changes the delay interval to **1000** seconds:

(config-ecfm-domain)**#association association1**
(config-ecfm-assoc)**#mep-validation start-delay 1000**
(config-ecfm-assoc)#

remote-mep *<mep id>*

Use the **remote-mep** command to create a list of remote maintenance endpoints (MEPs) for this association. Use the **no** form of this command to remove the MEP from the list.

Syntax Description

<mep id>	Specifies the unique ID given to the MEP. MEP ID range is **1** to **8191**.

Default Values

By default, no remote MEPs are listed.

Command History

Release 17.4	Command was introduced.

Functional Notes

Using the **remote-mep** command populates the maintenance association's (MA's) remote MEP list. Remote MEPs are MEPs not on this device, but communicate with other MEPs in the same MA. Local MEPs, or those on the same device, are automatically listed.

Each MEP ID is stored and can be compared to the MEP's continuity check message (CCM) database learned by listening to CCMs from other MEPs in the network. This allows each MEP to determine if it is receiving CCMs from expected MEPs, as well as detect any unexpected MEPs in the network.

You will need to repeat this command as many times as necessary to populate the MA's remote MEP list with all of the remote MEPs in your network.

For more information regarding Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example adds the remote MEP with the MEP ID of **1000** to this association's remote MEP list:

```
(config-ecfm-domain)#association association1
(config-ecfm-assoc)#remote-mep 1000
(config-ecfm-assoc)#
```

mp-sender-id

Use the **mp-sender-id** command to enable each maintenance endpoint (MEP) in this association to send sender ID type length values (TLVs) in transmitted packets. Use the **no** form of this command to revert the sender ID setting to that of the parent association. Variations of this command include:

mp-sender-id chassis-id
mp-sender-id chassis-id management-address
mp-sender-id management-address
mp-sender-id management-address chassis-id
mp-sender-id none

Syntax Description

chassis-id	Specifies that the chassis IDs are transmitted.
management-address	Specifies that management addresses are transmitted.
none	Specifies that no sender ID is transmitted.

Default Values

By default, the MEP's sender ID setting is the same as that of the parent association.

Command History

Release 17.4	Command was introduced.

Functional Notes

TLVs are included in continuity check messages (CCMs) and used in Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) fault detection.

It is important to note how the **chassis ID** and **management address** are created for the system. The chassis ID is created either from Simple Network Management Protocol (SNMP), using the command *snmp-server chassis-id "<string>" on page 1786*, or if SNMP is not configured, using the system medium access control (MAC) address. The management address is created either from SNMP through the primary IP of the source interface shown in the command *snmp-server source-interface <interface> on page 1819*, or if SNMP is not configured, using the primary IP of the MEP's interface.

For more information regarding Ethernet OAM CFM and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that MEPs in this association include their **chassis ID** in the sender ID TLVs:

```
(config-ecfm-domain)#association association1
(config-ecfm-ma-comp)#mp-sender-id chassis-id
(config-ecfm-ma-comp)#
```

alarm-priority-level

Use the **alarm-priority-level** command to configure the lowest level priority condition that generates an alarm on this maintenance endpoint (MEP). Use the **no** form of this command to return to the default priority condition. Variations of this command include:

alarm-priority-level errorccm
alarm-priority-level macstatus
alarm-priority-level none
alarm-priority-level rdi-ccm
alarm-priority-level remoteccm
alarm-priority-level xconccm

Syntax Description

errorccm	Specifies that priority conditions of **4** or higher generate alarms.
macstatus	Specifies that priority conditions of **2** or higher generate alarms.
none	Specifies that no priority conditions generate alarms.
rdi-ccm	Specifies that priority conditions of **1** or higher generate alarms.
remoteccm	Specifies that priority conditions of **3** or higher generate alarms.
xconccm	Specifies that priority conditions of **5** or higher generate alarms.

Default Values

By default, priority conditions of **1** or higher generate alarms.

Command History

Release 17.4	Command was introduced.

Functional Notes

Alarm notifications are sent either by using the AOS event priority system or through Simple Network Management Protocol (SNMP) notification. The alarms are sent as priority 1 (error), and cleared alarms are sent as priority 3 (notice). SNMP notification of alarms are sent to the fault alarm address configured on the MEP reporting the fault. No SNMP notification is sent when an alarm clears. You can specify using SNMP notification for alarms by using the command *snmp-trap fault alarm on page 4422*.

For more information regarding Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

The following table describes the five Ethernet OAM CFM defect conditions, as well as the root cause, the priority, and the importance of each.

Defect	Description	Cause(s)	Priority	Importance
DefXconCCM	Indicates an MEP that could be from another MA is sending CCMs to an MEP in this MA.	The CCM received is from an MEP that does not have a MAID that matches the local MEP's MAID, or that the transmitting MEP has an MD level lower than the local MEP's.	5	Highest
DefErrorCCM	Indicates erroneous CCMs are being received from some MEP in the local MEP's MA.	The transmitting MEP's ID is not in the MA's configured list of remote MEPs, the MEP ID is not the same as the receiving MEP's ID, or the CCM interval does not match the configured value.	4	
DefRemoteCCM	Indicates the local MEP is not receiving CCMs from an MEP in its configured list.	An MEP in this MEP's configured list has not sent a CCM in three CCM intervals.	3	
DefMACStatus	Indicates the last CCM received by this MEP from another MEP indicated the other MEP's associated MAC is reporting an error status via the Port or Interface Status TLV.	Either all remote MEPs are reporting Port Status TLV errors, or at least one remote MEP is reporting an Interface Status TLV error.	2	
DefRDICCM	Indicates the last CCM received by this MEP from some remote MEP contained the remote defect indication (RDI) bit.	At least one MEP is reporting RDI.	1	Lowest

Usage Examples

The following example specifies that events of a priority **3** or higher generate alarms:

(config-eth 0/1)**#ethernet-cfm mep Domain1 association1 100 down**
(config-eth 0/1-mep)**#alarm-priority-level remoteccm**
(config-eth 0/1-mep)#

alarm timers *<alarm time> <reset time>*

Use the **alarm timers** command to specify the amount of time a defect condition must occur in the maintenance endpoint (MEP) before it triggers an alarm and how long a defect condition must be absent before a new alarm can be triggered. Use the **no** form of this command to set the timers to their default value.

Syntax Description

<alarm time>	Specifies the time that a defect condition must be present before it is eligible to be reported as an alarm. Range is **2500** to **10000** milliseconds.
<reset time>	Specifies the time that defects must be absent before alarms are reset such that a new alarm can be triggered. Range is **2500** to **10000** milliseconds.

Default Values

By default, the alarm time is **2500** ms and the reset time is **10000** ms.

Command History

Release 17.4	Command was introduced.

Functional Notes

Timer values are stored in 1/1000 of a second. Therefore, entering the command as follows:

alarm timers 2514 10239

stores the timer values as **2510** and **10230**.

Defect conditions are the problems detected by Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM). These conditions are detailed in the *Functional Notes* section of the **alarm-priority-level** command. For more information on defect conditions and Ethernet OAM CFM in general, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the alarm time is **3000** ms and the reset time is **6000** ms for this MEP's alarm timers:

```
(config-eth 0/1)#ethernet-cfm mep Domain1 association1 100 down
(config-eth 0/1-mep)#alarm timers 3000 6000
(config-eth 0/1-mep)#
```

ccm-enabled

Use the **ccm-enabled** command to enable maintenance endpoint (MEP) continuity check message (CCM) transmissions. Use the **no** form of this command to disable CCM transmissions on the MEP.

Syntax Description

No subcommands.

Default Values

By default, CCM transmissions are disabled.

Command History

Release 17.4	Command was introduced.

Functional Notes

Even when CCM transmissions are disabled, the MEP can still process received CCMs.

For more information regarding Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables CCM transmissions on the MEP:

```
(config-eth 0/1)#ethernet-cfm mep Domain1 association1 100 down
(config-eth 0/1-mep)#ccm-enabled
(config-eth 0/1-mep)#
```

mep-enabled

Use the **mep-enabled** command to enable the maintenance endpoint (MEP) and all the MEPs in its association. Use the **no** form of this command to halt all associated MEP functionality for this MEP.

Syntax Description

No subcommands.

Default Values

By default, all MEPs are disabled.

Command History

Release 17.4	Command was introduced.

Functional Notes

When an MEP is disabled, no frames are sent or received by the MEP, but all other configuration properties are retained.

For more information regarding Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM), refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables an MEP:

```
(config-eth 0/1)#ethernet-cfm mep Domain1 association1 100 down
(config-eth 0/1-mep)#mep-enabled
(config-eth 0/1-mep)#
```

priority *<value>*

Use the **priority** command to specify the 802.1p priority given to Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) frames and linktrace messages transmitted by the maintenance endpoint (MEP). Use the **no** form of this command to return the priority to the default value.

Syntax Description

<value>	Specifies the priority. Range is **0** to **7**.

Default Values

By default, the priority value is **7**.

Command History

Release 17.4	Command was introduced.

Functional Notes

Priority only applies to CFM frames if the MEP's interface supports virtual local area network (VLAN) tags and the message will be sent with a tag.

For more information regarding Ethernet OAM CFM, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies a priority of **3** for CFM frames and linktrace messages transmitted by this MEP:

```
(config-eth 0/1)#ethernet-cfm mep Domain1 association1 100 down
(config-eth 0/1-mep)#priority 3
(config-eth 0/1-mep)#
```

snmp-trap fault alarm

Use the **snmp-trap fault alarm** command to configure and send Simple Network Management Protocol (SNMP) traps for fault alarms generated from a maintenance endpoint (MEP). Use the **no** form of this command to disable SNMP fault alarm notification.

Syntax Description

No subcommands.

Default Values

By default, SNMP fault alarm notification is disabled.

Command History

Release 17.4	Command was introduced.

Functional Notes

SNMP notification is an alternate method to configuring and receiving Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) alarm notifications through the AOS event priority system. SNMP notifications of alarms are sent to the fault alarm address configured on the MEP reporting the fault. No SNMP notification is sent when an alarm clears.

For more information regarding Ethernet OAM CFM, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables SNMP notification for alarm notifications from this MEP:

```
(config-eth 0/1)#ethernet-cfm mep Domain1 association1 100 down
(config-eth 0/1-mep)#snmp-trap fault alarm
(config-eth 0/1-mep)#
```

MAIL AGENT COMMAND SET

The mail agent feature of Adtran Operating System (AOS) provides a method of adding email notification to any AOS feature. The mail agent is configured through the command line interface (CLI) and operates with any AOS feature that has configuration or **show** commands. The mail agent captures output from specified commands and emails them to a specified address in the body of an email message. Email messages are created when a specified event occurs, and are mailed on a specified schedule. Multiple mail agents can be configured and used at one time. For more information about the creation of mail agents and their capabilities, refer to the *Generic Mail Agent quick configuration guide* available online at https://supportcommunity.adtran.com.

To activate the Mail Agent Configuration mode, enter the **mail-client** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#mail-client myagent
(config-mail-client-myagent)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

address on page 4424
body size <bytes> on page 4425
capture commands on page 4426
capture header on page 4427
capture trigger on page 4428
send test on page 4430
send trigger on page 4431
server <dns-name/ip address> on page 4432
subject <text> on page 4433

address

Use the **address** command to specify the CC, From, and To fields in the email messages. Use the **no** form of this command to remove the specified information from the email header. Variations of this command include:

address cc *<email address(es)>*
address from *<email address(es)>*
address to *<email address>*

Syntax Description

cc *<email address(es)>*	Specifies the CC field in the email message. Multiple email addresses are separated by semicolons.
from *<email address(es)>*	Specifies the From field in the email message. Multiple email addresses are separated by semicolons.
to *<email address>*	Specifies the To field in the email message.

Default Values

By default, the CC value is empty. The To default value is set using the command *logging email address-list <email address> ; <email address> on page 1582* and the From default value is set using the command *logging email sender on page 1594*.

Command History

Release 17.2	Command was introduced.

Functional Notes

The **address to** command uses a default value from the command *logging email address-list <email address> ; <email address> on page 1582*. If the **logging email address-list** command has been configured, and the mail agent notification will go to the same email, using the **address to** command is not necessary.

Usage Examples

The following example configures the CC, From, and To fields in the email notification sent by mail agent **myagent**:

(config)**#mail-client myagent**
(config-mail-client-myagent)**#address to manager@company.net**
(config-mail-client-myagent)**#address cc fellowemployee@company.net; assistntmngr@company.net**
(config-mail-client-myagent)**#address from goodemployee@company.net**

body size <*bytes*>

Use the **body size** command to set the maximum buffer size for the body text of the email message. Use the **no** form of this command to return to the default value.

Syntax Description

<*bytes*>	Specifies the maximum number of bytes the buffer holds. Range is **1** to **65535** bytes.

Default Values

By default, the buffer size is set to **4048** bytes.

Command History

Release 17.2	Command was introduced.

Functional Notes

All output generated after the buffer size has been reached will be ignored.

Usage Examples

The following example sets the body text buffer size to **6000** bytes for mail agent **myagent**:

(config)**#mail-client myagent**
(config-mail-client-myagent)**#body size 6000**

capture commands

Use the **capture commands** command to specify the command output to capture and include in the body of the email. Use the **no** form of this command to remove the specified commands.

Syntax Description

No subcommands.

Default Values

By default, no commands are specified.

Command History

Release 17.2	Command was introduced.

Functional Notes

The **capture commands** command specifies the command output to be captured by the mail agent. **Show** and **tcl** commands can be captured. When the **capture commands** command is entered, each command to be captured is specified with the **do** keyword followed by the command. The terminal configuration mode is enabled by default for the **capture commands** command, making it necessary to use the keyword **do**. List all commands to be sent in a single notification, followed by the **exit** keyword.

Usage Examples

The following example specifies that the mail agent **myagent** will capture the output from the **show ip route** and **show clock** commands:

(config)**#mail-client myagent**
(config-mail-client-myagent)**#capture commands**
Enter the commands you wish to run, one line at a time.
Entries are run from the terminal configuration prompt.
For example, you must enter ‘do show run’ or ‘int eth 0/1’.
When finished, type ‘exit’ on a new line to end.
#do show ip route
#do show clock
#exit
(config-mail-client-myagent)#

capture header

Use the **capture header** command to specify that header information (ASCII demarcation and a timestamp) is included when command output is captured. Use the **no** form of this command to remove the header information from captured command output.

Syntax Description

No subcommands.

Default Values

By default, header information is included in captured command output.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example removes header information from the captured command output for mail agent **myagent**:

```
(config)#mail-client myagent
(config-mail-client-myagent)#no capture header
```

capture trigger

Use the **capture trigger** command to configure the trigger that causes the mail agent to capture the command output. Use the **no** form of this command to remove the trigger. Variations of this command include:

capture trigger
capture trigger track <*name*> **fail**
capture trigger track <*name*> **pass**

Syntax Description

track <*name*> **fail**	Optional. Specifies the command output is captured when the named track changes from a pass state to a fail state.
track <*name*> **pass**	Optional. Specifies the command output is captured when the named track changes from a fail state to a pass state.

Default Values

By default, no tracks are configured and no trigger is defined.

Command History

Release 17.2	Command was introduced.

Functional Notes

If no trigger is specified, the mail agent will immediately run the specified commands and capture their output. If a track is specified as the capture trigger, the command output will be captured every time the track switches to the specified state. The track used should be a preconfigured track with an associated schedule. The track will change states when its associated schedule becomes active or inactive. For more information on schedules, refer to *schedule <name> on page 1695*. For more information on tracks, refer to the *Network Monitor Track Command Set on page 4098* of this guide. For more information on the functions of tracks and schedules as part of the mail agent feature, refer to the *Generic Mail Agent quick configuration guide* available online at https://supportcommunity.adtran.com.

The command *send trigger on page 4431* can be used without the **capture trigger** command. If only the **send trigger** command is used, the **send trigger** command will function as the **capture trigger** command and immediately capture the command output and send an email of the captured output. If both commands are used, the command output is captured at the time the capture trigger occurs, and then an email is sent at the time the send trigger occurs.

Usage Examples

The following example specifies that when the track **mail** changes to a **pass** state, the mail agent **myagent** will capture command output:

(config)**#mail-client myagent**
(config-mail-client-myagent)**#capture trigger track mail pass**

send test

Use the **send test** command to have the mail agent send a test email message to the email address(es) specified by the **address to** command (refer to *address on page 4424*) or the **logging email address-list** command (refer to *logging email address-list <email address> ; <email address> on page 1582*).

Syntax Description

No subcommands.

Default Values

By default, the test email is sent using your Simple Mail Transfer Protocol (SMTP) settings even if the mail client is currently shut down.

Command History

Release 17.2	Command was introduced.

Functional Notes

The command appends “This is a test message” onto the current message buffer and sends an email to the configured addresses. This command is used to test that the agent is sending emails to the proper addresses.

Usage Examples

The following example instructs mail agent **myagent** to send a test email to the previously configured email addresses:

(config)**#mail-client myagent**
(config-mail-client-myagent)**#send test**

send trigger

Use the **send trigger** command to configure when an email with command output is sent to the email address(es) specified by the **address to** command (refer to *address on page 4424*) or the **logging email address-list** command (refer to *logging email address-list <email address> ; <email address> on page 1582*). Use the **no** form of this command to remove the configuration. Variations of this command include:

send trigger
send trigger track <*name*> **fail**
send trigger track <*name*> **pass**

Syntax Description

track <*name*> **fail**	Optional. Specifies the email message is sent when the named track changes from a pass state to a fail state.
track <*name*> **pass**	Optional. Specifies the email message is sent when the named track changes from a fail state to a pass state.

Default Values

By default, no email is sent.

Command History

Release 17.2	Command was introduced.

Functional Notes

If no trigger is specified, the mail agent will immediately send the email. If a track is specified as the send trigger, the email will be sent every time the track switches to the specified state. The track used should be a preconfigured track with an associated schedule. The track will change states when its associated schedule becomes active or inactive. For more information on schedules, refer to the command *schedule <name> on page 1695*. For more information on tracks, refer to the *Network Monitor Track Command Set on page 4098* of this guide. For more information on the functions of tracks and schedules as part of the mail agent feature, refer to the *Generic Mail Agent quick configuration guide* available online at https://supportcommunity.adtran.com.

The **send trigger** command can be used without the **capture trigger** command (refer to *capture trigger on page 4428*). If only the **send trigger** command is used, the **send trigger** command will function as the **capture trigger** command and immediately capture the command output and send an email of the captured output. If both commands are used, the command output is captured at the time the capture trigger occurs, and then an email is sent at the time the send trigger occurs.

Usage Examples

The following example specifies when the track named **sendmail** changes to a **fail** state, mail agent **myagent** will send an email with captured command output:

(config)**#mail-client myagent**
(config-mail-client-myagent)**#send trigger track sendmail fail**

server *<dns-name/ip address>*

Use the **server** command to specify the Simple Mail Transfer Protocol (SMTP) server for sending mail agent notifications. Use the **no** form of this command to return the server setup to the default value.

Syntax Description

<dns-name>	Specifies the domain naming system (DNS) name of the SMTP server.
<ip address>	Specifies the IP address of the SMTP server. IP addresses are expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, the SMTP server is set to the value defined by the command *logging email receiver-ip <ipv4 address | hostname> on page 1591*.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example specifies that mail agent **myagent** use the SMTP server at IP address **172.5.67.99** to send email messages:

(config)**#mail-client myagent**
(config-mail-client-myagent)**#server 172.5.67.99**

subject <*text*>

Use the **subject** command to specify the Subject field in the mail agent email message. Use the **no** form of this command to clear the Subject field.

Syntax Description

<*text*>	Specifies the text of the Subject field.

Default Values

By default, this field is empty.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example specifies a Subject of **report1** for the email message sent my mail agent **myagent**:

(config)**#mail-client myagent**
(config-mail-client-myagent)**#subject report1**

NETWORK SYNC COMMAND SET

Network synchronization (Network Sync) is a networking feature that provides clock synchronization at the physical network layer through Ethernet and Digital Subscriber Line (DSL) ports. The feature synchronizes clock frequency on a port by timing the interface's bit clock from clock signals received over the physical layer of the network. By using the physical layer, rather than an external time division multiplexed (TDM) circuit, remote network elements can receive reliable timing information through the packet network.

Network Sync uses messages through the Ethernet Synchronization Message Channel (ESMC) to provide clock information to remote network elements. The ESMC funnels synchronization status messages (SSMs) that indicate the quality level of a synchronization signal. Synchronization information is transmitted to the network elements through an egress clock, and the ESMC communications provide timing from the most reliable sources. Configuration of Network Sync in AOS depends upon, at a minimum, configuring a connection from which synchronization signals are recovered and a connection to which synchronization information is transmitted.

To access the Network Sync Configuration mode, enter the **network-sync** command from the Global Configuration mode as follows:

```
#configure terminal
(config)#network-sync
(config-ntwk-sync)#
```

The following command is common to multiple command sets and is covered in a centralized section of this guide. For more information, refer to the section listed below:

exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

connect on page 4435
eec-option on page 4437
esmc-process on page 4438
holdover threshold eec on page 4439
revertive priority on page 4440
ssm-override <input> on page 4441
transmit-ql-threshold <input> on page 4443
wait-to-restore <value> on page 4445

connect

Use the **connect** command to specify the interfaces from which clock information is recovered and to which clock information is transmitted. Clock information is typically recovered from network-to-network interfaces (NNIs) and typically transmitted to user-to-network interfaces (UNIs). Use the **no** form of this command to remove the interface from the network synchronization (Network Sync) configuration. Variations of this command include:

connect <*interface*> **recover primary**
connect <*interface*> **recover primary ssm**
connect <*interface*> **recover primary no-ssm**
connect <*interface*> **recover secondary**
connect <*interface*> **recover secondary ssm**
connect <*interface*> **recover secondary no-ssm**
connect <*interface*> **transmit**
connect <*interface*> **transmit ssm**
connect <*interface*> **transmit no-ssm**

Syntax Description

<*interface*>	Specifies the interface from which clock information is recovered, and to which clock information is sent. Specify interfaces in the format **interface type** <*slot/port*>. Available interfaces for Network Sync configuration are Gigabit Ethernet, single-pair high-speed digital subscriber line (SHDSL), and very high-speed digital subscriber line (VDSL) interfaces.
recover	Specifies that the interface is one from which clock information is recovered.
primary	Specifies the interface is the primary source for clock information.
secondary	Specifies the interface is the secondary source for clock information.
transmit	Specifies that the interface is one to which clock information is transmitted.
ssm	Optional. Specifies that SSMs are received on source interfaces and transmitted on receiving interfaces.
no-ssm	Optional. Specifies that SSMs are not received on source interfaces and are not transmitted on receiving interfaces.

Default Values

By default, no interfaces are specified for use with Network Sync. When interfaces are configured for Network Sync, SSM is enabled by default.

Command History

Release R10.11.0	Command was introduced.

Functional Notes

For Network Sync to function, you must configure at least one interface as a clock source and one interface to which clock information is sent.

Usage Examples

The following example adds an interface to the Network Sync configuration as a primary clock source:

(config)**#network-sync**
(config-ntwk-sync)**#connect gigabit-ethernet 0/1 recover primary**

The following example specifies that Network Sync clock information is sent to the interface:

(config)**#network-sync**
(config-ntwk-sync)**#connect gigabit-ethernet 0/2 transmit**

eec-option

Use the **eec-option** command to specify which Ethernet equipment clock (EEC) option network synchronization (Network Sync) uses. Depending on the EEC option selected, available synchronization status message (SSM) override settings will differ (refer to the command *ssm-override <input> on page 4441*). Use the **no** form of this command to return to the default EEC option. Variations of this command include:

eec-option option1
eec-option option2

Syntax Description

option1	Specifies that EEC option 1 is used. This option is typically used in European networks.
option2	Specifies that EEC option 2 is used. This option is typically used in networks in the United States.

Default Values

By default, Network Sync uses EEC **option2**.

Command History

Release R10.11.0	Command was introduced.

Usage Examples

The following example changes the Network Sync EEC option:

(config)**#network-sync**
(config-ntwk-sync)**#eec-option option1**

esmc-process

Use the **esmc-process** command to enable Ethernet Synchronization Message Channel (ESMC) processing for network synchronization (Network Sync). ESMC processing provides a method for selecting the highest quality synchronization signal for remote network elements. Use the **no** form of this command to disable ESMC processing.

Syntax Description

No subcommands.

Default Values

By default, ESMC processing is disabled.

Command History

Release R10.11.0	Command was introduced.

Usage Examples

The following example enables Network Sync ESMC processing:

(config)**#network-sync**
(config-ntwk-sync)**#esmc-process**

holdover threshold eec

Use the **holdover threshold eec** command to enable the threshold for network synchronization (Network Sync) holdover mode. Use the **no** form of this command to remove the holdover threshold.

Syntax Description

No subcommands.

Default Values

By default, no holdover threshold is set. When the threshold is enabled, holdover is activated when the clock source quality is not greater than QL-EEC2.

Command History

Release R10.11.0	Command was introduced.

Functional Notes

This command is used when the Ethernet Synchronization Message Channel (ESMC) process is active and when a recovered clock source is configured to receive synchronization status messages (SSMs). It affects operation when the received quality level is equal to that of an EEC. This is either QL-EEC1 or QL-EEC2, depending on whether EEC option 1 or EEC option 2 has been selected (refer to the command *eec-option on page 4437*). By default, a source is considered DOWN when its received quality level is at EEC. In this scenario, if there is a need for the source to stay UP, enter the **holdover threshold eec** command.

Below EEC, a source is always DOWN. Also, it is DOWN if the physical characteristics of its recovered clock are out of tolerance. When a source is DOWN, it is excluded from the network synchronization selection process. When all sources are DOWN, the unit goes into holdover mode.

Usage Examples

The following example keeps the source in an UP state:

(config)**#network-sync**
(config-ntwk-sync)**#holdover threshold eec**

revertive priority

Use the **revertive priority** command to specify that the network synchronization (Network Sync) clock selection is revertive based on clock priority. Use the **no** command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is enabled.

Command History

Release R10.11.0	Command was introduced.

Functional Notes

Revertive clock selection means that if a clock source with a higher quality clock recovers after going down, Network Sync transitions back to the higher quality clock source as opposed to remaining on the currently selected clock source.

Usage Examples

The following example disables the revertive clock selection:

(config)**#network-sync**
(config-ntwk-sync)**#no revertive priority**

ssm-override *<input>*

Use the **ssm-override** command to configure the synchronization status message (SSM) override settings for network synchronization (Network Sync). Use the **no** form of this command to remove the override.

Syntax Description

<input>	Specifies the SSM quality level override option. Refer to the Functional Notes of this command for specifics.

Default Values

By default, SSM override options are those provided by Ethernet equipment clock (EEC) option 2.

Command History

Release R10.11.0	Command was introduced.

Functional Notes

The various *<input>* parameters available for SSM override vary according to the EEC option selected in the Network Sync configuration (refer to the command *eec-option on page 4437*). If you have not specified an EEC option, option 2 is used by default. The following tables outline the *<input>* parameters for the **ssm-override** command.

Table 3. SSM Override Parameters for EEC Option 1

SSM Override Parameter	Description
ql-dnu	Do Not Use for Synchronization (0xF)
ql-eec1	Synchronous Digital Hierarchy (SDH) Equipment Clock (0xB)
ql-prc	Primary Reference Clock (0x2)
ql-ssu-a	Primary Level Synchronization Supply Unit (0x4)
ql-ssu-b	Second Level Synchronization Supply Unit (0x8)
<input>	Enter SSM as a decimal or hexadecimal value

Table 4. SSM Override Parameters for EEC Option 2

SSM Override Parameter	Description
ql-dus	Do Not Use for Synchronization (0xF)
ql-eec2	Stratum 3 Traceable (0xA)
ql-prov	Provisioned by Network Operator (0xE)
ql-prs	Stratum 1 Traceable (0x1)

Table 4. SSM Override Parameters for EEC Option 2 (Continued)

SSM Override Parameter	Description
ql-smc	SONET Minimum Clock Traceable (0xC)
ql-st2	Stratum 2 Traceable (0x7)
ql-st3e	Stratum 3E Traceable (0xD)
ql-stu	Synchronized Traceability Unknown (0x0)
ql-tnc	Transit Node Clock Traceable (0x4)
<input>	Enter SSM as a decimal or hexadecimal value

SSM override is only configured on those interfaces with SSM enabled. Refer to the command *connect on page 4435*.

Usage Examples

The following example creates an SSM override for EEC option 2, specifically that SSM is provisioned by a network operator:

(config)**#network-sync**
(config-ntwk-sync)**#ssm-override ql-prov**

transmit-ql-threshold <*input*>

Use the **transmit-ql-threshold** command to configure the an upper limit on the value of quality level (QL) transmitted to the user-to-network interfaces (UNIs). Use the **no** form of this command to remove the threshold.

Syntax Description

<*input*>	Specifies the quality level threshold. Refer to the Functional Notes of this command for specifics.

Default Values

By default, this feature is disabled.

Command History

Release R11.10.0	Command was introduced.

Functional Notes

The various <*input*> parameters available for QL threshold vary according to the Ethernet equipment clock (EEC) option selected in the Network Sync configuration (refer to the command *eec-option on page 4437*). If you have not specified an EEC option, option 2 is used by default. The following tables outline the <*input*> parameters for the **transmit-ql-threshold** command.

Table 5. Transmit QL Parameters for EEC Option 1

SSM Override Parameter (highest to lowest)	Description
ql-ssu-a	Primary Level Synchronization Supply Unit (0x4)
ql-ssu-b	Secondary Level Synchronization Supply Unit (0x8)
ql-eec1	Synchronous Digital Hierarchy (SDH) Equipment Clock (0xB)
ql-dnu	Do Not Use for Synchronization (0xF)

Table 6. Transmit QL Parameters for EEC Option 2

SSM Override Parameter (highest to lowest)	Description
ql-stu	Synchronized Traceability Unknown (0x0)
ql-st2	Stratum 2 Traceable (0x7)
ql-tnc	Transit Node Clock Traceable (0x4)
ql-st3e	Stratum 3E Traceable (0xD)

Table 6. Transmit QL Parameters for EEC Option 2 (Continued)

SSM Override Parameter (highest to lowest)	Description
ql-eec2	Stratum 3 Traceable (0xA)
ql-dus	Do Not Use for Synchronization (0xF)

Usage Examples

The following example creates a QL threshold for EEC option 2:

(config)**#network-sync**
(config-ntwk-sync)**#transmit-ql-threshold ql-st2**

wait-to-restore *<value>*

Use the **wait-to-restore** command to specify the interval that network synchronization (Network Sync) waits to restore a down clock interface. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the time, in minutes, that Network Sync waits to restore the interface. Valid range is **0** to **31** minutes.

Default Values

By default, the wait-to-restore timer is set to **3** minutes.

Command History

Release R10.11.0	Command was introduced.

Usage Examples

The following example changes the wait-to-restore interval to **10** minutes:

(config)**#network-sync**
(config-ntwk-sync)**#wait-to-restore 10**

OVER-TEMPERATURE PROTECTION COMMAND SET

The AOS over-temperature protection feature provides threshold settings that when reached, allow an AOS unit (that supports the feature) through several precautions to avoid damage due to over heating. When a unit reaches the warning threshold, a Simple Network Management Protocol (SNMP) trap notification is sent to the SNMP host. Once the unit reaches the shutdown threshold, an additional SNMP trap notification is sent, and the unit reboots to a low-power mode. While in low-power mode, only console connections to the unit are allowed. If automatic recovery is disabled, manual intervention is required to recover from the event. The over-temperature protection feature is available on AOS products as outlined in the *AOS Feature Matrix*, available online at https://supportcommunity.adtran.com.

When configuring a recovery threshold or period, be sure to save the configuration changes. If the changes are not saved and the unit reboots due to an over-temperature event, the unit will not automatically recover from low-power mode. Manual intervention will be necessary.

*The recovery and warning thresholds values are stored as Celsius values in AOS. Setting your threshold(s) in Fahrenheit could cause the output of the **show over-temperature protection** command to display a value slightly different from what you entered. This is due to the conversion to Celsius and back to Fahrenheit.*

The recovery and warning thresholds values are stored as Celsius values in AOS. Setting your threshold(s) in Fahrenheit could cause the output of the **show over-temperature protection** command to display a value slightly different from what you entered. This is due to the conversion to Celsius and back to Fahrenheit.

To enter the Over-Temperature Protection Configuration mode, enter the **over-temperature protection** command at the Global Configuration mode prompt, for example:

```
>enable
#configure terminal
(config)#over-temperature protection
(config-over-temp-protection)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

recovery period on page 4447
recovery threshold on page 4448
warning threshold on page 4449

recovery period

Use the **recovery period** command to set a time period for recovery evaluation after an over-temperature event occurs. Use the **no** form of this command to return to the default setting.

Syntax Description

<0-60>	Specifies the amount of time to wait before the unit attempts recovery after an over-temperature event. Valid range is **0** to **60** minutes. A value of **0** will disable the automatic recovery of the unit from low power mode.

Default Values

By default, the recovery threshold period is 15 minutes.

Command History

Release R11.6.0	Command was introduced.

Functional Notes

When a unit exceeds the shutdown temperature threshold, an SNMP trap is sent and the unit is rebooted into a low-power mode. At that point, the recovery period timer begins. Upon completion of the recovery period, the temperature is reevaluated. If the temperature is below the user-defined recovery threshold, the unit will reboot resuming normal operation.

Usage Examples

The following example sets the recovery period for **20** minutes:

(config)**#over-temperature protection**
(config-over-temp-protection)**#recovery period 20**

recovery threshold

Use the **recovery threshold** command to set a recovery threshold temperature for the over-temperature protection feature. Use the **no** form of this command to return to the default setting. Variations of this command include:

recovery threshold <*temp*> **C**
recovery threshold <*temp*> **F**

Syntax Description

<*temp*> **C**	Specifies the recovery temperature threshold. Valid range is **0** to **75** degrees Celsius (C).
<*temp*> **F**	Specifies the recovery temperature threshold. Valid range is **32** to **167** degrees Fahrenheit (F).

Default Values

By default, the recovery threshold temperature is **70 C** (**158 F**).

Command History

Release R11.6.0	Command was introduced.

Functional Notes

When a unit exceeds the shutdown temperature threshold, an SNMP trap is sent and the unit is rebooted into a low-power mode. At that point, the recovery period timer begins. Upon completion of the recovery period, the temperature is reevaluated. If the temperature is below the user-defined recovery threshold, the unit will reboot resuming normal operation.

Usage Examples

The following example sets the recovery threshold to **65** degrees C:

(config)**#over-temperature protection**
(config-over-temp-protection)**#recovery threshold 65 C**

warning threshold

Use the **warning threshold** command to set the temperature threshold to send an SNMP trap during an over-temperature event. Use the **no** form of this command to return to the default setting. Variations of this command include:

warning threshold <*temp*> **C**
warning threshold <*temp*> **F**

Syntax Description

<*temp*> **C**	Specifies the warning temperature threshold. Valid range is **0** to **75** degrees Celsius (C).
<*temp*> **F**	Specifies the warning temperature threshold. Valid range is **32** to **167** degrees Fahrenheit (F).

Default Values

By default, the warning threshold is set to a value of **70 C** (**158 F**).

Command History

Release R11.6.0	Command was introduced.

Functional Notes

Once a unit exceeds the warning temperature threshold, an SNMP trap is sent.

Usage Examples

The following example sets the warning threshold to **70** degrees C:

(config)**#over-temperature protection**
(config-over-temp-protection)**#warning threshold 70 C**

PACKET CAPTURE COMMAND SET

The AOS packet capture feature is used with network monitoring to effectively capture data packets as they traverse the network. As data packets pass through an interface on which the packet capture feature is enabled, a packet-capture monitors the traffic and captures the header and payload of specified packets as they pass through. The captured packets are then exported and stored in either flash memory or CompactFlash storage, and can then be reviewed to determine the cause of network problems, identify security threats, and to maintain efficient data transmission over the network.

In AOS, packet capturing can be attached to one or more interfaces on the device, and can capture Internet Protocol version 4 (IPv4) packets on Layer 3 of the network open systems interconnection (OSI) model. Packet-captures capture both ingress and egress packets on the interface, and can export the captured packets to a Trivial File Transfer Protocol (TFTP) server, flash memory, or CompactFlash memory in libpcap format with a .pcap file extension. Each packet-capture can be limited to only capturing a specified type of traffic by using an access control list (ACL) to specify what type of traffic the packet-capture should capture. The packet-capture works on user-configured size and time limits, which determine when the Pcap file is exported and another capture is initiated. When the size or time limit for a packet-capture expires, the Pcap file is exported. At this point, the limits reset and a new Pcap file is created for subsequently captured packets.

There are two types of packet-captures available in AOS products: a standard packet-capture, and a Session Initiation Protocol (SIP) packet-capture. Standard packet-captures capture packets from all interfaces on which a packet-capture is attached, and archive these captures into a single Pcap file that is exported at regular intervals (based on the packet-capture's size and time limit configuration). The packets captured by standard packet-captures include all ingress and egress IPv4 packets allowed by the ACL associated with the packet-capture, for every interface on which the packet-capture is attached. SIP packet-captures differ from standard packet-captures in that they focus on capturing SIP packets, rather than all allowed IPv4 packets. These packet-captures capture all ingress or egress User Datagram Protocol (UDP) packets that are related to SIP messages, including those related to back-to-back user agent (B2BUA) calls, proxy calls, and messages not related to any call.

For more information about packet capturing, and its implementation and configuration in AOS, refer to the configuration guide *Configuring Packet Capture in AOS*, available online at http://supportforums.adtran.com.

To create a standard packet-capture, and enter the Packet Capture Configuration mode, enter the following command from the Global Configuration mode:

```
(config)#packet-capture 1CAPTURE standard
(config-packet-capture-1CAPTURE)#
```

To create a SIP packet-capture, and enter the Packet Capture Configuration mode, enter the following command from the Global Configuration mode:

```
(config)#packet-capture 1CAPTURE sip
(config-packet-capture-1CAPTURE)#
```

Once you have entered the Packet Capture Configuration mode, you can configure the specific aspects of the packet-capture.

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

export on page 4452
limit size <value> on page 4459
limit time <value> on page 4460
match list <ipv4 acl name> on page 4461
max-memory-usage <value> on page 4462
truncate-packet <value> on page 4463

export

Use the **export** command to specify the export mode used to export packet capture (Pcap) files. You can specify the location and type of export used for exporting the Pcap files. Use the **no** form of this command to remove an export entry in the packet-capture configuration. Variations of this command include:

export cflash
export cflash *<path>*

export flash
export flash *<path>*

export usbdrive0
export usbdrive0 *<path>*

export http auto-link
export http auto-link path *<path>*

export tftp <*ipv4 address*> **port** <*port*>

Syntax Description

cflash	Specifies the Pcap files are exported to CompactFlash. If the optional <*path*> parameter is not specified, files are exported to the **/PacketCapture** directory by default.
flash	Specifies the Pcap files are exported to flash memory. If the optional <*path*> parameter is not specified, files are exported to the **/PacketCapture** directory by default.
usbdrive0	Specifies the Pcap files are exported to the USB file system. If the optional <*path*> parameter is not specified, files are exported to the **/PacketCapture** directory by default.
<*path*>	Optional. Specifies a nondefault directory to store the Pcap files when they are exported using CompactFlash, flash, or USB memory. If the optional <*path*> parameter is not specified, files are exported to the **/PacketCapture** directory by default. A specified path can be between **1** and **255** characters in length. Remember that paths must be specified using **/** as the separating character, they must be unescaped, and if they contain spaces, they must be enclosed in quotation marks.
http	Specifies that the Pcap files are exported to a Hypertext Transfer Protocol (HTTP) server.
https	Specifies that the Pcap files are exported to a secure HTTP (HTTPS) server.
allow-tls1.0	Optional. Allows the use of Transport Layer Security protocol version 1.0 when exporting Pcap files. If **allow-tls1.0** is enabled, Secure Socket Layer version 3 (SSLv3) can also optionally be enabled.
allow-tls1.1	Optional. Allows the use of TLS protocol version 1.1 when exporting Pcap files. If **allow-tls1.1** is enabled, SSLv3 can also optionally be enabled.
allow-sslv3	Optional. Allows the use of SSLv3 when exporting Pcap files. If SSLv3 is enabled, TLS version 1.0 is automatically enabled.
auto-link	Specifies that the Pcap files are exported to an auto-link server.
<*ipv4 address* | *hostname*>	Specifies the IPv4 address or host name of the HTTP or HTTPs server to which you are exporting the Pcap files. IPv4 addresses should be expressed in dotted decimal notation, for example, **X.X.X.X**. Host names can be between **4** and **255** characters in length, for example, **hostname.com**.

port <*port*>	Optional. Specifies the port on the HTTP, HTTPS, or Trivial File Transfer Protocol (TFTP) server to which the Pcap files are sent. Valid port range is **1** to **65535**. If no port is specified, the files are sent to the default port of **80** (HTTP), **443** (HTTPS), or UDP port **69** (TFTP). Multiple HTTP(S) exports in the same packet-capture can have the same IPv4 address or host name as long as a different port is specified.
path <*path*>	Optional. Specifies the directory to which the Pcap files are exported. If a path is not specified, the default request path of **/adtran/pcash/aos/receiveCapture/** is used.
username <*username*>	
password <*password*>	Optional. Specifies that basic authentication credentials are sent with every HTTP(S) POST request. User names and passwords can be between **6** and **32** characters in length. User names cannot contain spaces, and if passwords contain spaces, they must be enclosed in quotation marks (for example, **"open sesame"**).
encrypted	Optional. Specifies that the password used in basic authentication for HTTP(S) Pcap file export is encrypted.
tftp <*ipv4 address*>	Specifies that the Pcap files are exported to a TFTP server, and also specifies the IPv4 address of that server. IPv4 addresses should be expressed in dotted decimal notation, for example, **X.X.X.X**.

Default Values

By default, no export location for the Pcap files is configured. When enabled, CompactFlash, flash, and USB exports use the directory **/PacketCapture** by default. When enabled, HTTP, HTTPS, and TFTP exports use the directory **/adtran/pcash/aos/receiveCapture/** by default. When enabled, Pcap files are sent to the default ports of **80** (HTTP), **443** (HTTPS), and UDP port **69** (TFTP).

Command History

Release R10.1.0	Command was introduced.
Release R10.7.0	Command was expanded to include the **auto-link** parameter.
Release R12.3.0	Command was expanded to include the **allow-tls1.0** and **allow-sslv3** parameters.
Release R13.9.0	Command was expanded to include the **allow-tls1.1** parameter.

Usage Examples

The following example specifies that Pcap files are exported to the default directory on the CompactFlash:

(config)**#packet-capture 1CAPTURE standard**
(config-packet-capture-1CAPTURE)**#export cflash**

The following example specifies that Pcap files are exported to the packet capture archival server HTTP(S) (PCASH) server at **10.10.2.5** using HTTP with the default directory and port, and without any authentication:

(config)**#packet-capture 1CAPTURE standard**
(config-packet-capture-1CAPTURE)**#export http 10.10.2.5**

The following example specifies that the Pcap files are exported to a TFTP server with an IPv4 address of **10.10.5.3**, using the default port:

(config)**#packet-capture 1CAPTURE standard**
(config-packet-capture-1CAPTURE)**#export tftp 10.10.5.3**

The following example specifies that the Pcap files are exported to an auto-link server. If a server failover occurs, packet captures exported to an auto-link server can automatically roll over to the new server for export.

(config)**#packet-capture 1CAPTURE standard**
(config-packet-capture-1CAPTURE)**#export http auto-link**

limit size *<value>*

Use the **limit size** command to trigger a packet capture (Pcap) file export after the combined size of all the packet-capture's open captures exceeds the specified size. Use the **no** form of this command to return the maximum open capture size limit to the default value.

Syntax Description

<value>	Specifies the maximum combined size of the packet-capture's open captures. This value can be expressed in bytes, kilobytes (**k** or **K**), or megabytes (**m** or **M**). Valid range is **0** to **4095M**. If the value is set to **0**, the size limit feature is disabled.

Default Values

By default, the maximum open capture size is set to **1M**.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

At least one capture limit, whether size or time, must be configured with a non-zero value before the packet-capture can be enabled. Configure a size limit using this command, or a time limit using the command *limit time <value> on page 4460*. Adtran recommends that you do not disable packet capture size or time limits.

Usage Examples

The following example changes the maximum combined open capture size limit to **3M**:

(config)**#packet-capture 1CAPTURE standard**
(config-packet-capture-1CAPTURE)**#limit size 3M**

limit time *<value>*

Use the **limit time** command to specify the time limit, in seconds, for the packet capture. This command triggers a packet capture (Pcap) file export after the given time value is exceeded. Use the **no** form of this command to return the time limit to the default value.

Syntax Description

<value>	Specifies the capture time limit in seconds. Valid range is **0** to **604800** seconds. Using a value of 0 disables the capture's time limit.

Default Values

By default, Pcap files are set to export after **900** seconds (15 minutes).

Command History

Release R10.1.0	Command was introduced.

Functional Notes

At least one capture limit, whether size or time, must be configured with a non-zero value before the packet-capture can be enabled. Configure a time limit using this command, or a size limit using the command *limit size <value> on page 4459*. Adtran recommends that you do not disable packet capture size or time limits.

Usage Examples

The following example specifies that Pcap files are exported after **2000** seconds:

(config)**#packet-capture 1CAPTURE standard**
(config-packet-capture-1CAPTURE)**#time limit 2000**

match list *<ipv4 acl name>*

Use the **match list** command to specify that the packet-capture uses an Internet Protocol version 4 (IPv4) access control list (ACL) to limit the type of traffic that is captured. This command can also be used to prevent feedback, if necessary, or to filter the type of traffic captured for other network management reasons. Use the **no** form of this command to remove the ACL from the packet-capture configuration.

Syntax Description

<ipv4 acl name>	Specifies the name of a previously created IPv4 ACL to use to limit the traffic captured. ACLs are created using the commands *ip access-list extended <ipv4 acl name> on page 1344* or *ip access-list standard <ipv4 acl name> on page 1346*.

Default Values

By default, no ACL is configured or applied to packet-captures.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example applies the previously created IPv4 ACL **PREVENTFEEDBACK** to the packet-capture:

(config)**#packet-capture 1CAPTURE standard**
(config-packet-capture-1CAPTURE)**#match list PREVENTFEEDBACK**

max-memory-usage *<value>*

Use the **max-memory-usage** command to specify the maximum memory the packet-capture is allowed to use. This command specifies a memory usage threshold for the capture. Use the **no** form of this command to return the threshold to the default value.

Syntax Description

<value>	Specifies the memory usage threshold in bytes, kilobytes (**k** or **K**), or megabytes (**m** or **M**). Valid range is **0** to **4294967295** bytes, **0** to **4194303** kilobytes, or **0** to **4095** megabytes.

Default Values

By default, the maximum memory usage threshold is set to **5M**.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

When this threshold is reached, the packet-capture enters memory usage critical (MUC) mode. When in MUC mode, the capture stops capturing packets, continues any ongoing exports, and closes any open captures to begin exporting them. The packet-capture remains in MUC mode until memory usage decreases to 75 percent of the maximum memory usage.

Usage Examples

The following example specifies the maximum memory usage threshold for the packet-capture is **10M**:

(config)**#packet-capture 1CAPTURE standard**
(config-packet-capture-1CAPTURE)**#max-memory usage 10M**

truncate-packet <*value*>

Use the **truncate-packet** command to specify the maximum number of bytes to be captured from each packet when using packet capture. This command is primarily used for performance reasons. This command allows you to specify that packets larger than the defined value are truncated. Use the **no** form of this command to return to the truncated packet size default value.

Syntax Description

<*value*>	Specifies the maximum number of captured bytes in a packet before the packet is truncated. This value can be expressed in bytes, kilobytes (**k** or **K**), or megabytes (**m** or **M**).

Default Values

By default, the truncated packet size is set to **0**, which indicates that packets should not be truncated.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example enables packet truncating, and specifies that after **28** bytes the packet is truncated:

(config)**#packet-capture 1CAPTURE standard**
(config-packet-capture-1CAPTURE)**#truncate-packet 28**

QUALITY OF SERVICE MAP COMMAND SET

A quality of service (QoS) policy is defined using a QoS map in the Adtran Operating System (AOS) command line interface (CLI). The QoS map is a named list with sequenced entries. An entry contains a single match reference and one or more actions. To activate the QoS map command set (which allows you to create and/or edit a map), enter a valid version of the **qos map** command at the Global Configuration mode prompt. Multiple map entries for the same QoS map are differentiated by a sequence number. The sequence number is used to assign match order.

Once created, a QoS map must be applied to an interface (using the **qos-policy** command from the desired interface command set) in order to actively process traffic. Any traffic for the interface that does not explicitly match a map entry is sent using the default queuing method for the interface, such as weighted fair queuing (WFQ).

Applying a QoS Map to a PPP or demand interface will cause the interface to drop briefly. This causes a temporary service interruption and the interface should come back up momentarily.

The following example creates and configures a QoS map:

```
>enable
#config terminal
(config)#qos map VOICEMAP 10
(config-qos-map)#match precedence 5
(config-qos-map)#priority 512
(config-qos-map)#exit
(config)#interface fr 1
(config-fr 1)#qos-policy out VOICEMAP
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

bandwidth on page 4466
match on page 4469
match dscp on page 4473
match precedence <value> on page 4477
police cir <rate> on page 4479

bandwidth

Use the **bandwidth** command to specify bandwidth allocation for individual traffic classes for class-based weighted fair queuing (CBWFQ) configurations. Use the **no** form of this command to remove a configured bandwidth allocation. Variations of this command include:

bandwidth <*rate*>
bandwidth <*rate*> **Kbps**
bandwidth <*rate*> **Mbps**
bandwidth percent <*value*>
bandwidth remaining percent <*value*>

Syntax Description

<*rate*>	Allocates the minimum bandwidth for a traffic class, specifying the minimum as an absolute bandwidth in kilobits per second (kbps). Range is **8** to **2000000** kbps.
Kbps	Optional. Indicates the rate specified is in kbps.
Mbps	Optional. Indicates the rate specified is in megabits per second (Mbps).
percent <*value*>	Allocates a minimum bandwidth for a traffic class, specifying the minimum as a percentage of the total interface bandwidth. Refer to *Functional Notes* below for more details.
remaining percent <*value*>	Allocates a minimum bandwidth for a traffic class, specifying the minimum as a percentage of the total interface bandwidth not allocated to priority classes in the quality of service (QoS) map. Refer to *Functional Notes* below for more details.

Default Values

By default, there is no bandwidth allocation configured for a QoS map entry. The bandwidth rate is assumed to be provided in **Kbps** unless **Mbps** is specified.

Command History

Release 10.1	Command was introduced.
Release 17.5	Command was expanded to allow specifying the rate in kbps and Mbps.

Functional Notes

When configuring **bandwidth** allocations for CBWFQ, there are a few rules that must be obeyed.

1. The units of the bandwidth (kbps, Mbps, percent, or remaining percent) must be consistent for all class-based entries (using the **bandwidth** command) in a QoS map set.

2. The total bandwidth between all priority entries (**priority** command) and class-based entries (**bandwidth** command) in a QoS map set should not be configured beyond the specified max-reserved-bandwidth (default 75 percent) on the interface to which the QoS policy is applied (using the **qos-policy** command), or the map will be disabled. In a QoS map, even though limits are defined

regarding consumption of bandwidth by traffic, traffic can burst up to the maximum interface rate when the output queue is not in a congested state. Qos maps are constantly classifying traffic when they are active on an interface, but some of their actions depend on the state of the output queue. When congestion is present, policies defined with the bandwidth command will be limited to the minimum value specified, with excess traffic being queued. During a congested state, policies defined with the priority command will be limited to the maximum value specified, with excess traffic being dropped. Policies defined with the shape or set commands are always enforced regardless of congestion.

When the configured QoS map is applied to a physical interface, AOS displays bandwidth information for the map and the physical interface. For example, if the Frame Relay interface (fr 1) has been connected to the E1 interface (e1 1/1) using the **cross-connect** command, applying the QoS map (MyMapA) to the Frame Relay interface (fr 1) produces the following status message:

2005.08.09 07:28:22 QOS.INTERFACE QOS policy "MyMapA" requires 1288 kbps of bandwidth and 1488 kbps is now available for interface fr 1 -> the QOS policy for this port has been forced ACTIVE.

This status message displays the total of the bandwidths specified in the QoS map (1288 kbps) and the available interface bandwidth using the total line rate configured on the interface (1488 kbps).

3. Up to eight class-based entries (**bandwidth** commands) can be configured in a particular QoS map set.

4. Within a QoS map entry, CBWFQ bandwidth and low latency priority actions are mutually exclusive. However, bandwidth and priority actions may be applied to different entries in the same QoS map.

Determining Bandwidth Entries

*When possible, use the **bandwidth** <value> command to specify an absolute amount of bandwidth (in kbps) for the traffic class.*

When determining the **percent** <*value*> entry, use the following formula:

$$\frac{\text{Bandwidth}}{\text{Line Rate}} \times 100$$

where

Bandwidth	Specifies the minimum amount of bandwidth needed for the traffic (in kbps).
Line Rate	Specifies the total data rate configured on the interface (for example, 8 DS0s (64 kbps per DS0) on a T1 equals a line rate of 512 kbps).

For example, to specify 76.8 kbps of data on an interface with a total of 512 kbps of available bandwidth, and reserving 5 percent of the bandwidth for best effort, routing, and L2 protocol traffic (**max-reserved-bandwidth** = 95) enter the following commands:

(config-qos-map)**#bandwidth percent 15**
(config)**#interface ethernet 0/1**
(config-eth 0/1)**#max-reserved-bandwidth 95**

When determining the **remaining percent** <*value*> entry, use the following formula:

$$\frac{\text{Bandwidth}}{\text{Line Rate}} \times 100$$

where

Bandwidth	Specifies the minimum amount of bandwidth needed for the traffic (in kbps).
Line Rate	Specifies the total data rate configured on the interface (for example, 8 DS0s (64 kbps per DS0) on a T1 equals a line rate of 512 kbps).

For example, to specify 76.8 kbps of data on an interface with a total of 512 kbps of available bandwidth, 256 kbps reserved (using the **priority** command), and reserving 15 percent of the bandwidth for best effort, routing, and L2 protocol traffic (**max-reserved-bandwidth** = 85) enter the following command:

(config-qos-map 1)**#bandwidth remaining percent 45**
(config)**#interface ethernet 0/1**
(config-eth 0/1)**#max-reserved-bandwidth 85**

Usage Examples

The following example creates a QoS map with four traffic classes (based on IP packet precedence values) and allocates bandwidth to each class:

(config)**#qos map MYMAP 1**
(config-qos-map)**#match precedence 5**
(config-qos-map)**#bandwidth percent 25**

(config)**#qos map MYMAP 2**
(config-qos-map)**#match precedence 3**
(config-qos-map)**#bandwidth percent 10**

(config)**#qos map MYMAP 3**
(config-qos-map)**#match precedence 2**
(config-qos-map)**#bandwidth percent 10**

(config)**#qos map MYMAP 4**
(config-qos-map)**#match precedence 1**
(config-qos-map)**#bandwidth percent 15**

match

Use the **match** command to specify which traffic should be processed by this quality of service (QoS) map entry. Use the **no** form of this command to discontinue matching. Variations of this command include:

match any
match fr-dlci *<number>*
match ip list *<ipv4 acl name>*
match ipv6 list *<ipv6 acl name>*
match ip rtp *<port>*
match ip rtp *<begin port> <end port range>*
match ip rtp *<begin port> <end port range>* **all**
match ipv6 rtp *<port>*
match ipv6 rtp *<begin port> <end port range>*
match protocol bridge
match protocol bridge netbeui
match protocol ip
match protocol ipv6
match vlan *<id>*

Syntax Description

any	Match all packets within a QoS map entry that were not matched in previous map entries. Since map entries are processed in the order of their sequence numbers, the **match any** command can be used to process all packets (both Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6) traffic) not previously matched by a map entry if it is specified as the last QoS map entry.
fr-dlci *<number>*	Match all packets by the specified Frame Relay data link connection identifier (DLCI). Indicate the valid DLCI number from **16** to **1007**.
ip list *<ipv4 acl name>*	Specifies the name of the IPv4 access control list (ACL) you want to use to match packets for this QoS map. Refer to *ip access-list extended <ipv4 acl name> on page 1344* for more information on creating IPv4 ACLs.
ipv6 list *<ipv6 acl name>*	Specifies the name of the IPv6 ACL you want to use to match packets for this QoS map. Refer to *ipv6 access-list extended <ipv6 acl name> on page 1500* for more information on creating IPv6 ACLs.
ip rtp *<port>*	Matches IPv4 Realtime Transport Protocol (RTP) packets with the specified User Datagram Protocol (UDP) destination port.
ip rtp *<begin port> <end port range>*	Matches IPv4 RTP packets with even UDP destination port numbers in the specified range.

all	Optional. Specifies matching all UDP port numbers in the specified range (even and odd). Valid only for **ip rtp** matches.
ipv6 rtp <*port*>	Matches IPv6 RTP packets with the specified UDP destination port.
ipv6 rtp <*begin port*> <*end port range*>	Matches IPv6 RTP packets with even UDP destination port numbers in the specified range.
protocol bridge	Matches frames being bridged by the router.
protocol bridge netbeui	Matches only network basic input/output system (NetBIOS) extended user interface (NetBEUI) frames being bridged by the router.
protocol ip	Matches only IPv4 packets.
protocol ipv6	Matches only IPv6 packets.
vlan <*id*>	Match packets associated with a particular virtual local area network (VLAN). Indicate the VLAN ID number from **1** to **4095**.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.
Release 17.2	Command was expanded to include the **any** and **vlan** <*id*> options.
Release 17.5	Command was expanded to include the **fr-dlci** <*number*> parameter.
Release R10.1.0	Command was expanded to include the **ip list**, **ipv6 list**, **ip rtp**, **ipv6 rtp**, **protocol ip**, and **protocol ipv6** parameters.

Functional Notes

QoS policies are configured in the Adtran Operating System (AOS) command line interface (CLI) to dictate the priority for servicing specified traffic types on a particular interface. QoS policies contain at least one match reference (using the **match** command) and one or more action items (using the **priority**, **bandwidth**, **shape average**, or **set** commands).

The **match** command specifies the criteria used when determining whether incoming traffic is a candidate for the QoS policy action. Multiple **match** statements can exist within the same QoS policy, allowing a single QoS policy to service various types of traffic. You can require *all* of the multiple conditions be met (AND logic) by including the **match-all** parameter when creating the QoS policy. Alternatively, you can choose to include traffic meeting *any* of the conditions (OR logic) by using the **match-any** parameter when creating the QoS policy. Both of these conditions are explained in *qos map <name> <number> on page 1673*.

*Each listed **match** statement is handled independently by the processor. Entering too many **match** statements in a QoS policy can burden the processor.*

For example, consider a network that contains CLASS A and CLASS B traffic (both IPv4 traffic) that each require 25 percent of the total allocated interface bandwidth, the following configuration would be appropriate:

(config)**#qos map MYMAP 10**
(config-qos-map)**#match ip list CLASS_A**
(config-qos-map)**#bandwidth percent 25**

(config)**#qos map MYMAP 20**
(config-qos-map)**#match ip list CLASS_B**
(config-qos-map)**#bandwidth percent 25**

In this example, the combination of both classes will not exceed 25 percent of the total allocated interface bandwidth. CLASS A and CLASS B will share the 25 percent allocation between them. Since there are two match statements in this QoS map entry, traffic can match either IPv4 ACL **CLASS_A** or **CLASS_B** to be processed. By default, this example assumes the **match-any** logic is being applied since it is not specifically configured:

(config)**#qos map MYMAP 10**
(config-qos-map)**#match ip list CLASS_A**
(config-qos-map)**#match ip list CLASS_B**
(config-qos-map)**#bandwidth percent 25**

To remove a configured **match** statement, enter the entire **match** statement with a preceding **no**. For example, to remove the **match** statements from the above configured QoS map:

(config)**#qos map MYMAP 10**
(config-qos-map)**#no match ip list CLASS_A**

and

(config)**#qos map MYMAP 20**
(config-qos-map)**#no match ip list CLASS_B**

Usage Examples

The following example configures QoS for a network with the following needs:

Reserve 15 percent of the line rate for routing IPv4 traffic and L2 protocol traffic (**max-reserved-bandwidth** = 85)

Line Rate = 512 kbps
Guaranteed 256 kbps for Voice
Guaranteed 96 kbps for Class 1
Guaranteed 52 kbps for Class 2

To configure this QoS policy, enter the following QoS map and interface commands:

1. Allocate low latency queuing (LLQ) priority voice traffic.

(config)**#qos map MYMAP 10**
(config-qos-map)**#match ip list VOICE**
(config-qos-map)**#priority 256**

2. Allocate the class-based weighted fair queuing (CBWFQ) data traffic bandwidth for Classes 1 and 2.

(config)**#qos map MYMAP 20**
(config-qos-map)**#match ip list CLASS_1**
(config-qos-map)**#bandwidth 96**

(config)**#qos map MYMAP 30**
(config-qos-map)**#match ip list CLASS_2**
(config-qos-map)**#bandwidth 52**

3. Specify the reserved bandwidth on the appropriate interface and apply the map.

(config-fr 1)**#max-reserved-bandwidth 85**
(config-fr 1)**#qos-policy out MYMAP**

match dscp

Use the **match dscp** command to specify which traffic should be processed by this quality of service (QoS) map based on the differentiated services code point (DSCP) value in the IP header of an Internet Protocol version 4 (IPv4) and/or Internet Protocol version 6 (IPv6) packet. Up to eight DSCP values or identifiers, separated by a space, may be specified in a **match dscp** command. Traffic matching any one of the DSCP values qualifies as a match for the given map entry. Use the **no** form of this command to discontinue matching. Variations of this command include:

match dscp <*value*>
match dscp <*value*> **af***xx*
match dscp <*value*> **cs***x*
match dscp af*xx*
match dscp cs*x*
match dscp default
match dscp ef
match ip dscp <*value*>
match ip dscp <*value*> **af***xx*
match ip dscp <*value*> **cs***x*
match ip dscp af*xx*
match ip dscp cs*x*
match ip dscp default
match ip dscp ef
match ipv6 dscp <*value*>
match ipv6 dscp <*value*> **af***xx*
match ipv6 dscp <*value*> **cs***x*
match ipv6 dscp af*xx*
match ipv6 dscp cs*x*
match ipv6 dscp default
match ipv6 dscp ef

Syntax Description

<*value*>	Specifies the DSCP numeric value. Valid range is **0** to **63**.
af*xx*	Specifies the assured forwarding (AF) class and subclass. Select from: **11** (001010), **12** (001100), **13** (001110), **21** (010010), **22** (010100), **23** (010110), **31** (011010), **32** (011100), **33** (011110), **41** (100010), **42** (100100), or **43** (100110). Up to 8 DSCP values or identifiers may be specified.
cs*x*	Specifies the class selector (CS) value. Valid range is **1** to **7**. Up to 8 DSCP values or identifiers may be specified.
default	Specifies the default DSCP value (000000).
ef	Specifies marking for expedited forwarding (EF).
ip	Specifies the match criteria only apply to IPv4 headers.
ipv6	Specifies the match criteria only apply to IPv6 headers.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.
Release R10.1.0	Command was expanded to include **ip** and **ipv6** parameters to accommodate IPv4 and IPv6 traffic.

Usage Examples

The following example instructs the QoS map named **MYMAP** to match the IPv4 header with a DSCP AF Class 1, Subclass 2 (**af12**):

(config)**#qos map MYMAP 20**
(config-qos-map)**#match ip dscp af12**

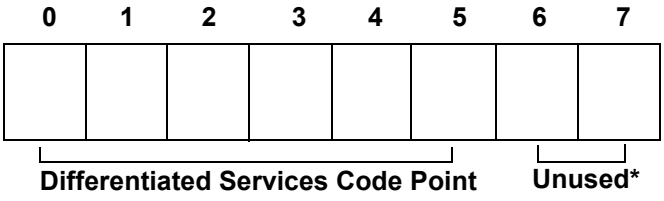
The following example instructs the QoS map named **MYMAP** to match either an IPv4 header or IPv6 header with a DSCP AF Class 1, Subclass 2 (**af12**):

(config)**#qos map MYMAP 20**
(config-qos-map)**#match dscp af12**

Technology Review

The DSCP model was created in RFC 2474 and 2475 to build on the original IPv4 header type of service (ToS) field by creating a 6-bit sequence (combining the precedence value with the delay, throughput, and reliability bits). (IPv6 headers have an 8-bit traffic class field serving the same purpose.) This 6-bit sequence increased the number of available values from 8 to 64. The DiffServ model introduced a new concept to QoS in the IP network environment: per-hop behaviors (PHBs). The PHB premise is that equipment using the DiffServ model have an agreed upon set of rules (PHB types) for handling certain network traffic. Though the RFC explicitly defines what each PHB should be capable of, it does not restrict vendor-specific implementation of the PHBs. Each vendor is free to decide how their network product implements the various defined PHBs.

According to RFC 2474, the differentiated services (DS) field contains the following bits:



*The previously unused bits in the DS field are now used for congestion control and are not discussed in this document.

Equipment following the DiffServ model (DSCP-compliant nodes) must use the entire 6-bit DSCP value to determine the appropriate PHB. The PHBs are defined as the following:

- Default PHB
- Class selector PHB
- Assured forwarding PHB (RFC 2597)
- Expedited forwarding PHB (RFC 2598)

Default PHB

All DSCP-compliant nodes must provide a default PHB to offer best-effort forwarding service. For default PHBs, the DSCP value is 0. Any packet that does not contain a standardized DSCP should be mapped to the default PHB and handled accordingly.

Class Selector PHB

In the class selector PHB, the first three bits in the DSCP value are used for backwards compatibility to systems implementing IP precedence. In this scenario, all but the first three bits of the DS field are set to 0. This compatibility requires DSCP-compliant nodes to provide the same data services as are provided by nodes implementing IP precedence. The following table is a comparison of IP precedence values to their corresponding DSCP values.

IP Precedence Value (bits)	DSCP Value (bits)
0 (000)	0 (000000)
1 (001)	8 (001000)
2 (010)	16 (010000)
3 (011)	24 (011000)
4 (100)	32 (100000)
5 (101)	40 (101000)
6 (110)	48 (110000)
7 (111)	56 (111000)

Assured Forwarding PHB

The flexibility of DiffServ allows for more developed subclasses of service within each main class using the last three bits of the DSCP. As defined in RFC 2597, the assured forwarding PHB creates four main classes of service:

Class	DSCP Bits
AF1	001XX0
AF2	010XX0
AF3	011XX0
AF4	100XX0
X indicates a do not care value.	

The first three bits of the DSCP specify the class and the last bit is always 0. Each class is separated into subclasses using the two remaining bits in the DSCP (bits 3 and 4). The subclasses are divided based on the likelihood that packets in the class are dropped in the event of network congestion. The higher the value for bits 3 and 4, the greater the likelihood that the packets will be dropped.

Bit 3	Bit 4	Drop Precedence
0	1	Low
1	0	Medium
1	1	High

The following table lists the assured forwarding PHB subclasses and their corresponding DSCP bits and values.

Class	Subclass	DSCP Bits	DSCP Value
AF1	1	001010	10
	2	001100	12
	3	001110	14
AF2	1	010010	18
	2	010100	20
	3	010110	22
AF3	1	011010	26
	2	011100	28
	3	011110	30
AF4	1	100010	34
	2	100100	36
	3	100110	38

Expedited Forwarding PHB

RFC 2598 created a new DiffServ PHB intended to provide the best service possible on an IP network. Packets using the expedited forwarding PHB markings should provide service to reduce latency, jitter, and dropped packets, and be guaranteed bandwidth during the entire end-to-end transmission journey through the network. The DSCP value for the expedited forwarding PHB is 46 (DSCP bits are 101110).

match precedence <*value*>

Use the **match precedence** command to specify which traffic should be processed by this quality of service (QoS) map based on the precedence value in the Internet Protocol version 4 (IPv4) and/or Internet Protocol version 6 (IPv6) header of a packet. Use the **no** form of this command to discontinue matching. Variations of this command include:

match precedence <*value*>
match ip precedence <*value*>
match ipv6 precedence <*value*>

Syntax Description

<*value*>	Specifies matching the IP precedence (in numeric value). Valid range is **0** to **7** in ascending order of importance.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.
Release R10.1.0	Command was expanded to include **ip** and **ipv6** parameters to accommodate IPv4 and IPv6 traffic.

Usage Examples

The following example instructs the QoS map named **MYMAP** to match the precedence value of **5** in either IPv4 or IPv6 traffic:

(config)**#qos map MYMAP 20**
(config-qos-map)**#match precedence 5**

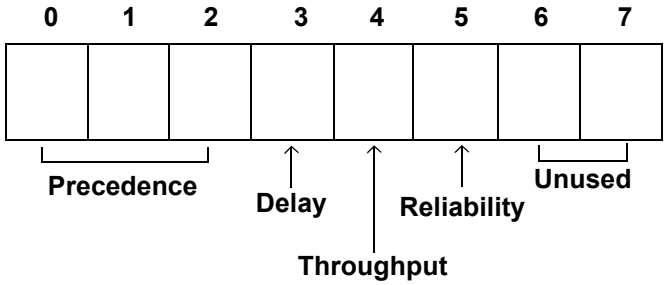
The following example instructs the QoS map named **MYMAP** to match the precedence value of **5** in IPv4 traffic only:

(config)**#qos map MYMAP 20**
(config-qos-map)**#match ip precedence 5**

Technology Review

RFC 791 created a single octet (labeled type of service (ToS) in IPv4 traffic) to help with the difficulty of trying to provide QoS handling in IP networks. IPv6 headers have an 8-bit traffic class field serving the same purpose.

According to RFC 791, the ToS field contains the following bits:



The 3-bit IP precedence values (0 through 7) are specified as:

111	Network Control Packets
110	Internetwork Control Packets
101	Critical Traffic
100	Flash Override
011	Flash
010	Immediate Servicing
001	Priority Traffic
000	Routine Data

The IP precedence values provide network routers with information about what kind of traffic is contained in the IP packet. Based on the IP precedence values, some networks (when supported) can offer special handling to certain packets. In addition, providing IP precedence values to critical traffic (such as route information) ensures that critical packets will always be delivered regardless of network congestion. This traffic is often critical to network and internetwork operation. In general, the higher the IP precedence value, the more important the traffic and the better handling it should receive in the network. It is important to remember that not all equipment in the public IP network will be configured to recognize and handle IP precedence values. While it is a good idea to set the values for important traffic, it does not guarantee special handling.

In addition to the precedence values, RFC 791 specifies bits for delay, throughput, and reliability to help balance the needs of particular traffic types when traveling on the IP network infrastructure. When these bits are set to 0, they are handled with normal operation. When set to 1, each bit specifies premium handling for that parameter. For example, a 1 in the delay position indicates that the traffic is delay sensitive and care should be taken to minimize delay. A 1 in the throughput position indicates that the traffic has higher bandwidth requirements that should be met. A 1 in the reliability position indicates that the traffic is sensitive to delivery issues and care should be taken to ensure proper delivery with all packets of this type. These extra bits are rarely used because they are quite difficult to balance the cost and benefits of each parameter (especially when more than one bit is set to 1).

police cir *<rate>*

Use the **police cir** command to limit the traffic in this quality of service (QoS) map to a specified committed information rate (CIR) threshold and committed burst size (CBS) threshold. If these thresholds are exceeded, the QoS map can drop the traffic. Use the **no** form of this command to disable this feature. Variations of this command include:

police cir *<rate>*
police cir *<rate>* **[count-eth-overhead]**
police cir *<rate>* **cbs** *<size>*
police cir *<rate>* **cbs** *<size>* **[count-eth-overhead]**
police cir *<rate>* **cbs** *<size>* **Bytes [count-eth-overhead]**
police cir *<rate>* **cbs** *<size>* **KB [count-eth-overhead]**
police cir *<rate>* **cbs** *<size>* **MB [count-eth-overhead]**

police cir *<rate>* **bps**
police cir *<rate>* **bps cbs** *<size>*
police cir *<rate>* **bps cbs** *<size>* **Bytes [count-eth-overhead]**
police cir *<rate>* **bps cbs** *<size>* **KB [count-eth-overhead]**
police cir *<rate>* **bps cbs** *<size>* **MB [count-eth-overhead]**
police cir *<rate>* **bps cbs** *<size>* **[count-eth-overhead]**
police cir *<rate>* **bps [count-eth-overhead]**

police cir *<rate>* **Kbps**
police cir *<rate>* **Kbps cbs** *<size>*
police cir *<rate>* **Kbps cbs** *<size>* **Bytes [count-eth-overhead]**
police cir *<rate>* **Kbps cbs** *<size>* **KB [count-eth-overhead]**
police cir *<rate>* **Kbps cbs** *<size>* **MB [count-eth-overhead]**
police cir *<rate>* **Kbps cbs** *<size>* **[count-eth-overhead]**
police cir *<rate>* **Kbps [count-eth-overhead]**

police cir *<rate>* **Mbps**
police cir *<rate>* **Mbps cbs** *<size>*
police cir *<rate>* **Mbps cbs** *<size>* **Bytes [count-eth-overhead]**
police cir *<rate>* **Mbps cbs** *<size>* **KB [count-eth-overhead]**
police cir *<rate>* **Mbps cbs** *<size>* **MB [count-eth-overhead]**
police cir *<rate>* **Mbps cbs** *<size>* **[count-eth-overhead]**
police cir *<rate>* **Mbps [count-eth-overhead]**

Syntax Description

cir <*rate*>	Specifies the CIR for traffic in the QoS map policer entry. This value specifies the average maximum data transmission rate of traffic allowed before the traffic can be dropped. Range is **8192** to **1000000000** bits per second (bps).
bps	Optional. Indicates the rate specified is in bits per second (bps).
Kbps	Optional. Indicates the rate specified is in kilobits per second (kbps).
Mbps	Optional. Indicates the rate specified is in megabits per second (Mbps).
cbs <*size*>	Optional. Specifies the CBS (in bytes) for traffic in this QoS map policer entry. This value specifies the maximum allowable number of bytes transmitted as a burst before the policer drops the traffic. Range is **1600** to **6250000** bytes.
Bytes	Optional. Indicates the burst size specified is in bytes.
KB	Optional. Indicates the burst size specified is in kilobytes (kB).
MB	Optional. Indicates the burst size specified is in megabytes (MB).
count-eth-overhead	Optional. Indicates to include the Ethernet header overhead bytes when determining packet size.

Default Values

The default policer CBS rate is specified in **bps**. The default CBS size is specified in **bytes**.

Command History

Release R11.9.0	Command was introduced.

Functional Notes

The policing function of the QoS map cannot be configured with other QoS map features. The QoS map used for traffic policing is applied to the tunnel interface using the command *qos-policy on page 3343*. If other configurations are included in the QoS map when it associated with the tunnel interface, the QoS map association is rejected.

Usage Examples

The following example creates a QoS map for policing traffic with a CIR of **2000** kbps:

(config)**#qos map POLICEQOS1**
(config-qos-map)**#police cir 2000 Kbps**

priority

Use the **priority** command to specify a high-priority queue, prioritizing this traffic above all others. If no traffic is present in any other queue, priority traffic is allowed to burst up to the interface rate; otherwise, priority traffic above the specified bandwidth is dropped. Use the **no** form of this command to disable this feature. Variations of this command include:

priority <*rate*>
priority <*rate*> **strict-rate-limiting**

priority <*rate*> <*burst size*>
priority <*rate*> <*burst size*> **strict-rate-limiting**
priority <*rate*> <*burst size*> **Bytes**
priority <*rate*> <*burst size*> **Bytes strict-rate-limiting**
priority <*rate*> <*burst size*> **KB**
priority <*rate*> <*burst size*> **KB strict-rate-limiting**
priority <*rate*> <*burst size*> **MB**
priority <*rate*> <*burst size*> **MB strict-rate-limiting**

priority <*rate*> **Kbps**
priority <*rate*> **Kbps strict-rate-limiting**
priority <*rate*> **Kbps** <*burst size*>
priority <*rate*> **Kbps** <*burst size*> **strict-rate-limiting**
priority <*rate*> **Kbps** <*burst size*> **Bytes**
priority <*rate*> **Kbps** <*burst size*> **Bytes strict-rate-limiting**
priority <*rate*> **Kbps** <*burst size*> **KB**
priority <*rate*> **Kbps** <*burst size*> **KB strict-rate-limiting**
priority <*rate*> **Kbps** <*burst size*> **MB**
priority <*rate*> **Kbps** <*burst size*> **MB strict-rate-limiting**

priority <*rate*> **Mbps**
priority <*rate*> **Mbps strict-rate-limiting**
priority <*rate*> **Mbps** <*burst size*>
priority <*rate*> **Mbps** <*burst size*> **strict-rate-limiting**
priority <*rate*> **Mbps** <*burst size*> **Bytes**
priority <*rate*> **Mbps** <*burst size*> **Bytes strict-rate-limiting**
priority <*rate*> **Mbps** <*burst size*> **KB**
priority <*rate*> **Mbps** <*burst size*> **KB strict-rate-limiting**
priority <*rate*> **Mbps** <*burst size*> **MB**
priority <*rate*> **Mbps** <*burst size*> **MB strict-rate-limiting**

priority unlimited

priority percent <*value*>
priority percent <*value*> **strict-rate-limiting**

priority percent <*value*> <*burst size*>
priority percent <*value*> <*burst size*> **strict-rate-limiting**
priority percent <*value*> <*burst size*> **Bytes**
priority percent <*value*> <*burst size*> **Bytes strict-rate-limiting**
priority percent <*value*> <*burst size*> **KB**
priority percent <*value*> <*burst size*> **KB strict-rate-limiting**
priority percent <*value*> <*burst size*> **MB**
priority percent <*value*> <*burst size*> **MB strict-rate-limiting**

*The **priority** command cannot be specified in conjunction with the **shape average** command in a quality of service (QoS) entry.*

Syntax Description

<*rate*>	Specifies the bandwidth rate, prioritizing this traffic above all other user traffic. Range is **8** to **1000000** kilobits per second (kbps).
<*burst size*>	Optional. Specifies the maximum burst size (MBS) (in bytes) for traffic in this priority queue. This parameter should be left unconfigured for optimal performance. Range for burst size is **32** to **1000000** bytes.
Kbps	Optional. Indicates the rate specified is in kbps.
Mbps	Optional. Indicates the rate specified is in megabits per second (Mbps).
Bytes	Optional. Indicates the burst size specified is in bytes.
KB	Optional. Indicates the burst size specified is in kilobytes (kB).
MB	Optional. Indicates the burst size specified is in megabytes (MB).
percent <*value*>	Allocates a maximum bandwidth for a traffic class, specifying the maximum as a percentage of the total interface bandwidth. This command is especially useful for protecting bandwidth allocation in multilink applications. Refer to *Functional Notes* for more details.
strict-rate-limiting	Optional. When used with the **priority** command, this feature limits priority traffic to a maximum rate as specified by the <*rate*> variable. When used with **priority percent** command, this feature limits priority traffic to a maximum percentage of the interface bandwidth as specified by the <*value*> variable.
unlimited	Optional. Specifies no limits on the priority queue bandwidth. Use of this feature could potentially use all of the available bandwidth on the interface, even when the **max-reserved-bandwidth** command is not set to 100 percent.

*Use the **priority unlimited** command with extreme caution as it could prevent vital Layer 2 traffic from being processed. A network outage could occur when excessive priority traffic is present and consumes all of the available bandwidth on the interface.*

Default Values

No default values are necessary for this command. The priority rate is assumed to be provided in **Kbps** unless **Mbps** is specified. The burst size is assumed to be provided in bytes unless **KB** or **MB** is specified.

Command History

Release 6.1	Command was introduced.
Release 17.5	Command was expanded to allow specifying the rate in kbps and Mbps. Specifying the burst size in bytes, MB, and kB was also added.
Release 18.1	Command was expanded to include the **strict-rate-limiting** parameter.

Functional Notes

Priority queues are intended for constant bit rate (CBR) traffic, such as voice (due to the rate limiting). Non-CBR traffic typically does not respond well to packet dropping when it is rate limited, so the transfer rate can be much less efficient. Important data traffic should typically use the class-based queue **bandwidth** command (refer to *bandwidth on page 4466*) instead.

The sum of the bandwidths reserved by **priority** and **bandwidth** commands for all entries of a QoS map cannot exceed the available bandwidth on the interface (calculated by the total interface bandwidth minus the **max-reserved-bandwidth** rate specified for the interfaces to which the QoS map is applied). Priority bandwidth is guaranteed bandwidth (in kbps).

Weighted fair queuing (WFQ) must be enabled on an interface to use priority queuing. By default, WFQ is enabled for all interfaces with maximum bandwidth speeds equivalent to T1/E1 and below. It is also employed when shaping is enabled.

Determining Bandwidth Entries

*When possible, use the **priority** <rate> command to specify an absolute amount of bandwidth (in kbps) for the priority queue.*

When determining the **priority percent** <*value*> entry, use the following formula:

$$\frac{\text{Bandwidth}}{\text{Line Rate}} \times 100$$

where

Bandwidth	Specifies the minimum amount of bandwidth needed for the traffic (in kbps).
Line Rate	Specifies the total data rate configured on the interface (for example, 8 DS0s (64 kbps per DS0) on a T1 equals a line rate of 512 kbps).

For example, to specify 76.8 kbps of data on an interface with a total of 512 kbps of available bandwidth, enter the following command:

(config-qos-map 1)**#priority percent 15**

Usage Examples

The following example configures QoS for a network with the following needs:

Reserve 15 percent of the line rate for routing traffic and L2 protocol traffic (**max-reserved-bandwidth** = 85).

Line Rate = 512 kbps
Guaranteed 256 kbps for Voice
Guaranteed 96 kbps for Class 1
Guaranteed 52 kbps for Class 2

To configure this QoS policy, enter the following QoS map and interface commands:

1. Allocate low latency queuing (LLQ) priority voice traffic.

(config)**#qos map MYMAP 10**
(config-qos-map)**#match ip list VOICE**
(config-qos-map)**#priority 256**

2. Allocate the class-based weighted fair queuing (CBWFQ) data traffic bandwidth for CLASS 1 and CLASS 2.

(config)**#qos map MYMAP 20**
(config-qos-map)**#match ip list CLASS_1**
(config-qos-map)**#bandwidth 96**

(config)**#qos map MYMAP 30**
(config-qos-map)**#match ip list CLASS_2**
(config-qos-map)**#bandwidth 52**

3. Specify the reserved bandwidth on the appropriate interface and apply the map.

(config-fr 1)**#max-reserved-bandwidth 85**
(config-fr 1)**#qos-policy out MYMAP**

priority queue-limit *<value>*

Use the **priority queue-limit** command to set the maximum number of packets to store in the priority queue. This command allows the the priority queue to be configured to optimize quality of service (QoS) configurations for higher speed Voice over IP (VoIP) applications. To use this command, you must first enable priority queueing in the QoS map using the command *priority on page 4481*. Use the **no** form of this command to return the queue limit to the default value.

Syntax Description

<value>	Specifies the maximum number of packets to store in the priority queue. Valid range is **256** to **1024** packets.

Default Values

By default, the priority queue limit is set to **256** packets.

Command History

Release R10.3.0	Command was introduced.

Functional Notes

When a priority queue limit is configured on a child QoS map, the parent QoS map's priority queue limit can change. The parent's priority queue limit is based on the the configured priority queue limit for the parent queue, the largest nondefault configured priority queue limit of one of the parent's child QoS map entries, and the default queue limit.

In addition, increasing the priority queue limit also increases the possible latency for priority packets.

Usage Examples

The following example specifies that the priority queue limit for the QoS map **VOICEMAP** is set to **500** packets:

(config)**#qos map VOICEMAP 10**
(config-qos-map)**#priority queue-limit 500**

qos-policy *<map name>*

Use the **qos-policy** command within a parent map to divide a quality of service (QoS) policy map into more specific subclasses. Use the **no** form of this command to remove the subclass and policy mapping attributes of the parent map.

Syntax Description

<map name>	Specifies the QoS map name.

Default Values

No default values are necessary for this command.

Command History

Release 17.2	Command was introduced.

Functional Notes

The **qos-policy** command has two functions in the Adtran Operating System (AOS) command line interface (CLI). In the application described here, it is used to further subdivide a class into more specific subclasses. From the interface configuration command set, it is used to apply a QoS map to the interface. Refer to *qos-policy on page 2306* in the *Ethernet Interface Command Set* for more information on using the **qos-policy** command in the interface configuration command set.

When subdividing a QoS policy map, the most specific (or child map) QoS map should be created first and then the map is referenced using the **qos-policy** command within the QoS map entry of the base map that is being subdivided. The base (or parent map) is applied to the interface using the **qos-policy out** command (refer to *qos-policy on page 2306*).

Only two levels of maps are allowed, meaning child maps (or subclasses) cannot have additional child maps beneath them. A child map cannot reference another child map. If the child map referenced by this command is deleted, then the **qos-policy** command is also deleted from the parent map.

Usage Examples

For example, the following configuration uses the **SHAPEEVCS** QoS map to constrain each VLAN's Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6) traffic to specific rates. The virtual local area network (VLAN) 2 traffic that is put into the shaping queue is broken up into class-based queuing (CBQ) or low latency queuing (LLQ) subclasses using the **CLASSQUEUES** QoS map. Traffic not matching a QoS map entry is treated as best effort, and is dynamically assigned to a best effort weighted fair queue (WFQ).

```
(config)#qos map CLASSQUEUES 10
(config-qos-map)#match dscp ef
(config-qos-map)#priority 200
(config-qos-map)#qos map CLASSQUEUES 20
(config-qos-map)#match dscp af31 af32 af33
(config-qos-map)#bandwidth 500          ! class based rate in Kbps
```

(config-qos-map)**#qos map SHAPEEVCS 10**
(config-qos-map)**#match vlan 2**
(config-qos-map)**#shape average 1000000** ! *vlan2Rate in bps*
(config-qos-map)**#qos-policy CLASSQUEUES**

(config-qos-map)**#qos map SHAPEEVCS 20**
(config-qos-map)**#match vlan 3**
(config-qos-map)**#shape average 2000000** ! *vlan3Rate*

(config-qos-map)**#interface eth 0/1**
(config-eth 0/1)**#encapsulation 802.1q**
(config-eth 0/1)**#qos-policy out SHAPEEVCS**

(config-eth 0/1)**#interface eth 0/1.2**
(config-eth 0/1.2)**#vlan-id 2**
(config-eth 0/1.2)**#interface eth 0/1.3**
(config-eth 0/1.3)**#vlan-id 3**

set ce-vlan-pri *<value>*

Use the **set ce-vlan-pri** command to override an Ethernet customer equipment (CE) virtual local area network (VLAN) priority field for the quality of service (QoS) policy map. Use the **no** form of this command to return the priority field value to the default setting.

Syntax Description

<value>	Specifies the CE VLAN priority field value. Valid range is **0** to **7**.

Default Values

By default, the packet's priority value field is not set.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies a CE VLAN priority field value of **3** for **MAP1**:

(config)**#qos map MAP1**
(config-qos-map)**#set ce-vlan-pri 3**

set cos *<value>*

Use the **set cos** command to modify the Layer 2 class of service (CoS) value (on matching packets) to the specified value. Use the **no** form of this command to discontinue the action from the quality of service (QoS) policy map.

Syntax Description

<value>	Specifies the CoS numeric value. Valid range is **0** to **7**.

Default Values

No default values are necessary for this command.

Command History

Release 17.2	Command was introduced.

Functional Notes

QoS policies are configured in the Adtran Operating System (AOS) command line interface (CLI) to dictate the priority for servicing specified traffic types on a particular interface. QoS policies contain at least one match reference (using the **match** command) and one or more action items (using the **priority**, **bandwidth**, **shape**, or **set** commands).

The **set cos** command can be used to change the Ethernet 802.1p priority field for traffic serviced by the QoS policy. Every 802.1q tagged Ethernet frame contains a 3-bit CoS field used for marking data types requiring special handling when traveling through the network.

Usage Examples

The following example sets the CoS value, for all matching traffic within the specified QoS map entry, to **1**:

(config)**#qos map VOICEMAP 10**
(config-qos-map)**#set cos 1**

The following example removes all CoS value change requests from the QoS map entry:

(config)**#qos map VOICEMAP 10**
(config-qos-map)**#no set cos**

set dscp

Use the **set dscp** command to modify the differentiated services code point (DSCP) field (on matching Internet Protocol version 4 (IPv4) and/or Internet Protocol version 6 (IPv6) packets) to the specified value. For more details on determining the DSCP field, refer to the *Technology Review* section of the command *match dscp on page 4473*. Use the **no** form of this command to remove a specified DSCP value. Variations of this command include:

set dscp *<value>*
set dscp af*xx*
set dscp cs*x*
set dscp default
set dscp ef

Syntax Description

<value>	Specifies the DSCP numeric value. Valid range is **0** to **63**.
af*xx*	Specifies the assured forwarding (AF) class and subclass. Select from: **11** (001010), **12** (001100), **13** (001110), **21** (010010), **22** (010100), **23** (010110), **31** (011010), **32** (011100), **33** (011110), **41** (100010), **42** (100100), or **43** (100110).
cs*x*	Specifies the class selector (CS) value. Valid range is **1** to **7**.
default	Specifies the default IP DSCP value (000000).
ef	Specifies marking for expedited forwarding (EF).

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.

Functional Notes

Quality of service (QoS) policies are configured in the Adtran Operating System (AOS) command line interface (CLI) to dictate the priority for servicing specified traffic types on a particular interface. QoS policies contain at least one match reference (using the **match** command) and one or more action items (using the **priority**, **bandwidth**, **shape**, or **set** commands).

The **set dscp** command can be used to change the differentiated services (DS or DiffServ) field for incoming IPv4 and IPv6 traffic serviced by the quality of service (QoS) policy. Every IPv4 header contains an 8-bit type of service (ToS) field used for marking data types requiring special handling when traveling through the network. IPv6 headers have an 8-bit traffic class field serving the same purpose. Originally this ToS field was used for IP precedence markings (using only the first three bits of the 8-bit field), and was later revised in RFC 2474 to create the 6-bit DS field (reserving the last two bits of the field for future use). The DS field can be manipulated to indicate higher or lower traffic priority using decimal values between 0 and 63.

Usage Examples

This command sets the DSCP value, for all matching traffic within the specified QoS map entry, to **46**:

(config)**#qos map VOICEMAP 10**
(config-qos-map)**#set dscp 46**

set egress-queue <*value*>

Use the **set egress-queue** command to specify the Metro Ethernet network (MEN) egress queue used for traffic that matches the QoS map. Use the **no** form of this command to disable this feature.

Syntax Description

<*value*>	Specifies the MEN egress queue to which the matched traffic is mapped. Valid range is **0** to **7**.

Default Values

By default, this command is disabled.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies that traffic matching QoS map **Map1** is queued in MEN egress queue **4**:

(config)**#qos map Map1**
(config-qos-map)**#set egress-queue 4**

set men-c-tag-pri *<priority>*

Use the **set men-c-tag-pri** command to specify the C-tag priority value used for C-tagged egress traffic from a network-to-network interface (NNI) port. Use the **no** form of this command to disable this feature.

Syntax Description

<priority>	Configures the priority for C-tagged egress traffic. Valid range is **0** to **7**.

Default Values

By default, this command is disabled.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

Quality of service (QoS) policies are configured in the Adtran Operating System (AOS) command line interface (CLI) to dictate the priority for servicing specified traffic types on a particular interface. QoS policies contain at least one match reference (using the **match** command) and one or more action items (using the **priority**, **bandwidth**, **shape**, or **set** commands).

The **set men-c-tag-pri** command applies to the C-tag priority of egress traffic from an NNI port. This command overrides the sub-interface's **men-c-tag-pri** setting.

Usage Examples

The following example specifies that C-tagged traffic matching QoS map **Map1** is given a priority of **5**:

(config)**#qos map Map1**
(config-qos-map)**#set men-c-tag-pri 5**

set men-pri *<priority>*

Use the **set men-pri** command to specify the S-tag priority value for S-tagged egress traffic from a network-to-network interface (NNI) port. Use the **no** form of this command to disable this feature.

Syntax Description

<priority>	Configures the priority for S-tagged egress traffic. Valid range is **0** to **7**.

Default Values

By default, this command is disabled.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

Quality of service (QoS) policies are configured in the Adtran Operating System (AOS) command line interface (CLI) to dictate the priority for servicing specified traffic types on a particular interface. QoS policies contain at least one match reference (using the **match** command) and one or more action items (using the **priority**, **bandwidth**, **shape**, or **set** commands).

The **set men-pri** command applies to the S-tag priority of egress traffic from an NNI port. This command overrides the sub-interface's **men-pri** setting.

Usage Examples

The following example specifies that S-tagged traffic matching QoS map **Map1** is given a priority of **5**:

(config)**#qos map Map1**
(config-qos-map)**#set men-pri 5**

set precedence <*value*>

Use the **set precedence** command to modify the precedence value (on matching packets) in the Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) header to the specified value. For more details on precedence, refer to the *Technology Review* section of the command *match precedence <value> on page 4477*. Use the **no** form of this command to discontinue the action from the quality of service (QoS) policy map.

Syntax Description

<value>	Specifies the IP precedence numeric value. Valid range is **0** to **7** in ascending order of importance.

Default Values

No default values are necessary for this command.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example sets the precedence value, for all matching traffic within the specified QoS map entry, to **1**:

(config)**#qos map VOICEMAP 10**
(config-qos-map)**#set precedence 1**

The following example removes all precedence value change requests from the QoS map entry:

(config)**#qos map VOICEMAP 10**
(config-qos-map)**#no set precedence**

shape average

Use the **shape average** command to shape the traffic in this class to an average rate. Use the **no** form of this command to disable this feature. Variations of this command include:

shape average <*rate*> **[count-eth-overhead]**

shape average <*rate*> **bps**
shape average <*rate*> **bps burst** <*size*>
shape average <*rate*> **bps burst** <*size*> **Bytes [count-eth-overhead]**
shape average <*rate*> **bps burst** <*size*> **KB [count-eth-overhead]**
shape average <*rate*> **bps burst** <*size*> **MB [count-eth-overhead]**
shape average <*rate*> **bps burst** <*size*> **[count-eth-overhead]**
shape average <*rate*> **bps [count-eth-overhead]**

shape average <*rate*> **Kbps**
shape average <*rate*> **Kbps burst** <*size*>
shape average <*rate*> **Kbps burst** <*size*> **Bytes [count-eth-overhead]**
shape average <*rate*> **Kbps burst** <*size*> **KB [count-eth-overhead]**
shape average <*rate*> **Kbps burst** <*size*> **MB [count-eth-overhead]**
shape average <*rate*> **Kbps burst** <*size*> **[count-eth-overhead]**
shape average <*rate*> **Kbps [count-eth-overhead]**

shape average <*rate*> **Mbps**
shape average <*rate*> **Mbps burst** <*size*>
shape average <*rate*> **Mbps burst** <*size*> **Bytes [count-eth-overhead]**
shape average <*rate*> **Mbps burst** <*size*> **KB [count-eth-overhead]**
shape average <*rate*> **Mbps burst** <*size*> **MB [count-eth-overhead]**
shape average <*rate*> **Mbps burst** <*size*> **[count-eth-overhead]**
shape average <*rate*> **Mbps [count-eth-overhead]**

shape average <*rate*> **burst** <*size*> **[count-eth-overhead]**
shape average <*rate*> **burst** <*size*> **Bytes [count-eth-overhead]**
shape average <*rate*> **burst** <*size*> **KB [count-eth-overhead]**
shape average <*rate*> **burst** <*size*> **MB [count-eth-overhead]**

*The **shape average** command cannot be specified in conjunction with the **priority** command in a quality of service (QoS) entry.*

Syntax Description

<rate>	Specifies an average bandwidth. Range is **8192** to **1000000000** bits per second (bps).
burst *<size>*	Optional. Specifies the maximum burst size (MBS) (in bytes) for traffic in this QoS map entry. This parameter should be left unconfigured for optimal performance. Range is **1600** to **6250000** bytes.
count-eth-overhead	Optional. Indicates to include the Ethernet header overhead bytes when determining packet size.
bps	Optional. Indicates the rate specified is in bps.
Kbps	Optional. Indicates the rate specified is in kilobits per second (kbps).
Mbps	Optional. Indicates the rate specified is in megabits per second (Mbps).
Bytes	Optional. Indicates the burst size specified is in bytes.
KB	Optional. Indicates the burst size specified is in kilobytes (kB).
MB	Optional. Indicates the burst size specified is in megabytes (MB).

Default Values

The default shape average rate is specified in **bps**. The default burst size is specified in **bytes**.

Command History

Release 17.2	Command was introduced.
Release 17.5	Command was expanded to allow specifying shape average rate in bps, kbps, and Mbps. Specifying the burst size in bytes, MB, and kB was also added.

Functional Notes

Traffic shaping allows the traffic to be smoothed in order to maintain a uniform rate to take full advantage of the provided bandwidth. Short bursts of traffic above the configured rate are allowed when there is sufficient budget. Traffic outside of the current budget is put into a shaping queue and transmitted once the budget is available.

Usage Examples

The following example shapes the traffic in this QoS class to an average rate of **2000000** bps:

(config)**#qos map VOICEMAP 10**
(config-qos-map)**#shape average 2000000**

RADIUS GROUP COMMAND SET

The remote authentication dial-in user service (RADIUS) Group Command Set details how to create a RADIUS server group and how to add servers to this group. Configured groups of RADIUS servers can be created to be used as methods for authentication, authorization, and accounting (AAA) services in AOS. These subsets are used when defining method lists for AAA actions and can keep you from having to specify that all configured RADIUS servers are used for AAA.

To work with RADIUS server groups, AAA must be enabled. Refer to the command *aaa on on page 1187* for more information. Any RADIUS servers you want to add to the RADIUS server group must already be configured before attempting to add them to the server group. For more information about configuring RADIUS servers, refer to the commands *radius-server on page 1680* and *radius-server host on page 1682*.

RADIUS server groups are first defined in the Global Configuration mode using the **aaa group server** command. Entering this command allows you to create a group of RADIUS servers, and then enters the RADIUS Group Configuration mode in order to add servers to the group. For more information about creating a server group, refer to the command *aaa group server on page 1184*.

For more information about configuring RADIUS server groups for use with AAA, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

To activate the RADIUS Group Configuration mode, enter the **aaa group server radius** <*name*> command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#aaa group server radius RADAuthgroup
(config-sg-radius)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

server <hostname | ip address> on page 4499
vrf <name> server <hostname | ip address> on page 4501

server <*hostname | ip address*>

Use the **server** command to add a predefined remote authentication dial-in user service (RADIUS) server to the RADIUS server group for use with authentication, authorization, and accounting (AAA). This command applies the configuration to the default unnamed VRF. Use the command *vrf <name> server <hostname | ip address> on page 4501* to apply the configuration to a specific VRF instance. Use the **no** form of this command to remove the server from the group. Variations of this command include:

server <*hostname* | *ip address*>
server <*hostname* | *ip address*> **acct-port** <*number*>
server <*hostname* | *ip address*> **auth-port** <*number*>

Syntax Description

<*hostname*	*ip address*>	Specifies the server to add to the group. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). If a host name is used, a domain naming system (DNS) server should be learned by the AOS device using Dynamic Host Configuration Protocol (DHCP), Point-to-Point Protocol (PPP), or specified in the Global Configuration mode with the command *name-server on page 1622*.
acct-port <*number*>	Optional. Specifies the User Datagram Protocol (UDP) port for AAA accounting services with the RADIUS server being added to the RADIUS server group. Port range is **0** to **65535**. This command is reserved for future use. Currently, AOS does not allow RADIUS servers for use with accounting.
auth-port <*number*>	Optional. Specifies the UDP port for AAA authentication services with the RADIUS server being added to the RADIUS server group. Port range is **0** to **65535**.

Default Values

By default, the accounting port is set to **1813** and the authentication port is set to **1812**.

Command History

Release 5.1	Command was introduced.

Functional Notes

Empty RADIUS server groups are not saved. When the last server is removed from a group, AOS automatically deletes the group.

If you choose to change the default authentication port for the RADIUS server, you can then create multiple host entries for the same server. Server groups can have multiple host entries for the same server as long as each entry has a unique identifier (an IP address and a UDP port). If you configure two host entries on the same RADIUS server and are using both host entries for the same service (for example, using both entries for authentication), then the second entry functions as a failover. RADIUS host entries are tried in the order they are configured, so the failover entry is the second configured entry.

For more information about server groups, refer to the command *aaa group server on page 1184*.

Usage Examples

The following example specifies that the RADIUS servers at IP address **192.168.1.2** and **192.168.1.3** are added to the server group **RADAuthgroup**:

(config)**#aaa group server radius RADAuthgroup**
(config-sg-radius)**#server 192.168.1.2**
(config-sg-radius)**#server 192.168.1.3**
(config-sg-radius)**#exit**
(config)**#**

vrf <*name*> server <*hostname | ip address*>

Use the **vrf** <*name*> **server** command to add a predefined remote authentication dial-in user service (RADIUS) server to the RADIUS server group for use with authentication, authorization, and accounting (AAA) on the specified virtual routing and forwarding (VRF) instance. Use the command *server <hostname | ip address> on page 4499* to apply the configuration to the default unnamed VRF instance. Use the **no** form of this command to remove the server from the group. Variations of this command include:

vrf <*name*> **server** <*hostname | ip address*>
vrf <*name*> **server** <*hostname | ip address*> **acct-port** <*number*>
vrf <*name*> **server** <*hostname | ip address*> **auth-port** <*number*>

Syntax Description

<*hostname	ip address*>	Specifies the server to add to the group. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). If a host name is used, a domain naming system (DNS) server should be learned by the AOS device using Dynamic Host Configuration Protocol (DHCP), Point-to-Point Protocol (PPP), or specified in the Global Configuration mode with the command *name-server on page 1622*.
acct-port <*number*>	Optional. Specifies the User Datagram Protocol (UDP) port for AAA accounting services with the RADIUS server being added to the RADIUS server group. Port range is **0** to **65535**. This command is reserved for future use. Currently, AOS does not allow RADIUS servers for use with accounting.
auth-port <*number*>	Optional. Specifies the UDP port for AAA authentication services with the RADIUS server being added to the RADIUS server group. Port range is **0** to **65535**.
vrf <*name*>	Specifies the name of the VRF to which to assign the RADIUS server. If no VRF is specified, the association is applied to the default unnamed VRF.

Default Values

By default, the accounting port is set to **1813** and the authentication port is set to **1812**.

Command History

Release R10.7.0	Command was introduced.

Functional Notes

Empty RADIUS server groups are not saved. When the last server is removed from a group, AOS automatically deletes the group.

If you choose to change the default authentication port for the RADIUS server, you can then create multiple host entries for the same server. Server groups can have multiple host entries for the same server as long as each entry has a unique identifier (an IP address and a UDP port). If you configure two host entries on the same RADIUS server and are using both host entries for the same service (for example, using both entries for authentication), then the second entry functions as a failover. RADIUS host entries are tried in the order they are configured, so the failover entry is the second configured entry.

For more information about server groups, refer to the command *aaa group server on page 1184*.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example specifies that the RADIUS servers at IP address **192.168.1.2** and **192.168.1.3** on the vrf **RED** are added to the server group **RADAuthgroup**:

(config)**#aaa group server radius RADAuthgroup**
(config-sg-radius)**#vrf RED server 192.168.1.2**
(config-sg-radius)**#vrf RED server 192.168.1.3**
(config-sg-radius)**#exit**
(config)#

SECURITY MONITOR COMMAND SET

The AOS security monitor feature simplifies the collection and display of network information that is relevant to the security of the network. It provides a general overview of network security status that allows the user to quickly and easily assess security threats and firewall status. In the AOS GUI, the security monitor feature is called the security dashboard. For more information about configuring the security monitor feature, refer to the *Security Dashboard* configuration guide available online at https://supportcommunity.adtran.com.

To enter the Security Monitor Configuration mode, enter the **ip security monitor** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ip security monitor
(config-secmon)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the section listed below:

cross-connect on page 76
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order:

color on page 4504
stats-filter <name> on page 4505
threat on page 4506

color

Use the **color** command to display threats in the security monitor using a colored background to correspond to their threat level. Use the **no** version of this command to restore the system default.

Syntax Description

No subcommands.

Default Values

By default, no color is displayed.

Command History

Release 17.5	Command was introduced.

Usage Examples

The following example turns on color in the security monitor:

```
(config-)#ip security monitor
(config-secmon)#color
```

stats-filter <*name*>

Use the **stats-filter** command to apply a previously created security monitor statistics filter globally. Use the **no** version of this command to remove the filter.

Syntax Description

<*name*>	Specifies the filter to be applied.

Default Values

No default values are necessary for this command.

Command History

Release 17.5	Command was introduced.

Functional Notes

A security monitor statistic filter is created from the Global Configuration mode using the command *ip security monitor stats-filter <name> on page 1485*.

Usage Examples

The following example applies a filter named **F1**:

(config-)**#ip security monitor**
(config-secmon)**# stats-filter F1**

threat

Use the **threat** command to define a filter. Use the **no** version of this command to remove all threats from the filter.Variations of this command include:

threat all
threat all except <*id(s)*>
threat add <*id(s)*>
threat add <*id(s)*> **except** <*id(s)*>
threat none
threat remove <*id(s)*>
threat remove <*id(s)*> **except** <*id(s)*>

Syntax Description

all	Adds all security threats to the filter.
<*id(s)*>	Specifies the ID of the security threat.
add	Adds the specified security threats to the filter.
except	Optional. Specifies security threats to be exempted from the filter.
none	Removes all security threats from the filter.
remove	Removes the specified security threats from the filter.

Default Values

No default values are necessary for this command.

Command History

Release 17.5	Command was introduced.

Functional Notes

A list of security threat IDs can be displayed using the command *show ip security on page 780*. The security monitor stats filter is created from the global configuration mode using the command *ip security monitor stats-filter <name> on page 1485*.

Usage Examples

The following example adds all security threats to the filter:

(config-)**#ip security monitor stats-filter F1**
Creating new filter “F1”.
(config-secmon-filter)**#threat all**
(config-secmon-filter)#

TACACS+ GROUP COMMAND SET

The terminal access controller access control system plus (TACACS+) Group Command Set details how to create a TACACS+ server group and how to add servers to this group. Configured groups of TACACS+ servers can be created to be used as methods for authentication, authorization, and accounting (AAA) services in AOS. These subsets are used when defining method lists for AAA actions and can keep you from having to specify that all configured TACACS+ servers are used for AAA.

To work with TACACS+ server groups, AAA must be enabled. Refer to the command *aaa on on page 1187* for more information. Any TACACS+ servers you want to add to the TACACS+ server group must already be configured before attempting to add them to the server group. For more information about configuring TACACS+ servers, refer to the commands *tacacs-server on page 1867* and *tacacs-server host on page 1868*.

TACACS+ server groups are first defined in the Global Configuration mode using the **aaa group server** command. Entering this command allows you to create a group of TACACS+ servers, and then enters the TACACS+ Group Configuration mode in order to add servers to the group. For more information about creating a server group, refer to the command *aaa group server on page 1184*.

For more information about configuring TACACS+ server groups for use with AAA, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

To activate the TACACS+ Group Configuration mode, enter the **aaa group server tacacs+** *<name>* command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#aaa group server tacacs+ TACAuthgroup
(config-sg-tacacs+)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

server <hostname | ip address> on page 4508
vrf <name> server <hostname | ip address> on page 4509

server *<hostname | ip address>*

Use the **server** command to add a predefined terminal access controller access control system plus (TACACS+) server to the TACACS+ server group for use with authentication, authorization, and accounting (AAA). This command applies the configuration to the default unnamed VRF. Use the command *vrf <name> server <hostname | ip address> on page 4509* to apply the configuration to a specific VRF instance. Use the **no** form of this command to remove the server from the group.

Syntax Description

<hostname | ip address>	Specifies the server to add to the group. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). If a host name is used, a domain naming system (DNS) server should be learned by the AOS device using Dynamic Host Configuration Protocol (DHCP), Point-to-Point Protocol (PPP), or specified in the Global Configuration mode with the command *name-server on page 1622*.

Default Values

By default, no TACACS+ server groups are configured.

Command History

Release 5.1	Command was introduced.

Functional Notes

Empty TACACS+ server groups are saved. When the last server is removed from a group, AOS automatically maintains the group.

For more information about server groups, refer to the command *aaa group server on page 1184*.

Usage Examples

The following example specifies that the TACACS+ servers at IP address **192.168.1.4** and **192.168.1.5** are added to the server group **TACAuthgroup**:

```
(config)#aaa group server tacacs+ TACAuthgroup
(config-sg-tacacs+)#server 192.168.1.4
(config-sg-tacacs+)#server 192.168.1.5
(config-sg-tacacs+)#exit
(config)#
```

vrf <*name*> server <*hostname | ip address*>

Use the **vrf** <*name*> **server** command to add a predefined terminal access controller access control system plus (TACACS+) server to the TACACS+ server group for use with authentication, authorization, and accounting (AAA) on the specified virtual routing and forwarding (VRF) instance. Use the command *server <hostname | ip address> on page 4508* to apply the configuration to the default unnamed VRF instance. Use the **no** form of this command to remove the server from the group.

Syntax Description

<hostname | ip address>	Specifies the server to add to the group. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). If a host name is used, a domain naming system (DNS) server should be learned by the AOS device using Dynamic Host Configuration Protocol (DHCP), Point-to-Point Protocol (PPP), or specified in the Global Configuration mode with the command *name-server on page 1622*.
vrf <*name*>	Specifies the name of the VRF to which to assign the TACACS+ server.

Default Values

By default, no TACACS+ server groups are configured.

Command History

Release R10.7.0	Command was introduced.

Functional Notes

Empty TACACS+ server groups are saved. When the last server is removed from a group, AOS automatically maintains the group.

For more information about server groups, refer to the command *aaa group server on page 1184*.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default unnamed VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example specifies that the TACACS+ servers at IP address **192.168.1.4** and **192.168.1.5** are added to the server group **TACAuthgroup**:

```
(config)#aaa group server tacacs+ TACAuthgroup
(config-sg-tacacs+)#vrf RED server 192.168.1.4
(config-sg-tacacs+)#vrf RED server 192.168.1.5
(config-sg-tacacs+)#exit
(config)#
```

TOP TRAFFIC COMMAND SET

To activate the Top Traffic Configuration mode, enter the **ip flow top-talkers** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ip flow top-talkers
(config-top-talkers)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

interval

Use the **interval** command to specify the minimum interval for which Top Talkers data is collected. Use the **no** form of this command to reset the interval to the default value. Variations of this command include:

interval 5
interval 10
interval 15

If the interval is changed after Top Talkers has been enabled, all accumulated data will be lost.

Syntax Description

5	Collects Top Talkers data at **5**-minute intervals.
10	Collects Top Talkers data at **10**-minute intervals.
15	Collects Top Talkers data at **15**-minute intervals.

Default Values

By default, the interval for Top Talkers data collection is set to **5**-minute intervals.

Command History

Release 17.1	Command was introduced.

Functional Notes

When viewing Top Talkers data, the current interval displayed is the interval set with this command. As the specified interval for data accumulation ends, the data is compiled into hourly, 24 hourly, and daily readouts.

Usage Examples

The following example sets the interval for Top Talkers data collection to **10-minute** intervals:

(config)**#ip flow top-talkers**
(config-top-talkers)**#interval 10**

match list *<name>*

Use the **match list** command to specify an access control list (ACL) be used to filter the data that can be used in Top Talkers listings. Use the **no** form of this command to specify no ACL is used and all traffic is considered.

Syntax Description

<name>	Specifies the name of the ACL to be used to filter Top Talkers data collection.

Default Values

By default, no ACL is assigned and all traffic is considered.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example applies the ACL named **engineering** to filter Top Talkers data collection:

(config)**#ip flow top-talkers**
(config-top-talkers)**#match list engineering**

monitor port <*number*> <*description*>

Use the **monitor port** command to add a custom port to the port monitoring list in the Top Talkers feature. Use the **no** form of this command to remove the port from the monitoring list.

Syntax Description

<*number*>	Specifies the port number to be monitored.
<*description*>	Optional. Specifies the application name associated with the port.

Default Values

By default, port monitoring is enabled and monitors well-known Transmission Control Protocol (TCP) and User Datagram Protocol (UDP) ports when Top Talkers is enabled. Up to 32 custom ports can be added to the port monitoring list.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example adds port **3724**, the World of Warcraft gaming port, to Top Talkers' port monitoring list:

(config)**#ip flow top-talkers**
(config-top-talkers)**#monitor port 3724 World of Warcraft Gaming**

sort-by

Use the **sort-by** command to specify the type of data for the Top Talkers collection. Use the **no** form of this command to return the sorting procedure to the default setting. Variations of this command include the following:

sort-by packets
sort-by bytes

If the statistic to be gathered is changed once Top Talkers is configured, all existing data will be lost.

Syntax Description

packets	Specifies packet statistics are monitored for Top Talkers collection.
bytes	Specifies byte statistics are monitored for Top Talkers collection.

Default Values

By default, Top Talkers will collect **byte** statistics.

Command History

Release 17.1	Command was introduced.

Functional Notes

Data used in the Top Talkers collection can be collected by monitoring the number of packets sent or received or the number of bytes sent or received in a specified amount of time. Collection by byte count and packet count are mutually exclusive and must be configured by the user. Yet each can be helpful depending on specific network needs. Using packet counts to monitor hosts can make it easier to identify the source of problems in cases where a host is infected by a virus, or attacking the network with a port scan. Using byte counts can display overall bandwidth consumption on a host-by-host basis.

Usage Examples

The following example specifies **packet** statistics for collection:

(config)**#ip flow top-talkers**
(config-top-talkers)**#sort-by packets**

top *<number>*

Use the **top** command to specify the number of listings included in the Top Talkers report. Use the **no** form of this command to return to the default value.

If the number of listings is changed after Top Talkers has been enabled, all accumulated data will be lost.

Syntax Description

<number>	Specifies the number of listings shown in the Top Talkers report. Range is **1** to **20**.

Default Values

By default, Top Talkers will display **5** listings in a report.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example specifies that **10** listings will be included in the Top Talkers report:

(config)**#ip flow top-talkers**
(config-top-talkers)**#top 10**

VOICE COMMAND SETS

The voice command sets are divided into the following sections:

VOICE ACCOUNTS COMMAND SETS

This section includes the following command sets:

VOICE LINE ACCOUNT COMMAND SET

The voice line account commands help you to configure the lines used by voice users. These commands allow you to configure call coverages, call permissions, system activities, and to monitor the quality of the voice connections. Voice line account configurations work hand-in-hand with other voice features, such as system modes, shared line accounts (SLAs), and shared call appearances (SCAs). For more information on system modes, refer to the *NetVanta 7000 Series System Modes* quick configuration guide available online at https://supportcommunity.adtran.com. For more information on SLAs, refer to the *Shared Line Accounts over Analog Trunks* configuration guide, and for more information on SCAs, refer to the *NetVanta 7000 Series Shared Call Appearances* quick configuration guide, both available online at https://supportcommunity.adtran.com.

To create a voice line account and enter the Voice Line Account Configuration mode, enter the **voice line** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice line SALES
(config-SALES)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

description <text> on page 80
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

accept <template> on page 4520
alc on page 4522
anlp on page 4523
codec-group <name> on page 4524
coverage on page 4525
echo-cancellation on page 4527
held-call-pickup-number <number> on page 4528
member <number> on page 4529
member <number> ring-option <name> on page 4530
nls on page 4531
num-rings <value> on page 4532
password <password> on page 4533
plc on page 4534
reject <template> on page 4535

accept *<template>*

Use the **accept** command to specify numbers that users can dial. This command controls the type of outbound calls users can place. Use the **no** form of this command to remove a configured dial pattern and return to the default setting.

Syntax Description

<template>	Specifies the patterns users can dial. You can enter a complete phone number or wildcards can be used to help define accepted numbers. Refer to *Functional Notes* below for more information on using wildcards.

Default Values

By default, the cost value is **zero**.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.

Functional Notes

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.

2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.

3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].

4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example allows users on the line **SALES** to dial any local number:

(config)**#voice line SALES**
(config-SALES)**#accept Nxxxxxx**

alc

Use the **alc** command to enable auto level control (ALC). ALC reduces Realtime Transport Protocol (RTP) received signals that are out of specification to the predefined levels. It is not necessary to enable ALC on those networks that guarantee signal levels to be within specification. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 14.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.

Usage Examples

The following example activates the ALC for line **SALES**:

(config)**#voice line SALES**
(config-SALES)**#alc**

anlp

Use the **anlp** command to enable advanced nonlinear processing which adds attenuation of residual echo level by way of a nonlinear processor (NLP) placed in the send path of an echo canceller. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **anlp** is disabled.

Command History

Release A4.08	Command was introduced.

Usage Examples

The following example enables anlp:

```
(config)#voice line SALES
(config-SALES)#anlp
```

codec-group *<name>*

Use the **codec-group** command to specify the coder-decoder (CODEC) list to be used by this account. Use the **no** form of this command to remove the CODEC list from the account.

Syntax Description

<name>	Specifies the CODEC list to be used for this account.

Default Values

By default, no CODEC lists are assigned.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was expanded to include the integrated services digital network (ISDN) trunk.
Release 15.1	Command was added to the Voice Line Configuration command set.
Release A1	Command was included in the Voice Loopback Account Configuration command set.
Release A2	Command was added to the Media Gateway Control Protocol (MGCP) Configuration command set.

Functional Notes

The **codec-group** command applies a previously configured CODEC list to an interface, voice trunk, or voice account. These lists are lists of CODECs used by the interface, trunk, or account in call negotiation, and are arranged in preferred order with the first listed CODEC being the most preferred.

CODEC lists are created using the **codec** command from the Voice CODEC List Configuration mode prompt. For more information about creating CODEC lists, refer to the *Voice CODEC List Command Set on page 4893.*

Usage Examples

The following example applies the CODEC list **List1** to the voice line **sales**:

(config)**#voice line sales**
(config-sales)**#codec-group List1**

coverage

Use the **coverage** command to configure call coverage parameters for the line. The call coverage setting determines how a call is handled if the party dialed does not answer after a specified number of rings. Use the **no** form of this command to remove an individual coverage parameter. Variations of this command include:

coverage aa
coverage aa <*number*>
coverage internal <*number*> **num-rings** <*value*>
coverage operator
coverage operator num-rings <*value*>
coverage override <*value*>
coverage vm
coverage vm <*number*>
coverage <*system mode*> **aa**
coverage <*system mode*> **aa** <*number*>
coverage <*system mode*> **external** <*number*>
coverage <*system mode*> **internal** <*number*>
coverage <*system mode*> **internal** <*number*> **num-rings** <*value*>
coverage <*system mode*> **operator**
coverage <*system mode*> **operator num-rings** <*value*>
coverage <*system mode*> **vm**
coverage <*system mode*> **vm** <*number*>

Syntax Description

<*system mode*>	Optional. Specifies the system mode to configure for call coverage. Choose from **custom1**, **custom2**, **custom3**, **lunch**, **night**, or **weekend**. Refer to the *Functional Notes* of this command for more information on configuring system modes.
aa	Forwards the call to the default auto attendant.
aa <*number*>	Forwards the call to a specific extension programmed for the auto attendant. If no extension is specified, the phone is forwarded to the default auto attendant.
external <*number*>	Forwards the call to the specified external number. If no number is entered, the default auto answer is used.
internal <*number*>	Forwards the call to the specified internal number.
num-rings <*value*>	Optional. Specifies the number of rings for the call before performing the next action. Valid range is **1** to **9**.
operator	Forwards the call to the operator.
override <*value*>	Ignores the programmed system mode schedule.
vm	Forwards the call to voicemail.
vm <*number*>	Optional. Forwards the call to the specified mailbox number.

Default Values

By default, no call coverage is specified.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was updated to include the voicemail and number of rings options.
Release 12.1	Command was updated to include the auto attendant, global, and operator options.
Release A1	Command was updated to include the system mode feature options.

Functional Notes

System mode call coverage provides more diverse functionality for call handling. In previous versions of AOS (revision 15.1 or earlier), up to five coverage modes were allowed. Calls were processed in the order in which the coverage options were entered into the system.

With the addition of the system mode options, up to five coverage options per system mode are allowed. The system modes can be modified using the command *voice system-mode on page 1971*.

Usage Examples

The following example specifies that the line be forwarded after **3** rings to the internal extension **8500** when in the **night** system mode:

(config)**#voice line sales**
(config-sales)**#coverage night internal 8500 num-rings 3**

echo-cancellation

Use the **echo-cancellation** command to improve voice quality for packetized-based voice calls, such as Voice over Internet Protocol (VoIP) or Media Gateway Control Protocol (MGCP). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **echo-cancellation** is enabled.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.

Usage Examples

The following example activates **echo-cancellation** for voice line **sales**:

(config)**#voice line sales**
(config-sales)**#echo-cancellation**

held-call-pickup-number <*number*>

Use the **held-call-pickup-number** <*number*> command to configure an extension to dial to retrieve a call that is put on hold by the shared line appearance (SLA). Use the **no** version of this command to remove the number.

Syntax Description

<*number*>	Specifies the extension to dial to retrieve SLA calls put on hold.

Default Values

No default values are necessary for this command.

Command History

Release R10.6.0	Command was introduced.

Usage Examples

The following example configures **6535** as the held call pickup number for SLA **SALES**:

(config)**#voice line SALES**
(config-SALES)**#held-call-pickup-number 6535**

member <*number*>

Use the **member** command to add members to a voice shared line appearance (SLA). Use the **no** version of this command to remove the member from the SLA.

Syntax Description

<*number*>	Specifies the extension of the member to be added to the SLA.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example adds extension **6535** as a member of the SLA:

(config)**# voice line SALES**
(config-SALES)**#member 6535**

member <*number*> ring-option <*name*>

Use the **member** <*number*> **ring-option** command to assign a ring option to a member of the specified voice shared line appearance (SLA). Use the **no** version of this command to remove the ring option from the member.

Syntax Description

<*number*>	Specifies the extension of the member to be configured.
<*name*>	Specifies the name of the ring option to apply to the SLA member.

Default Values

No default values are necessary for this command.

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example assigns ring option **NORM** to the **6535,** which is a member of the SLA **SALES**:

(config)**#voice line SALES**
(config-SALES)**#member 6535 ring-option NORM**

nls

Use the **nls** command to enable the non-linear suppression (NLS) option for the line. This option sets the echo canceller to reduce acoustic echo. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 14.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.

Usage Examples

The following example enables NLS for voice line **SALES**:

```
(config)#voice line SALES
(config-SALES)#nls
```

num-rings <*value*>

Use the **num-rings** command to specify the number of rings for call pickup before the system redirects the call. Each system mode call coverage action can be configured with a different number of rings based on preference. Use the **no** form of this command to return to the default setting. Variations of this command include:

num-rings <*value*>
num-rings <*system mode*> <*value*>
num-rings override <*value*>

Syntax Description

<*system mode*>	Optional. Specifies the system mode to configure for call coverage. Choose from **custom1**, **custom2**, **custom3**, **lunch**, **night**, or **weekend**. Refer to the *Functional Notes* of this command for more information on configuring system modes.
override	Ignores the programmed system mode schedule.
<*value*>	Specifies the number of rings before the next action. The valid range is **1** to **9**.

Default Values

By default, **num-rings** is set to **4**.

Command History

Release 9.3	Command was introduced.
Release A1	Command was updated to include the system mode feature options.

Functional Notes

System mode call coverage provides more diverse functionality for call handling. In previous versions of AOS (revision 15.1 or earlier), up to five coverage modes were allowed. Calls were processed in the order in which the coverage options were entered into the system.

With the addition of the system mode options, up to five coverage options per system mode are allowed. The system modes can be modified using the command *voice system-mode on page 1971*.

Usage Examples

The following example sets the number of rings for voice line **SALES** to **6**:

(config)**#voice line SALES**
(config-SALES)**#num-rings 6**

password *<password>*

Use the **password** command to create a password or personal identification number (PIN) to protect voice settings and messages. Use the **no** form of this command to remove a password.

*The password configured must be used when configuring the IP phone using the **IP Phone Configs** Web-based graphical user interface (GUI) menu.*

Syntax Description

<password>	Specifies a 4-digit password or PIN.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.

Usage Examples

The following example sets the password for voice line **SALES** to **4321**:

(config)**#voice line SALES**
(config-SALES)**#password 4321**

plc

Use the **plc** command to enable packet loss concealment (PLC). PLC is used to prevent choppy connections by concealing a packet loss by replacing the lost packet with another voice packet in the data stream. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, PLC is enabled.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.

Usage Examples

The following example disables PLC for the voice line **SALES**:

(config)**#voice line SALES**
(config-SALES)**#no plc**

reject *<template>*

Use the **reject** command to specify numbers users cannot dial on the line. This feature allows administrators to restrict callers from unwanted outbound calls, such as international calls and 900 numbers. Use the **no** form of this command to disable this feature.

Syntax Description

<template>	Specifies the patterns that users cannot dial on the line. You can enter a complete phone number or wildcards can be used to help define rejected numbers. Refer to *Functional Notes* below for more information on using wildcards. For example, you can enter **900$** to prevent users from dialing all 900 numbers.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.

Functional Notes

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example blocks calls to any 900 number on the line **SALES**:

(config)**#voice line SALES**
(config-SALES)**#reject 1900$**

rtp delay-mode

Use the **rtp delay-mode** command to configure the Realtime Transport Protocol (RTP) jitter buffer packet delay mode settings. RTP is used to prevent static on voice connections by enhancing the quality of the packet delivery. Use the **no** form of this command to return to the default setting. Variations of this command include:

rtp delay-mode adaptive
rtp delay-mode fixed

Syntax Description

adaptive	Configures the RTP jitter buffer packet delay to adjust during a call based on network conditions.
fixed	Configures the RTP jitter buffer packet delay to remain constant.

Default Values

By default, the RTP delay mode is set to **adaptive**. This allows for minimal latency by adjusting the average packet delay based on the conditions of the network.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.

Usage Examples

The following example configures RTP delay mode as fixed:

(config)**#voice line SALES**
(config-SALES)**#rtp delay-mode fixed**

rtp dtmf-relay

Use the **rtp dtmf-relay** command to configure the method by which Realtime Transport Protocol (RTP) dual tone multi-frequency (DTMF) events are relayed. The dial digits can be sent inband or out-of-band (OOB) of the voice stream. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp dtmf-relay inband
rtp dtmf-relay nte <*value*>

Syntax Description

inband	Specifies that RTP DTMF events be relayed inband in the RTP stream.
nte <*value*>	Specifies that RTP DTMF events be relayed OOB using named telephone events (NTEs). Enter an NTE value between **96** and **127**.

Default Values

By default, the **rtp dtmf-relay** is set for **NTE 101**.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.

Usage Examples

The following example configures RTP DTMF relay events for **inband**:

(config)**#voice line SALES**
(config-SALES)**#rtp dtmf-relay inband**

rtp frame-packetization <*value*>

Use the **rtp frame-packetization** command to configure the Realtime Transport Protocol (RTP) frame packetization time in milliseconds for individual trunks and users. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Configures the RTP frame packetization time value in milliseconds. Select from **10**, **20**, **30**, or **40** milliseconds.

Default Values

By default, the **rtp frame-packetization** time is set to **20** milliseconds on all trunks and users.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release R10.8.0	Command was expanded to include **40** milliseconds.

Usage Examples

The following example sets the frame packetization time for voice line **SALES** to **10** milliseconds:

(config)**#voice line SALES**
(config-SALES)**#rtp frame-packetization 10**

rtp packet-delay

Use the **rtp packet-delay** command to configure the maximum Realtime Transport Protocol (RTP) packet delays. This command is used to set the allowable limits of latency on the network. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp packet-delay maximum <*value*>
rtp packet-delay nominal <*value*>

Syntax Description

maximum <*value*>	Sets the maximum delay time value in increments of **10** milliseconds. Range is **40** to **320** milliseconds.
nominal <*value*>	Sets the nominal delay time value in increments of **10** milliseconds. Range is **10** to **240** milliseconds.

Default Values

By default, the RTP packet delay for maximum is **100**, and for nominal is **50**.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.

Usage Examples

The following example configures the RTP maximum delay time on voice line SALES to **200** milliseconds:

(config)**#voice line SALES**
(config-SALES)**#rtp packet-delay maximum 200**

rtp qos dscp <*value*>

Use the **rtp qos dscp** command to configure the maximum Realtime Transport Protocol (RTP) quality of service (QoS) parameters for differentiated services code point (DSCP). Use the **no** form of this command to return to the default global value.

Syntax Description

<*value*>	Configures the RTP QoS parameter for DSCP. Enter a value between **0** and **63**.

Default Values

By setting the **rtp qos dscp** value on an individual trunk or user, you will override the global **rtp qos dscp** setting for RTP packets. The default global DSCP value for RTP is **46**.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.

Functional Notes

By setting the **rtp qos dscp** value on an individual trunk or user, you will override the global **rtp qos dscp** setting for RTP packets. QoS is set using a DSCP value. Valid DSCP values are **0** to **63**, and a higher DSCP value has a higher priority. The default global DSCP value for RTP is **46**. Remember that if you are using a public IP connection, such as the Internet, for Voice over Internet Protocol (VoIP), end-to-end QoS may not be guaranteed. The default DSCP value for Session Initiation Protocol (SIP) is **26**. To configure QoS for the RTP traffic that carries the voice conversation, use the command **ip rtp qos dscp** followed by the desired DSCP value.

Usage Examples

The following example configures the RTP QoS DSCP for voice line SALES to **60**:

(config)**#voice line SALES**
(config-SALES)**#rtp qos dscp 60**

seize-timeout <*seconds*>

Use the **seize-timeout** command to specify the maximum time the trunk will be seized before placing a call. Use the **no** form of this command to return to the default timeout interval.

Syntax Description

<*seconds*>	Specifies maximum number of seconds the trunk will be seized before placing a call. Valid range is **5** to **120** seconds.

Default Values

By default, the **seize-timeout** period is set to **30** seconds.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example sets the **seize-timeout** period to **20** seconds:

(config)**#voice line SALES**
(config-SALES)**#seize-timeout 20**

sip-keep-alive

Use the **sip-keep-alive** command to configure the type of keep-alive method for this Session Initiation Protocol (SIP) trunk. Keep-alive messages must be sent between SIP device and the registrar to keep the connected channel open for communication. Use the **no** form of this command to return to disable this feature. Variations of this command include the following:

sip-keep-alive info
sip-keep-alive info <*value*>
sip-keep-alive options
sip-keep-alive options <*value*>

Syntax Description

info	Specifies the INFO method to be used for the keep-alives on the trunk.
options	Specifies the OPTIONS method to be used for the keep-alives on the trunk.
<*value*>	Optional. Specifies the amount of time in seconds between the type of SIP keep-alive messages being sent during a call. Range is **30** to **3600** seconds.

Default Values

By default, **sip-keep-alive** is set to **info 60** on NetVanta 7000 Series products. For IP business gateways (Total Access 900(e) Series and NetVanta 6000 Series) **sip-keep-alive** is disabled by default.

Command History

Release 13.1	Command was introduced
Release A2.04	Command was added to the Voice Line and Voice User command sets.

Usage Examples

The following example sets the keep-alive method to **info**:

(config)**#voice line SALES**
(config-SALES)**#sip-keep-alive info**

trunk <*Txx*>

Use the **trunk** command to specify the trunk the voice line will use. Use the **no** form of this command to remove a configured trunk group.

Syntax Description

<*Txx*>	Specifies an ID number for the trunk. The trunk ID is in the format Txx, where xx is the trunk ID number. Enter a trunk ID between **1** and **99**. For example, trunk **T02**.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.

Usage Examples

The following example adds trunk **T02** to the voice line SALES:

(config)**#voice line SALES**
(config-SALES)**#trunk t02**

vad

Use the **vad** command to enable voice activity detection (VAD). VAD blocks out noise categorized as silence during a voice connection. The silent voice packets are not transmitted, allowing bandwidth usage to be reduced. Although VAD saves bandwidth, the quality of the voice call may be compromised. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, VAD is enabled for all T1 robbed-bit signaling (RBS) trunks and users.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.

Usage Examples

The following example disables VAD on voice line SALES:

(config)**#voice line SALES**
(config-SALES)**#no vad**

VOICE LOOPBACK ACCOUNT COMMAND SET

A loopback account is an internal account that creates a Realtime Transport Protocol (RTP) loopback. Loopback calls allow you to actively troubleshoot voice issues. Loopback calls can be originated from the command line interface (CLI), or the configured loopback extension can automatically answer an incoming call. During the loopback call, you hear a mirror copy of the transmitted audio path. The loopback call gives you the ability to verify two-way audio, test latency, and judge call quality. Unlike normal calls between two endpoints, statistics are not recorded on loopback calls. Since the audio in the call is simply a retransmission of the RTP stream, the call is not handled by digital signal processor (DSP) so information on packet loss, delay, and jitter are not available on loopback calls.

In order to place loopback calls, you will need to configure a loopback extension. This is a special type of user account that the AOS unit will use to place and/or receive the actual loopback call. A loopback extension has the same basic configurable options that affect call quality as a normal user account. Loopback accounts also require the same configuration that any other user account would need in order to properly interact with the Session Initiation Protocol (SIP) server, SIP identity, external caller ID override, etc. A dial plan must also be configured for the loopback account. The dial plan is needed for the unit to accept and route the call. The commands in this section are used for creating and configuring a loopback account. For additional information about configuring loopback accounts, refer to the *Configuring the AOS Voice Loopback Account* configuration guide available online at https://supportcommunity.adtran.com.

To create a loopback account and enter the Voice Loopback Account Configuration mode, enter the **voice loopback** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice loopback 5555
(config-LB-5555)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

alc

Use the **alc** command to enable auto level control (ALC). ALC reduces Realtime Transport Protocol (RTP) received signals that are out of specification to the predefined levels. It is not necessary to enable ALC on those networks that guarantee signal levels to be within specification. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 14.1	Command was introduced.
Release A1	Command was included in the Voice Loopback Account Configuration command set.

Usage Examples

The following example activates ALC for loopback **5555**:

(config)**#voice loopback 5555**
(config-LB-5555)**#alc**

appearances *<value>*

Use the **appearances** command to specify the number of simultaneous loopback calls allowed on the system. The maximum number of calls allowed is five. Use the **no** form of this command to reset the number of call appearances allowed on this account.

Syntax Description

<value>	Configures the number of calls. Range is **1** to **5**.

Default Values

By default, the call appearances is set to **1**.

Command History

Release A1	Command was introduced.

Usage Examples

The following example specifies that **3** simultaneous loopback calls be allowed on the system:

(config)**#voice loopback 5555**
(config-LB-5555)**#appearances 3**

caller-id

Use the **caller-id** command to specify a name or number to display as the caller ID information. Use the **no** form of this command to return to the default value. Variations of this command include:

caller-id name <*name*>
caller-id number <*number*>

Syntax Description

name <*name*>	Specifies the name of the loopback account.
number <*number*>	Specifies the number of the loopback account.

Default Values

By default, the caller ID will display the extension number used when creating the loopback account. If no **name** or alternate **number** is specified, the loopback extension number will be displayed.

Command History

Release A1	Command was introduced.

Usage Examples

The following example sets the caller ID information for the loopback account:

(config)**#voice loopback 5555**
(config-LB-5555)**#caller-id name VQMTesting**
(config-LB-5555)**#caller-id number 372-5555**

codec-list *<name>*

Use the **codec-list** command to specify the coder-decoder (CODEC) list to be used by this account. This CODEC can be used for normal voice traffic or for Session Border Controller (SBC) transcoding. Use the **no** form of this command to remove the CODEC list from the account. Variations of this command include:

codec-list *<name>*
codec-list *<name>* **both**
codec-list *<name>* **in**
codec-list *<name>* **out**
codec-list any
codec-list any both
codec-list any in
codec-list any out

Syntax Description

<name>	Specifies the CODEC list to be used for this account.
any	Specifies that any possible CODEC is allowed on this account.
both	Optional. Specifies that the CODEC list is applied to both transmitted and received Session Description Protocol (SDP) transmissions.
in	Optional. Specifies that the CODEC list is applied to received SDP only.
out	Optional. Specifies that the CODEC list is applied to transmitted SDP only.

Default Values

By default, no CODEC lists are assigned.

Command History

Release R10.4.0	Command was introduced and replaced the **codec-group** command.

Functional Notes

The **codec-list** command applies a previously configured CODEC list to an interface, voice trunk, or voice account. These lists are lists of CODECs used by the interface, trunk, or account in call negotiation and are arranged in preferred order with the first listed CODEC being the most preferred.

CODEC lists are created using the **codec** command from the Voice CODEC List Configuration mode prompt. For more information about creating CODEC lists, refer to the *Voice CODEC List Command Set on page 4893*.

In addition, CODEC lists can be used for the SBC transcoding feature. For more information about this feature, its uses, and its configuration, refer to the configuration guide *Configuring Transcoding in AOS*, available online at https://supportcommunity.adtran.com.

> NOTE *Because you can choose to specify that any CODEC is used by a Session Initiation Protocol (SIP) endpoint with the **any** keyword, do not create a CODEC list with the name of **any**.*

Usage Examples

The following example applies the CODEC list **LIST1** to incoming SDP traffic on loopback account **5555**:

(config)#**voice loopback 5555**
(config-LB-5555)#codec-list LIST1 in

echo-cancellation

Use the **echo-cancellation** command to improve voice quality for packetized-based voice calls, such as Voice over Internet Protocol (VoIP) or Media Gateway Control Protocol (MGCP). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **echo-cancellation** is enabled.

Command History

Release 9.3	Command was introduced.
Release A1	Command was included in the Voice Loopback Account Configuration command set.

Usage Examples

The following example activates **echo-cancellation** for loopback **5555**:

(config)**#voice loopback 5555**
(config-LB-5555)**#echo-cancellation**

media-loopback

Use the **media-loopback** command to designate a voice loopback account to be used for media loopback. Media loopback enables media sessions to be established where the media is looped back to the transmitter. This is typically referred to as active monitoring of services. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **media-loopback** is disabled.

Command History

Release A4.03	Command was introduced.

Usage Examples

The following example configures voice loopback account **5555** to be used for media loopback:

```
(config)#voice loopback 5555
(config-LB-5555)#media-loopback
```

nls

Use the **nls** command to enable the non-linear suppression (NLS) option for the user. This option sets the echo canceller to reduce acoustic echo. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 14.1	Command was introduced.
Release A1	Command was included in the Voice Loopback Account Configuration command set.

Usage Examples

The following example enables NLS for loopback **5555**:

(config)**#voice loopback 5555**
(config-LB-5555)**#nls**

num-rings <*value*>

Use the **num-rings** command to specify the number of rings before the loopback account answers (when called). Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the number of rings before answering. Specify **0** through **9** rings. Entering **0** specifies answering the call immediately.

Default Values

By default, **num-rings** is set to **0**.

Command History

Release 9.3	Command was introduced.
Release A1	Command was included in the Voice Loopback Account Configuration command set.

Usage Examples

The following example sets the number of rings for loopback **5555** to **3**:

(config)**#voice loopback 5555**
(config-LB-5555)**#num-rings 3**

plc

Use the **plc** command to enable packet loss concealment (PLC). PLC is used to prevent choppy connections by replacing a lost packet with another voice packet in the data stream. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, PLC is enabled.

Command History

Release 11.1	Command was introduced.
Release A1	Command was included in the Voice Loopback Account Configuration command set.

Usage Examples

The following example disables PLC for loopback **5555**:

(config)**#voice loopback 5555**
(config-LB-5555)**#no plc**

rtp delay-mode

Use the **rtp delay-mode** command to configure the Realtime Transport Protocol (RTP) jitter buffer packet delay mode settings. RTP is used to prevent static on voice connections by enhancing the quality of the packet delivery. Use the **no** form of this command to return to the default setting. Variations of this command include:

rtp delay-mode adaptive
rtp delay-mode fixed

Syntax Description

adaptive	Configures the RTP jitter buffer packet delay to adjust during a call based on network conditions.
fixed	Configures the RTP jitter buffer packet delay to remain constant.

Default Values

By default, the RTP delay mode is set to **adaptive**. This allows for minimal latency by adjusting the average packet delay based on the conditions of the network.

Command History

Release 11.1	Command was introduced.
Release A1	Command was included in the Voice Loopback Account Configuration command set.

Usage Examples

The following example configures the RTP delay mode as fixed:

(config)**#voice loopback 5555**
(config-LB-5555)**#rtp delay-mode fixed**

rtp dtmf-relay

Use the **rtp dtmf-relay** command to configure the method by which Realtime Transport Protocol (RTP) dual tone multi-frequency (DTMF) events are relayed. The dial digits can be sent inband or out-of-band (OOB) of the voice stream. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp dtmf-relay inband
rtp dtmf-relay nte <*value*>

Syntax Description

inband	Specifies that RTP DTMF events be relayed inband in the RTP stream.
nte <*value*>	Specifies that RTP DTMF event value be relayed OOB using named telephone events (NTEs). Enter a named telephone event (NTE) value between **96** and **127**.

Default Values

By default, the **rtp dtmf-relay** is set for **nte 101**.

Command History

Release 9.3	Command was introduced.
Release A1	Command was included in the Voice Loopback Account Configuration command set.

Usage Examples

The following example configures RTP DTMF relay events for **inband**:

(config)**#voice loopback 5555**
(config-LB-5555)**#rtp dtmf-relay inband**

rtp frame-packetization <*value*>

Use the **rtp frame-packetization** command to configure the Realtime Transport Protocol (RTP) frame packetization time in milliseconds for individual trunks and users. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Configures the RTP frame packetization time value in milliseconds. Select from **10**, **20**, **30**, or **40** milliseconds.

Default Values

By default, the **rtp frame-packetization** time is set to **20** milliseconds on all trunks and users.

Command History

Release 9.3	Command was introduced.
Release A1	Command was included in the Voice Loopback Account Configuration command set.
Release R10.8.0	Command was expanded to include **40** milliseconds.

Usage Examples

The following example sets the frame packetization time for loopback account **5555** to **10** milliseconds:

(config)**#voice loopback 5555**
(config-LB-5555)**#rtp frame-packetization 10**

rtp packet-delay

Use the **rtp packet-delay** command to configure the maximum Realtime Transport Protocol (RTP) packet delays. This command is used to set the allowable limits of latency on the network. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp packet-delay fax <*value*>
rtp packet-delay maximum <*value*>
rtp packet-delay nominal <*value*>

Syntax Description

fax <*value*>	Sets the fax delay time value in milliseconds. Range is **0** to **500** milliseconds.
maximum <*value*>	Sets the maximum delay time value in increments of 10 milliseconds. Range is **40** to **320** milliseconds.
nominal <*value*>	Sets the nominal delay time value in increments of 10 milliseconds. Range is **10** to **240** milliseconds.

Default Values

By default, the RTP packet delays are **fax 300**, **maximum 100**, and **nominal 50**.

Command History

Release 11.1	Command was introduced.
Release A1	Command was included in the Voice Loopback Account Configuration command set.

Usage Examples

The following example configures the RTP fax delay time for loopback **5555** to **200** milliseconds:

(config)**#voice loopback 5555**
(config-LB-5555)**#rtp packet-delay fax 200**

rtp qos dscp <*value*>

Use the **rtp qos dscp** command to configure the Realtime Transport Protocol (RTP) differentiated services code point (DSCP) value. Use the **no** form of this command to return to the default global value.

Syntax Description

<*value*>	Configures the RTP value for DSCP. The DSCP values are **0** to **63**.

Default Values

By setting the **rtp qos dscp** value on an individual trunk or user, you will override the global **rtp qos dscp** setting for RTP packets. The default global DSCP value for RTP is **46**.

Command History

Release 9.3	Command was introduced.
Release A1	Command was included in the Voice Loopback Account Configuration command set.

Functional Notes

By setting the **rtp qos dscp** value on an individual trunk or user, you will override the global **rtp qos dscp** setting for RTP packets. QoS is set using a DSCP value. Valid DSCP values are **0** to **63**, and a higher DSCP value has a higher priority. The default global DSCP value for RTP is **46**. Remember that if you are using a public IP connection, such as the Internet, for Voice over Internet Protocol (VoIP), end-to-end QoS may not be guaranteed. The default DSCP value for Session Initiation Protocol (SIP) is **26**. To configure QoS for the RTP traffic that carries the voice conversation, use the command **ip rtp qos dscp** followed by the desired DSCP value.

Usage Examples

The following example sets the RTP quality of service (QoS) DSCP value to **14**:

(config)**#voice loopback 5555**
(config-LB-5555)**#rtp qos dscp 14**

sip-identity

Use the **sip-identity** command to configure the Session Initiation Protocol (SIP) registration options for the user. Use the **no** form of this command to disable the setting. Variations of this command include the following:

sip-identity <*station*> <*Txx*>
sip-identity <*station*> <*Txx*> **register**
sip-identity <*station*> <*Txx*> **register auth-name** <*username*> **password** <*password*>

Syntax Description

<*station*>	Specifies the station to be used for SIP trunk (e.g., **station extension**).
<*Txx*>	Specifies the SIP trunk through which to register the server. The trunk is specified in the format Txx (e.g., **T01**).
register	Registers the user to the server.
auth-name <*username*>	Optional. Sets the user name that will be required as authentication for registration to the SIP server.
password <*password*>	Optional. Sets the password that will be required as authentication for registration to the SIP server.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.
Release A1	Command was included in the Voice Loopback Account Configuration command set.

Usage Examples

The following example specifies trunk **T02** and extension **4400** for SIP identity on the loopback account:

(config)**#voice loopback 5555**
(config-LB-5555)**#sip-identity 4400 T02**

VOICE USER ACCOUNT COMMAND SET

Voice user accounts are used to define phone users that are registered to an AOS voice product. There are three different types of user accounts: Session Initiation Protocol (SIP), analog, and virtual. SIP user accounts are associated with a SIP user agent. Analog user accounts are user accounts that are associated with a physical foreign exchange station (FXS) interface. Virtual user accounts are not associated with a physical port. These user types can be used for special applications such as forwarding calls.

The commands in this section describe how to configure voice features for user accounts. For more information about configuring voice users, refer to the configuration guide *Configuring User Accounts on the NetVanta 7000 Series* available online at https://supportcommunity.adtran.com.

To create a user account and enter the Voice User Account Configuration mode, enter the **voice user** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice user 4444
(config-4444)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

All other commands for this command set are described in this section in alphabetical order.

alc

Use the **alc** command to enable automatic level control (ALC). ALC reduces Realtime Transport Protocol (RTP) received signals that are out of specification to the predefined levels. It is not necessary to enable ALC on those networks that guarantee signal levels to be within specification. Use the **no** form of this command to disable this feature. Variations of this command include:

alc
alc level -16
alc level -17
alc level -18
alc level -19
alc level -20
alc level -21
alc level -22

Syntax Description

level -16	Optional. Specifies the ALC attenuation level is -16 dBm0.
level -17	Optional. Specifies the ALC attenuation level is -17 dBm0.
level -18	Optional. Specifies the ALC attenuation level is -18 dBm0.
level -19	Optional. Specifies the ALC attenuation level is -19 dBm0.
level -20	Optional. Specifies the ALC attenuation level is -20 dBm0.
level -21	Optional. Specifies the ALC attenuation level is -21 dBm0.
level -22	Optional. Specifies the ALC attenuation level is -22 dBm0.

Default Values

By default, ALC is disabled.

Command History

Release 14.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the Media Gateway Control Protocol (MGCP) endpoint configuration.
Release A2.04	Command was expanded to include the **level** parameters.

Usage Examples

The following example activates the ALC for voice user **4444**:

(config)**#voice user 4444**
(config-4444)**#alc**

billing-codes

Use the **billing-codes** command to specify that billing codes are allowed or required for all external calls on the voice user account. Using the **no** form of this command indicates billing codes are not allowed on the account. Variations of this command include:

billing-codes allowed
billing-codes required

Syntax Description

allowed	Specifies that billing codes are allowed for external calls on the user account.
required	Specifies that billing codes are required for external calls on the user account.

Default Values

By default, billing codes are not used.

Command History

Release R10.3.0	Command was introduced.

Usage Examples

The following example specifies that billing codes are required for voice user **4444**:

(config)**#voice user 4444**
(config-4444)**#billing-codes required**

block-caller-id

Use the **block-caller-id** command to block all inbound caller ID delivery to this user. This command prevents the selected user from receiving caller ID information. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example activates the **block-caller-id** command for user **4444**:

(config)**#voice user 4444**
(config-4444)**#block-caller-id**

busy-out alert-mode

Use the **busy-out alert-mode** command to specify the busy-out monitoring alert mode received by the voice user when attempting to make a call when the voice trunk is in busied out mode. Use the **no** form of this command to return to the default busy-out alert mode. Variations of this command include:

busy-out alert-mode fast-busy
busy-out alert-mode no-battery
busy-out alert-mode no-dialtone

Syntax Description

fast-busy	Specifies that a fast busy tone is heard on the port when the voice trunk is in busied out mode.
no-battery	Specifies the battery is removed from the port when the voice trunk is in busied out mode.
no-dialtone	Specifies there is no dialtone on the port when the voice trunk is in busied out mode.

Default Values

By default, the busy-out alert is set to **no-dialtone**.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example specifies the busy-out alert type as **fast-busy** for voice user **4444**:

(config)**#voice user 4444**
(config-4444)**#busy-out alert-mode fast-busy**

busy-out monitor track <*name*>

Use the **busy-out monitor track** command to enable busy-out monitoring on the port used by this voice user. Use the **no** version of this command to disable the busy-out monitoring feature.

Syntax Description

<*name*>	Specifies a track to associate with the voice port for busy-out monitoring use.

Default Values

By default, busy-out monitoring is not enabled on the port.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example enables busy-out monitoring and associates the track **TESTTRACK** with the port used by voice user **4444**:

(config)**#voice user 4444**
(config-4444)**#busy-out monitor track TESTTRACK**

caller-id-override

Use the **caller-id-override** command to manipulate caller ID information for the user. This command is used to conceal user's name and number or to display a different name and number for internal or external caller ID. Use the **no** form of this command to disable this feature. Variations of this command include:

caller-id-override emergency-number <*number*>
caller-id-override external-number <*number*>
caller-id-override external-name <*name*>
caller-id-override external-name empty
caller-id-override internal-name empty
caller-id-override internal-name <*name*>
caller-id-override internal-number empty
caller-id-override internal-number <*number*>

Syntax Description

emergency-number <*number*>	Replaces the caller ID number on emergency calls with the specified number.
external-number <*number*>	Replaces the caller ID number on external calls with the specified number.
external-name <*name*>	Replaces the caller ID name on external calls with the specified name.
internal-name <*name*>	Replaces the caller ID name on internal calls with the specified name.
internal-number <*number*>	Replaces caller ID number on internal calls with the specified number.
empty	Makes the caller ID name or number on internal calls and the caller ID name on external calls display as blank.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.
Release A4.01	Command was expanded to include the **emergency-number** and **external-name** parameters.

Usage Examples

The following example activates the **caller-id-override** command for external numbers for user **4444**:

(config)**#voice user 4444**
(config-4444)**#caller-id-override external-number 256-555-8000**

This example activates the **caller-id-override** command for names with internal calls and makes the display appear blank:

(config)**#voice user 4444**
(config-4444)**#caller-id-override internal-number empty**

call-waiting

Use the **call-waiting** command to enable call waiting for a user. The selected user will be allowed to receive caller ID information. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example activates the **call-waiting** command for user **4444**:

```
(config)#voice user 4444
(config-4444)#call-waiting
```

codec-list *<name>*

Use the **codec-list** command to specify the coder-decoder (CODEC) list to be used by this account. This CODEC can be used for normal voice traffic or for Session Border Controller (SBC) transcoding. Use the **no** form of this command to remove the CODEC list from the account. Variations of this command include:

codec-list *<name>*
codec-list *<name>* **both**
codec-list *<name>* **in**
codec-list *<name>* **out**
codec-list any
codec-list any both
codec-list any in
codec-list any out

Syntax Description

<name>	Specifies the CODEC list to be used for this account.
any	Specifies that any possible CODEC is allowed on this account.
both	Optional. Specifies that the CODEC list is applied to both transmitted and received Session Description Protocol (SDP) transmissions.
in	Optional. Specifies that the CODEC list is applied to received SDP only.
out	Optional. Specifies that the CODEC list is applied to transmitted SDP only.

Default Values

By default, no CODEC lists are assigned.

Command History

Release R10.4.0	Command was introduced and replaced the **codec-group** command.

Functional Notes

The **codec-list** command applies a previously configured CODEC list to an interface, voice trunk, or voice account. These lists are lists of CODECs used by the interface, trunk, or account in call negotiation and are arranged in preferred order with the first listed CODEC being the most preferred.

CODEC lists are created using the **codec** command from the Voice CODEC List Configuration mode prompt. For more information about creating CODEC lists, refer to the *Voice CODEC List Command Set on page 4893***.**

In addition, CODEC lists can be used for the SBC transcoding feature. For more information about this feature, its uses, and its configuration, refer to the configuration guide *Configuring Transcoding in AOS*, available online at https://supportcommunity.adtran.com.

> NOTE *Because you can choose to specify that any CODEC is used by a Session Initiation Protocol (SIP) endpoint with the **any** keyword, do not create a CODEC list with the name of **any**.*

Usage Examples

The following example applies the CODEC list **LIST1** to incoming SDP traffic for voice user **4444**:

(config)**#voice user 4444**
(config-4444)**#codec-list LIST1 in**

connect

Use the **connect** command to associate physical ports with the user. This command assigns a specific station or port type to the user. Use the **no** form of this command to remove associations. Variations of this command include:

connect fxs <*slot/port*>
connect sip

Syntax Description

fxs <*slot/port*>	Specifies that a foreign exchange station (FXS) port is associated with the user.
sip	Specifies that this is a Session Initiation Protocol (SIP) user.

Default Values

By default, users are not associated with physical ports.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example associates the physical FXS slot 1/port 1 interface with the user **4444**:

(config)#**voice user 4444**
(config-4444)#**connect fxs 1/1**

The following example associates a SIP port with the user **4444**.

(config)#**voice user 4444**
(config-4444)#**connect sip**

contact-group *<group number>*

Use the **contact-group** command to create a FindMe-FollowMe contact group for the user and enter the group's configuration mode. Using the **no** form of this command removes the contact group from the user's configuration.

Syntax Description

<group number>	Specifies the contact group number. Valid range is **1** to **5**.

Default Values

By default, no contact groups are configured.

Command History

Release A4.01	Command was introduced.

Functional Notes

FindMe-FollowMe must be enabled on the user account to use configured contact groups. FindMe-FollowMe is enabled using the command *findme-followme on page 4593*.

Each contact group is numbered, and group numbers specify which contact group FindMe-FollowMe searches first. For example, the calling party number will be matched to the permitted calling party number list in contact group 1 before contact group 2. If a match is found, the actions for contact group 1 are performed. Otherwise, the next contact group is searched for matches. Each user account can have up to **5** contact groups.

The **contact-group** command creates a FindMe-FollowMe contact group and enters the group's configuration mode. Commands in this configuration mode are detailed in the section *FindMe-FollowMe Contact Group Command Set on page 4752*.

Usage Examples

The following example creates contact group **1** for voice user **4444**, and enters the group's configuration mode:

```
(config)#voice user 4444
(config-4444)#contact-group 1
(config-4444-cg-1)#
```

cos

Use the **cos** command to set class of service (CoS) mode for the user. The CoS can be set to change for the user based on the current system mode by including the system mode parameter. The CoS defines the types of phone service that will be available to the user during the time period. Use the **no** form of this command to disable this feature. Variations of this command include:

cos <*name*>
cos <*system mode*> <*name*>
cos no-access
cos <*system mode*> **no-access**
cos override <*name*>
cos override no-access

Syntax Description

<*name*>	Specifies the predefined CoS.
<*system mode*>	Optional. Specifies the system mode to configure. Choose from **custom1**, **custom2**, **custom3**, **lunch**, **night**, or **weekend**. Refer to the *Functional Notes* of this command for more information on configuring system modes.
no-access	Blocks users from placing calls when the CoS is applied.
override	Ignores the programmed system mode schedule.

Default Values

By default, the CoS is set to **no-access**.

Command History

Release 9.3	Command was introduced.
Release A1	Command was expanded to include the system mode options.

Functional Notes

Additional functionality for this feature is provided by assigning a CoS to a specific system mode. When the system mode changes at a trigger point, the user's CoS changes.

For example, a CoS applied to the user when the system mode is specified as **night** can be used to prevent outbound calls during evening hours. System modes are defined from the Global Configuration mode using the command *voice system-mode on page 1971*.

Usage Examples

The following example specifies the CoS **Assistant** for the user **4444**.

(config)**#voice user 4444**
(config-4444)**#cos Assistant**

The following example configures the user's CoS to change to **general** when the system mode changes to **night**.

(config)**#voice user 4444**
(config-4444)**#cos night general**

coverage

Use the **coverage** command to configure call coverage parameters for the user. The call coverage setting determines how a call is handled if the dialed party does not answer after a specified number of rings. Use the **no** form of this command to remove an individual coverage parameter. Variations of this command include:

coverage aa
coverage aa <*number*>
coverage findme-followme
coverage global <*name*>
coverage internal <*number*>
coverage internal <*number*> **num-rings** <*value*>
coverage operator
coverage operator num-rings <*value*>
coverage override external <*number*>
coverage override global <*name*>
coverage override internal <*number*>
coverage override internal <*number*> **num-rings** <*value*>
coverage override operator
coverage override operator num-rings <*value*>
coverage override vm
coverage override vm <*number*>
coverage vm
coverage vm <*number*>
coverage <*system mode*> **aa**
coverage <*system mode*> **aa** <*number*>
coverage <*system mode*> **external** <*number*>
coverage <*system mode*> **findme-followme**
coverage <*system mode*> **global** <*name*>
coverage <*system mode*> **internal** <*number*>
coverage <*system mode*> **internal** <*number*> **num-rings** <*value*>
coverage <*system mode*> **operator**
coverage <*system mode*> **operator num-rings** <*value*>
coverage <*system mode*> **vm**
coverage <*system mode*> **vm** <*number*>

Syntax Description

<*system mode*>	Optional. Specifies the system mode to configure for call coverage. Choose from **custom1**, **custom2**, **custom3**, **lunch**, **night**, or **weekend**. Refer to the *Functional Notes* of this command for more information on configuring system modes.
aa	Forwards the call to the default auto attendant.
aa <*number*>	Forwards the call to a specific extension programmed for the auto attendant. If no extension is specified, the phone is forwarded to the default auto attendant.

external <*number*>	Forwards the call to the specified external number. If no number is entered, the default auto answer is used.
findme-followme	Specifies that FindMe-FollowMe is the preferred coverage type for this user.
global <*name*>	Uses the specified global call coverage list.
internal <*number*>	Forwards the call to the specified internal number.
num-rings <*value*>	Optional. Specifies the number of rings for the call before performing the next action. Valid range is **1** to **9**.
operator	Forwards the call to the operator.
override	Ignores the programmed system mode schedule.
vm	Forwards the call to voicemail.
vm <*number*>	Optional. Forwards the phone to the specified mailbox number.

Default Values

By default, no system mode call coverage is specified.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was updated to include the **voicemail** and **num-rings** parameters.
Release 12.1	Command was updated to include the **aa**, **global**, and **operator** parameters.
Release A1	Command was updated to include the system mode feature options.
Release A4.01	Command was updated to include the **findme-followme** parameter.

Functional Notes

System mode call coverage provides more diverse functionality for call handling. In previous versions of AOS (revision 15.1 or earlier), up to five coverage modes were allowed. Calls were processed in the order in which the coverage options were entered into the system.

With the addition of the system mode options, up to five coverage options per system mode are allowed. The system modes can be modified using the command *voice system-mode on page 1971*.

The FindMe-FollowMe feature can be used instead of other call coverages. When FindMe-FollowMe is enabled as the call coverage mode, incoming callers are directed according to the user's configuration of the FindMe-FollowMe feature. For more information about configuring FindMe-FollowMe, refer to the commands *contact-group <group number> on page 4577* and *findme-followme on page 4593*, as well as to the command sets *FindMe-FollowMe Contact Group Command Set on page 4752* and *FindMe-FollowMe Action Script Command Set on page 4744*. If you would like more information about FindMe-FollowMe, its configuration, and how it relates to call coverage, refer to the *Configuring User Accounts on the NetVanta 7000 Series* quick configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the user's phone be forwarded to the internal extension **8500** when in the **night** system mode after **3** rings.

(config)**#voice user 4444**
(config-4444)**#coverage night internal 8500 num-rings 3**

The following example specifies that incoming calls to the user extension **4444** follow the call coverage outlined in the user's FindMe-FollowMe configuration:

(config)**#voice user 4444**
(config-4444)**#coverage findme-followme**

did <*number*>

Use the **did** command to configure direct inward dialing (DID) parameters for the extension. DID is used if a service provider is providing digits to the unit on inbound calls or if the unit needs to provide DID information to a piece of customer premises equipment (CPE). Use the **no** form of this command to disable this feature.

Syntax Description

<*number*>	Specifies the DID number for the user.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example assigns a **did** number of **555-4560** to user **4444**:

(config)**#voice user 4444**
(config-4444)**#did 5554560**

directory-include

Use the **directory-include** command to add this user in a dial-by-name (DBN) directory. Adding users to the directory allows the users to call parties by the voice user's name stored in the system. Use the **no** form of this command to disable this feature. Variations of this command include:

directory-include
directory-include first-name <*name*>
directory-include first-name <*name*> **last-name** <*name*>
directory-include <*directory name*>
directory-include <*directory name*> **first-name** <*name*>
directory-include <*directory name*> **first-name** <*name*> **last-name** <*name*>

Syntax Description

first-name <*name*>	Optional. Specifies the directory entry of the user's first name to be included in the directory.
last-name <*name*>	Optional. Specifies the directory entry of the user's last name to be included in the directory.
<*directory name*>	Optional. Specifies the name of a directory.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.
Release 14.1	Command was expanded.

Functional Notes

Using this command automatically retrieves the values stored in the **first-name** and **last-name** for the DBN directory. If a user also uses an alias, you may add extra entries into the DBN directory by specifying the first and last names within the **directory-include** command.

By default, a system directory is always available. All voice users are automatically added as members of the system directory.

Usage Examples

The following example adds the user **4444** to a DBN directory:

(config)**#voice user 4444**
(config-4444)**#directory-include**

dnd

Use the **dnd** command to enable the do-not-disturb (DND) option for the user. This setting prevents the phone extension assigned to the user from ringing. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example enables DND for user **4444**:

(config)**#voice user 4444**
(config-4444)**#dnd**

dnis-digits <*value*>

Use the **dnis-digits** command to enable the dialed number identification service (DNIS) delay feature and to specify the number of DNIS dual tone multi-frequency (DTMF) digits that are outpulsed to the terminal when a call is routed to an automatic call distributor (ACD), such as a fax server, that is connected to a foreign exchange station (FXS) port. For more information on how this feature works, refer to the *Functional Notes* and *Technology Review* sections below. Use the **no** form of this command to disable the DNIS delay feature. Variations of this command include:

dnis-digits <*value*>
dnis-digits <*value*> **digit-delay** <*value*>
dnis-digits <*value*> **digit-delay** <*value*> **cut-through-delay** <*value*>

Syntax Description

dnis-digits <*value*>	Specifies the number of DNIS digits that are to be outpulsed. Range is **1** to **16** digits.
digit-delay <*value*>	Optional. Specifies the delay (in milliseconds) between the terminal going off-hook and the first DNIS digit outpulse. The delay is specified in **100** ms increments and the range is **100** to **1000** ms.
cut-through-delay <*value*>	Optional. Specifies the delay (in milliseconds) between the outpulsing of the final DNIS digit and the start of two-way voice traffic. The delay is specified in **100** ms increments and the range is **100** to **2000** ms.

Default Values

By default, this feature is disabled and zero DNIS digits are outpulsed. When the shortest version of the command is used (**dnis-digits** <*value*>), the digit delay is set to **200** ms and the cut-through-delay is set to **500** ms by default.

Command History

Release A2.04	Command was introduced.

Functional Notes

The DNIS delay feature is used when an FXS port is connected to an ACD, such as a fax server. When the switchboard routes a call to the port and the terminal answers, the trailing digits of the called number are outpulsed to allow the terminal to finish routing the call. The **dnis-digits** command allows you to configure how many digits are outpulsed. For more information on how the feature operates, refer to the *Technology Review* section of this command.

This feature is available only when the voice user type is specified as FXS.

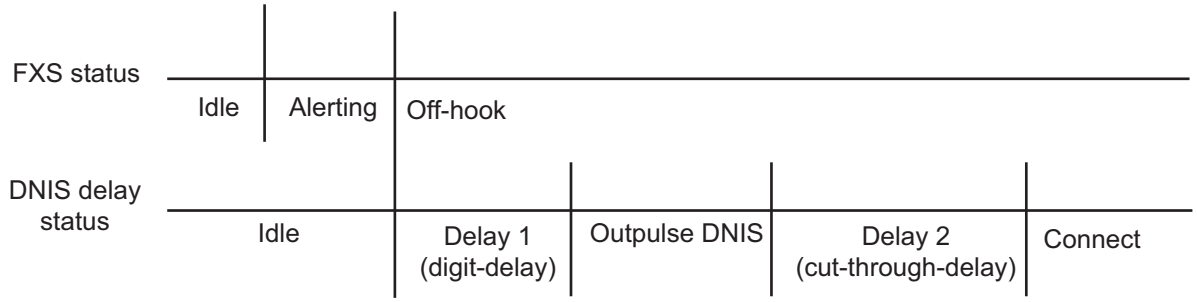
Usage Examples

The following example specifies that the voice user's terminal outpulse **4** DNIS digits and use the delay default values (**200** ms for **digit-delay** and **500** ms for **cut-through-delay**):

(config)**#voice user 4444**
(config-4444)**#dnis-digits 4**

Technology Review

The following diagram demonstrates the actions taken by the FXS port and the DNIS delay feature:



The diagram shows that the DNIS feature is idle while the FXS port is alerting and waiting for the terminal to go off-hook. After the terminal is off-hook, the DNIS feature enters the Delay 1 state, specified by the **digit-delay** parameter of this command. Entering this state allows sufficient time for any transients audible on the two-way wire to die away, and for the terminal to attach a digit register. After Delay 1 times out, DNIS DTMF digits are outpulsed to the terminal. The feature then enters the Delay 2 state, specified by the **cut-through-delay** parameter of this command. Entering this state allows for the connected terminal to finish routing the call. Once the feature enters the Connect state, a two-way voice band connection is established. Using the **dnis-digits** command allows you to specify the number of DNIS digits outpulsed and the duration of both delay periods in this process.

This feature is intended for use with a fax server, where multiple inbound fax numbers are all routed to a single analog port. To use this feature effectively, follow these steps:

1. Create a voice user account using the command *voice user <extension> on page 1983*. The extension number assigned can be arbitrary, or it can be one of the desired inbound fax lines.

2. Connect an analog port using the command *connect on page 4576*.

3. Assign an alias for each inbound fax line to be steered into the fax server using the command *alias "<text>" on page 75*.

4. Set the number of DNIS digits using the dnis-digits command. These digits must be set in conjunction with the fax server configuration.

The configuration of the DNIS digits feature appears as follows:

(config)**#voice user 4444**
(config-4444)**#connect fxs 0/1**
(config-4444)**#description “fax-server”**
(config-4444)**#alias 2565552081**
(config-4444)**#alias 2565552082**
(config-4444)**#alias 2568882093**
(config-4444)**#alias 2568882094**
(config-4444)**#dnis-digits 7**
(config-4444)**#exit**

door-phone

Use the **door-phone** command to enable the door phone mode for this extension. Use the **no** form of this command to disable the door phone mode for this extension.

Syntax Description

No subcommands.

Default Values

By default, the door phone mode is disabled.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example makes extension **4444** the door phone extension.

(config)**#voice user 4444**
(config-4444)**#door-phone**

echo-cancellation

Use the **echo-cancellation** command to improve voice quality for packetized-based voice calls, such as Voice over Internet Protocol (VoIP) or Media Gateway Control Protocol (MGCP). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **echo-cancellation** is enabled.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example activates **echo-cancellation** for user **4444**:

```
(config)#voice user 4444
(config-4444)#echo-cancellation
```

email <*address*>

Use the **email** command to configure the primary email notification address for this extension. Use the **no** form of this command to remove a configured email address.

Syntax Description

<*address*>	Specifies the primary email notification address for this extension.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example configures the primary email notification address for this extension as **first.last@company.com**.

(config)**#voice user 4444**
(config-4444)**#email first.last@company.com**

email-secondary *<address>*

Use the **email-secondary** command to configure the secondary email notification address for this extension. The secondary email address will be used based on the email notification schedule. Use the **no** form of this command to remove a configured secondary email address.

Syntax Description

<address>	Specifies the secondary email notification address for this extension.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example configures the secondary email notification address for this extension as **first.last@company.com**.

(config)**#voice user 4444**
(config-4444)**#email-secondary first.last@company.com**

findme-followme

Use the **findme-followme** command to enable the FindMe-FollowMe feature for the user. Use the **no** form of this command to disable the feature. Variations of this command include:

findme-followme
findme-followme enhanced

Syntax Description

enhanced	Optional. Specifies that the enhanced version of FindMe-FollowMe is enabled on the user account.

Default Values

By default, FindMe-FollowMe is disabled.

Command History

Release A4.01	Command was introduced.

Functional Notes

The **enhanced** version of FindMe-FollowMe allows the AOS device to remain in the talk path only for external calls with press-to-accept enabled.

FindMe-FollowMe is a complex feature requiring a large amount of system resources. Decreasing the amount of enhanced FindMe-FollowMe can reduce the amount of system resources used by the feature.

This command must be enabled on the user account for additional FindMe-FollowMe configurations. For more information about configuring the FindMe-FollowMe feature, refer to *FindMe-FollowMe Contact Group Command Set on page 4752* and *FindMe-FollowMe Action Script Command Set on page 4744*, or the *Configuring User Accounts for the NetVanta 7000 Series* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables the basic FindMe-FollowMe feature for voice user **4444**:

(config)**#voice user 4444**
(config-4444)**#findme-followme**

findme-followme caller-id-override external-number *<name/number>*

Use the **findme-followme caller-id-override external-number** command to specify if caller ID override will be used on the voice user's account for FindMe-FollowMe calls. This command allows the user to specify the inbound caller ID and name when external FindMe-FollowMe calls are received. Use the **no** version of this command to disable the caller ID override on the voice user's FindMe-FollowMe settings.

Syntax Description

<name/number>	Specifies the external number (up to 16 digits) to use in the caller ID.

Default Values

By default, FindMe-FollowMe caller ID override is disabled.

Command History

Release R10.2.0	Command was introduced.

Functional Notes

FindMe-FollowMe must be enabled on the user account using the command *findme-followme on page 4593* before configuring FindMe-FollowMe caller ID override.

For more information about configuring the FindMe-FollowMe feature, refer to *FindMe-FollowMe Contact Group Command Set on page 4752* and *FindMe-FollowMe Action Script Command Set on page 4744*, or the *Configuring User Accounts on the NetVanta 7000 Series* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the FindMe-FollowMe caller ID override for voice user **4444**:

(config)**#voice user 4444**
(config-4444)**#findme-followme**
(config-4444)**#findme-followme caller-id-override external number 2565551212**

first-name <*name*>

Use the **first-name** command to specify the user's first name. The name will represent the user's first name in the system. Use the **no** form of this command to remove a first name.

Syntax Description

<*name*>	Specifies the user's first name.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example specifies the first name of user **4444**:

(config)**#voice user 4444**
(config-4444)**#first-name John**

forward

Use the **forward** command to redirect all calls to this extension to a specified number. Forwarding calls allows the user to receive incoming calls at a different number. Use the **no** form of this command to disable this feature. Variations of this command include:

forward <*number*>
forward busy <*number*>
forward no-answer <*number*>

Syntax Description

<*number*>	Forwards all calls to the specified number. Do not include dashes or hyphens in the number.
busy <*number*>	Forwards calls to the specified number when the extension is busy. Do not include dashes or hyphens in the number.
no-answer <*number*>	Forwards unanswered calls to the specified number. Do not include dashes or hyphens in the number.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.
Release R10.8.0	Command was expanded to include the **busy** and **no-answer** parameters.

Usage Examples

The following example forwards all calls to user **4444** to the number **256-555-8000**:

(config)**#voice user 4444**
(config-4444)**#forward 2565558000**

forward-disconnect

Use the **forward-disconnect** command to specify the method of manipulating the polarity to signal a disconnect of the line. Use the **no** form of this command to return to the default value. Variations of this command include:

forward-disconnect battery none
forward-disconnect battery remove
forward-disconnect battery reverse
forward-disconnect delay <*value*>

Syntax Description

battery none	Specifies that the battery will not be removed or reversed upon disconnect.
battery remove	Specifies that the battery will be removed upon disconnect.
battery reverse	Specifies that the battery will be reversed upon disconnect.
delay <*value*>	Sets a forward disconnect delay time value in milliseconds. Specify **250**, **500**, **750**, **1000**, or **2000** milliseconds.

Default Values

By default, **forward-disconnect battery remove** is enabled.

Command History

Release 9.3	Command was introduced.
Release A4.05	Command was expanded to include the **battery none** parameter.

Usage Examples

The following example removes the battery upon disconnect for user **4444**. This command is used most often with a fax machine that needs to be alerted that a call has ended:

(config)**#voice user 4444**
(config-4444)**#forward-disconnect battery remove**

fwd-courtesy

Use the **fwd-courtesy** command to enable the courtesy ring feature when a call is forwarded to notify the user that an incoming call has been re-routed. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example sends a courtesy ring when a call is forwarded:

(config)**#voice user 4444**
(config-4444)**#fwd-courtesy**

group-ring-call-waiting

Use the **group-ring-call-waiting** command to enable the user to receive multiple calls from a ring group. Use the **no** form of this command to disable the feature.

Syntax Description

No subcommands.

Default Values

By default, users cannot receive multiple calls from a ring group.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example enables user **4444** to receive multiple calls from a ring group:

(config)**#voice user 4444**
(config-4444)**#group-ring-call-waiting**

hotel

Use the **hotel** command to allow extension reassignment to an alternate phone. Use the **no** form of this command to deny extension reassignment.

Syntax Description

No subcommands.

Default Values

By default, the hotel feature is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example enables the user to assign extension **4444** to an alternate phone:

(config)**#voice user 4444**
(config-4444)**#hotel**

hotline <*number*>

Use the **hotline** command to configure the user's phone as a hotline phone. When the user picks up the phone, it will automatically ring the extension assigned. Use the **no** form of this command to disable this feature.

Syntax Description

<*number*>	Specifies the hotline number to dial when the phone is off-hook.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example sets up user **4444** as a hotline and specifies that the number **256-555-8000** will be dialed when user 4444's phone is off-hook:

(config)**#voice user 4444**
(config-4444)**#hotline 2565558000**

last-name *<name>*

Use the **last-name** command to specify the user's last name. The stored name will appear in the caller ID information and directory for the user. Use the **no** form of this command to remove a last name.

Syntax Description

<name>	Specifies the user's last name.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example specifies the last name of user **4444**:

(config)**#voice user 4444**
(config-4444)**#last-name Smith**

location *<text>*

Use the **location** command to specify the user's physcial location within the company's physical address. The user's location is used to enhance emergency call email alert notification with the location of the caller. Use the **no** form of this command to remove the user's location.

Syntax Description

<text>	Specifies the user's location using no more than 40 characters.

Default Values

No default values are necessary for this command.

Command History

Release A4.03	Command was introduced.

Usage Examples

The following example specifies the location of user **4444**:

(config)**#voice user 4444**
(config-4444)**#location 5th floor, room 582**

message-waiting

Use the **message-waiting** command to configure message-waiting notification methods. Use this command to select the phone alert used to notify users of new voicemail. Use the **no** form of this command to disable this feature. Variations of this command include:

message-waiting both
message-waiting dialtone-only
message-waiting lamp-only

Syntax Description

both	Sets message-waiting notification for both dial tone and lamp.
dialtone-only	Sets message-waiting notification for dial tone only.
lamp-only	Sets message-waiting notification for lamp-only.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example sets message-waiting notification for user **4444** for both dial tone and lamp:

(config)**#voice user 4444**
(config-4444)**#message-waiting both**

modem-passthrough

Use the **modem-passthrough** command to switch to passthrough mode on fax or modem tone detection. This command allows modem and fax calls to maintain a connection without altering the signals with the voice improvement settings, such as echo cancellation and voice activity detection (VAD). Use the **no** form of this command to disable this feature. Variations of this command include:

modem-passthrough
modem-passthrough detection-time <*value*>
modem-passthrough cng-early-detect

Syntax Description

detection-time <*value*>	Optional. Specifies the fax and/or modem detection time length value in seconds. Range is **0** to **8** seconds.
cng-early-detect	Optional. Enables early (first burst) detection of fax calling (CNG) tone.

Default Values

By default, **modem-passthrough** is enabled.

Command History

Release 11.1	Command was introduced.
Release 12.1	Command was expanded to include the **detection-time** parameter.
Release R10.8.0	Command was expanded to include the **cng-early-detect** parameter.

Usage Examples

The following example disables **modem-passthrough**:

(config)**#voice user 4444**
(config-4444)**#no modem-passthrough**

nls

Use the **nls** command to enable the non-linear suppression (NLS) option for the user. This option sets the echo canceller to reduce acoustic echo. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 14.1	Command was introduced.

Usage Examples

The following example enables NLS for user **4444**:

```
(config)#voice user 4444
(config-4444)#nls
```

notify email

Use the **notify email** command to indicate either the primary or secondary email address for voicemail notification during the voicemail notification schedule. The primary and secondary email addresses must be configured using the commands *email <address> on page 4591* and *email-secondary <address> on page 4592*. Use the **no** form of this command to disable this feature. Variations of this command include the following:

notify email primary
notify email secondary

Syntax Description

primary	Specifies that email notifications for this schedule will be sent to the primary email address.
secondary	Specifies that email notifications for this schedule will be sent to the secondary email address.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.
Release 15.1	Command was expanded.

Usage Examples

The following example configures the unit to send email notification for this schedule to the secondary email address.

(config)**#voice user 4444**
(config-4444)**#voicemail notify schedule monday 06:00 am**
Configuring New Schedule “monday 06:00 am”.
(config-4444-mon-06:00am)**#notify email secondary**

num-rings

Use the **num-rings** command to specify the number of rings for call pickup before the system redirects the call. Each system mode call coverage action can be configured with a different number of rings based on preference. Use the **no** form of this command to return to the default setting. Variations of this command include:

num-rings <*value*>
num-rings disabled
num-rings <*system mode*> <*value*>
num-rings <*system mode*> **disabled**
num-rings override <*value*>

Syntax Description

disabled	Optional. Specifies that the extension does not ring. This parameter is used when the FindMe-FollowMe feature is in call coverage mode and causes the FindMe-FollowMe actions to begin as soon as the incoming call is placed.
<*system mode*>	Optional. Specifies the system mode to configure for call coverage. Choose from **custom1**, **custom2**, **custom3**, **lunch**, **night**, or **weekend**. Refer to the *Functional Notes* of this command for more information on configuring system modes.
override	Ignores the programmed system mode schedule.
<*value*>	Specifies the number of unanswered rings before the next call action begins. Specify **0** through **9** rings. Entering **0** specifies an unlimited number of rings.

Default Values

By default, the **num-rings** is set to **4**.

Command History

Release 9.3	Command was introduced.
Release A1	Command was updated to include the system mode feature options.
Release A4.01	Command was expanded to include the **disabled** parameter.

Functional Notes

System mode call coverage provides more diverse functionality for call handling. In previous versions of AOS (revision 15.1 or earlier), up to five coverage modes were allowed. Calls were processed in the order in which the coverage options were entered into the system.

With the addition of the system mode options, up to five coverage options per system mode are allowed. The system modes can be modified using the command *voice system-mode on page 1971*.

The **disabled** parameter specifies that the extension does not ring. This parameter is useful when the FindMe-FollowMe feature is enabled on the user account and is set as the preferred call coverage mode. For more information about configuring FindMe-FollowMe, refer to the *Configuring User Accounts on the NetVanta 7000 Series* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example allows the extension **4444** to ring **6** times before redirecting the call:

(config)**#voice user 4444**
(config-4444)**#num-rings 6**

The following example sets the number of rings to **1** before redirecting the call when the system mode is set to **weekend**:

(config)**#voice user 4444**
(config-4444)**#num-rings weekend 1**

The following example specifies that extension **4444** will not ring during lunch when the **lunch** system mode is enabled:

(config)**#voice user 4444**
(config-4444)**#num-rings lunch disabled**

password *<password>*

Use the **password** command to create a password or personal identification number (PIN) to protect voice settings and messages. Use the **no** form of this command to remove a password.

Syntax Description

<password>	Specifies a 4-digit password or PIN.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example sets the password for user **4444** to **4321**:

(config)#**voice user 4444**
(config-4444)#**password 4321**

plc

Use the **plc** command to enable packet loss concealment (PLC). PLC is used to prevent choppy connections by concealing a packet loss by replacing the lost packet with another voice packet in the data stream. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, PLC is enabled.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example disables PLC for user **4444**:

```
(config)#voice user 4444
(config-4444)#no plc
```

ppm queue reporting

Use the **ppm queue reporting** command to enable the viewing of call queue reporting statistics on the user's personal phone manager. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, users cannot view call queue reporting statistics from the personal phone manager.

Command History

Release R10.2.0	Command was introduced.

Usage Examples

The following example enables call queue reporting statistics are available to voice user **4444**:

(config)**#voice user 4444**
(config-4444)**#ppm queue reporting**

remote-phone

Use the **remote-phone** command to specify using the source IPv4 address and port for routing rather than the Contact address specified in the SIP messaging. Enabling this feature also enables media anchoring for the voice user. Use the **no** form of this command to disable the settings.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example configures the voice user for extension **4444** as a remote phone:

(config)**#voice user 4444**
(config-4444)**#remote-phone**

rtp delay-mode

Use the **rtp delay-mode** command to configure the Realtime Transport Protocol (RTP) jitter buffer packet delay mode settings. RTP is used to prevent static on voice connections by enhancing the quality of the packet delivery. Use the **no** form of this command to return to the default setting. Variations of this command include:

rtp delay-mode adaptive
rtp delay-mode fixed

Syntax Description

adaptive	Configures RTP jitter buffer packet delay to adjust during a call based on network conditions.
fixed	Configures the RTP jitter buffer packet delay to remain constant.

Default Values

By default, the RTP delay mode is set to **adaptive**. This allows for minimal latency by adjusting the average packet delay based on the conditions of the network.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures RTP delay mode as f**ixed**:

(config)**#voice user 4444**
(config-4444)**#rtp delay-mode fixed**

rtp dtmf-relay

Use the **rtp dtmf-relay** command to configure the method by which Realtime Transport Protocol (RTP) dual tone multi-frequency (DTMF) events are relayed. The dial digits can be sent inband or out-of-band (OOB) of the voice stream. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp dtmf-relay inband
rtp dtmf-relay nte <*value*>

Syntax Description

inband	Specifies that RTP DTMF events be relayed inband in the RTP stream.
nte <*value*>	Specifies that RTP DTMF event value be relayed OOB using named telephone event (NTE). Enter an NTE value between **96** and **127**.

Default Values

By default, the **rtp dtmf-relay** is set for **NTE 101**.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example configures RTP DTMF relay events for **inband**:

(config)**#voice user 4444**
(config-4444)**#rtp dtmf-relay inband**

rtp dtmf-relay offer

Use the **rtp dtmf-relay offer** command to specify which dualtone multifrequency (DTMF) relay mode to offer to a particular Session Initiation Protocol (SIP) endpoint when using DTMF transcoding. Use the **no** form of this command to return the DTMF method to default value. Variations of this command include:

rtp dtmf-relay offer inband
rtp dtmf-relay offer nte <*value*>

Syntax Description

inband	Specifies that the DTMF relay method is in-band.
nte <*value*>	Specifies that the DTMF relay method is an RFC 2833 named telephone events (NTE). Valid NTE value range is **96** to **127**.

Default Values

By default, there is no preferred DTMF relay mode on the SIP endpoint, and the Session Border Controller (SBC) can choose a DTMF value that does not require transcoding to complete a call.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

The **rtp dtmf-relay offer** command is used to enable and configure DTMF transcoding on the AOS device when it is acting as an SBC. Transcoding is a method of translating media types in which the SBC operates as a translator for SIP devices using different media types that are attempting a connection. The AOS device translates one media type to another to allow the communication to succeed. For more information about transcoding and its configuration, refer to the configuration guide *Configuring Transcoding in AOS*, available online at https://supportcommunity.adtran.com.

Before you can configure the DTMF relay method for transcoding, you must enable media anchoring using the command *ip rtp media-anchoring on page 1458*.

Usage Examples

The following example specifies the NTE 101 DTMF relay method for transcoding for voice user **4444**:

(config)**#ip rtp media-anchoring transcoding dtmf**
(config)**#voice user 4444**
(config-4444)**#rtp dtmf-relay offer nte 101**

rtp frame-packetization <*value*>

Use the **rtp frame-packetization** command to configure the Realtime Transport Protocol (RTP) frame packetization time in milliseconds for individual trunks and users. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Configures the RTP frame packetization time value in milliseconds. Select from **10**, **20**, **30**, or **40** milliseconds.

Default Values

By default, the **rtp frame-packetization** time is set to **20** milliseconds on all trunks and users.

Command History

Release 9.3	Command was introduced.
Release R10.8.0	Command was expanded to include **40** milliseconds.

Usage Examples

The following example sets the frame packetization time for user **4444** to **10** milliseconds:

(config)**#voice user 4444**
(config-4444)**#rtp frame-packetization 10**

rtp frame-packetization mode

Use the **rtp frame-packetization mode** command to specify the method for determining the Realtime Transport Protocol (RTP) frame packetization period on received calls. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp frame-packetization mode fixed
rtp frame-packetization mode negotiated

Syntax Description

fixed	Specifies that received calls always use the configured packetization period. This period is set using the command *rtp frame-packetization <value> on page 4617*.
negotiated	Specifies that the trunks and users use the packetization period specified in the Session Description Protocol (SDP) offer.

Default Values

By default, the **rtp frame-packetization mode** is set to **negotiated**.

Command History

Release A2.04	Command was introduced.

Usage Examples

The following example sets the method for determining the frame packetization mode for user **4444** to **fixed**:

(config)**#voice user 4444**
(config-4444)**#rtp frame-packetization mode fixed**

rtp media video filter

Use the **rtp media video filter** command to filter out video media attributes from transmitted or received Session Description Protocol (SDP) messages on an AOS device acting as a session border controller (SBC). You can filter out video media on a Session Initiation Protocol (SIP) endpoint by entering the command from the SIP endpoint's configuration mode. Use the **no** form of this command to disable the media filtering feature.

Syntax Description

No subcommands.

Default Values

By default, media filtering is disabled and all video SDP media attributes are passed through the SBC device.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

Media filtering is a part of the transcoding feature that is available when the AOS device is acting as an SBC. For more information about transcoding and the media filtering feature, refer to the configuration guide *Configuring Transcoding in AOS*, available online at https://supportofurms.adtran.com.

Usage Examples

The following example enables media filtering for voice user **4444**:

(config)**#voice user 4444**
(config-4444)**#rtp media video filter**

rtp packet-delay

Use the **rtp packet-delay** command to configure the maximum Realtime Transport Protocol (RTP) packet delays. This command is used to set the allowable limits of latency on the network. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp packet-delay fax <*value*>
rtp packet-delay maximum <*value*>
rtp packet-delay nominal <*value*>

Syntax Description

fax <*value*>	Sets the fax delay time value in milliseconds. Range is **0** to **500** milliseconds.
maximum <*value*>	Sets the maximum delay time value in increments of **10** milliseconds. Range is **40** to **320** milliseconds.
nominal <*value*>	Sets the nominal delay time value in increments of **10** milliseconds. Range is **10** to **240** milliseconds.

Default Values

By default, the RTP packet delay for fax is **300**, maximum is **100**, and nominal is **50**.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures the RTP fax delay time for user **4444** to **200** milliseconds:

(config)**#voice user 4444**
(config-4444)**#rtp packet-delay fax 200**

rtp qos dscp <*value*>

Use the **rtp qos dscp** command to configure the maximum Realtime Transport Protocol (RTP) quality of service (QoS) parameters for differentiated services code point (DSCP). Use the **no** form of this command to return to the default global value.

Syntax Description

<*value*>	Configures the RTP QoS parameter for DSCP. Enter a value between **0** and **63**.

Default Values

By setting the **rtp qos dscp** value on an individual trunk or user, you will override the global **rtp qos dscp** setting for RTP packets. The default global DSCP value for RTP is **46**.

Command History

Release 9.3	Command was introduced.

Functional Notes

By setting the **rtp qos dscp** value on an individual trunk or user, you will override the global **rtp qos dscp** setting for RTP packets. QoS is set using a DSCP value. Valid DSCP values are **0** to **63**, and a higher DSCP value has a higher priority. The default global DSCP value for RTP is **46**. Remember that if you are using a public IP connection, such as the Internet, for Voice over Internet Protocol (VoIP), end-to-end QoS may not be guaranteed. The default DSCP value for Session Initiation Protocol (SIP) is **26**. To configure QoS for the RTP traffic that carries the voice conversation, use the command **ip rtp qos dscp** followed by the desired DSCP value.

Usage Examples

The following example configures the RTP QoS DSCP for user **4444** to **60**:

(config)**#voice user 4444**
(config-4444)**#rtp qos dscp 60**

script *<name>*

Use the **script** command to create a FindMe-FollowMe action script for the user and to enter the script's configuration mode. Use the **no** form of this command to remove the script from the user's FindMe-FollowMe configuration.

Syntax Description

<name>	Specifies the name of the action script using no more than **10** characters.

Default Values

By default, no FindMe-FollowMe action scripts are configured.

Command History

Release A4.01	Command was introduced.

Functional Notes

Each FindMe-FollowMe action script is the set of actions taken when FindMe-FollowMe is enabled and set as the call coverage mode for the user. Action scripts are associated with FindMe-FollowMe contact groups, and each group has one associated script. When the **script** command is entered from the user account's configuration mode, you will enter the action script configuration mode. Each action script can hold **10** actions.

For more information about enabling FindMe-FollowMe and specifying it as the call coverage mode for the user, refer to the commands *findme-followme on page 4593* and *coverage on page 4580*. For more information about contact group configuration, refer to *FindMe-FollowMe Contact Group Command Set on page 4752*. For more information about action script configuration, refer to *FindMe-FollowMe Action Script Command Set on page 4744*. For more information about configuring the FindMe-FollowMe feature, refer to the *Configuring User Accounts on the NetVanta 7000 Series* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example creates the action script **BUSINESS** for user **4444**, and enters the script's configuration mode:

```
(config)#voice user 4444
(config-4444)#script BUSINESS
(config-4444-sc-BUSINESS)#
```

show voice mail

Use the **show voice mail** command to display a user's voicemail information. This command can also be executed from the Enable mode prompt using the syntax explained in *show voice mail on page 1081*. Variations of this command include:

show voice mail
show voice mail notify-schedule

> *The output of all **show** commands can be limited by appending the following modifiers to the end of the command: | **begin** <text>, | **exclude** <text>, and | **include** <text>. The **include** modifier limits output to lines that contain the specified text, the **exclude** modifier excludes any lines with the specified text, and the **begin** modifier displays the first line of output with the specified text and all lines thereafter.*
>
> *For specific instructions and examples regarding these modifiers, refer to the introduction of the Enable Mode Command Set on page 94.*

Syntax Description

notify-schedule	Displays the voicemail notification schedule.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.
Release 17.1	Command was expanded to include the modifiers **begin**, **exclude**, and **include**.

Usage Examples

The following example shows sample output from the **show voice mail** command for extension **4444**:

```
(config)#voice user 4444
(config-4444)#show voice mail
Voicemail information for account: 4444
VM Class of Service: normal_voicemail
Standard Greeting (min): 01:00      Total Voicemail Usage (min): 05:00
Alternate Greeting (min): 01:00     Total Voicemail Free (min): 10:00
Recorded Name (min): 00:10
```

The following is sample output for the **show voice mail notify-schedule** command for extension **4444**:

(config)**#voice user 4444**
(config-4444)**#voicemail notify schedule monday 06:00 am**
Configuring New Schedule "monday 06:00 am".
(config-4444-mon-06:00am)**#show voice mail notify-schedule**

Start	End	Email 1	Email 2
Sun 12:00am	Sun11:59pm	---	---
Mon 12:00am	Mon5:59am	---	---
Mon 6:00am	at11:59pm	---	---

sip-authentication password *<password>*

Use the **sip-authentication password** command to configure the Session Initiation Protocol (SIP) authentication password for this user. Use the **no** form of this command to return the password to the default value.

Syntax Description

<password>	Specifies a string of up to 16 characters to be sent as the password in authentication.

Default Values

By default, the SIP authentication password is set to the same value as the currently configured SPRE PIN (typically **1234**) on all AOS devices except the NetVanta 7000 Series. By default, the SIP password for NetVanta 7000 Series products is a randomly generated 16 character password.

Command History

Release A2.04	Command was introduced.
Release R10.2.0	Command functionality was changed from using the SPRE password by default to being set to a randomly generated 16 character password by default for NetVanta 7000 Series products.

Usage Examples

The following example specifies that user **4444** will use the password **Password** for authentication:

(config)**#voice user 4444**
(config-4444)**#sip-authentication password Password**

The following example specifies that user **4444** on a NetVanta 7000 Series product will use a randomly generated 16 character password for authentication:

(config)**#voice user 4444**
(config-4444)**#no sip-authentication password**

sip-identity

Use the **sip-identity** command to configure the Session Initiation Protocol (SIP) registration options for the user. Use the **no** form of this command to disable the settings. Variations of this command include the following:

sip-identity <*station*> <*Txx*>
sip-identity <*station*> <*Txx*> **register**
sip-identity <*station*> <*Txx*> **register auth-name** <*username*> **password** <*password*>

Syntax Description

<*station*>	Specifies the station to be used for SIP trunk (e.g., **station extension**).
<*Txx*>	Specifies the SIP trunk through which to register the server. The trunk is specified in the format Txx (e.g., **T01**).
register	Registers the user to the server.
auth-name <*username*>	Optional. Sets the user name that will be required as authentication for registration to the SIP server.
password <*password*>	Optional. Sets the password that will be required as authentication for registration to the SIP server.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example specifies trunk **T02** and extension **4400** for SIP **identity**:

(config)**#voice user 4444**
(config-4444)**#sip-identity 4400 T02**

sip-keep-alive

Use the **sip-keep-alive** command to configure the type of keep-alive method for this Session Initiation Protocol (SIP) trunk. Keep-alive messages must be sent between SIP device and the registrar to keep the connected channel open for communication. Use the **no** form of this command to return to disable this feature. Variations of this command include the following:

sip-keep-alive info
sip-keep-alive info <*value*>
sip-keep-alive options
sip-keep-alive options <*value*>

Syntax Description

info	Specifies the INFO method to be used for the keep-alives on the trunk.
options	Specifies the OPTIONS method to be used for the keep-alives on the trunk.
<*value*>	Optional. Specifies the amount of time in seconds between the type of SIP keep-alive messages being sent during a call. Range is **30** to **3600** seconds.

Default Values

By default, **sip-keep-alive** is set to **info 60** on NetVanta 7000 Series products. For IP business gateways (Total Access 900(e) Series and NetVanta 6000 Series) **sip-keep-alive** is disabled by default.

Command History

Release 13.1	Command was introduced
Release A2.04	Command was added to the Voice Line and Voice User command sets.

Usage Examples

The following example sets the keep-alive method to **info**:

(config)**#voice user 4444**
(config-4444)**#sip-keep-alive info**

sip-register send-unsynced

Use the **sip-register send-unsynced** command to disable the Session Initiation Protocol (SIP) synchronized registration method used for this voice user. When this command is enabled, AOS will register sip-identities regardless of whether the remote entity is registered. Use the **no** form of this command to use the synchronized registration method, in which SIP-identities will not be registered unless the remote entity is registered.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example specifies the use of synchronized registration for extension **4444**:

(config)**#voice user 4444**
(config-4444)**#no sip-register send-unsynced**

special-ring-cadences

Use the **special-ring-cadences** command to enable special ring cadences for this user. This command allows the user to be alerted with a distinctive ring. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example enables special ring cadences for user **4444**:

(config)**#voice user 4444**
(config-4444)**#special-ring-cadences**

speed-dial *<number>*

Use the **speed-dial** command to assign a number (1 through 20) to the user. The speed dial number allows the user to call each other by simply dialing 1- or 2-digit numbers. Use the **no** form of this command to disable this feature.

Syntax Description

<number>	Specifies the speed dial number for the user. Select from numbers **1** through **20**.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example assigns a **speed-dial** number to user **4444**:

(config)#**voice user 4444**
(config-4444)#**speed-dial 2**

station-lock

Use the **station-lock** command to lock the (station) against inbound or outbound calls. Locking a station will restrict phone privileges. Use the **no** form of this command to disable this feature. Variations of this command include:

station-lock admin
station-lock admin inbound
station-lock admin inbound-outbound
station-lock user
station-lock user inbound
station-lock user inbound-outbound

Syntax Description

admin	Allows the administrator to block calls.
user	Allows the user to block calls.
inbound	Optional. Blocks inbound calls.
inbound-outbound	Optional. Blocks both inbound and outbound calls.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example configures an administrator inbound and outbound station lock:

(config)**#voice user 4444**
(config-4444)**#station-lock admin inbound-outbound**

t38

Use the **t38** command to enable T.38 fax operation. Use the **no** form of this command to disable this feature.

The command modem-passthrough on page 4605 must be enabled for T.38 operation to work.

Syntax Description

No subcommands.

Default Values

By default, T.38 is disabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables T.38 for user **4444**:

(config)**#voice user 4444**
(config-4444)**#t38**

Technology Review

T.38 is an International Telecommunication Union (ITU) specification that allows Group-3 Fax (T.30) data to be transported over the Internet. It is similar to dual tone multi-frequency (DTMF) relay (RFC 2833) in that the digital signal processor (DSP) decodes tones and demodulated fax data and converts them into packets. A similar device on the other end takes the packets/tones and remodulates them so that an analog fax machine on the other end can receive the fax. AOS's previous support (revisions 12 through 15) for fax/modem signals was simply detecting a tone and forcing the coder-decoder (CODEC) into G.711 and disabling/enabling echo cancellers based on the tones detected. When packet loss becomes high, sending faxes over G.711 becomes problematic, due to dropped messages and timeouts/retrains.

T.38 can be used in conjunction with various call-control schemes, such as H.323, Session Initiation Protocol (SIP), and Media Gateway Control Protocol (MGCP). AOS only supports SIP as the call-control method. This is typically referred to T.38/Annex-D. Annex-D describes the Session Initiation Protocol/Session Description Protocol (SIP/SDP) call establishment procedures.

t38 ced auto-generate

Use the **t38 ced auto-generate** command to specify when the digital signal processor (DSP) should regenerate the called station identifier (CED) signal toward the time division multiplexed (TDM) endpoint. If auto-generate is enabled, the DSP generates the CED signal only when it does not receive CED indicator packets from the Voice over IP (VoIP) endpoint. If auto-generate is disabled, the DSP generates the CED signal only when it does receive CED indicator packets from the VoIP endpoint. Using the **no** version of this command disables CED auto-generate.

Syntax Description

No subcommands.

Default Values

By default, CED auto-generate is disabled.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Usage Examples

The following example enables CED auto-generate for the T.38 session for user **4444**:

(config)**#voice user 4444**
(config-4444)**#t38 ced auto-generate**

t38 ced length <*time*>

Use the **t38 ced length** command to set the maximum duration of a regenerated called station identifier (CED) signal, in milliseconds, from the digital signal processor (DSP) toward the time division multiplexed (TDM) endpoint when a T.38 session is active. Using the **no** form of this command returns the duration to the default value.

Syntax Description

<time>	Specifies the maximum duration of a regenerated CED signal in milliseconds. Valid range is **0** to **4000** ms.

Default Values

By default, the maximum duration of a regenerated CED signal is **3000** ms.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Setting the maximum duration of a regenerated CED signal to **0** effectively prevents any CED generation.

Usage Examples

The following example decreases the maximum duration of the CED signal to **2000** ms for the T.38 session for user **4444**:

(config)**#voice user 4444**
(config-4444)**#t38 ced length 2000**

t38 cng-relay-selective

Use the **t38 cng-relay-selective** command to enable fax calling tones (CNG) relay only when V.21 messages are not being transmitted. Use the **no** version of this command to disable selective CNG relay.

Syntax Description

No subcommands.

Default Values

Selective CNG relay is disabled by default.

Command History

Release R10.4.0	Command was introduced.

Usage Examples

The following example enables T.38 CNG relay:

(config)**#voice user 4444**
(config-4444)**#t38 cng-relay-selective**

t38 ecm

Use the **t38 ecm** command to enable or disable error correction mode (ECM) during T.38 sessions. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 ecm enable
t38 ecm disable

Syntax Description

enable	Enables ECM during T.38 sessions.
disable	Disables ECM during T.38 sessions.

Default Values

By default, ECM is enabled.

Command History

Release R10.8.0	The command was introduced

Usage Examples

The following example disables ECM for T.38 sessions involving user **4444**:

(config)**#voice user 4444**
(config-4444)**#t38 ecm disable**

t38 error-correction

Use the **t38 error-correction** command to specify the type of fax error correction. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 error-correction fec
t38 error-correction redundancy

Syntax Description

fec	Specifies forward error correction (FEC) as the fax error correction. FEC is a system of error control where the sender adds redundant data to its messages, allowing the receiver to detect and correct errors (within certain bounds) without the need to request additional data from the sender.
redundancy	Specifies redundancy as the fax error correction. Redundancy error correction replicates the payload a user-specified number of times to determine if errors are present. The number of redundant packets is set using the command *t38 v21-preamble-timeout <value> on page 4644*).

Default Values

By default, **t38 error-correction** is set to **redundancy** for the Total Access 900(e) Series, the NetVanta 6310/6330 Series, the NetVanta 6355 Series, the NetVanta 6240/6250 Serires, and the NetVanta 640 Series.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default value changed to **fec** for the Total Access 900(e) Series, the NetVanta 6310/6330 Series, the NetVanta 6355 Series, and the NetVanta 7000 Series products.
Release R10.8.0	The default values for this command were updated.

Usage Examples

The following example sets the **t38 error-correction** to **fec** for user **4444**:

(config)**#voice user 4444**
(config-4444)**#t38 error-correction fec**

t38 fallback-mode g711

Use the **t38 fallback-mode** command to specify the transmission mode used when T.38 fax relay cannot be successfully negotiated at the time of the fax transfer. Use the **no** form of this command to disable this feature.

Syntax Description

g711	Specifies that fax operation revert back to analog mode (G.711).

Default Values

By default, **t38 fallback-mode** is to **G.711**.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default was changed to **G.711**.

Usage Examples

The following example enables the **t38 fallback-mode** for user **4444**:

(config)**#voice user 4444**
(config-4444)**#t38 fallback-mode g711**

t38 generate-cng

Use the **t38 generate-cng** command to specify whether the digital signal processor (DSP) will begin a T.38 session by generating the calling signal (CNG) toward the time division multiplexed (TDM) endpoint. Using the **no** version of this command disables CNG generation.

Syntax Description

No subcommands.

Default Values

By default, CNG generation is disabled.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

With the introduction of this command, the CNG generation behavior of the T.38 session is now configurable. In AOS firmware prior to A5.01, this behavior was not configurable, but rather was set to always generate this signal.

Usage Examples

The following example enables CNG generation for the T.38 session for user **4444**:

(config)**#voice user 4444**
(config-4444)**#t38 generate-cng**

t38 max-buffer <*value*>

Use the **t38 max-buffer** command to set the maximum buffer size for T.38 fax operation. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the value of the **max-buffer** attribute in the Session Description Protocol (SDP) offer when the T.38 session is initiated. Range is **0** to **800** bytes.

Default Values

By default, the maximum buffer size is set to **200**.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example sets the **t38 max-buffer** to **100** for user **4444**:

(config)**#voice user 4444**
(config-4444)**#t38 max-buffer 100**

t38 max-datagram <*value*>

Use the **t38 max-datagram** command to set the maximum datagram value in this unit. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the value of the **max-datagram** attribute in the Session Description Protocol (SDP) offer when the T.38 session is initiated. Range is **0** to **300** bytes.

Default Values

By default, the maximum datagram value is set to **72** bytes.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default was changed to **72** bytes.

Usage Examples

The following example sets the **t38 max-datagram** to **100** for user **4444**:

(config)**#voice user 4444**
(config-4444)**#t38 max-datagram 100**

t38 max-rate

Use the **t38 max-rate** command to specify the fax maximum rate. The actual transmission rate could be lower than specified rate if the receiving end cannot support the maximum rate. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 max-rate 14400
t38 max-rate 12000
t38 max-rate 2400
t38 max-rate 4800
t38 max-rate 7200
t38 max-rate 9600

Syntax Description

14400	Specifies 14400 bits per second (bps) as fax maximum rate.
12000	Specifies 12000 bps as fax maximum rate.
2400	Specifies 2400 bps as fax maximum rate.
4800	Specifies 4800 bps as fax maximum rate.
7200	Specifies 7200 bps as fax maximum rate.
9600	Specifies 9600 bps as fax maximum rate.

Default Values

By default, the maximum fax rate is set to **14400** bps.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example sets the **t38 max-rate** to **4800** bps for user **4444**:

(config)#**voice user 4444**
(config-4444)#**t38 max-rate 4800**

t38 redundancy

Use the **t38 redundancy** command to set the number of redundant packets sent when the **t38 error-correction redundancy** feature is enabled. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 redundancy high-speed <*value*>
t38 redundancy low-speed <*value*>

Syntax Description

high-speed <*value*>	Specifies the number of redundant T.38 fax packets to be sent for data messages (high-speed fax machine image data). Range is **0** (no redundancy) to **4** packets.
low-speed <*value*>	Specifies the number of redundant T.38 fax packets to be sent for the signaling messages (low-speed fax machine protocol). Range is **0** (no redundancy) to **7** packets.

Default Values

By default, high-speed and low-speed redundancy values are set to **0** (no redundancy).

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables **t38 error-correction redundancy** and sets the number of redundant data messages to **3** for user **4444**:

(config)**#voice user 4444**
(config-4444)**#t38 error-correction redundancy**
(config-4444)**#t38 redundancy high-speed 3**

t38 v21-preamble-timeout *<value>*

Use the **t38 v21-preamble-timeout** command to set the maximum amount of time that the digital signal processor (DSP) waits for peer device activity after starting to transmit a V.21 preamble event before spoofing a response to the time division multiplexed (TDM) endpoint. Using the **no** version of this command returns the timeout value to the default setting.

Syntax Description

<value>	The time, in milliseconds, that the DSP will wait for peer activity. Valid range is **1** to **3000** ms.

Default Values

By default, the V.21 preamble timeout is set to **1700** ms.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Usage Examples

The following example specifies the V.21 preamble timeout value as **2000** ms for voice user **4444**:

(config)**#voice user 4444**
(config-4444)**#t38 v21-preamble-timeout 2000**

vad

Use the **vad** command to enable voice activity detection (VAD). VAD blocks out noise categorized as silence during a voice connection. The silent voice packets are not transmitted, allowing bandwidth usage to be reduced. Although VAD saves bandwidth, the quality of the voice call may be compromised. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, VAD is enabled for all voice trunks and users.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example disables VAD for user **4444**:

```
(config)#voice user 4444
(config-4444)#no vad
```

voicemail

Use the **voicemail** command to configure the voicemail options for the user. Use the **no** form of this command to disable the settings. Variations of this command include the following:

voicemail attachment-level <*dB*>
voicemail attachment-level disabled
voicemail auth-mode full
voicemail auth-mode none
voicemail auth-mode password
voicemail auto-play
voicemail cos <*name*>
voicemail delete-msg-on-email
voicemail envelope-play
voicemail greeting alternate
voicemail greeting default
voicemail greeting standard
voicemail language-preference English
voicemail language-preference FrenchCanadian
voicemail language-preference Irish
voicemail language-preference LatinAmSpanish
voicemail language-preference UKEnglish
voicemail new-user
voicemail notify email
voicemail notify email-secondary
voicemail notify email attach-message pcm
voicemail notify email attach-message pcm max-size <*size*>
voicemail notify email text-only
voicemail oper-assist <*number*>
voicemail password <*password*>

Syntax Description

attachment-level <*dB*>	Specifies the number of decibels for voicemail attachment files. Valid entries are **-30**, **-25**, **-20**, **-15**, or **-10** dB.
attachment-level disabled	Disables the automatic gain control (AGC) for voicemail attachments.
auth-mode	Specifies the authentication mode to access voicemail.
full	Specifies that the extension and password are required to access voicemail.
none	Specifies that voicemail authentication is disabled.
password	Specifies that the password is required to access voicemail. Only the password is required if set to password authentication mode.
auto-play	Specifies automatic playback of messages when entering the mailbox.
cos <*name*>	Configures the voicemail class of service (CoS) type by entering the name of the selected CoS.
delete-msg-on-email	Enables deletion of voicemail in email attachments.

envelope-play	Automatically plays message envelopes during message playback.
greeting	Specifies which greeting to use for voicemail.
alternate	Specifies using the alternate recorded voicemail greeting.
default	Specifies using the default voicemail greeting.
standard	Specifies using the user's standard recorded voicemail greeting.
language-preference	Specifies the language of the user's voicemail audio prompts.
English	Specifies English as the language of the user's voicemail audio prompts.
FrenchCanadian	Specifies French Canadian as the language of the user's voicemail audio prompts.
Irish	Specifies Irish as the language of the user's voicemail audio prompts.
LatinAmSpanish	Specifies Latin American Spanish as the language of the user's voicemail audio prompts.
UKEnglish	Specifies UK English as the language of the user's voicemail audio prompts.
new-user	Executes the new-user wizard for voicemail configuration.
notify email	Specifies sending an email notification when a new voicemail is received. This email is sent to the user's primary email address specified by the command *email <address> on page 4591*.
secondary	Specifies that the email notification is sent to the user's secondary email address. This address is specified by the command *email-secondary <address> on page 4592*.
attach-message	Sends the voicemail as a WAV file attachment to the specified email. The email client must be configured for email options to work.
pcm	Indicates that voicemail messages sent as email attachment will be in pulse-code modulation (PCM) format.
max-size <*size*>	Optional. Indicates truncating email attachments at the specified maximum size in kilobits (kb). Minimum size entry is **10** kb.
text-only	Sends only a text message to the specified email address.
oper-assist <*number*>	Directs all operator calls to the specified phone number.
password <*password*>	Creates the password/personal identification number (PIN) that will be required to access voicemail.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.
Release 15.1	Command was expanded.
Release A2	Command was expanded to include the **notify email** parameters.
Release A2.04	Command was expanded to include **attachment-level** parameters.
Release A4.01	Command was expanded to include **auth-mode none** parameters.

Release A4.03	Command was expanded to include the **language-preference** parameter.
Release R10.2.0	Command was expanded to include the **Irish** language preference.
Release R10.5.0	Command was expanded to include the **UKEnglish** language preference.

Usage Examples

The following example sets the voicemail CoS for this user to **class1**:

(config)**#voice user 4444**
(config-4444)**#voicemail cos class1**

voicemail notify schedule

Use the **voicemail notify schedule** command to create a notification schedule for the user's voicemail message notification. When you create a notification schedule, you also enter the schedule's configuration mode. Using the **no** form of this command removes the notification schedule from the user's configuration. Variations of this command include:

voicemail notify schedule <*day*> <*HH:MM*> **am**
voicemail notify schedule <*day*> <*HH:MM*> **pm**

Once you have entered the **voicemail notify schedule** command, you are in the notification schedule configuration mode. From this mode you can enter the **notify email** command to specify whether notifications are sent to the primary or secondary user email address. Use the **no** form of this command to disable email notification. Variations of this command include:

notify email primary
notify email secondary

Syntax Description

<*day*>	Specifies the day of the week for the voicemail notification. Options include: **Monday**, **Tuesday**, **Wednesday**, **Thursday**, **Friday**, **Saturday**, and **Sunday**.
<*HH:MM*>	Specifies the time of day voicemail notifications are sent in the HH:MM format. For example, to send a notification at **5:00**, enter **05:00**.
am	Specifies the voicemail notification time is in the a.m.
pm	Specifies the voicemail notification time is in the p.m.
primary	Specifies the email notification is sent to the user's primary email address. This address is specified using the command *email <address> on page 4591*.
secondary	Specifies the email notification is sent to the user's secondary email address. This address is specified using the command *email-secondary <address> on page 4592*.

Default Values

By default, no voicemail notification schedule is configured.

Command History

Release 12.1	Command was introduced.
Release 15.1	Command was expanded to include the secondary email address.

Usage Examples

The following example configures a voicemail notification schedule for user **4444**. This user is scheduled to receive voicemail notifications on **Monday** at **3:00 pm** by an email sent to the **primary** email address:

(config)**#voice user 4444**
(config-4444)**#voicemail notify schedule monday 03:00 pm**
Configuring New Schedule “monday 03:00 pm”.
(config-4444-mon-03:00pm)**#notify email primary**

warmline <*number*>

Use the **warmline** <*number*> command to configure the voice user to automatically call a specified phone number if an off-hook condition is detected, and a digit is not dialed within the specified time frame. Use the **no** version of this command to disable this feature. Variations of this command include:

warmline <*number*>
warmline <*number*> **delay** <*1-60*>

Syntax Description

<*number*>	Specifies a phone number to dial when an off-hook condition is detected.
delay <*1-60*>	Specifies the delay period to wait before dialing the warm line number. Valid range is **1** to **60** seconds.

Default Values

By default, there is no pre-provisioned warm line phone number. If a delay is not specified, the default delay is 20 seconds.

Command History

Release R11.10.0	Command was introduced.

Usage Examples

The following example configures a warm line phone number of **6002** using the default delay of **20** seconds for voice user **4444**:

(config)#**voice user 4444**
(config-4444)#**warmline 6002**

VOICE GROUPS COMMAND SETS

This section includes the following command sets:

VOICE CALL PICKUP GROUP COMMAND SET

Call pickup is a feature on AOS voice products that allows users to pick up calls ringing on other extensions without having to park calls. Call pickup works in two ways: either through directed call pickup, or call pickup groups. In directed call pickup, a user can answer the call dialing a special prefix (SPRE) code that includes the extension of the ringing phone. In call pickup groups, a group of users is created which allows calls to be answered by dialing the group extension. For example, to use the call pickup group, members of the group enter the four-digit extension of the call pickup group to answer a call. Ringing phones are identified either by hearing the phone ring or by monitoring the busy lamp field (BLF) on the IP phone. In a small office, for example, the receptionist might hear an employee's phone ringing. If the receptionist knows that employee is unable to answer, he or she can answer the call using the call pickup group. To do so, the receptionist dials **8509** (the extension of the call pickup group) and answers the call.

This section contains the commands necessary to create a call pickup group. A maximum of 10 call pickup groups can be created. For more information about the call pickup feature, refer to the *Configuring the Call Pickup Feature on AOS Voice Products* quick configuration guide available online at https://supportcommunity.adtran.com.

To create a call pickup group and enter the Call Pickup Group Configuration mode, enter the **voice pickup-group** at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice pickup-group Sales
Configuring New Pickup Group "Sales"
(config-Sales)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. for more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
exit on page 83

All other commands for this command set are described in this section in alphabetical order.

member <extension> on page 4654
pickup-extension <extension> on page 4655

member <*extension*>

Use the **member** command to add members to the call pickup group. Use the **no** form of this command to remove the member from the group.

Syntax Description

<*extension*>	Specifies the four-digit extension of the user being added to the group.

Default Values

By default, no members are included in call pickup groups.

Command History

Release A4.01	Command was introduced.

Functional Notes

Use the **member** command as many times as necessary to add the desired number of members to the group.

Usage Examples

The following example adds the user with extension **1234** to the call pickup group **Sales**:

(config)**#voice pickup-group Sales**
(config-Sales)**#member 1234**

pickup-extension <*extension*>

Use the **pickup-extension** command to specify the extension dialed by members of the call pickup group to answer calls. To be used by the call pickup group, this extension must not be assigned to another user. Use the **no** form of this command to remove the extension from the call pickup group.

Syntax Description

<*extension*>	Specifies the four-digit extension used by members of the call pickup group to answer calls.

Default Values

By default, there is no pickup extension defined for call pickup groups.

Command History

Release A4.01	Command was introduced.

Functional Notes

The extension specified for the group must be a previously unassigned extension.

Usage Examples

The following example specifies that extension **8510** is used by the members of the call pickup group **Sales** to answer calls:

(config)**#voice pickup-group Sales**
(config-Sales)**#pickup-extension 8510**

VOICE ISDN GROUP COMMAND SET

Integrated services digital network (ISDN) groups are groups of ISDN trunks. Trunk groups combine one or more trunk accounts and assign outbound call characteristics to the grouped trunks. Individual trunk groups can be created for each trunk account. The trunk group is assigned outbound call capabilities (local calls, long distance calls, etc.). Additionally, a cost is assigned to each attribute in the outbound call template. For more information about configuring trunk groups in general, refer to the *NetVanta 7000 Series Trunk Accounts* configuration guide available online at https://supportcommunity.adtran.com.

In order to create a new ISDN group, you must first create the necessary ISDN trunks for your network. For more information on creating ISDN trunks, refer to the *Voice ISDN Trunk Command Set on page 5008*. There is also information on creating ISDN trunks in the *Total Access 900 Series ISDN PRI Interface* quick configuration guide available online at https://supportcommunity.adtran.com.

Once you have configured the necessary ISDN trunks, the ISDN trunk group is created by adding the trunk accounts to the ISDN group and defining the outbound call templates and costs. The commands for these procedures are covered in this command set.

To create an ISDN group and enter the ISDN Group Configuration mode, enter the **isdn-group** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#isdn-group 1
(config-isdn-group 1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

call-type on page 4657
connect on page 4658
incoming-accept-number <number> on page 4659
max-channels <value> on page 4661
min-channels <value> on page 4662
resource pool-member <name> on page 4663

call-type

Use the **call-type** command to specify the type of communication allocated for this group. Use the **no** form of this command to return to the default value. Variations of this command include:

call-type analog
call-type any
call-type data
call-type voice

Syntax Description

analog	Configures the type of communication as 3.1 kHz audio.
any	Specifies that there are no restrictions on communication type.
data	Configures the type of communication as digital line.
voice	Configures the type of communication as speech.

Default Values

By default, the call type is set to **voice**.

Command History

Release 11.1	Command was introduced.
Release A4.03	Command was expanded to include **analog** call type.
Release R10.4.0	Command was expanded to include **any** and **data** call types.

Usage Examples

The following example sets the call type for integrated services digital network (ISDN) group **1** to **voice**:

(config)**#isdn-group 1**
(config-isdn-group 1)**#call-type voice**

connect

Use the **connect** command to associate a specific interface with the integrated services digital network (ISDN) group. Use the **no** form of this command to disconnect the specified interface from the ISDN group. Variations of this command include:

connect bri <*slot/port*>
connect pri <*interface id*>

Syntax Description

bri <*slot/port*>	Connects a basic rate interface (BRI) to the ISDN group. Slot and port number ranges are dependent upon the hardware installed in the unit. Type **connect bri ?** for information regarding valid ranges.
pri <*interface id*>	Connects a primary rate interface (PRI) to the ISDN group. Valid interface ID range is **1** to **255**.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.
Release R10.5.0	Command was expanded to include the BRI interface.

Usage Examples

The following example associates the **pri 1** interface with ISDN group **1**:

(config)**#isdn-group 1**
(config-isdn-group 1)**#connect pri 1**

incoming-accept-number <*number*>

Use the **incoming-accept-number** command to configure the incoming number to be accepted by this group from the public switched telephone network (PSTN). Use the **no** form of this command to remove a configured accept number.

Syntax Description

<*number*>	Specifies the phone number(s) accepted for this integrated services digital network (ISDN) group. The accept number entered should match the digits that populate the called party information element received on the ISDN interface for the call. Refer to the *Functional Notes* for more information on entering the number.

Default Values

By default, there are no configured incoming accept numbers. The ISDN group will not be able to accept calls without a configured incoming accept number.

Command History

Release 11.1	Command was introduced.

Functional Notes

Special characters (parentheses, commas, and dashes) can be entered in the incoming accept number for readability, but they are ignored by the system. Incoming accept numbers are entered as a single number, or as a range of numbers using the available wildcard characters.

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

The following list provides some examples for proper wildcard usage:

Wildcard characters are especially useful in situations where ISDN hunt groups are deployed and the ISDN interfaces are all assigned to the same ISDN group in the router. ISDN hunt groups bundle multiple ISDN interfaces (with unique local directory numbers (LDNs)) together into a single group at the central office. When a call to any of the LDNs assigned to the ISDN interfaces in the hunt group is received at the central office, the switch sends the call to the first available ISDN interface. The ISDN group must be able to accept calls to multiple LDNs. Wildcard characters can simplify a configuration by allowing a single entry to match several numbers.

Usage Examples

The following example configures the group to accept calls for **256-555-1000** through **256-555-2000**:

(config)**#isdn-group 1**
(config-isdn-group 1)**#incoming-accept-number 256-555-[1,2]XXX**

max-channels <*value*>

Use the **max-channels** command to specify the maximum number of channels allocated for the integrated services digital network (ISDN) group. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the maximum number of channels allocated for the ISDN group. Valid range is from **1** to **255** channels.

Default Values

By default, the maximum number of channels is set to **0**. When **max-channels** is set to **0**, the group does not limit the number of usable channels and can use all available channels. Use the **no max-channels** command to return to the default value.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the maximum number of channels for ISDN group **1** to **50**:

(config)**#isdn-group 1**
(config-isdn-group 1)**#max-channels 50**

min-channels *<value>*

Use the **min-channels** command to specify the minimum number of channels allocated for the integrated services digital network (ISDN) group. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the minimum number of channels allocated for the ISDN group. Valid range is from **1** to **255** channels.

Default Values

By default, the minimum number of channels is set to **0**. When **min-channels** is set to **0**, no channels are reserved for this group. This group can use available channels, but does not have any channels specifically reserved. Use the **no min-channels** command to return to the default value.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the minimum number of channels for ISDN group **1** to **10**:

(config)**#isdn-group 1**
(config-isdn-group 1)**#min-channels 10**

resource pool-member <*name*>

Use the **resource pool-member** command to assign the group to a resource pool, making it a demand routing resource. Use the **no** form of this command to return to the default value.

Syntax Description

<*name*>	Specifies the name of the resource pool to which this group is assigned.

Default Values

By default, the group is not assigned to any resource pool.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures the integrated services digital network (ISDN) group **1** as a member of resource pool **MyPool**:

(config)**#isdn-group 1**
(config-isdn-group 1)**#resource pool-member MyPool**

VOICE OPERATOR GROUP COMMAND SET

Voice operator groups are a subset of voice ring groups. Voice ring groups are groups of user accounts that can be called in a coordinated way with a single extension, and voice operator groups are one of these groups. Ring group members can log in when they want to receive calls from the group, and log out when they do not want to receive group calls.

Ring groups ring all members of the group simultaneously, and contain a single voice mailbox for the entire group. Operator groups can be configured to ring members by using a linear hunt method, in which calls are distributed to members in the order in which they were added to the group; by using uniform call distribution (UCD) method, in which calls are distributed to group members in the order in which they were added to the group in a uniform, round-robin fashion; and by using an all ring method, in which all members of the group are called and the first extension to pick up receives the call. Operator groups can also be configured to display operator calling-party identification.

Operator groups are always tied to extension zero, and calls from the operator group have a special ring cadence called a priority ring. A priority ring has two short rings, a long ring, and then silence. All other settings for the operator group are similar to those of normal ring groups.

For more information on voice operator groups and voice ring groups in general, refer to the *NetVanta 7000 Series Ring Groups and Operator Groups* quick configuration guide available online at https://supportcommunity.adtran.com, or to the *Voice Ring Group Command Set on page 4685*.

To enter the Voice Operator Group Configuration mode, enter the **voice operator-group** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice operator-group
(config-operator-group)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

coverage on page 4666
did <number> on page 4668
email <address> on page 4669
email-secondary <address> on page 4670

coverage

Use the **coverage** command to configure call coverage parameters for members of this group. The call coverage setting determines how a call is handled if the party dialed does not answer after a specified number of rings. Use the **no** form of this command to remove an individual coverage parameter. Variations of this command include:

coverage aa
coverage aa <*number*>
coverage internal <*number*>
coverage internal <*number*> **num-rings** <*value*>
coverage override aa
coverage override aa <*number*>
coverage override internal <*number*>
coverage override internal <*number*> **num-rings** <*value*>
coverage override vm
coverage override vm <*number*>
coverage vm
coverage vm <*number*>
coverage <*system mode*> **aa**
coverage <*system mode*> **aa** <*number*>
coverage <*system mode*> **internal** <*number*>
coverage <*system mode*> **internal** <*number*> **num-rings** <*value*>
coverage <*system mode*> **vm**
coverage <*system mode*> **vm** <*number*>

Syntax Description

<*system mode*>	Optional. Specifies the system mode to use for call coverage. Choose from **custom1**, **custom2**, **custom3**, **lunch**, **night**, or **weekend**. Refer to the *Functional Notes* of this command for more information on configuring system modes.
aa	Forwards the call to the default auto attendant.
aa <*number*>	Forwards the call to a specific extension programmed for the auto attendant. If no extension is specified, the phone is forwarded to the default auto attendant.
internal <*number*>	Forwards the call to the specified internal number.
num-rings <*value*>	Optional. Specifies the number of rings for the call before performing the next action. Valid range is **1** to **9**.
override	Ignores the programmed system mode schedule.
vm	Forwards the call to voicemail.
vm <*number*>	Optional. Forwards the call to the specified mailbox number.

Default Values

By default, no call coverage is specified.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was updated to include the voicemail and number of rings options.
Release 12.1	Command was updated to include the auto attendant options.
Release A1	Command was updated to include the system mode feature options.

Functional Notes

System mode call coverage provides more diverse functionality for call handling. In previous versions of AOS (revision 15.1 or earlier), up to five coverage modes were allowed. Calls were processed in the order in which the coverage options were entered into the system.

With the addition of the system mode options, up to five coverage options per system mode are allowed. The system modes can be modified using the command *voice system-mode on page 1971*.

Usage Examples

The following example specifies that the call be forwarded to the internal extension **8500** after **3** rings.

(config)**#voice operator-group**
(config-operator-group)**#coverage internal 8500 num-rings 3**

did <*number*>

Use the **did** command to configure direct inward dialing (DID) for this group. DID is used if a service provider is providing digits to the unit on inbound calls or if the unit needs to provide DID information to a piece of customer premises equipment (CPE). Use the **no** form of this command to disable this feature.

Syntax Description

<*number*>	Defines the DID number assigned to the operator group.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example assigns DID **44** to the operator group:

(config)**#voice operator-group**
(config-operator-group)**#did 44**

email <*address*>

Use the **email** command to enter the email address for this operator group. Use the **no** form of this command to disable this feature.

Syntax Description

<*address*>	Specifies an email address for this group.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example creates an email contact for this group:

(config)**#voice operator-group**
(config-operator-group)**#email admin@helpdesk.com**

email-secondary *<address>*

Use the **email-secondary** command to enter a secondary email address for this operator group. Use the **no** form of this command to disable this feature.

Syntax Description

<address>	Specifies a contact email address for this group.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example creates a secondary email contact for this group:

(config)**#voice operator-group**
(config-operator-group)**#email-secondary lead@helpdesk.com**

login-member *<number>*

Use the **login-member** command to log an existing member of the operator group into the system. The **member** command must first be used to create a new group member. Use the **no** form of this command to disable this feature. Refer to *member <number> on page 4673* for more information.

Syntax Description

<number>	Specifies the extension number of the user who is logging in.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Functional Notes

This command allows a user to log in and out of an operator group, letting the system know when a user is available to accept calls.

Usage Examples

The following example logs in the user at extension **4422**:

(config)**#voice operator-group**
(config-operator-group)**#login-member 4422**

max-inbound <*value*>

Use the **max-inbound** command to define the maximum number of calls that can be inbound at the same time. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the maximum number of calls that can be inbound at the same time. Range is **1** to **10** calls.

Default Values

By default, the maximum number of inbound calls is set to **1**.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example sets the maximum number of inbound calls to **3**:

(config)**#voice operator-group**
(config-operator-group)**#max-inbound 3**

member *<number>*

Use the **member** command to create a new member of the operator group. Use the **no** form of this command to remove a user's extension from an operator group.

Syntax Description

<number>	Specifies the extension number of the user to be added as an operator group member.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Functional Notes

A user can log in and out of the operator group using the **login-member** and **no login-member** commands. Refer to *login-member <number> on page 4671* for more information.

Usage Examples

The following example adds the user at extension **4422** to the operator group:

(config)**#voice operator-group**
(config-operator-group)**#member 4422**

num-rings <*value*>

Use the **num-rings** command to specify the number of rings for call pickup before the system redirects the call. Each system mode call coverage action can be configured with a different number of rings based on preference. Use the **no** form of this command to return to the default setting. Variations of this command include:

num-rings <*value*>
num-rings <*system mode*> <*value*>
num-rings override <*value*>

Syntax Description

<*system mode*>	Optional. Specifies the system mode to configure for call coverage. Choose from **custom1**, **custom2**, **custom3**, **lunch**, **night**, or **weekend**. Refer to the *Functional Notes* of this command for more information on configuring system modes.
override	Ignores the programmed system mode schedule.
<*value*>	Specifies the number of rings before the next action. Specify **1** through **9** rings.

Default Values

By default, the maximum number of rings allowed at each extension is **2**.

Command History

Release 10.1	Command was introduced.
Release A1	Command was updated to include the system mode feature options.

Functional Notes

System mode call coverage provides more diverse functionality for call handling. In previous versions of AOS (revision 15.1 or earlier), up to five coverage modes were allowed. Calls were processed in the order in which the coverage options were entered into the system.

With the addition of the system mode options, up to five coverage options per system mode are allowed. The system modes can be modified using the command *voice system-mode on page 1971*.

Usage Examples

The following example sets the maximum number of rings for the operator group to **6**:

(config)**#voice operator-group**
(config-operator-group)**#num-rings 6**

prefix

Use the **prefix** command to turn on the caller ID prefix for this ring group, causing **GRP:** to display in front of the caller ID information. Use the **no** form of this command to turn the prefix off. Variations of this command include:

prefix
prefix <*prefix*>

Syntax Description

<*prefix*>	Optional. Specifies an alphanumeric outbound calling name prefix. Maximum length is **40** characters.

Default Values

By default, no prefixes are enabled.

Command History

Release 10.1	Command was introduced.
Release A2.04	Command was expanded to include the optional <*prefix*> parameter.

Usage Examples

The following example turns on the caller ID prefix for the operator group:

(config)#**voice operator-group**
(config-operator-group)#**prefix**

sip-identity

Use the **sip-identity** command to configure the Session Initiation Protocol (SIP) registration options for the user. Use the **no** form of this command to disable the setting. Variations of this command include the following:

sip-identity <*station*> <*Txx*>
sip-identity <*station*> <*Txx*> **register**
sip-identity <*station*> <*Txx*> **register auth-name** <*username*> **password** <*password*>

Syntax Description

<*station*>	Specifies the station to be used for SIP trunk (e.g., **station extension**).
<*Txx*>	Specifies the SIP trunk through which to register the server. The trunk is specified in the format Txx (e.g., **T01**).
register	Registers the user to the server.
auth-name <*username*>	Optional. Sets the user name that will be required as authentication for registration to the SIP server.
password <*password*>	Optional. Sets the password that will be required as authentication for registration to the SIP server.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.
Release 13.1	Command functionality was introduced to this section.

Usage Examples

The following example specifies trunk **T02** and extension **4400** for SIP identity:

(config)**#voice operator-group**
(config-operator-group)**#sip-identity 4400 t02**

type

Use the **type** command to configure the group type for the operator group. Variations of this command include:

type all
type executive
type linear
type ucd

Syntax Description

all	Configures the group as an all-inclusive operator group. When an operator group call comes in, all phones ring simultaneously.
executive	Configures an executive operator group. Refer to *email <address> on page 4692* for more information.
linear	Configures the group as a linear hunt operator group. Member phones ring one at a time until the call is picked up. When the next call comes in, the call cycle begins again by ringing the first operator group member. Refer to *member <number> on page 4673* for more information.
ucd	Configures the group as a uniform call distribution (UCD) operator group. Member phones ring one at a time until the call is picked up. When the next call comes in, the system remembers which member extension it last dialed and then continues the call cycle by ringing the next member in the operator group.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example configures all phones in the operator group to ring each time a call comes in:

(config)**#voice operator-group**
(config-operator-group)**#type all**

voicemail

Use the **voicemail** command to configure the voicemail options for the user. Use the **no** form of this command to disable the settings. Variations of this command include the following:

voicemail attachment-level <*dB*>
voicemail attachment-level disabled
voicemail auth-mode full
voicemail auth-mode password
voicemail auto-play
voicemail cos <*name*>
voicemail delete-msg-on-email
voicemail envelope-play
voicemail greeting alternate
voicemail greeting default
voicemail greeting standard
voicemail new-user
voicemail notify email attach-message pcm
voicemail notify email attach-message pcm max-size <*size*>
voicemail notify email text-only
voicemail oper-assist <*number*>
voicemail password <*password*>

Syntax Description

attachment-level <*dB*>	Specifies the number of decibels for voicemail attachment files. Valid entries are **-30**, **-25**, **-20**, -15, or **-10** dB.
attachment-level disabled	Disables the automatic gain control (AGC) for voicemail attachments.
auth-mode full	Specifies that the extension and password are required to access voicemail.
auth-mode password	Specifies that the password is required to access voicemail. Only the password is required if set to password authentication mode.
auto-play	Specifies automatic playback of messages when entering the mailbox.
cos <*name*>	Configures the voicemail class of service (CoS) type by entering the name of the selected CoS.
delete-msg-on-email	Enables deletion of stored voicemail on email attachments.
envelope-play	Automatically plays message envelopes during message playback.
greeting	Specifies which greeting to use for voicemail.
alternate	Specifies using the alternate recorded voicemail greeting.
default	Specifies using the default voicemail greeting.
standard	Specifies using the standard recorded voicemail greeting.
new-user	Executes the new-user wizard for voicemail configuration.
notify email	Specifies sending an email notification when a new voicemail is received.
attach-message	Sends the voicemail as a WAV file attachment to the specified email. The email client must be configured for email options to work.

pcm	Indicates message sent as email attachment will be in pulse-code modulation (PCM) format.
max-size <*size*>	Optional. Indicates truncating email attachments at the specified maximum size in kilobits (kb). Minimum size entry is **10** kb.
text-only	Sends only a text message to the specified email address.
oper-assist <*number*>	Directs all operator calls to the specified phone number.
password <*password*>	Creates the password/personal identification number (PIN) that will be required to access voicemail.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.
Release 15.1	Command was expanded.
Release A2	Command was expanded to include the **notify email** parameters.
Release A2.04	Command was expanded to include **attachment-level** parameters.

Usage Examples

The following example sets the voicemail CoS to **class1**:

```
(config)#voice operator-group
(config-operator-group)#voicemail cos class1
```

VOICE PAGING GROUP COMMAND SET

The voice paging group configures handset paging parameters. Handset paging is a feature that provides paging to select groups of users through their IP phone handset. Handset paging works through a one-way audio transmission received as a call on individual IP phones, rather than on an overhead speaker using a private branch exchange (PBX) as overhead paging does. A handset page is initiated by a member of the paging group and sent to other members of the group. Voice paging groups are defined and organized using the commands in this section. For more information on using handset paging, refer to the *Handset Paging for the NetVanta 7000 Series* quick configuration guide available online at https://supportcommunity.adtran.com.

To activate the Voice Paging Group Configuration mode, enter the **voice paging-group** <*extension*> command from the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice paging-group 8956
  Configuring new paging group “8956”.
(config-8956)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

description <text> on page 80
do on page 81
end on page 82
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

codec on page 4681
include-paging-port on page 4682
member <extension> on page 4683
page-timeout <seconds> on page 4684

codec

Use the **codec** command to specify the coder-decoder (CODEC) that is used for the audio of the paging group. Use the **no** form of this command to return to the default. Variations of this command include:

codec g711alaw
codec g711ulaw
codec g722
codec g729

Syntax Description

g711alaw	Specifies the audio of the paging group is set to G.711 A-law 64 kilobits per second (Kbps).
g711ulaw	Specifies the audio of the paging group is set to G.711 U-law 64 Kbps.
g722	Specifies the audio of the paging group is set to G.722 8 Kbps.
g729	Specifies the audio of the paging group is set to G.729 8 Kbps.

Default Values

By default, the CODEC for the paging group is set to **G.729**.

Command History

Release A2.04	Command was introduced in the Voice Paging Group.

Functional Notes

The default CODEC used by paging groups is G.729, and is recommended for bandwidth optimization. Other CODECs can be used when a page initiator or recipient does not support G.729.

This **codec** command is not to be confused with the **codec** command used when creating CODEC lists (refer to *Voice CODEC List Command Set on page 4893* or *codec on page 4894*). This command does not create a list of CODECs, nor can it be entered multiple times. This **codec** command, used when configuring the voice paging group, specifies a single CODEC to be used by the paging group. If another CODEC is entered from the Voice Paging Group Configuration mode prompt, it will override any previous CODEC entries.

Usage Examples

The following example specifies the paging group using extension **8956** will use CODEC **G.722** for audio:

(config)**#voice paging-group 8956**
(config-8956)**#codec g722**

include-paging-port

Use the **include-paging-port** command to enable overhead paging for the paging group. Use the **no** form of this command to disable overhead paging for the paging group.

Syntax Description

No subcommands.

Default Values

By default, overhead paging is not enabled in paging groups.

Command History

Release A2.04	Command was introduced.

Functional Notes

Enabling the paging port for a handset paging group allows the page to transmit through IP phone handsets and an overhead paging system. This option will only function if an overhead paging system is available.

Usage Examples

The following example enables overhead paging for the paging group using extension **8956**:

(config)**#voice paging-group 8956**
(config-8956)**#include-paging-port**

member <*extension*>

Use the **member** command to add a new member to the paging group. Use the **no** form of this command to remove a member from the paging group.

Syntax Description

<*extension*>	Specifies the four-digit extension of the user to add to the paging group.

Default Values

By default, no members are included in a paging group.

Command History

Release A2.04	Command was introduced.

Usage Examples

The following example adds a user at extension **4567** to the paging group using extension **8956**:

(config)**#voice paging-group 8956**
(config-8956)**#member 4567**

page-timeout <*seconds*>

Use the **page-timeout** command to specify the amount of time page group users have to connect to the page before the call is started. Use the **no** form of this command to return to the default value.

Syntax Description

<*seconds*>	Specifies the time (in seconds) that users have to connect to a page before information is transmitted. Range is **1** to **10** seconds.

Default Values

By default, the page timeout is set to **2** seconds.

Command History

Release A2.04	Command was introduced.

Functional Notes

If no connection is made before the timeout period expires, the paging call is terminated.

Usage Examples

The following example sets the page timeout to **5** seconds for the paging group using extension **8956**:

(config)**#voice paging-group 8956**
(config-8956)**#page-timeout 5**

VOICE RING GROUP COMMAND SET

Voice ring groups define groups of user accounts that can be called in a coordinated way with a single extension. Ring group members can log in when they want to receive calls from the group, and log out when they do not want to receive group calls.

There are five ring group types to select from when creating a new ring group. The first of these types is a linear hunt group. In this type of group, calls are distributed to members in the order in which they were added to the ring group. The second type is the all ring group. In this type of group, all members of the group are called, and the first extension to answer receives the call. The third type is the uniform call distribution (UCD) group. In this group type, calls are distributed to members in the order in which they were added to the group, but in a uniform, round-robin fashion. The fourth type is an executive ring group. In this group type, calls are made to both the executive's and assistant's extensions, but the calls use the executive's call coverage. The last type is the operator ring group. This group type is detailed in the *Voice Operator Group Command Set on page 4664*.

Ring group's extensions must be unique and cannot begin with a **0** or a **9**. When configuring a new ring group, the extension defaults to one greater than the highest number ring group extension currently configured, or **8001** if no ring groups are configured. For more information about specific ring group configuration, refer to the *NetVanta 7000 Series Ring Groups and Operator Groups* quick configuration guide available online at https://supportcommunity.adtran.com.

To activate the Voice Ring Group Configuration mode, enter the **voice ring-group** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice ring-group xxxx*
(config-xxxx)#
```

*where xxxx = the ring group's four-digit extension.

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

assistant-extension <*number*>

Use the **assistant-extension** command to tie an assistant's extension to an executive's extension.

*This command only applies to a ring group of **type executive**. Refer to type on page 4701 for more information.*

Syntax Description

<*number*>	Specifies the number of the assistant's extension.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Functional Notes

This command is used in conjunction with the **executive-extension** command (refer to *executive-extension <number> on page 4694*). When the executive's extension is dialed, both the assistant's and the executive's phones will ring. If neither phone is answered (or both are busy or set to do-not-disturb (DND)), the call is forwarded through the executive's call coverage list.

Usage Examples

The following example creates the executive ring group **1234** and causes both the executive (extension **4440**) and the assistant (extension **4444**) phones to ring when the executive extension is dialed:

(config)**#voice ring-group 1234**
(config-1234)**#type executive**
(config-1234)**#executive-extension 4440**
(config-1234)**#assistant-extension 4444**

cos

Use the **cos** command to set class of service (CoS) mode for the ring group. The CoS can be set to change for the members of the ring group based on the current system mode by including the system mode parameter. The CoS defines the types of phone service that will be available to the user during the time period. Use the **no** form of this command to disable this feature. Variations of this command include:

cos <*name*>
cos <*system mode*> <*name*>
cos no-access
cos <*system mode*> **no-access**
cos override <*name*>
cos override no-access

Syntax Description

<*name*>	Specifies the predefined CoS.
<*system mode*>	Optional. Specifies the system mode to configure. Choose from **custom1**, **custom2**, **custom3**, **lunch**, **night**, or **weekend**. Refer to the *Functional Notes* of this command for more information on configuring system modes.
no-access	Blocks users from placing calls when applied to the CoS.
override	Ignores the programmed system mode schedule.

Default Values

By default, CoS is set to **no-access**.

Command History

Release 9.3	Command was introduced.
Release A1	Command was expanded to include the system mode options.

Functional Notes

Additional functionality for this feature is provided by assigning a CoS to a specific system mode. When the system mode changes at a trigger point, the ring group's CoS changes.

For example, a CoS applied to the ring group when the system mode is specified as **night** can be used to prevent outbound calls during evening hours. System modes are defined from the Global Configuration mode using the command *voice system-mode on page 1971*.

Usage Examples

The following example assigns the CoS **Assistant** to the ring group **1234**:

(config)**#voice ring-group 1234**
(config-1234)**#cos Assistant**

coverage

Use the **coverage** command to configure call coverage parameters for members of this group. The call coverage setting determines how a call is handled if the party dialed does not answer after a specified number of rings. Use the **no** form of this command to remove an individual coverage parameter. Variations of this command include:

coverage aa
coverage aa <*number*>
coverage internal <*number*>
coverage internal <*number*> **num-rings** <*value*>
coverage operator
coverage operator num-rings <*value*>
coverage override aa
coverage override aa <*number*>
coverage override external <*number*>
coverage override internal <*number*>
coverage override internal <*number*> **num-rings** <*value*>
coverage override operator
coverage override operator num-rings <*value*>
coverage override vm
coverage override vm <*number*>
coverage vm
coverage vm <*number*>
coverage <*system mode*> **aa**
coverage <*system mode*> **aa** <*number*>
coverage <*system mode*> **external** <*number*>
coverage <*system mode*> **internal** <*number*>
coverage <*system mode*> **internal** <*number*> **num-rings** <*value*>
coverage <*system mode*> **operator**
coverage <*system mode*> **operator num-rings** <*value*>
coverage <*system mode*> **vm**
coverage <*system mode*> **vm** <*number*>

Syntax Description

<*system mode*>	Optional. Specifies the system mode to configure for call coverage. Choose from **custom1**, **custom2**, **custom3**, **lunch**, **night**, or **weekend**. Refer to the *Functional Notes* of this command for more information on configuring system modes.
aa	Forwards the call to the default auto attendant.
aa <*number*>	Forwards the call to a specific extension programmed for the auto attendant. If no extension is specified, the phone is forwarded to the default auto attendant.
external <*number*>	Forwards the call to the specified external number. If no number is entered, the default auto answer is used.

internal <*number*>	Forwards the call to the specified internal number.
num-rings <*value*>	Optional. Specifies the number of rings for the call before performing the next action. Valid range is **1** to **9**.
operator	Forwards the call to the operator.
override	Ignores the programmed system mode schedule.
vm	Forwards the call to voicemail.
vm <*number*>	Optional. Forwards the phone to the specified mailbox number.

Default Values

By default, no call coverage is specified.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was updated to include the voicemail and number of rings options.
Release 12.1	Command was updated to include the auto attendant and operator options.
Release A1	Command was updated to include the system mode feature options.

Functional Notes

System mode call coverage provides more diverse functionality for call handling. In previous versions of AOS (revision 15.1 or earlier), up to five coverage modes were allowed. Calls were processed in the order in which the coverage options were entered into the system.

With the addition of the system mode options, up to five coverage options per system mode are allowed. The system modes can be modified using the command *voice system-mode on page 1971*.

Usage Examples

The following example specifies that calls to the ring group **1234** be forwarded to the internal extension **8500** when in the **night** system mode.

(config)**#voice ring-group 1234**
(config-1234)**#coverage night internal 8500**

did <*number*>

Use the **did** command to configure direct inward dialing (DID) for this group. DID is used if a service provider is providing digits to the unit on inbound calls or if the unit needs to provide DID information to a piece of customer premises equipment (CPE). Use the **no** form of this command to disable this feature.

Syntax Description

<*number*>	Defines the DID number assigned to the ring group.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example assigns DID **44** to the ring group **1234**:

(config)**#voice ring-group 1234**
(config-1234)**#did 44**

email <*address*>

Use the **email** command to enter the email address for this user's group. Use the **no** form of this command to disable this feature.

Syntax Description

<*address*>	Specifies an email address for this group.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example creates an email contact for this group:

(config)**#voice ring-group 1234**
(config-1234)**#email admin@helpdesk.com**

email-secondary *<address>*

Use the **email-secondary** command to enter a secondary email address for this user's group. Use the **no** form of this command to disable this feature.

Syntax Description

<address>	Specifies a contact email address for this group.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example creates a secondary email contact for this group:

(config)**#voice ring-group 1234**
(config-1234)**#email-secondary lead@helpdesk.com**

executive-extension *<number>*

Use the **executive-extension** command to tie an executive's extension to an assistant's extension.

*This command only applies to **type executive** ring group(s). Refer to type on page 4701 for more information.*

Syntax Description

<number>	Specifies the number of the executive's extension.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Functional Notes

This command is used in conjunction with the **assistant-extension** command (refer to *assistant-extension <number> on page 4687*). When the executive's extension is dialed, both the assistant's and the executive's phones will ring. If neither phone is answered (or both are busy or set to do-not-disturb (DND)), the call is forwarded through the executive's call coverage list.

Usage Examples

The following example creates the executive ring group **1234** and causes both the executive (extension **4440**) and the assistant (extension **4444**) phones to ring when the executive extension is dialed:

(config)**#voice ring-group 1234**
(config-1234)**#type executive**
(config-1234)**#executive-extension 4440**
(config-1234)**#assistant-extension 4444**

login-member *<number>*

Use the **login-member** command to log an existing member of the ring group into the system. You must first use the member command to create a new group member. Use the **no** form of this command to disable this feature. Refer to *member <number> on page 4697* for more information.

Syntax Description

<number>	Specifies the extension number of the user who is logging in.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Functional Notes

This command allows a user to log in and out of a ring group, letting the system know when a user is available to accept calls.

Usage Examples

The following example logs in the user at extension **4422**:

(config)**#voice ring-group 1234**
(config-1234)**#login-member 4422**

max-inbound <*value*>

Use the **max-inbound** command to define the maximum number of calls that can be inbound at the same time. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the maximum number of calls that can be inbound at the same time. Range is **1** to **10** calls.

Default Values

By default, the maximum number of inbound calls is set to **1**.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example sets the maximum number of inbound calls on ring group **1234** to **3**:

(config)**#voice ring-group 1234**
(config-1234)**#max-inbound 3**

member *<number>*

Use the **member** command to create a new member of the ring group. Use the **no** form of this command to remove a user's extension from a ring group.

Syntax Description

<number>	Specifies the extension number of the user you want to add as a ring group member.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Functional Notes

A user can log in and out of the ring group using the **login-member** and **no login-member** commands. Refer to *login-member <number> on page 4695* for more information.

Usage Examples

The following example adds the user at extension **4422** to the ring group **1234**:

(config)**#voice ring-group 1234**
(config-1234)**#member 4422**

num-rings

Use the **num-rings** command to specify the number of rings for call pickup before the system redirects the call. Each system mode call coverage action can be configured with a different number of rings based on preference. Use the **no** form of this command to return to the default setting. Variations of this command include:

num-rings <*value*>
num-rings <*system mode*> <*value*>
num-rings override <*value*>

Syntax Description

<*system mode*>	Optional. Specifies the system mode to configure for call coverage. Choose from **custom1**, **custom2**, **custom3**, **lunch**, **night**, or **weekend**. Refer to the *Functional Notes* of this command for more information on configuring system modes.
override	Ignores the programmed system mode schedule.
<*value*>	Specifies the number of rings before the next action. Specify **0** through **9** rings. Entering **0** specifies an unlimited number of rings.

Default Values

By default, the **num-rings** is set to **4**.

Command History

Release 9.3	Command was introduced.
Release A1	Command was updated to include the system mode feature options.

Usage Examples

The following example sets the number of rings for this ring group to **6**:

(config)**#voice ring-group 1234**
(config-1234)**#num-rings 6**

prefix

Use the **prefix** command to turn on the caller ID prefix for this ring group, causing **GRP:** to display in front of the caller ID information. Use the **no** form of this command to turn the prefix off. Variations of this command include:

prefix
prefix <*prefix*>

Syntax Description

<*prefix*>	Optional. Specifies an alphanumeric outbound calling name prefix. Maximum length is **40** characters.

Default Values

By default, no prefixes are enabled.

Command History

Release 10.1	Command was introduced.
Release A2.04	Command was expanded to include the optional <*prefix*> parameter.

Usage Examples

The following example turns on the caller ID prefix for ring group **1234**:

(config)#**voice ring-group 1234**
(config-1234)#**prefix**

sip-identity

Use the **sip-identity** command to configure the Session Initiation Protocol (SIP) registration options for the user. Use the **no** form of this command to disable the settings. Variations of this command include the following:

sip-identity <*station*> <*Txx*>
sip-identity <*station*> <*Txx*> **register**
sip-identity <*station*> <*Txx*> **register auth-name** <*username*> **password** <*password*>

Syntax Description

<*station*>	Specifies the station to be used for SIP trunk (e.g., **station extension**).
<*Txx*>	Specifies the SIP trunk through which to register the server. The trunk is specified in the format Txx (e.g., **T01**).
register	Registers the user to the server.
auth-name <*username*>	Optional. Sets the user name that will be required as authentication for registration to the SIP server.
password <*password*>	Optional. Sets the password that will be required as authentication for registration to the SIP server.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example specifies trunk **T02** and extension **4400** for SIP **identity**:

(config)**#voice ring-group 1234**
(config-1234)**#sip-identity 4400 T02**

type

Use the **type** command to configure the group type for the ring group. Variations of this command include:

type all
type executive
type linear
type ucd

Syntax Description

all	Configures the group as an all-inclusive ring group. When a ring group call comes in, all phones ring simultaneously.
executive	Configures an executive ring group. Refer to *executive-extension <number> on page 4694* for more information.
linear	Configures the group as a linear hunt ring group. Member phones ring one at a time until the call is picked up. When the next call comes in, the call cycle begins again by ringing the first ring group member. Refer to *member <number> on page 4697* for more information.
ucd	Configures the group as a uniform call distribution (UCD) ring group. Member phones ring one at a time until the call is picked up. When the next call comes in, the system remembers which member extension it last dialed and then continues the call cycle by ringing the next member in the ring group.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example configures the ring group **1234** to ring all phones in the ring group each time a call comes in:

(config)**#voice ring-group 1234**
(config-1234)**#type all**

voicemail

Use the **voicemail** command to configure the voicemail options for the user. Use the **no** form of this command to disable the settings. Variations of this command include the following:

voicemail attachment-level <*dB*>
voicemail attachment-level disabled
voicemail auth-mode full
voicemail auth-mode password
voicemail auto-play
voicemail cos <*name*>
voicemail delete-msg-on-email
voicemail envelope-play
voicemail greeting alternate
voicemail greeting default
voicemail greeting standard
voicemail new-user
voicemail notify email attach-message pcm
voicemail notify email attach-message pcm max-size <*size*>
voicemail notify email text-only
voicemail oper-assist <*number*>
voicemail password <*password*>

Syntax Description

attachment-level <*dB*>	Specifies the number of decibels for voicemail attachment files. Valid entries are **-30**, **-25**, **-20**, -15, or **-10** dB.
attachment-level disabled	Disables the automatic gain control (AGC) for voicemail attachments.
auth-mode full	Specifies that the extension and password are required to access voicemail.
auth-mode password	Specifies that the password is required to access voicemail. Only the password is required if set to password authentication mode.
auto-play	Specifies automatic playback of messages when entering the mailbox.
cos <*name*>	Configures the voicemail class of service (CoS) type by entering the name of the selected CoS.
delete-msg-on-email	Enables deletion of stored voicemail on email attachments.
envelope-play	Automatically plays message envelopes during message playback.
greeting	Specifies which greeting to use for voicemail.
alternate	Specifies using the alternate recorded voicemail greeting.
default	Specifies using the default voicemail greeting.
standard	Specifies using the standard recorded voicemail greeting.
new-user	Executes the new-user wizard for voicemail configuration.
notify email	Specifies sending an email notification when a new voicemail is received.
attach-message	Sends the voicemail as a WAV file attachment to the specified email. The email client must be configured for email options to work.

pcm	Indicates message sent as email attachment will be in pulse-code modulation (PCM) format.
max-size <*size*>	Optional. Indicates truncating email attachments at the specified maximum size in kilobits (kb). Minimum size entry is **10** kb.
text-only	Sends only a text message to the specified email address.
oper-assist <*number*>	Directs all operator calls to the specified phone number.
password <*password*>	Creates the password/personal identification number (PIN) that will be required to access voicemail.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.
Release 15.1	Command was expanded.
Release A2	Command was expanded to include the **notify email** parameters.
Release A2.04	Command was expanded to include **attachment-level** parameters.

Usage Examples

The following example sets the voicemail CoS for this user to **class1**:

(config)**#voice ring-group 1234**
(config-1234)**#voicemail cos class1**

VOICE TRUNK GROUP COMMAND SET

Voice trunks are digital or analog subscriber lines delivered by service providers that allow communication devices to connect to the outside world. Voice trunk groups combine one or more trunk accounts and assign outbound call characteristics to the group. Individual trunk groups can be created for each trunk account. The trunk group is assigned outbound call capabilities (local calls, long distance calls, etc.). Additionally, a cost is assigned to each attribute in the outbound call template.

To create a trunk group, you must first configure individual trunk accounts. For more information on creating voice trunk accounts, refer to the following sections of this document:

- *Voice Analog Trunk Command Set on page 4959*
- *Voice SIP Trunk Command Set on page 5052*
- *Voice T1 Trunk Command Set on page 5151*

For more information about configuring trunk groups, refer to the *NetVanta 7000 Series Trunk Accounts* configuration guide available online at https://supportcommunity.adtran.com.

Integrated services digital network (ISDN) trunk groups are created using the command isdn-group <number> on page 1565. For more information regarding the creation of ISDN trunk groups, refer to the Voice ISDN Group Command Set on page 4656.

To enter the Voice Trunk Group Configuration mode, enter the **voice grouped-trunk** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice grouped-trunk TestGroup
(config-TestGroup)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

accept *<template>*

Use the **accept** command to specify numbers that users can dial on the trunk. This command controls the type of outbound calls users can place on the system. Use the **no** form of this command to remove a configured dial pattern and return to the default setting. Variations of this command include:

accept *<template>*
accept *<template>* **cost** *<value>*

Syntax Description

<template>	Specifies the patterns users can dial on the trunk. You can enter a complete phone number or wildcards can be used to help define accepted numbers. Refer to *Functional Notes* below for more information on using wildcards.
cost *<value>*	Specifies the cost value for the trunk. This option is used if a call is accepted by several trunks. The call will be routed to the trunk with the lowest cost value. The valid range is **0** to **499**.

Default Values

By default, the cost value is **zero**.

Command History

Release 9.3	Command was introduced.

Functional Notes

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example allows users on the trunk **TestGroup** to dial any local number:

(config)**#voice grouped-trunk TestGroup**
(config-TestGroup)**#accept Nxxxxxx**

deny

Use the **deny** command to add a proxy, automatic number identification (ANI) list, or trunk list to a voice trunk group's deny policy. Use the **no** form of this command to remove the proxy, ANI list, or trunk list from the deny policy. Variations of this command include:

deny list <*name*>
deny proxy

Syntax Description

list <*name*>	Specifies that either a trunk list or ANI list is added to the trunk group's deny policy.
proxy	Specifies that the proxy is added to the trunk group's deny policy.

Default Values

By default, no list or proxy is part of the trunk group's deny policy.

Command History

Release A2	Command was introduced.

Functional Notes

The trunk and ANI lists are created as part of the Source and ANI Based Routing (SABR) feature on AOS voice products. For more information about SABR, refer to the *SABR in AOS* configuration guide available online at https://supportcommunity.adtran.com. For more information about creating ANI or trunk lists, refer to *voice ani-list <name> on page 1891* or *voice trunk-list <name> on page 1979*.

Although there is no limit on the number of lists applied to voice trunk groups, it is important to remember that the more lists that are applied to a trunk group, the more the runtime performance of call routing will be affected.

Usage Examples

The following example applies the **TEST2** list to the deny policy of trunk group **TestGroup**:

(config)**#voice grouped-trunk TestGroup**
(config-TestGroup)**#deny list TEST2**

permit

Use the **permit** command to add a proxy, automatic number identification (ANI) list, or trunk list to a voice trunk group's permit policy. Use the **no** form of this command to remove the proxy, ANI list, or trunk list from the permit policy. Variations of this command include:

permit list <*name*>
permit proxy

Syntax Description

list <*name*>	Specifies that either a trunk list or ANI list is added to the trunk group's permit policy.
proxy	Specifies that the proxy is added to the trunk group's permit policy.

Default Values

By default, no list or proxy is part of the trunk group's permit policy.

Command History

Release A2	Command was introduced.

Functional Notes

The trunk and ANI lists are created as part of the Source and ANI Based Routing (SABR) feature on AOS voice products. For more information about SABR, refer to the *SABR in AOS* configuration guide available online at https://supportcommunity.adtran.com. For more information about creating ANI or trunk lists, refer to *voice ani-list <name> on page 1891* or *voice trunk-list <name> on page 1979*.

Although there is no limit on the number of lists applied to voice trunk groups, it is important to remember that the more lists that are applied to a trunk group, the more the runtime performance of call routing will be affected.

Usage Examples

The following example applies the **TEST1** list to the permit policy of trunk group **TestGroup**:

(config)**#voice grouped-trunk TestGroup**
(config-TestGroup)**#permit list TEST1**

reject *<template>*

Use the **reject** command to specify numbers users cannot dial on the trunk. This feature allows administrators to restrict callers from unwanted outbound calls, such as international calls and 900 numbers. Use the **no** form of this command to disable this feature.

Syntax Description

<template>	Specifies the patterns that users cannot dial on the trunk. You can enter a complete phone number or wildcards can be used to help define rejected numbers. Refer to *Functional Notes* below for more information on using wildcards. For example, you can enter **900$** to prevent users from dialing all 900 numbers.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Functional Notes

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.

2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.

3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].

4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example blocks calls to any 900 number on the trunk **TestGroup**:

(config)**#voice grouped-trunk TestGroup**
(config-TestGroup)**#reject 900$**

resource-selection

Use the **resource-selection** command to determine how the switchboard uses outbound call resources contained within a time division multiplexing (TDM) based trunk group. Use the **no** form of this command to disable this feature. Variations of this command include:

resource-selection circular
resource-selection circular ascending
resource-selection circular descending
resource-selection linear
resource-selection linear ascending
resource-selection linear descending

Syntax Description

circular	Performs call load balancing among available DS0s/B-channels in this trunk. Subsequent calls will be delivered to the next available DS0/B-channel in a round-robin fashion.
linear	Specifies that a call being delivered to this trunk will be accepted out the first available DS0/B-channel available at the time the call is received.
ascending	Optional. Distributes calls in an order from the lowest to the highest channel (DS0 1, 2, 3 through 24).
descending	Optional. Distributes calls in an order from the highest to the lowest channel (DS0 24, 23, 22 through 1).

Default Values

By default, resource selection is set to **linear**.

Command History

Release 9.3	Command was introduced.
Release 13.1	Command was expanded to include the ascending and descending subcommands.

Usage Examples

The following example specifies **circular** resource selection on the trunk **TestGroup**:

(config)**#voice grouped-trunk TestGroup**
(config-TestGroup)**#resource-selection circular**

trunk <*Txx*>

Use the **trunk** command to add an existing trunk to the trunk group so outbound calls may be placed out that particular trunk as well. Use the **no** form of this command to remove a configured trunk group.

Syntax Description

<*Txx*>	Specifies an ID number for the trunk. The trunk ID is in the format **Txx** where **xx** is the trunk ID number. Enter a trunk ID between **1** and **99**. For example, trunk **T02**.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example adds trunk **T02** to the trunk group **TestGroup**:

(config)**#voice grouped-trunk TestGroup**
(config-TestGroup)**#trunk t02**

VOICE SERVICES COMMAND SETS

This section includes the following command sets:

AUTO ATTENDANT COMMAND SET

Auto attendant is a voice feature that allows callers to be automatically transferred to an extension without any operator action. The commands in this section allow you to configure an auto attendant and to specify which files the auto attendant will use, as well as to configure Session Initiation Protocol (SIP) parameters so the auto attendant can be used in conjunction with system modes. For more information on configuring the voice auto attendant, refer to the *Configuring the Auto Attendant for NetVanta 7000 Series* configuration guide available online at https://supportcommunity.adtran.com.

To create an auto attendant and enter the Voice Auto Attendant Configuration mode, enter the **voice autoattendant** *<name> <extension>* command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice autoattendant Example 1212
(config-aa1212)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

entry-filename <name> on page 4716
sip-identity on page 4717

entry-filename *<name>*

Use the **entry-filename** command to enter the extensible markup language (XML) file to use for this auto attendant. Use the **no** form of this command to disable the setting.

Syntax Description

<name>	Specifies the name of the XML file name to use for this auto attendant.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example shows the **entry-filename** command being executed to select the XML file to use for this auto attendant:

(config)**#voice autoattendant Example 1212**
(config-aa1212)**#entry-filename Operaa**

sip-identity

Use the **sip-identity** command to configure Session Initiation Protocol (SIP) registration options for the user. Use the **no** form of this command to disable the setting. Variations of this command include the following:

sip-identity <*station*> <*Txx*>
sip-identity <*station*> <*Txx*> **register**
sip-identity <*station*> <*Txx*> **register auth-name** <*username*> **password** <*password*>

Syntax Description

<*station*>	Specifies the station to be used for SIP trunk (e.g., **station extension**).
<*Txx*>	Specifies the SIP trunk through which to register the server. The trunk is specified in the format Txx (e.g., **T01**).
register	Registers the user to the server.
auth-name <*username*>	Sets the user name that will be required as authentication for registration to the SIP server.
password <*password*>	Sets the password that will be required as authentication for registration to the SIP server.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example configures the auto attendant to use extension **5000** as its identity on trunk **T02**:

(config)**#voice autoattendant Example 1212**
(config-aa1212)**#sip-identity 5000 T02**

CALL COVERAGE COMMAND SET

The Call Coverage Command Set covers the commands used to configure the global call coverage list used on the AOS product. The call coverage list is used to control call routing when a voice user's phone is not answered. Call coverage can also be set on a per-user basis using the command *coverage on page 4580* from the user account configuration mode.

To create a global call coverage list and enter the list's configuration mode, enter the **voice coverage** command from the Global Configuration mode prompt as follows:

```
>enable
#configure terminal
(config)#voice coverage Evening
Configuring New Global Call Handling List "Evening".
(config-gch)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

do on page 81
exit on page 83

All other commands for this command set are described in this section in alphabetical order.

coverage on page 4719
default on page 4721

coverage

Use the **coverage** command to configure global call coverage parameters for the AOS unit. The call coverage setting determines how a call is handled if the dialed party does not answer after a specified number of rings. Use the **no** form of this command to remove an individual coverage parameter. Variations of this command include:

coverage aa
coverage aa <*number*>
coverage internal <*number*>
coverage internal <*number*> **num-rings** <*value*>
coverage operator
coverage operator num-rings <*value*>
coverage override external <*number*>
coverage override global <*name*>
coverage override internal <*number*>
coverage override internal <*number*> **num-rings** <*value*>
coverage override operator
coverage override operator num-rings <*value*>
coverage override vm
coverage override vm <*number*>
coverage vm
coverage vm <*number*>
coverage <*system mode*> **aa**
coverage <*system mode*> **aa** <*number*>
coverage <*system mode*> **external** <*number*>
coverage <*system mode*> **internal** <*number*>
coverage <*system mode*> **internal** <*number*> **num-rings** <*value*>
coverage <*system mode*> **operator**
coverage <*system mode*> **operator num-rings** <*value*>
coverage <*system mode*> **vm**
coverage <*system mode*> **vm** <*number*>

Syntax Description

<*system mode*>	Optional. Specifies the system mode to configure for call coverage. Choose from **custom1**, **custom2**, **custom3**, **lunch**, **night**, or **weekend**. Refer to the *Functional Notes* of this command for more information on configuring system modes.
aa	Forwards the call to the default auto attendant.
aa <*number*>	Forwards the call to a specific extension programmed for the auto attendant. If no extension is specified, the phone is forwarded to the default auto attendant.
external <*number*>	Forwards the call to the specified external number. If no number is entered, the default auto answer is used.
internal <*number*>	Forwards the call to the specified internal number.

num-rings <*value*>	Optional. Specifies the number of rings for the call before performing the next action. Valid range is **1** to **9**.
operator	Forwards the call to the operator.
override	Ignores the programmed system mode schedule.
vm	Forwards the call to voicemail.
vm <*number*>	Optional. Forwards the phone to the specified mailbox number.

Default Values

By default, no system mode call coverage is specified.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was updated to include the voicemail and number of rings options.
Release 12.1	Command was updated to include the auto attendant, global, and operator options.
Release A1	Command was updated to include the system mode feature options.

Functional Notes

System mode call coverage provides more diverse functionality for call handling. In previous versions of AOS (revision 15.1 or earlier), up to five coverage modes were allowed. Calls were processed in the order in which the coverage options were entered into the system.

With the addition of the system mode options, up to five coverage options per system mode are allowed. The system modes can be modified using the command *voice system-mode on page 1971*.

Usage Examples

The following example specifies that the user's phone be forwarded to the internal extension **8500** when in the **night** system mode after **3** rings.

(config)**#voice coverage Evening**
(config-gch)**#coverage night internal 8500 num-rings 3**

default

Use the **default** command to specify the global call coverage list as the default list for the AOS unit. Use the **no** form of this command to remove the list as the default list.

Syntax Description

No subcommands.

Default Values

By default, no global call coverage list is configured.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example specifies that the global call coverage list **Evening** is the default coverage list and is used for all new users unless coverage is configured on a per-user basis:

```
(config)#voice coverage Evening
(config-gch)#default
```

CALL QUEUING COMMAND SET

Call queuing is a voice feature that pools multiple incoming calls into a single call queue that can be answered by members of the queue. The call queuing feature can be configured to play on-hold music and user-customized messages that inform callers of the status of their call.

For more information about configuring call queuing, refer to the quick configuration guide *Configuring Call Queuing on the NetVanta 7000 Series* available online at https://supportcommunity.adtran.com.

To create a call queue and enter the Voice Call Queuing Configuration mode, enter the **voice queue** <*extension*> command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice queue 6407
(config-6407)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the section listed below:

cross-connect on page 76
do on page 81
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order:

call-distribution

Use the **call-distribution** command to specify the manner in which queued calls are distributed to members of the call queue. Use the **no** version of this command to restore the default.

Syntax Description

linear-hunt	Specifies that members of the call queue will be called in a linear, progressive fashion based on the foreign exchange service (fxs) port to which the queue member is connected.
most-idle-agent	Specifies that the member of the call queue who has not been on a call queue phone call for the longest duration of time will be called. Calls that end before the call queue greeting is played are not count as calls for the distribution list.
ring-all	Specifies that all members of the call queue will be called simultaneously.

Default Values

By default, all members of the call queue will be called simultaneously.

Command History

Release A5.01	Command was introduced.

Usage Examples

The following example configures the call-distrubtion as most-idle-agent:

(config)**# voice queue 6407**
(config-6407)**# call-distribution most-idle-agent**

deliver-member <*extension*>

Use the **deliver-member** command to send a call to a member extension even though that member is currently on the phone. Use the **no** version of this command to disable this feature.

Syntax Description

<*extension*>	Specifies the member extension.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sends a call to the member at extension **6535**:

(config)**# voice queue 6407**
(config-6407)**# deliver-member 6535**

dequeue-extension

Use the **dequeue-extension** command to set the dequeue extension for a call queue. People who are not members of the queue can call the dequeue extension to answer queued calls. Use the **no** version of this command to remove the dequeue extension.

Syntax Description

<*extension*>	Specifies the extension to be used as the dequeue extension.

Default Values

By default, no **dequeue-extension** is specified.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the dequeue extension of the call queue to **7900**:

(config)**# voice queue 6407**
(config-6407)**#dequeue-extension 7900**

description <*text*>

Use the **description** command to define a description for the call queue. Use the **no** version of this command to remove the description.

Syntax Description

<*text*>	Describes the call queue.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the call queue's description to **tech support queue**:

(config)**# voice queue 6407**
(config-6407)**#description tech support queue**

digit-action dial-extension <*extension*>

Use the **digit-action dial-extension** command to define the extension to which a queued caller will be forwarded if they press any digit on their phone while waiting in the queue. Use the **no** version of this command to disable this feature.

Syntax Description

<*extension*>	Specifies the extension to which callers will be forwarded.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the **digit-action dial-extension** for the call queue to **5150**:

(config)**# voice queue 6407**
(config-6407)**#digit-action dial-extension 5150**

greeting

Use the **greeting** command to configure all greeting types associated with the call queuing feature. Use the **no** version of this command to restore the system defaults.Variations of this command include:

greeting auto-page
greeting auto-page <*file*>
greeting auto-page extension <*extension*>
greeting auto-page immediate
greeting auto-page interval <*seconds*>
greeting periodic <*number*> <*file*>
greeting periodic <*number*> <*file*> **time** <*seconds*>
greeting pickup <*file*>
greeting welcome <*file*>

Syntax Description

<*file*>	Specifies the file name to be used as the greeting. If this file is not the default greeting file, it must be a G.729/G.711u/G.711a CODEC .wav file that was previously uploaded to the system by the system administrator using the **Audio Prompts** menu in the AOS graphical user interface (GUI).
auto-page	Specifies to page with a custom greeting plus a system generated prompt with the number of callers and the dequeue extension. The greeting will be followed by a system generated message saying **You have XX call(s) on YYYY**, where **XX** is the number of callers parked waiting in the queue and **YYYY** is the configured dequeue extension for this queue, or queue extension if the dequeue extension is not configured. If no <*file*> is specified for the greeting, the system precedes the system generated message with the call queue extension.
extension <*extension*>	Optional. Specifies a paging group extension from which to place the outgoing page. If no extension is specified, the message will go out over the overhead paging port.
immediate	Optional. Specifies to deliver a page immediately instead of waiting for the configured interval.
interval <*seconds*>	Optional. Specifies the number of seconds to wait to page after initiating the prior page. The valid range is **10** to **60** seconds.
periodic	Configures a call queue periodic greeting.
<*number*>	Specifies the index of the greeting to be configured.
time <*seconds*>	Optional. Specifies the number of seconds between periodic greetings. The valid range is **0** to **3600** seconds.
pickup	Configures a call queue pickup greeting.
welcome	Configures a call queue welcome greeting.

Default Values

By default, AOS uses system default periodic, pickup, and welcome greetings. The default settings for auto-page are **immediate** with an interval of **27** seconds.

Command History

Release A4.01	Command was introduced.
Release R10.10.0	Command was expanded to include the **auto-page** parameters. In addition, up to six queues are allowed.

Usage Examples

The following example sets the first periodic greeting for a call queue to **FILE1**:

(config)**# voice queue 6407**
(config-6407)**#greeting periodic 1 FILE1**

lock

Use the **lock** command to prevent new calls from entering the call queue. Use the **no** version of this command to unlock the call queue.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example locks the call queue:

(config)**# voice queue 6407**
(config-6407)**#lock**

login-member <*extension*>

Use the **login-member** command to log an existing queue member into the call queue. Use the **no** version of this command to log a member out of the call queue.

Syntax Description

<*extension*>	Specifies the extension of the call queue member.

Default Values

By default, members are logged out of the call queue.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example logs existing queue member **6535** into the call queue:

(config)**# voice queue 6407**
(config-6407)**# login-member 6535**

max-number-calls <*number*>

Use the **max-number-calls** command to define the maximum number of calls allowed in the call queue. Use the **no** version of this command to restore the system default.

Syntax Description

<*number*>	Specifies the maximum number of calls allowed in the call queue. The range for this command is dependent upon the NetVanta unit and will be reflected in an error message if the range is exceeded.

Default Values

By default, 16 calls are allowed in the call queue.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the maximum number of calls allowed in the queue to **10**:

(config)**# voice queue 6407**
(config-6407)**#max-number-calls 10**

max-wait-time <*seconds*>

Use the **max-wait-time** command to define the maximum amount of time a call can wait in the queue before being sent to the overflow extension. If no overflow extension is set, the call will remain in the queue until it is answered or the caller hangs up. Use the **no** version of this command to restore the default value.

Syntax Description

<*seconds*>	Indicates the maximum wait time in seconds, with a range from **30** to **6400**.

Default Values

By default, the **max-wait-time** is **3600** seconds.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the call queue's maximum wait time to **900** seconds:

(config)**# voice queue 6407**
(config-6407)**#max-wait-time 900**

member <*extension*>

Use the **member** command to add members to a call queue. Use the **no** version of this command to remove the member from the queue.

Syntax Description

<*extension*>	Specifies the extension of the member to be added.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example adds extension **6535** as a member of the call queue:

(config)**# voice queue 6407**
(config-6407)**#member 6535**

moh-external

Use the **moh-external** command to specify that a caller waiting for a call to be answered should hear music sourced from the external music on hold port (MOH). Use the **no** version of this command to return to the default setting. If external hold music is configured, the setting configured with the *lock on page 4731* will be ignored. The setting of the command *ringback-only on page 4742* overrides this setting.

Syntax Description

No subcommands.

Default Values

By default, the **moh-external** mode is disabled.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies to use music on hold sourced from the MOH port for call queue extension **6407**:

(config)**# voice queue 6407**
(config-6407)**#moh-external**

moh-player <*name*>

Use the **moh-player** command to specify the name of the music on hold (MOH) player to use for queued callers. If the command *moh-external on page 4736* is configured, this setting will be ignored. The setting of the command *ringback-only on page 4742* overrides this setting. Use the **no** version of this command to return to the default setting.

Syntax Description

<*name*>	Specifies the name of the player.

Default Values

By default, the system's **default** MOH player, defined using the command *default on page 4854*, will be used if no player is specified for call queuing.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example specifies the name of the MOH player used for call queue extension **6407** as **CQPLAYER**:

(config)**# voice queue 6407**
(config-6407)**#moh-player CQPLAYER**

name <*queue*>

Use the **name** command to define the name of a call queue. Use the **no** version of this command to remove the name of the queue.

Syntax Description

<*queue*>	Specifies the name of the call queue.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example defines the name of the call queue on extension **6407** as **TSQueue**:

(config)**# voice queue 6407**
(config-6407)**#name TSQueue**

overflow-extension <*extension*>

Use the **overflow-extension** command to define the extension to which a queued caller will be forwarded if the call queue is not available. This includes when the queue is locked, shutdown, at maximum capacity, or the call has been in queue past the maximum wait time. Use the **no** version of this command to remove the overflow extension.

Syntax Description

<*extension*>	Specifies the extension to which callers will be forwarded.

Default Values

By default, if no overflow extension is specified, queued calls will be dropped.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the overflow extension for the call queue to **5309**:

(config)**# voice queue 6407**
(config-6407)**#overflow-extension 5309**
(config-6407)#

prefix <*characters*>

Use the **prefix** command to define the characters that are pre-pended to calls coming into the call queue. The prefix is displayed along with the calling number in the call queue member's caller ID. Use the **no** version of this command to restore the system default.

Syntax Description

<*characters*>	Specifies the characters to be prepended to queued calls.

Default Values

By default, AOS pre-pends **CQ_** to all calls entering the call queue.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the prefix for the call queue to **TSQ**:

(config)**# voice queue 6407**
(config-6407)**#prefix TSQ**

rest-period <*seconds*>

Use the **rest-period** command to set the rest period for a call queue. The rest period is the amount of time after hanging up before another queued call can be sent to the member extension. Use the **no** version of this command to restore the system default.

Syntax Description

<*seconds*>	Specifies the length of the rest period, from **0** to **600** seconds.

Default Values

By default, the rest period is **120** seconds.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the call queue's rest period to **60** seconds:

(config)**# voice queue 6407**
(config-6407)**#rest-period 60**

ringback-only

Use the **ringback-only** command to set the call queue to ringback-only mode. Queued calls will hear only ringback instead of hold music and greetings, conserving system resources. Use the **no** version of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, the ringback-only mode is disabled and the full-featured queue is available.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the call queue to ringback only mode:

(config)**# voice queue 6407**
(config-6407)**#ringback-only**

ring-time

Use the **ring-time** command to define the time (in seconds) that outbound calls from the call queue are allowed to ring logged-in members. Use the **no** version of this command to restore the system default.

Syntax Description

<seconds>	Specifies the ring-time, from **0** (unlimited) to **60** seconds..

Default Values

By default, the ring-time is **30** seconds.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the ring time for the call queue to **60** seconds:

(config)**# voice queue 6407**
(config-6407)**#ring-time 60**

FINDME-FOLLOWME ACTION SCRIPT COMMAND SET

FindMe-FollowMe is a feature supported by AOS that enables calls to be redirected based on who is calling and the availability of the called party. When the FindMe-FollowMe feature is enabled and configured, an incoming call rings the called party's extension for the amount of time specified by the number of rings, and then is redirected based on the configuration of the FindMe-FollowMe feature.

Configuring FindMe-FollowMe revolves around two main actions: configuring the user's contact group(s), and configuring the scripts used to determine which numbers are dialed in the FindMe-FollowMe call sequence. Contact groups are the groups of callers the user anticipates permitting to use the FindMe-FollowMe feature. For more information about configuring contact groups, refer to *FindMe-FollowMe Contact Group Command Set on page 4752*.

The second part of configuring FindMe-FollowMe is to specify the actions taken when an incoming call is received. The configurable actions include: calling the user extension, calling an internal extension, calling an external number, forwarding the call to an auto attendant, forwarding the call to voicemail, or sending an email to the called party. FindMe-FollowMe actions do not, however, include calling ring groups. Each of these actions that places a call can be configured for a specific timeout in which to stop the call, as well as prompt the called party for dual tone multi-frequency (DTMF) digits to manage the call. Each FindMe-FollowMe contact group can have **1** action script associated with it, and each script can have up to **10** actions, each of which can place up to **4** calls. Actions are numbered in the order you want them to be performed, but they can be entered in the command line interface (CLI) in any order. If you are working with actions in parallel, rather than sequence, configuring different ring times for different actions causes FindMe-FollowMe to delay the next action until the maximum ring time expires for the first action. This command set outlines the available commands for configuring FindMe-FollowMe action scripts.

For more information about configuring the FindMe-FollowMe feature, refer to the *Configuring User Accounts on the NetVanta 7000 Series* configuration guide available online at https://supportcommunity.adtran.com.

To create a FindMe-FollowMe action script for a voice user, enter the **script** command at the voice user configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice user 4444
(config-4444)#script Business
(config-4444-sc-Business)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81

All other commands for this command set are described in this section in alphabetical order.

action <*number*> email

Use the **action** <*number*> **email** command to specify that FindMe-FollowMe sends the called party an email notification of the call. Use the **no** form of this command to remove email notification from the action list. Variations of this command include:

action <*number*> **email primary**
action <*number*> **email secondary**

Syntax Description

<*number*>	Specifies the order number for the action. Valid range is **1** to **10**.
primary	Specifies that the email is sent to the user's primary email address.
secondary	Specifies that the email is sent to the user's secondary email address.

Default Values

By default, no action lists are configured.

Command History

Release A4.01	Command was introduced.

Functional Notes

This action sends an email to the called party's primary or secondary email address. These addresses are specified in the user account configuration mode using the commands *email <address> on page 4591* and *email-secondary <address> on page 4592*.

Usage Examples

The following example specifies that the **first** action for the action script **Business**, in user **4444**'s FindMe-FollowMe configuration, is to send a notification email to the user's **primary** email address:

(config)**#voice user 4444**
(config-4444)**#script Business**
(config-4444-sc-Business)**#action 1 email primary**

action <*number*> external <*phone number*>

Use the **action** <*number*> **external** command to specify that FindMe-FollowMe rings an external phone number to locate the called party. Use the **no** form of this command to remove this action from the action script. Variations of this command include:

action <*number*> **external** <*phone number*> **press-to-accept**
action <*number*> **external** <*phone number*> **press-to-accept ring-time** <*seconds*>
action <*number*> **external** <*phone number*> **no-press-to-accept**
action <*number*> **external** <*phone number*> **no press-to-accept ring-time** <*seconds*>

Syntax Description

<*number*>	Specifies the order number for the action. Valid range is **1** to **10**.
<*phone number*>	Specifies the external number to ring.
press-to-accept	Specifies that the called party is prompted to enter a digit to answer the call, generally selecting **1** to accept the call.
no-press-to-accept	Specifies that the called party is not prompted to enter a digit to answer the call.
ring-time <*seconds*>	Optional. Specifies the time (in seconds) that FindMe-FollowMe rings the external number before moving on to the next action in the list. Range is **1** to **60** seconds.

Default Values

By default, no external numbers are specified and the ring time is set to **24** seconds.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example specifies that the first action for the action script **Business**, in user **4444**'s FindMe-FollowMe configuration, is to ring the external number of **12565550980**. For this action, the called party presses a digit to answer the call, and the ring time is specified at **30** seconds:

(config)**#voice user 4444**
(config-4444)**#script Business**
(config-4444-sc-Business)**#action 1 external 12565550980 press-to-accept ring-time 30**

action <*number*> internal <*extension*>

Use the **action** <*number*> **internal** command to specify that FindMe-FollowMe rings an internal extension to locate the called party. Use the **no** form of this command to remove this action from the action script. Variations of this command include:

action <*number*> **internal** <*extension*> **press-to-accept**
action <*number*> **internal** <*extension*> **press-to-accept ring-time** <*seconds*>
action <*number*> **internal** <*extension*> **no-press-to-accept**
action <*number*> **internal** <*extension*> **no-press-to-accept ring-time** <*seconds*>

Syntax Description

<*number*>	Specifies the order number for the action. Valid range is **1** to **10**.
<*extension*>	Specifies the internal extension to ring.
press-to-accept	Specifies that the called party is prompted to enter a digit to answer the call, generally selecting **1** to accept the call.
no-press-to-accept	Specifies that the called party is not prompted to enter a digit to answer the call.
ring-time <*seconds*>	Optional. Specifies the time (in seconds) that FindMe-FollowMe rings the external number before moving on to the next action in the list. Range is **1** to **60** seconds.

Default Values

By default, no internal numbers are specified and the ring time is set to **24** seconds.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example specifies that the first action for the action script **Business**, in user **4444**'s FindMe-FollowMe configuration, is to ring the internal extension of **8989**. For this action, the called party presses a digit to answer the call, and the ring time is specified at **30** seconds:

(config)**#voice user 4444**
(config-4444)**#script Business**
(config-4444-sc-Business)**#action 1 internal 8989 press-to-accept ring-time 30**

action <*number*> refer <*extension*>

Use the **action** <*number*> **refer** command to specify that FindMe-FollowMe refers an incoming call to another user. Use the **no** form of this command to remove the action from the action script.

Syntax Description

<*number*>	Specifies the order number for the action. Valid range is **1** to **10**.
<*extension*>	Specifies the user extension to which the call is referred.

Default Values

By default, no action scripts are configured.

Command History

Release A4.01	Command was introduced.

Functional Notes

When a **refer** action is added to the action script, no other actions are performed after the **refer**. When a FindMe-FollowMe call is referred to another user, the call no longer uses the FindMe-FollowMe action script, but rather uses the call coverage configured for the user to which the call was referred.

Usage Examples

The following example specifies that the fifth and final action for the action script **Business**, in user **4444**'s FindMe-FollowMe configuration, is to refer the call to user **1234**. When the call is accepted by extension **1234**, the call follows the call coverage configured for that user.

(config)**#voice user 4444**
(config-4444)**#script Business**
(config-4444-sc-Business)**#action 5 refer 1234**

action <*number*> vm

Use the **action** <*number*> **vm** command to specify that FindMe-FollowMe sends the caller to voicemail. Use the **no** form of this command to remove the action from the action script. Variations of this command include:

action <*number*> **vm**
action <*number*> **vm** <*mailbox*>

Syntax Description

<*number*>	Specifies the order number for the action. Valid range is **1** to **10**.
<*mailbox*>	Optional. Sends the caller to a specific voice mailbox, rather than the user's mailbox.

Default Values

By default, the call is sent to the user's voice mailbox unless another mailbox is specified.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example specifies that the fourth action for the action script **Business**, in user **4444**'s FindMe-FollowMe configuration, is to send the call to the user's voice mailbox:

(config)**#voice user 4444**
(config-4444)**#script Business**
(config-4444-sc-Business)**#action 4 vm**

description *<"text">*

Use the **description** command to enter a short description of the action script. This description can be useful when you have multiple scripts and contact groups configured. Use the **no** form of this command to remove the description.

Syntax Description

<"text">	Describes the action script. The text should be enclosed in quotation marks.

Default Values

By default, no action scripts are configured.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example creates a description (**New Business Contacts**) for the action script **Business** (in user **4444**'s FindMe-FollowMe configuration):

(config)**#voice user 4444**
(config-4444)**#script Business**
(config-4444-sc-Business)**#description "New Business Contacts"**

FINDME-FOLLOWME CONTACT GROUP COMMAND SET

FindMe-FollowMe is a feature supported by AOS that enable calls to be redirected based on who is calling. When the FindMe-FollowMe feature is enabled and configured, an incoming call rings the called party's extension for a specified number of rings, and then is redirected based on the configuration of the FindMe-FollowMe feature.

Configuring FindMe-FollowMe revolves around two main actions: configuring the user's contact group(s), and configuring the scripts used to determine which numbers are dialed in the FindMe-FollowMe sequence. Contact groups are the groups of callers the user anticipates permitting to use the FindMe-FollowMe feature. For example, a user might have a contact group for family and one for business partners. New contact groups can be added or removed at any time, and each user can have up to **5** contact groups. In addition, contact groups can be configured to play a courtesy greeting, prompt the caller for their name, enable callers to leave a voicemail, provide ringback to the inbound caller, and add or remove group members based on their calling number. This command set outlines the available commands for configuring FindMe-FollowMe contact groups.

For more information about configuring action scripts, refer to *FindMe-FollowMe Action Script Command Set on page 4744*. For more information about configuring the FindMe-FollowMe feature, refer to the *Configuring User Accounts on the NetVanta 7000 Series* configuration guide available online at https://supportcommunity.adtran.com.

To create a FindMe-FollowMe contact group for a voice user, enter the **contact-group** command at the voice user configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice user 4444
(config-4444)#contact-group 1
(config-4444-cg-1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81

All other commands for this command set are described in this section in alphabetical order.

ringback on page 4761

courtesy-greeting

Use the **courtesy-greeting** command to enable a courtesy greeting for the inbound caller while FindMe-FollowMe performs actions to locate the called party. The courtesy greeting provided by AOS tells callers to "Please wait while I locate your party." Using the **no** form of this command disables the courtesy greeting.

Syntax Description

No subcommands.

Default Values

By default, the courtesy greeting is enabled.

Command History

Release A4.01	Command was introduced.

Functional Notes

If ringback is enabled in the FindMe-FollowMe contact group, then all prompts and greetings are ignored.

Usage Examples

The following example disables the courtesy greeting for contact group **2** in voice user **4444**'s FindMe-FollowMe configuration:

(config)**#voice user 4444**
(config-4444)**#contact-group 2**
(config-4444-cg-2)**#no courtesy-greeting**

digit-prompt

Use the **digit-prompt** command to enable dual tone multi-frequency (DTMF) digit prompting for the FindMe-FollowMe contact group. When DTMF digit prompting is enabled, inbound callers can control the incoming call using DTMF tones. When callers hear the prompt "To leave a voicemail at any time, press 1," they can then press 1 to leave a voicemail message. Using the **no** form of this command disables DTMF digit prompting for the contact group.

Syntax Description

No subcommands.

Default Values

By default, DTMF digit prompting is disabled in FindMe-FollowMe.

Command History

Release A4.01	Command was introduced.

Functional Notes

To use DTMF digit prompting, enhanced FindMe-FollowMe must be enabled on the user account. Refer to the command *findme-followme on page 4593* for more information.

Usage Examples

The following example enables DTMF digit prompting for contact group **2** in voice user **4444**'s FindMe-FollowMe configuration:

```
(config)#voice user 4444
(config-4444)#contact-group 2
(config-4444-cg-2)#digit-prompt
```

group-description *<"text">*

Use the **group-description** command to enter a short description for the contact group. Using the **no** form of this command removes the group description.

Syntax Description

<"text">	Describes the contact group. Enter the descriptions in quotation marks.

Default Values

By default, no group description exists.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example describes contact group **2** in voice user **4444**'s FindMe-FollowMe configuration as **Business Contacts**:

(config)**#voice user 4444**
(config-4444)**#contact-group 2**
(config-4444-cg-2)**#group-description "Business Contacts"**

implicitly-allow

Use the **implicitly-allow** command to specify the callers that are implicitly allowed into the user's FindMe-FollowMe contact group. Using the **no** form of this command removes implicit users from the contact group. Variations of this command include:

implicitly-allow all
implicitly-allow external
implicitly-allow internal

Syntax Description

all	Specifies that all callers are implicitly included in the contact group.
external	Specifies that only external callers are implicitly included in the contact group.
internal	Specifies that only internal callers are implicitly included in the contact group.

Default Values

By default, no users are included implicitly in a contact group.

Command History

Release A4.01	Command was introduced.

Usage Examples

In the following example, **external** callers are implicitly included in contact group **2** for voice user **4444**'s FindMe-FollowMe configuration:

(config)**#voice user 4444**
(config-4444)**#contact-group 2**
(config-4444-cg-2)**#implicitly-allow external**

permit-caller-id number <*number*>

Use the **permit-caller-id number** command to add explicitly known numbers to the contact group and make them members of the group. Using the **no** form of this command removes the member from the group. Variations of this command include:

permit-caller-id number <*number*>
permit-caller-id number <*number*> <*"description"*>

Syntax Description

<*number*>	Specifies the calling number of the known member to add to the contact group.
<*"description"*>	Optional. Specifies a short description of the member to add to the group. Descriptions should be in quotation marks.

Default Values

By default, no members are explicitly included in the contact group.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example adds the member **Company A VIP** (who calls from number **12565557890**) to contact group **2** of voice user **4444**'s FindMe-FollowMe configuration:

(config)#**voice user 4444**
(config-4444)#**contact-group 2**
(config-4444-cg-2)#**permit-caller-id number 12565557890 "Company A VIP"**

presence available script <*name*>

Use the **presence available script** command to associate previously configured action scripts with a user's FindMe-FollowMe contact group. Using the **no** form of this command removes the script from the contact group.

Syntax Description

<*name*>	Specifies which action script is associated with the contact group.

Default Values

By default, no action scripts are associated with the contact group.

Command History

Release A4.01	Command was introduced.

Functional Notes

FindMe-FollowMe works by executing actions to locate the called party. These actions are determined by configuring action scripts for each contact group. Each contact group can have **1** action script associated with it, and each action script can support up to **10** actions. For more information about configuring FindMe-FollowMe action scripts, refer to *FindMe-FollowMe Action Script Command Set on page 4744*.

Usage Examples

In the following example, the action script **Business** is associated with contact group **2** in voice user **4444**'s FindMe-FollowMe configuration:

(config)**#voice user 4444**
(config-4444)**#contact-group 2**
(config-4444-cg-2)**#presence available script Business**

record-calling-name

Use the **record-calling-name** command to enable a prompt that asks incoming callers to record their names. When the name recording option is enabled, the system records **3** seconds of audio before moving on to other scripts or actions. Using the **no** form of this command disables the name recording feature.

Syntax Description

No subcommands.

Default Values

By default, callers are not prompted to record their names.

Command History

Release A4.01	Command was introduced.

Functional Notes

When ringback is enabled for the contact group, all prompts and greetings are ignored.

Usage Examples

The following example enables caller name recording in contact group **2** of voice user **4444**'s FindMe-FollowMe configuration:

(config)**#voice user 4444**
(config-4444)**#contact-group 2**
(config-4444-cg-2)**#record-calling-name**

ringback

Use the **ringback** command to enable ringback for the contact group. When ringback is enabled, inbound FindMe-FollowMe calls are only answered when an outbound call is answered or if one of the FindMe-FollowMe actions requires the call to be answered (for example, voicemail). If ringback is disabled, then the call is answered immediately, any configured greetings are played, and music on hold is eventually played while the called party is located. Using the **no** form of this command disables ringback.

Syntax Description

No subcommands.

Default Values

By default, ringback is disabled.

Command History

Release A4.01	Command was introduced.

Functional Notes

Ringback must be disabled for any contact group configured prompts or greetings to be played. However, using the prompts and greetings can drain system resources. Adtran recommends you use ringback as much as possible to save these resources.

Usage Examples

The following example enables ringback for contact group **2** in voice user **4444**'s FindMe-FollowMe configuration:

(config)**#voice user 4444**
(config-4444)**#contact-group 2**
(config-4444-cg-2)**#ringback**

HMR COMMAND SET

Header manipulation rules (HMR) manipulation is a feature used in AOS that allows the manipulation of both headers and message bodies in Session Initiation Protocol (SIP) transmissions, based on configurable rules. These rules can be applied to both outbound and inbound messages, and can be used to modify existing headers or the body of SIP messages, match, add, or remove SIP headers, and store variable information. In addition, message manipulation rules can use regular expressions to modify SIP headers and message bodies. One of the benefits of using SIP header and message manipulation is that the feature can give you enhanced control over the behavior of SIP traffic on your AOS device, as well as help solve interoperability issues between the AOS device and other products.

SIP header manipulation is achieved by creating an HMR policy, a set of HMR rules, and applying those rules to the HMR policy. The policy is then applied to a SIP trunk, to all SIP traffic in the AOS device, to SIP traffic sent or received by a SIP proxy user, or to SIP traffic sent or received by a SIP proxy server. The HMR policies can be applied to either inbound or outbound SIP traffic. In addition, HMR variables can be created, which store text used in header manipulation. These variables can be public or private, indicating their scope of access, or Call-ID variables. Public variables are accessible and shared by all HMR policies. Private variables exist within an instance of a policy. Call-ID variables are similar to public variables, in that they are available to all policies, but their value is limited in scope to the current Call-ID. In addition, system variables can be used to provide predefined variables (such as public, private, or Call-ID variables) access to system-level information.

The following are the basic configuration steps needed to create SIP header manipulation in AOS:

1. Create an HMR rule set (using the Global Configuration mode command *hmr rule-set <name> on page 1315*).
2. Create HMR rule(s) for the rule set (using the command *rule-set on page 4802*).
3. Specify each HMR rule's action (add, match, modify, remove using the appropriate commands in this section).
4. Optionally, configure variables for the HMR rule (using the commands *set private-variable on page 4806* and *set public-variable on page 4809*).
5. Create an HMR policy (using the Global Configuration mode command *hmr policy <name> on page 1314*).
6. Assign the HMR rule set to the appropriate HMR policy (using the command *rule-set on page 4802*).
7. Apply the HMR policy to the appropriate SIP traffic (using the Global Configuration mode commands *sip hmr on page 1723* and *sip proxy hmr on page 1750*).

The commands covered in this section include those executed from the SIP HMR Policy Configuration mode, the HMR Rule Set Configuration mode, and the HMR Message Rule Configuration mode. For more information about using SIP HMR, refer to the configuration guide *Manipulating SIP Headers and Messages in AOS*, available online at http://supportforums.adtran.com.

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76

To create a SIP HMR policy, and enter the SIP HMR Policy Configuration mode, enter the **hmr policy** <*name*> parameter from the Global Configuration mode as follows:

```
(config)#hmr policy POLICY1
(config-policy-POLICY1)#
```

The commands available in the HMR Policy Configuration mode are listed in alphabetical order below:

rule-set on page 4802

To create a SIP HMR rule set, and enter the HMR Rule Set Configuration mode, enter the **hmr rule-set** <*name*> command from the Global Configuration mode as follows:

```
(config)#hmr rule-set SET1
(config-rule-set-SET1)#
```

The commands available in the HMR Rule Set Configuration mode are listed in alphabetical order below:

message-rule on page 4791

To configure the actions of the HMR message rules, enter the HMR Message Rule Configuration mode by entering the **message-rule** command from the HMR Rule Set Configuration mode as follows:

```
(config)#hmr rule-set SET1
(config-rule-set-SET1)#message-rule RULE1 message-type any 5
(config-msg-rule-RULE1)#
```

The commands available in the HMR Message Rule Configuration mode are listed in alphabetical order below:

add header position

Use the **add header position** command from the Message Rule Set Configuration mode to add headers to Session Initiation Protocol (SIP) messages using SIP header manipulation. Use the **no** form of this command to remove the header addition rule from the rule set. Variations of this command include:

add header <*header*> **position first new-value** <*value string*>
add header <*header*> **position first new-value** <*value string*> <*sequence number*>
add header <*header*> **position if-not-present new-value** <*value string*>
add header <*header*> **position if-not-present new-value** <*value string*> <*sequence number*>
add header <*header*> **position last new-value** <*value string*>
add header <*header*> **position last new-value** <*value string*> <*sequence number*>

Syntax Description

<*header*>	Specifies the SIP header type that you want to add to the SIP message. Header types are outlined in the *Functional Notes* below.
first	Specifies that the new header is added as the first header of the specified header type within the SIP message.
if-not-present	Specifies that the new header is added only if the specified header type is not already present within the SIP message.
last	Specifies that the new header is added as the last of the specified header type within the SIP message.
new-value <*value string*>	Specifies the value to assign to the new header and is expressed as a text string. Text strings must be enclosed in quotation marks.
<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no SIP headers are configured for addition to SIP messages. When configured, if no sequence number is given, the rules are sequenced in increments of 10, and all rules are processed in sequence.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

Multiple headers of the same type can occur in SIP messages, and therefore, the specified position of the header can determine whether a match occurs. For more information, refer to *Appendix B: Matching Regular Expressions in SIP Messages with Multiples of the Same Header* in the configuration guide *Manipulating SIP Headers and Messages in AOS*, available online at http://supportforums.adtran.com.

SIP headers available for matching include the following:

Accept-Contact	Allow	Allow-Events
Call-Id	Contact	Content-Encoding
Content-Length	Content-Type	Diversion
Event	From	Identity
Identity-info	P-Asserted-Identity	P-Preferred-Identity
Record-Route	Refer-To	Referred-By
Reject-Contact	Replaces	Request-Disposition
Route	Session-Expires	Sip-Req-Uri
Sip-Status-Line	Subject	Supported
To	Via	<*name*> (specifies another header not listed here)

SIP headers can also be expressed in compact form in a SIP message. Compact forms of the header name will match the full SIP header name.

Usage Examples

The following example adds a new SIP header **Proprietary1** to the SIP message from the HMR Message Rule Configuration mode:

(config-rule-set-SET1)**#message-rule RULE1 message-type any 5**
(config-msg-rule-RULE1)**#add header Propietary1 position first new-value “localID=unit195;remoteID=unit272”**

all

Use the **all** command from the Message Rule Set Configuration mode to specify that a Session Initiation Protocol (SIP) header manipulation rule (HMR) is executed only if all tests in the condition block evaluate as true. Use the **no** version of this command to remove the action. Variations of this command include:

all
all <*sequence number*>

Syntax Description

<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no header manipulation rules are configured.

Command History

Release R11.10.0	Command was introduced.

Functional Notes

If the **all** command is present in the message rule's configuration, the message rule is processed only if all the stated conditions in the condition block are resolved as true. The condition blocks also use the command *end on page 4775* which signifies the end of the conditions that must be met.

The condition block is entered using the **if** or **for** commands (refer to the commands *if on page 4781* and *for on page 4779*), which signify the beginning of the logical block. The logical block is configured to discard or enforce HMR actions (such as modifying, adding, or removing headers, etc.) based on the use of the **not**, **all**, or **any** logical commands. Additionally, the **compare** and **evaluate** commands can be used in an **if** block to specify whether conditional logic criteria are met by comparing or evaluating specified criteria. Based on the logical commands contained within the block, HMR actions are enforced or discarded according to the configured action.

Usage Examples

The following example configures the HMR rule **RULE1** to be applied if all configured conditions are resolved to true. In this case, the rule is configured to match based on the SIP Via and Identity headers and to modify the body of messages with both those headers. These actions are carried out if all the conditions are met.

(config)**#hmr rule-set SET1**
(config-rule-set-SET1)**#message-rule RULE1**
(config-msg-rule-RULE1)**#if**
(config-msg-rule-RULE1)**#all**
(config-msg-rule-RULE1)**#match header via**
(config-msg-rule-RULE1)**#match header identity**
(config-msg-rule-RULE1)**#end-all**
(config-msg-rule-RULE1)**#modify body new-value PATTERN1**
(config-msg-rule-RULE1)**#end-if**

any

Use the **any** command from the Message Rule Set Configuration mode to specify that a Session Initiation Protocol (SIP) header manipulation rule (HMR) is executed if any of the configured conditions in the condition block are met. Use the **no** version of this command to remove the action. Variations of this command include:

any
any <*sequence number*>

Syntax Description

<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no header manipulation rules are configured.

Command History

Release R11.10.0	Command was introduced.

Functional Notes

If the **any** command is present in the message rule's configuration, the message rule is processed if any of the previously stated conditions in the condition block are resolved as true.

The condition block is entered using the **if** or **for** commands (refer to the commands *if on page 4781* and *for on page 4779*), which signify the beginning of the logical block. The logical block is configured to discard or enforce HMR actions (such as modifying, adding, or removing headers, etc.) based on the use of the **not**, **all**, or **any** logical commands. Additionally, the **compare** and **evaluate** commands can be used in an **if** block to specify whether conditional logic criteria are met by comparing or evaluating specified criteria. Based on the logical commands contained within the block, HMR actions are enforced or discarded according to the configured action.

Usage Examples

The following example configures the HMR rule **RULE1** to be applied if any configured conditions are resolved to true. In this case, the rule is configured to match both the SIP Via and Identity headers, and then to modify the body of messages with either header. These actions are carried out if either of the conditions are met.

(config)**#hmr rule-set SET1**
(config-rule-set-SET1)**#message-rule RULE1**
(config-msg-rule-RULE1)**#if**
(config-msg-rule-RULE1)**#any**
(config-msg-rule-RULE1)**#match header via**
(config-msg-rule-RULE1)**#match header identity**
(config-msg-rule-RULE1)**#end-any**
(config-msg-rule-RULE1)**#modify body new-value PATTERN1**
(config-msg-rule-RULE1)**#end-if**

compare

Use the **compare** command from the Message Rule Set Configuration mode to compare two string values when using Session Initiation Protocol (SIP) header manipulation rule (HMR). These comparisons are used within condition blocks to determine whether HMR rules are applied. Use the **no** version of this command to remove the action. Variations of this command include:

compare <*"string"*> **equal** <*"string"*>
compare <*"string"*> **equal** <*"string"*> <*sequence number*>
compare <*"string"*> **greater-equal** <*"string"*>
compare <*"string"*> **greater-equal** <*"string"*> <*sequence number*>
compare <*"string"*> **greater** <*"string"*>
compare <*"string"*> **greater** <*"string"*> <*sequence number*>
compare <*"string"*> **less-equal** <*"string"*>
compare <*"string"*> **less-equal** <*"string"*> <*sequence number*>
compare <*"string"*> **less** <*"string"*>
compare <*"string"*> **less** <*"string"*> <*sequence number*>
compare <*"string"*> **not-equal** <*"string"*>
compare <*"string"*> **not-equal** <*"string"*> <*sequence number*>

Syntax Description

<*"string"*>	Specifies the text string to be used for comparison. Text strings should be enclosed in quotation marks.
equal	Specifies the condition is returned true if the first expression is equal to the second expression.
greater-equal	Specifies the condition is returned true if the first expression is greater than or equal to the second expression.
greater	Specifies the condition is returned true if the first expression is greater than the second expression.
less-equal	Specifies the condition is returned true if the first expression is less than or equal to the second expression.
less	Specifies the condition is returned true if the first expression is less than the second expression.
not-equal	Specifies the condition is returned true if the first expression is not equal to the second expression.
<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no header manipulation rules are configured.

Command History

Release R11.10.0	Command was introduced.

Functional Notes

The **compare** command is used to compare two string expressions. The comparison results in a true or false logical condition, which in turn causes other HMR rules to be enforced or discarded based on the rule's configured condition blocks.

The condition block is entered using the **if** or **for** commands (refer to the commands *if on page 4781* and *for on page 4779*), which signify the beginning of the logical block. The logical block is configured to discard or enforce HMR actions (such as modifying, adding, or removing headers, etc.) based on the use of the **not**, **all**, or **any** logical commands. Additionally, the **compare** and **evaluate** commands can be used in an **if** block to specify whether conditional logic criteria are met by comparing or evaluating specified criteria. Based on the logical commands contained within the block, HMR actions are enforced or discarded according to the configured action.

Usage Examples

The following example configures the HMR rule **RULE1** to be applied if the string comparison conditions are resolved to true. In this case, the rule is configured to compare two strings for equality, and then modify the SIP header if the text strings are equal.

(config)**#hmr rule-set SET1**
(config-rule-set-SET1)**#message-rule RULE1**
(config-msg-rule-RULE1)**#if**
(config-msg-rule-RULE1)**#compare "teststring1" equal "teststring2"**
(config-msg-rule-RULE1)**#modify body new-value PATTERN1**
(config-msg-rule-RULE1)**#end-if**

else

Use the **else** command from the Message Rule Set Configuration mode to specify an alternative action is taken by a Session Initiation Protocol (SIP) header manipulation rule (HMR) when the condition block returns false. Use the **no** version of this command to remove the action. Variations of this command include:

else
else <*sequence number*>

Syntax Description

<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no header manipulation rules are configured.

Command History

Release R11.10.0	Command was introduced.

Functional Notes

The **else** command is used to specify alternative processing for conditional failure within the HMR rule's configuration, and is used in conjunction with the command *if on page 4781*. The **if** command specifies an action to be taken if specified conditions resolve as true, and the optional **else** command specifies alternative actions if the specified conditions resolve as false. The conditional block ends with the **end-if** command.

The condition block is entered using the **if** or **for** commands (refer to the commands *if on page 4781* and *for on page 4779*), which signify the beginning of the logical block. The logical block is configured to discard or enforce HMR actions (such as modifying, adding, or removing headers, etc.) based on the use of the **not**, **all**, or **any** logical commands. Additionally, the **compare** and **evaluate** commands can be used in an **if** block to specify whether conditional logic criteria are met by comparing or evaluating specified criteria. Based on the logical commands contained within the block, HMR actions are enforced or discarded according to the configured action.

Usage Examples

The following example configures the HMR rule **RULE1** to perform a body modification on a SIP message who's header matches the Sip-Req-Uri header if the condition block (in the following example, a comparison) returns false.

(config)**#hmr rule-set SET1**
(config-rule-set-SET1)**#message-rule RULE1**
(config-msg-rule-RULE1)**#match header sip-req-uri match-value /^REFER.*/**
(config-rule-set-SET1)**#if**
(config-msg-rule-RULE1)**#compare "teststring1" equal "teststring2"**
(config-msg-rule-RULE1)**#else**
(config-msg-rule-RULE1)**#modify body new-value PATTERN1**
(config-msg-rule-RULE1)**#end-if**

end

Use the **end** command from the Message Rule Set Configuration mode to signal the end of a condition block in Session Initiation Protocol (SIP) header manipulation rule (HMR) configuration. Use the **no** version of this command to remove the action. Variations of this command include:

end-all
end-all <*sequence number*>
end-any
end-any <*sequence number*>
end-for
end-for <*sequence number*>
end-if
end-if <*sequence number*>
end-not
end-not <*sequence number*>

Syntax Description

all	Specifies the end of an **all** condition block. Refer to the command *all on page 4767*.
any	Specifies the end of an **any** condition block. Refer to the command *any on page 4769*.
for	Specifies the end of a **for** condition block. Refer to the command *for on page 4779*.
if	Specifies the end of an **if** condition block. Refer to the command *if on page 4781*.
not	Specifies the end of a **not** condition block. Refer to the command *not on page 4797*.
<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no header manipulation rules are configured. When a conditional block is configured, the default condition is **all**.

Command History

Release R11.10.0	Command was introduced.

Functional Notes

The **end** commands are used in conjunction with the conditional block commands **all**, **any**, **for**, **if**, and **not**. These commands are entered to signal the beginning of a block of actions taken based on the conditional logic specified by the command, and the **end** version is used to signal the end of the block of conditional logic. Only the criteria specified between the two commands is used for the conditional logic of that block. These commands take the results of a true or false logical condition, and enforce or discard other HMR rules based on the rule's configuration. If the conditional block commands (**all**, **any**, or **not**) are not specified, **all** is used by default and the **end** command does not need to be entered.

The condition block is entered using the **if** or **for** commands (refer to the commands *if on page 4781* and *for on page 4779*), which signify the beginning of the logical block. The logical block is configured to discard or enforce HMR actions (such as modifying, adding, or removing headers, etc.) based on the use of the **not**, **all**, or **any** logical commands. Additionally, the **compare** and **evaluate** commands can be used in an **if** block to specify whether conditional logic criteria are met by comparing or evaluating specified criteria. Based on the logical commands contained within the block, HMR actions are enforced or discarded according to the configured action.

Usage Examples

The following example configures the HMR rule **RULE1** to perform a match on a SIP header, and if the match condition is true, to then modify the body of the message.The **end-if** command is used to specify the end of the actions taken based on the logical **if**.

(config)**#hmr rule-set SET1**
(config-rule-set-SET1)**#message-rule RULE1**
(config-msg-rule-RULE1)**#if**
(config-msg-rule-RULE1)**#match header sip-req-uri match-value /^REFER.*/**
(config-msg-rule-RULE1)**#modify body new-value PATTERN1**
(config-msg-rule-RULE1)**#end-if**

evaluate

Use the **evaluate** command from the Message Rule Set Configuration mode to trigger an expression evaluation within the Session Initiation Protocol (SIP) header manipulation rule (HMR) condition block configuration. Use the **no** version of this command to remove the action. Variations of this command include:

evaluate *<pattern>*
evaluate *<pattern> <sequence number>*

Syntax Description

<pattern>	Specifies the expression to evaluate. This can be a regular expression or a text string, and can reference variable names. A text string must be enclosed in quotation marks.
<sequence number>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no header manipulation rules are configured.

Command History

Release R11.10.0	Command was introduced.

Functional Notes

The **evaluate** command is used to trigger the evaluation of a specific expression. If the expression can be executed, the results of the evaluation are true. If the expression cannot be executed, the results of the evaluation are false. This command allows HMR rules to be enforced or discarded within the condition block based on the results of the evaluation.

The condition block is entered using the **if** or **for** commands (refer to the commands *if on page 4781* and *for on page 4779*), which signify the beginning of the logical block. The logical block is configured to discard or enforce HMR actions (such as modifying, adding, or removing headers, etc.) based on the use of the **not**, **all**, or **any** logical commands. Additionally, the **compare** and **evaluate** commands can be used in an **if** block to specify whether conditional logic criteria are met by comparing or evaluating specified criteria. Based on the logical commands contained within the block, HMR actions are enforced or discarded according to the configured action.

Usage Examples

The following example configures the HMR rule **RULE1** to evaluate the text string **teststring1**, and perform a body modification on the SIP message if the evaluation results are returned true.

(config)**#hmr rule-set SET1**
(config-rule-set-SET1)**#message-rule RULE1**
(config-msg-rule-RULE1)**#if**
(config-msg-rule-RULE1)**#evaluate teststring1**
(config-msg-rule-RULE1)**#modify body new-value PATTERN1**
(config-msg-rule-RULE1)**#end-if**

for

Use the **for** command from the Message Rule Set Configuration mode to configure a loop of conditional logic or specific actions for the specified Session Initiation Protocol (SIP) header or variable in the header manipulation rule (HMR) configuration. Use the **no** version of this command to remove the loop. Variations of this command include:

for callid-variable <*name*>
for callid-variable <*name*> <*sequence number*>
for header <*header*>
for header <*header*> <*sequence number*>
for private-variable <*name*>
for private-variable <*name*> <*sequence number*>
for public-variable <*name*>
for public-variable <*name*> <*sequence number*>

Syntax Description

callid-variable	Specifies that a processing loop will be created for a call ID variable.
header <*header*>	Specifies the SIP header type for which you want to create the processing loop. Header types are outlined in the *Functional Notes* below.
private-variable	Specifies that a processing loop is created for a private variable.
public-variable	Specifies that a processing loop is created for a public variable.
<*name*>	Specifies the name of the variable for which you want to create the processing loop.
<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of 10, and all rules are processed in sequence.

Default Values

By default, no header manipulation rules are configured.

Command History

Release R11.10.0	Command was introduced.
Release R12.2.0	Command was expanded to include the **callid-variable**, **private-variable**, and **public-variable** parameters.

Functional Notes

SIP headers available for loop processing include the following:

Accept-Contact	Allow	Allow-Events
Call-Id	Contact	Content-Encoding

Content-Length	Content-Type	Diversion
Event	From	Identity
Identity-Info	P-Asserted-Identity	P-Preferred-Identity
Record-Route	Refer-To	Referred-By
Reject-Contact	Replaces	Request-Disposition
Route	Session-Expires	Sip-Req-Uri
Sip-Status-Line	Subject	Supported
To	Via	<*name*> (specifies another header not listed here)

When a header or variable is specified using the **for** command, a **for** processing loop is created for the specified header or variable. This loop can specify actions, such as header modification or variable configurations, or conditional blocks to be applied to the specified header. The command is used in conjunction with the **end-for** command (refer to *end on page 4775*), which signals the end of the processing block.

Usage Examples

The following example configures the HMR rule **RULE1** to create a processing loop for the Via header. The processing loop sets the private variable **VAR1** for the header. The **end-for** command specifies the end of the processing loop for that header.

(config)**#hmr rule-set SET1**
(config-rule-set-SET1)**#message-rule RULE1**
(config-msg-rule-RULE1)**#for header Via**
(config-msg-rule-RULE1)**#set private variable VAR1**
(config-msg-rule-RULE1)**#end-for**

if

Use the **if** command from the Message Rule Set Configuration mode to specify an action is taken by a Session Initiation Protocol (SIP) header manipulation rule (HMR) when the condition block returns as true. Use the **no** version of this command to remove the action. Variations of this command include:

if
if <*sequence number*>

Syntax Description

<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no header manipulation rules are configured.

Command History

Release R11.10.0	Command was introduced.

Functional Notes

The **if** command is used to specify the beginning of a condition block within the HMR rule's configuration, and is used in conjunction with the commands **if** and **else**. The **if** command specifies an action to be taken if specified conditions resolve as true, and the optional **else** command specifies alternative actions if the specified conditions resolve as false. The conditional block ends with the **end-if** command.

The condition block is entered using the **if** or **for** commands (refer to the commands *if on page 4781* and *for on page 4779*), which signify the beginning of the logical block. The logical block is configured to discard or enforce HMR actions (such as modifying, adding, or removing headers, etc.) based on the use of the **not**, **all**, or **any** logical commands. Additionally, the **compare** and **evaluate** commands can be used in an **if** block to specify whether conditional logic criteria are met by comparing or evaluating specified criteria. Based on the logical commands contained within the block, HMR actions are enforced or discarded according to the configured action.

Usage Examples

The following example configures the HMR rule **RULE1** to perform a body modification on a SIP message who's header matches the SIP Identity header, if the condition block (in the following example, a comparison) returns true.

(config)**#hmr rule-set SET1**
(config-rule-set-SET1)**#message-rule RULE1**
(config-msg-rule-RULE1)**#match header identity**
(config-msg-rule-RULE1)**#if**
(config-msg-rule-RULE1)**#compare "teststring1" equal "teststring2"**
(config-msg-rule-RULE1)**#modify body new-value PATTERN1**
(config-msg-rule-RULE1)**#end-if**

int-compare

Use the **int-compare** command from the Message Rule Set Configuration mode to compare two integer values when using Session Initiation Protocol (SIP) header manipulation rule (HMR). These comparisons are used to determine whether other configured HMR rules are applied by condition blocks. Use the **no** version of this command to remove the action. Variations of this command include:

int-compare <*pattern*> **equal** <*pattern*>
int-compare <*pattern*> **equal** <*pattern*> <*sequence number*>
int-compare <*pattern*> **greater-equal** <*pattern*>
int-compare <*pattern*> **greater-equal** <*pattern*> <*sequence number*>
int-compare <*pattern*> **greater** <*pattern*>
int-compare <*pattern*> **greater** <*pattern*> <*sequence number*>
int-compare <*pattern*> **less-equal** <*pattern*>
int-compare <*pattern*> **less-equal** <*pattern*> <*sequence number*>
int-compare <*pattern*> **less** <*pattern*>
int-compare <*pattern*> **less** <*pattern*> <*sequence number*>
int-compare <*pattern*> **not-equal** <*pattern*>
int-compare <*pattern*> **not-equal** <*pattern*> <*sequence number*>

Syntax Description

<*pattern*>	Specifies the expression to be used for comparison. This can be a test string, a regular expression, a variable, or a variable function. Text strings should be enclosed in quotation marks. This pattern returns an integer value for HMR processing.
equal	Specifies the condition is returned true if the first expression is equal to the second expression.
greater-equal	Specifies the condition is returned true if the first expression is greater than or equal to the second expression.
greater	Specifies the condition is returned true if the first expression is greater than the second expression.
less-equal	Specifies the condition is returned true if the first expression is less than or equal to the second expression.
less	Specifies the condition is returned true if the first expression is less than the second expression.
not-equal	Specifies the condition is returned true if the first expression is not equal to the second expression.
<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no header manipulation rules are configured.

Command History

Release R11.10.0	Command was introduced.

Functional Notes

The **int-compare** command is used to compare two integer expressions. The integer value is derived from the information contained in the expression. The comparison results in a true or false logical condition, which in turn causes other HMR rules to be enforced or discarded based on the rule's configured condition blocks.

The condition block is entered using the **if** or **for** commands (refer to the commands *if on page 4781* and *for on page 4779*), which signify the beginning of the logical block. The logical block is configured to discard or enforce HMR actions (such as modifying, adding, or removing headers, etc.) based on the use of the **not**, **all**, or **any** logical commands. Additionally, the **compare** and **evaluate** commands can be used in an **if** block to specify whether conditional logic criteria are met by comparing or evaluating specified criteria. Based on the logical commands contained within the block, HMR actions are enforced or discarded according to the configured action.

Usage Examples

The following example configures the HMR rule **RULE1** to be applied if the expression comparison conditions are resolved to true. In this case, the rule is configured to compare two expressions for equality, judged on the integer value, and then to modify the SIP header if the expressions are equal.

(config)**#hmr rule-set SET1**
(config-rule-set-SET1)**#message-rule RULE1**
(config-msg-rule-RULE1)**#if**
(config-msg-rule-RULE1)**#int-compare "teststring1" equal "teststring2"**
(config-msg-rule-RULE1)**#modify body new-value PATTERN1**
(config-msg-rule-RULE1)**#end-if**

match body

Use the **match body** command from the Message Rule Set Configuration mode to specify a Session Initiation Protocol (SIP) message body to match in SIP messages using SIP header manipulation rules (HMR). Match commands allow you to specify conditions that must be true in order for the SIP message rule to be processed. Use the **no** form of this command to remove the message body matching rule from the rule set. Variations of this command include:

match body
match body match-value <*pattern*>

Syntax Description

match-value <*pattern*>	Optional. Specifies the pattern to be used for matching. This can be a regular expression or a text string, and can reference variable names.

Default Values

By default, no message body matching rules are configured.

Command History

Release R11.3.0	Command was introduced.

Usage Examples

The following example specifies that the HMR rule matches the body of a SIP message when it contains the pattern **PATTERN1**:

(config-rule-set-SET1)**#message-rule RULE1 message-type any 5**
(config-msg-rule-RULE1)**#match body match-value /PATTERN1/**

match call-variable

Use the **match call-variable** command to match a Session Initiation Protocol (SIP) message based on a previously configured call ID variable when using SIP header manipulation rules (HMR). Call ID variables are created based on the call ID from SIP messages. Use the **no** form of this command to remove the variable matching rule from the HMR message rule set. Variations of this command include:

match call-variable <*variable*>
match call-variable <*variable*> **match-value** <*pattern*>

Syntax Description

<*variable*>	Specifies a previously created call ID variable to use for matching. Call ID variables are expressed in the format **%callid.myVariable%**.
match-value <*pattern*>	Optional. Specifies the pattern to be used for matching. This can be a regular expression or a text string, and can reference variable names. A text string must be enclosed in quotation marks.

Default Values

By default, no call ID variables are configured.

Command History

Release R12.1.0	Command was introduced.

Functional Notes

If a pattern value is specified, the variable must contain the specified value in order for the rule to be processed. If the pattern is not specified, the match resolves as true if the variable is defined.

Call ID variable storage for a given call ID is limited to the lifetime of the associated call structure or lifetime of the SIP proxy call. Call ID variable storage for a non-call call ID is limited to 20 seconds beyond the last detected usage of the variable associated with the call ID.

Usage Examples

The following example creates a rule to match the call ID variable **callid.myUnitNumber** with a pattern of **253**:

(config-rule-set-SET1)**#message-rule RULE1 message-type any 5**
(config-msg-rule-RULE1)**#match call-variable calllid.myUnitNumber match-value “253”**

match header

Use the **match header** command from the Message Rule Set Configuration mode to specify a Session Initiation Protocol (SIP) header to match in SIP messages using SIP header manipulation rules (HMR). Match commands allow you to specify conditions that must be true in order for the SIP message rule to be processed. Use the **no** form of this command to remove the header matching rule from the rule set. Variations of this command include:

match header <*header*>
match header <*header*> **match-value** <*pattern*>

Syntax Description

<*header*>	Specifies the SIP header type in the SIP message that you want to match. Header types are outlined in the *Functional Notes* below.
match-value <*pattern*>	Optional. Specifies the pattern to be used for header matching. This can be a regular expression or a text string, and can reference variable names. A text string must be enclosed in quotation marks.

Default Values

By default, no header matching rules are configured.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

If a **match header** command is present in the message rule's configuration, the message rule is processed only if the **match header** resolves as true. Multiple match header commands can be present in a message rule, but all of them must resolve as true for the message rule to be processed.

SIP headers available for matching include the following:

Accept-Contact	Allow	Allow-Events
Call-Id	Contact	Content-Encoding
Content-Length	Content-Type	Diversion
Event	From	Identity
Identity-info	P-Asserted-Identity	P-Preferred-Identity
Record-Route	Refer-To	Referred-By
Reject-Contact	Replaces	Request-Disposition
Route	Session-Expires	Sip-Req-Uri
Sip-Status-Line	Subject	Supported

To	Via	<*name*> (specifies another header not listed here)

SIP headers can also be expressed in compact form in a SIP message. Compact forms of the header name will match the full SIP header name.

If both the header and a match pattern are specified, the indicated SIP header must be present in the SIP message and must contain the specified pattern for the rule to resolve as true. If only the SIP header is specified, the SIP message must contain the specified SIP header for the rule to resolve as true.

Usage Examples

The following example specifies that the HMR rule matches SIP headers based on a specific header and the pattern in REFER requests:

(config-rule-set-SET1)**#message-rule RULE1 message-type any 5**
(config-msg-rule-RULE1)**#match header sip-req-uri match-value /^REFER.*/**

match private-variable

Use the **match private-variable** command to match a Session Initiation Protocol message based on a previously configured private variable when using SIP header manipulation rules (HMR). Private variables are configured using the command *set private-variable on page 4806*. Use the **no** form of this command to remove the variable matching rule from the HMR message rule set. Variations of this command include:

match private-variable <*variable*>
match private-variable <*variable*> **match-value** <*pattern*>

Syntax Description

<*variable*>	Specifies a previously configured variable to use for matching. Variables are expressed in the format **%private.VariableName%**.
match-value <*pattern*>	Optional. Specifies the pattern to be used for matching. This can be a regular expression or a text string, and can reference variable names. A text string must be enclosed in quotation marks.

Default Values

By default, no private variables are configured.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

If a pattern value is specified, the variable must contain the specified value in order for the rule to be processed. If the pattern is not specified, the match resolves as true if the variable is defined.

Usage Examples

The following example creates a rule to match the private variable **myUnitNumber** with a pattern of **253**:

(config-rule-set-SET1)**#message-rule RULE1 message-type any 5**
(config-msg-rule-RULE1)**#match private-variable myUnitNumber match-value “253”**

match public-variable

Use the **match public-variable** command to match a Session Initiation Protocol message based on a previously configured public variable when using SIP header manipulation rules (HMR). Public variables are configured using the command *set public-variable on page 4809*. Use the **no** form of this command to remove the variable matching rule from the HMR message rule set. Variations of this command include:

match public-variable <*variable*>
match public-variable <*variable*> **match-value** <*pattern*>

Syntax Description

<*variable*>	Specifies a previously configured variable to use for matching. Variables are expressed in the format **%public.VariableName%**.
match-value <*pattern*>	Optional. Specifies the pattern to be used for matching. This can be a regular expression or a text string, and can reference variable names. Text strings must be enclosed in quotation marks.

Default Values

By default, no public variables are configured.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

If a pattern value is specified, the variable must contain the specified value in order for the rule to be processed. If the pattern is not specified, the match resolves as true if the variable is defined.

Usage Examples

The following example creates a rule to match the public variable **myUnitNumber** with a pattern of **262**:

(config-rule-set-SET1)**#message-rule RULE1 message-type any 5**
(config-msg-rule-RULE1)**#match private-variable myUnitNumber match-value “262”**

message-rule

Use the **message-rule** command from the Session Initiation Protocol (SIP) header manipulation rule (HMR) Rule Set Configuration mode to create a message rule for the rule set, and enter the message rule's configuration mode. This command specifies the type of messages to which the manipulation rules are applied. Use the **no** form of this command to remove the message rule. Variations of this command include:

message-rule <*name*>
message-rule <*name*> <*sequence number*>
message-rule <*name*> **message-type any**
message-rule <*name*> **message-type any** <*sequence number*>
message-rule <*name*> **message-type request**
message-rule <*name*> **message-type request** <*sequence number*>
message-rule <*name*> **message-type response**
message-rule <*name*> **message-type response** <*sequence number*>

Syntax Description

<*name*>	Specifies the name of the message rule. Message rule names must be unique within the HMR rule set.
message-type any	Optional. Specifies that the message rule is applied to both SIP request and response messages.
message-type request	Optional. Specifies that the message rule is applied to SIP request messages.
message-type response	Optional. Specifies that the message rule is applied to SIP response messages.
<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no message rules are configured.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

A message rule is a collection of one or more header commands, which determine the types of SIP headers to act upon, and the action to be taken. When a message rule is applied to a SIP message, all matching header commands are processed. Message rules are processed in the order determined by the sequence number of the message rule within the rule set. When multiple rules are applied to a message, the results of each rule are applied before the next rule is evaluated and applied.

Usage Examples

The following example creates a message rule named **RULE1** that applies to **any** SIP message type and has a sequence number of **5**. In addition, the example enters the rule's configuration mode:

(config)**#hmr rule-set SET1**
(config-rule-set-SET1)**#message-rule RULE1 message-type any 5**
(config-msg-rule-RULE1)#

modify body

Use the **modify body** command to use Session Initiation Protocol (SIP) header manipulation rules (HMR) to modify the body of a SIP message. This command is entered from the HMR Message Rule Set Configuration mode. Use the **no** form of this command to remove the rule from the message rule set. Variations of this command include:

modify body match-value <*pattern*> **new-value** <*pattern*>
modify body match-value <*pattern*> **new-value** <*pattern*> <*sequence number*>
modify body new-value <*pattern*>
modify body new-value <*pattern*> <*sequence number*>

Syntax Description

match-value <*pattern*>	Optional. Specifies the pattern to be used for matching. This can be a regular expression or a text string, and can reference variable names.
new-value <*pattern*>	Specifies the value to be assigned to the SIP message body. This can be a regular expression or a text string. Text strings must be enclosed in quotation marks.
<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no message body manipulation rules are configured.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

If the match pattern is provided, the content of the message is only modified if the message contains the specified match pattern. If no match pattern is specified, the message body is modified unconditionally.

When the SIP message body is modified, SIP HMR automatically adjusts the Content-Length header of the message to match the length of the new value.

Usage Examples

The following example specifies that body of a SIP message is modified when it matches the variable **PATTERN1**:

(config-rule-set-SET1)**#message-rule RULE1 message-type any 5**
(config-msg-rule-RULE1)**#modify body new-value PATTERN1**

modify header position

Use the **modify header position** command from the Session Initiation Protocol (SIP) header manipulation rule (HMR) Message Rule Set Configuration mode to specify a SIP header to modify. Use the **no** form of this command to remove the header modification rule from the rule set. Variations of this command include:

modify header <*header*> **position all new-value** <*pattern*>
modify header <*header*> **position all new-value** <*pattern*> <*sequence number*>
modify header <*header*> **position all match-value** <*pattern*> **new-value** <*pattern*>
modify header <*header*> **position all match-value** <*pattern*> **new-value** <*pattern*> <*sequence number*>
modify header <*header*> **position first new-value** <*pattern*>
modify header <*header*> **position first new-value** <*pattern*> <*sequence number*>
modify header <*header*> **position first match-value** <*pattern*> **new-value** <*pattern*>
modify header <*header*> **position first match-value** <*pattern*> **new-value** <*pattern*> <*sequence number*>
modify header <*header*> **position first-match new-value** <*pattern*>
modify header <*header*> **position first-match new-value** <*pattern*> <*sequence number*>
modify header <*header*> **position first-match match-value** <*pattern*> **new-value** <*pattern*>
modify header <*header*> **position first-match match-value** <*pattern*> **new-value** <*pattern*> <*sequence number*>
modify header <*header*> **position last new-value** <*pattern*>
modify header <*header*> **position last new-value** <*pattern*> <*sequence number*>
modify header <*header*> **position last match-value** <*pattern*> **new-value** <*pattern*>
modify header <*header*> **position last match-value** <*pattern*> **new-value** <*pattern*> <*sequence number*>

Syntax Description

<*header*>	Specifies the SIP header type in the SIP message that you want to modify. Header types are outlined in the *Functional Notes* below.
all	Specifies that all matching headers of the specified type are modified.
first	Specifies that the first header of the specified type is modified.
first-match	Specifies that the first matching header of the specified header type, regardless of its position within the message, is modified.
last	Specifies the last header of the specified type is modified.
match-value <*pattern*>	Optional. Specifies the pattern to be used for header matching. This can be a regular expression or a text string, and can reference variable names.
new-value <*pattern*>	Specifies the value to be assigned to the header. This can be a regular expression or a text string.
<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no SIP headers are modified.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

Multiple headers of the same type can occur in SIP messages, and therefore, the specified position of the header can determine whether a match occurs. For more information, refer to *Appendix B: Matching Regular Expressions in SIP Messages with Multiples of the Same Header* in the configuration guide *Manipulating SIP Headers and Messages in AOS*, available online at http://supportforums.adtran.com.

SIP headers available for matching include the following:

Accept-Contact	Allow	Allow-Events
Call-Id	Contact	Content-Encoding
Content-Length	Content-Type	Diversion
Event	From	Identity
Identity-info	P-Asserted-Identity	P-Preferred-Identity
Record-Route	Refer-To	Referred-By
Reject-Contact	Replaces	Request-Disposition
Route	Session-Expires	Sip-Req-Uri
Sip-Status-Line	Subject	Supported
To	Via	<*name*> (specifies another header not listed here)

SIP headers can also be expressed in compact form in a SIP message. Compact forms of the header name will match the full SIP header name.

If both the header and a match pattern are specified, the indicated SIP header must be present in the SIP message and must contain the specified pattern for the rule to resolve as true. If only the SIP header is specified, the SIP message must contain the specified SIP header for the rule to resolve as true.

Usage Examples

The following example modifies the Contact header in the SIP message by adding **<>** to Contact headers that do not contain them:

(config-rule-set-SET1)**#message-rule RULE1 message-type any 5**
(config-msg-rule-RULE1)**#modify header contact position all match-value /([^<]*)(sip:.*@.*[^;])(.*/ new-value /\1<\2>\3/**

not

Use the **not** command from the Message Rule Set Configuration mode to specify that a Session Initiation Protocol (SIP) header manipulation rule (HMR) is executed after a test for the negative of the configured logical block conditions. Use the **no** version of this command to remove the action. Variations of this command include:

not
not <*sequence number*>

Syntax Description

<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no header manipulation rules are configured.

Command History

Release R11.10.0	Command was introduced.

Functional Notes

If the **not** command is present in the message rule's configuration, the message rule is processed if any of the previously stated conditions in the condition block are resolved as false. The condition blocks also use the command *end on page 4775*, which signifies the end of the conditions that must be met.

The condition block is entered using the **if** or **for** commands (refer to the commands *if on page 4781* and *for on page 4779*), which signify the beginning of the logical block. The logical block is configured to discard or enforce HMR actions (such as modifying, adding, or removing headers, etc.) based on the use of the **not**, **all**, or **any** logical commands. Additionally, the **compare** and **evaluate** commands can be used in an **if** block to specify whether conditional logic criteria are met by comparing or evaluating specified criteria. Based on the logical commands contained within the block, HMR actions are enforced or discarded according to the configured action.

Usage Examples

The following example configures the HMR rule **RULE1** to be applied if any configured conditions are resolved to be false. In this case, the rule is configured to match both the Via header and the Identity header, and then to modify the body of messages without either header using the **not** command. Like other conditional block commands in HMR, this configuration requires the **end-not** command to signal the end of the conditional block.

(config)**#hmr rule-set SET1**
(config-rule-set-SET1)**#message-rule RULE1**
(config-msg-rule-RULE1)**#if**
(config-msg-rule-RULE1)**#not**
(config-msg-rule-RULE1)**#modify body new-value PATTERN1**
(config-msg-rule-RULE1)**#end-not**
(config-msg-rule-RULE1)**#match header via**
(config-msg-rule-RULE1)**#match header identity**
(config-msg-rule-RULE1)**#end-if**

remove header position

Use the **remove header position** command to remove Session Initiation Protocol (SIP) headers from SIP messages when the header is matched using SIP header manipulation rules (HMR). This command is executed from the HMR Message Rule Set Configuration mode. Use the **no** form of this command to remove the rule from the message rule set. Variations of this command include:

remove header <*header*> **position all**
remove header <*header*> **position all** <*sequence number*>
remove header <*header*> **position all match-pattern** <*pattern*>
remove header <*header*> **position all match-pattern** <*pattern*> <*sequence number*>
remove header <*header*> **position first**
remove header <*header*> **position first** <*sequence number*>
remove header <*header*> **position first match-pattern** <*pattern*>
remove header <*header*> **position first match-pattern** <*pattern*> <*sequence number*>
remove header <*header*> **position first-match**
remove header <*header*> **position first-match** <*sequence number*>
remove header <*header*> **position first-match match-pattern** <*pattern*>
remove header <*header*> **position first-match match-pattern** <*pattern*> <*sequence number*>
remove header <*header*> **position last**
remove header <*header*> **position last** <*sequence number*>
remove header <*header*> **position last match-pattern** <*pattern*>
remove header <*header*> **position last match-pattern** <*pattern*> <*sequence number*>

Syntax Description

<*header*>	Specifies the SIP header type that you want to remove from the SIP message. Header types are outlined in the *Functional Notes* below.
all	Specifies that all matching headers of the specified type are removed.
first	Specifies that the first header of the specified type is removed.
first-match	Specifies that the first matching header of the specified header type, regardless of its position within the message, is removed.
last	Specifies the last header of the specified type is removed.
match-value <*pattern*>	Optional. Specifies the pattern to be used for header matching. This can be a regular expression or a text string, and can reference variable names.
<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no remove header rules are configured.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

Multiple headers of the same type can occur in SIP messages, and therefore, the specified position of the header can determine whether a match occurs. For more information, refer to *Appendix B: Matching Regular Expressions in SIP Messages with Multiples of the Same Header* in the configuration guide *Manipulating SIP Headers and Messages in AOS*, available online at http://supportforums.adtran.com.

SIP headers available for matching include the following:

Accept-Contact	Allow	Allow-Events
Call-Id	Contact	Content-Encoding
Content-Length	Content-Type	Diversion
Event	From	Identity
Identity-info	P-Asserted-Identity	P-Preferred-Identity
Record-Route	Refer-To	Referred-By
Reject-Contact	Replaces	Request-Disposition
Route	Session-Expires	Sip-Req-Uri
Sip-Status-Line	Subject	Supported
To	Via	<*name*> (specifies another header not listed here)

SIP headers can also be expressed in compact form in a SIP message. Compact forms of the header name will match the full SIP header name.

If both the header and a match pattern are specified, the indicated SIP header must be present in the SIP message and must contain the specified pattern for the rule to resolve as true. If only the SIP header is specified, the SIP message must contain the specified SIP header for the rule to resolve as true.

Usage Examples

The following example specifies that the **Proprietary1** header is removed from the first position in all SIP messages:

(config-rule-set-SET1)**#message-rule RULE1 message-type any 5**
(config-msg-rule-RULE1)**#remove header Proprietary1 position first**

renumber

Use the **renumber** command with the Session Initiation Protocol (SIP) header manipulation rules (HMR) configuration to renumber individual actions within a message rule. This command is executed from the HMR Message Rule Set Configuration mode. The new number assignments start at 10 and are incremented by 10 for each action.

Syntax Description

No subcommands.

Default Values

By default, rule actions are numbered by the order in which they were entered, in increments of 10, starting with zero (unless otherwise defined).

Command History

Release R12.2.0	Command was introduced.

Usage Examples

The following example renumbers the **if** action rules within **RULE1**:

(config)**#hmr rule-set SET1**
(config-rule-set-SET1)**#message-rule RULE1**
(config-msg-rule-RULE1)**#match header sip-req-uri match-value /^REFER.*/**
(config-msg-rule-RULE1)**#if**
(config-msg-rule-RULE1)**#compare “teststring1” equal “teststring2”**
(config-msg-rule-RULE1)**#else**
(config-msg-rule-RULE1)**#modify body new-value PATTERN1**
(config-msg-rule-RULE1)**#end-if**
(config-msg-rule-RULE1)**#if**
(config-msg-rule-RULE1)**#match header sip-req-uri match-value /^REFER.*/**
(config-msg-rule-RULE1)**#modify body new-value PATTERN1**
(config-msg-rule-RULE1)**#end-if**
(config-msg-rule-RULE1)**#renumber**

rule-set

Use the **rule-set** command to apply a rule set to a Session Initiation Protocol (SIP) header manipulation rule (HMR) policy. This command is executed from the HMR Policy Configuration mode. Use the **no** form of this command to remove the rule set from the policy. Variations of this command include:

rule-set <*name*>
rule-set <*name*> <*sequence number*>

Syntax Description

<*name*>	Specifies the previously created rule set that you want to apply to the HMR policy. Multiple rule sets can be added to a single policy. When multiple rule sets are applied to a policy, the results of each rule set are applied before the next rule set is evaluated and applied.
<*sequence number*>	Optional. Specifies the sequence number given to the rule set, which determines the order in which the rule sets are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no HMR rule sets are configured or applied to HMR policies.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example adds the previously created rule set **SET1** to the HMR policy **POLICY1**:

(config)**#hmr policy POLICY1**
(config-policy-POLICY1)**#rule-set SET1**

set callid-variable

Use the **set callid-variable** command to set the value of a call ID variable to use with Session Initiation Protocol (SIP) header manipulation rules (HMR) configuration. This command is executed from the HMR Message Rule Set Configuration mode. Use the **no** form of this command to delete the variable. Variations of this command include:

set callid-variable <*name*> **body match-value** <*pattern*> **new-value** <*pattern*>
set callid-variable <*name*> **body match-value** <*pattern*> **new-value** <*pattern*> <*sequence number*>
set callid-variable <*name*> **header** <*header*> **position first match-value** <*pattern*> **new-value** <*pattern*>
set callid-variable <*name*> **header** <*header*> **position first match-value** <*pattern*> **new-value** <*pattern*> <*sequence number*>
set callid-variable <*name*> **header** <*header*> **position first-match match-value** <*pattern*> **new-value** <*pattern*>
set callid-variable <*name*> **header** <*header*> **position first-match match-value** <*pattern*> **new-value** <*pattern*> <*sequence number*>
set callid-variable <*name*> **header** <*header*> **position last match-value** <*pattern*> **new-value** <*pattern*>
set callid-variable <*name*> **header** <*header*> **position last match-value** <*pattern*> **new-value** <*pattern*> <*sequence number*>
set callid-variable <*name*> **match-value** <*pattern*> **new-value** <*pattern*>
set callid-variable <*name*> **match-value** <*pattern*> **new-value** <*pattern*> <*sequence number*>
set callid-variable <*name*> **new-value** <*pattern*>
set callid-variable <*name*> **new-value** <*pattern*> <*sequence number*>
set callid-variable <*name*> **new-value** <*pattern*> **match-value** <*pattern*>
set callid-variable <*name*> **new-value** <*pattern*> **match-value** <*pattern*> <*sequence number*>

Syntax Description

<*name*>	Specifies the name of the call ID variable. Call ID variables are referenced in the format **%callid.variablename%**.
body	Optional. Specifies that matching occurs on the body of the SIP message.
header <*header*>	Optional. Specifies whether the optional match pattern applies to the contents of a SIP header or to the existing contents of the variable. Available header types are outlined in the *Functional Notes* below.
match-value <*pattern*>	Optional. Specifies the pattern to be used for matching. This can be a regular expression or a text string, and can reference variable names.
new-value <*pattern*>	Specifies the value to be assigned to the variable. This can be a regular expression or a text string.
position first	Optional. Specifies that the first header of the specified type is used as a data source for the variable.
position first-match	Optional. Specifies that the first matching header of the specified header type, regardless of its position within the message, is used as a data source for the variable.
position last	Optional. Specifies the last header of the specified type is used as a data source for the variable.

<sequence number>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of 10 and all rules are processed in sequence.

Default Values

By default, no variables are configured.

Command History

Release R12.2.0	Command was introduced.

Functional Notes

Call ID variables allow the storage and retrieval of data to and from named variables. The variables are scoped by the call ID from the SIP messages (thus preventing confusion of data between call threads). In addition, call ID information from the two separate SIP call legs within one call structure are associated with each other, allowing HMR rules to access information from both.

Call ID variables are stored for the lifetime of the associated call structure, or the lifetime of the SIP proxy call. The lifetime of a call ID variable for a given non-call call ID is limited to 20 seconds beyond the last detected usage of a variable associated with the call ID.

Multiple headers of the same type can occur in SIP messages, and therefore, the specified position of the header can determine whether a match occurs. For more information, refer to *Appendix B: Matching Regular Expressions in SIP Messages with Multiples of the Same Header* in the configuration guide *Manipulating SIP Headers and Messages in AOS*, available online at http://supportforums.adtran.com.

SIP headers available for matching include the following:

Accept-Contact	Allow	Allow-Events
Call-Id	Contact	Content-Encoding
Content-Length	Content-Type	Diversion
Event	From	Identity
Identity-Info	P-Asserted-Identity	P-Preferred-Identity
Record-Route	Refer-To	Referred-By
Reject-Contact	Replaces	Request-Disposition
Route	Session-Expires	Sip-Req-Uri
Sip-Status-Line	Subject	Supported
To	Via	*<name>* (specifies another header not listed here)

SIP headers can also be expressed in compact form in a SIP message. Compact forms of the header name will match the full SIP header name.

If both the header and a match pattern are specified, the indicated variable is modified if the header is present and contains the match value. If only the match pattern is specified, the match pattern is applied to the variable's current value.

In AOS firmware release R11.6.0, additional manipulation capability is included for both public and private variables. These features allow you to perform additional operations on the content of both public and private variables. These operations include (but are not limited to) appending to, deleting from, or replacing variable content as well as searching or comparing variable content. To perform these operations on variable content, manipulative actions are specified in the variable's pattern definition. When the variable is defined with one of these commands, a new value (**new-value** *<pattern>*) or a match value (**match-value** *<pattern>*) can also be defined. These values, specified in the *<pattern>* parameter, are expressed as a regular expressions or text strings. To perform additional operations on the content of the variable, you can specify an action in the *<pattern>* parameter of the new or matched value. In this case, the *<pattern>* parameter is not just a regular expression or text string, but rather a combination of the variable name and the operation you want to perform on the variable's content; it is expressed as *<variable name>.<function>*, so that, for example, **set callid-variable %CALLIDVAR1% match-value MATCH** becomes **set callid-variable %CALLIDVAR1% match-value %CALLIDVAR1%.add(1)**. The *<variable name>* parameter in this instance is the variable that contains the content to be manipulated, and the *<function>* parameter is the manipulative action to be applied to that content. Function pattern definitions are outlined in the configuration guide *Manipulating SIP Headers and Messages in AOS*, available online at http://supportforums.adtran.com.

Usage Examples

The following example sets a call ID variable called **callID1**:

(config)**#hmr rule-set SET1**
(config-rule-set-SET1)**#message-rule RULE1**
(config-msg-rule-RULE1)**#set callid-variable callID1 new-value callID2**

set private-variable

Use the **set private-variable** command to set the value of a private variable to use with Session Initiation Protocol (SIP) header manipulation rules (HMR) configuration. Private variables are only visible within a single HMR policy. This command is executed from the HMR Message Rule Set Configuration mode. Use the **no** form of this command to delete the variable. Variations of this command include:

set private-variable <*name*> **body match-value** <*pattern*> **new-value** <*pattern*>
set private-variable <*name*> **body match-value** <*pattern*> **new-value** <*pattern*> <*sequence number*>
set private-variable <*name*> **header** <*header*> **position first new-value** <*pattern*>
set private-variable <*name*> **header** <*header*> **position first new-value** <*pattern*> <*sequence number*>
set private-variable <*name*> **header** <*header*> **position first new-value** <*pattern*> **match-value** <*pattern*>
set private-variable <*name*> **header** <*header*> **position first new-value** <*pattern*> **match-value** <*pattern*> <*sequence number*>
set private-variable <*name*> **header** <*header*> **position first-match new-value** <*pattern*>
set private-variable <*name*> **header** <*header*> **position first-match new-value** <*pattern*> <*sequence number*>
set private-variable <*name*> **header** <*header*> **position first-match new-value** <*pattern*> **match-value** <*pattern*>
set private-variable <*name*> **header** <*header*> **position first-match new-value** <*pattern*> **match-value** <*pattern*> <*sequence number*>
set private-variable <*name*> **header** <*header*> **position last new-value** <*pattern*>
set private-variable <*name*> **header** <*header*> **position last new-value** <*pattern*> <*sequence number*>
set private-variable <*name*> **header** <*header*> **position last new-value** <*pattern*> **match-value** <*pattern*>
set private-variable <*name*> **header** <*header*> **position last new-value** <*pattern*> **match-value** <*pattern*> <*sequence number*>
set private-variable <*name*> **new-value** <*pattern*>
set private-variable <*name*> **new-value** <*pattern*> <*sequence number*>
set private-variable <*name*> **new-value** <*pattern*> **match-value** <*pattern*>
set private-variable <*name*> **new-value** <*pattern*> **match-value** <*pattern*> <*sequence number*>

Syntax Description

<*name*>	Specifies the name of the variable. Variables are referenced in the format **%private.variablename%**.
body	Optional. Specifies that the match pattern applies to the body of the SIP message.
header <*header*>	Optional. Specifies whether the optional match pattern applies to the contents of a SIP header or to the existing contents of the variable. Available header types are outlined in the *Functional Notes* below.
position first	Optional. Specifies that the first header of the specified type is used as a data source for the variable.
position first-match	Optional. Specifies that the first matching header of the specified header type, regardless of its position within the message, is used as a data source for the variable.

position last	Optional. Specifies the last header of the specified type is used as a data source for the variable.
match-value <*pattern*>	Optional. Specifies the pattern to be used for matching. This can be a regular expression or a text string, and can reference variable names.
new-value <*pattern*>	Specifies the value to be assigned to the variable. This can be a regular expression or a text string.
<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no variables are configured.

Command History

Release R10.1.0	Command was introduced.
Release R11.3.0	Command was expanded to include the **body** parameter.
Release R11.6.0	Command was expanded to include variable manipulation in the <*pattern*> parameter.

Functional Notes

Multiple headers of the same type can occur in SIP messages, and therefore, the specified position of the header can determine whether a match occurs. For more information, refer to *Appendix B: Matching Regular Expressions in SIP Messages with Multiples of the Same Header* in the configuration guide *Manipulating SIP Headers and Messages in AOS*, available online at http://supportforums.adtran.com.

SIP headers available for matching include the following:

Accept-Contact	Allow	Allow-Events
Call-Id	Contact	Content-Encoding
Content-Length	Content-Type	Diversion
Event	From	Identity
Identity-info	P-Asserted-Identity	P-Preferred-Identity
Record-Route	Refer-To	Referred-By
Reject-Contact	Replaces	Request-Disposition
Route	Session-Expires	Sip-Req-Uri
Sip-Status-Line	Subject	Supported
To	Via	<*name*> (specifies another header not listed here)

SIP headers can also be expressed in compact form in a SIP message. Compact forms of the header name will match the full SIP header name.

If both the header and a match pattern are specified, the indicated variable is modified if the header is present and contains the match value. If only the match pattern is specified, the match pattern is applied to the variable's current value.

In AOS firmware release R11.6.0, additional manipulation capability is included for both public and private variables. These features allow you to perform additional operations on the content of both public and private variables. These operations include (but are not limited to) appending to, deleting from, or replacing variable content as well as searching or comparing variable content. To perform these operations on variable content, manipulative actions are specified in the variable's pattern definition. When the variable is define with one of these commands, a new value (**new-value** *<pattern>*) or a match value (**match-value** *<pattern>*) can also be defined. These values, specified in the *<pattern>* parameter, are expressed as a regular expressions or text strings. To perform additional operations on the content of the variable, you can specify an action in the *<pattern>* parameter of the new or matched value. In this case, the *<pattern>* parameter is not just a regular expression or text string, but rather a combination of the variable name and the operation you want to perform on the variable's content; it is expressed as *<variable name>.<function>*, so that, for example, **set private-variable %PRIVATEVAR1% match-value MATCH** becomes **set private-variable %PRIVATEVAR1% match-value %PRIVATEVAR1%.add(1)**. The *<variable name>* parameter in this instance is the variable that contains the content to be manipulated, and the *<function>* parameter is the manipulative action to be applied to that content. Function pattern definitions are outlined in the configuration guide *Manipulating SIP Headers and Messages in AOS*, available online at http://supportforums.adtran.com.

Usage Examples

The following example sets a private variable called **UNITID** that holds the value of the unit ID parameter from the **target-unit** header of the SIP message:

```
(config-rule-set-SET1)#message-rule RULE1 message-type any 5
(config-msg-rule-RULE1)#set private-variable UNITID header target-unit position first match-value
    /.*unitID=(.*)/ new-value /\1/
```

The following example manipulates the **inviteCount** private variable:

```
(config)#hmr rule-set INVITECOUNT
(config-rule-set-INVITECOUNT)#message-rule TestAdd1
(config-msg-rule-TestAdd1)#match header sip-req-uri match-value /INVITE/
(config-msg-rule-TestAdd1)#set private-variable inviteCount new-value
    /%public.inviteCount%.add(1)/
(config-msg-rule-TestAdd1)#exit
(config-rule-set-INVITECOUNT)#message-rule TestAdd2
(config-msg-rule-TestAdd2)#match private-variable match-value /10/
(config-msg-rule-TestAdd2)#add header MyInviteNotification position first new-value "INVITE count
    just hit 10!"
```

set public-variable

Use the **set public-variable** command to set the value of a public variable to use with Session Initiation Protocol (SIP) header manipulation rules (HMR) configuration. This command is executed from the HMR Message Rule Set Configuration mode. However, you can also configure public variables using the command *hmr set public-variable <variable> new-value <pattern> on page 1316*. Use the **no** form of this command to delete the variable. Variations of this command include:

set public-variable *<name>* **body match-value** *<pattern>* **new-value** *<pattern>*
set public-variable *<name>* **body match-value** *<pattern>* **new-value** *<pattern>* *<sequence number>*
set public-variable *<name>* **header** *<header>* **position first new-value** *<pattern>*
set public-variable *<name>* **header** *<header>* **position first new-value** *<pattern>* *<sequence number>*
set public-variable *<name>* **header** *<header>* **position first new-value** *<pattern>* **match-value** *<pattern>*
set public-variable *<name>* **header** *<header>* **position first new-value** *<pattern>* **match-value** *<pattern>* *<sequence number>*
set public-variable *<name>* **header** *<header>* **position first-match new-value** *<pattern>*
set public-variable *<name>* **header** *<header>* **position first-match new-value** *<pattern>* *<sequence number>*
set public-variable *<name>* **header** *<header>* **position first-match new-value** *<pattern>* **match-value** *<pattern>*
set public-variable *<name>* **header** *<header>* **position first-match new-value** *<pattern>* **match-value** *<pattern>* *<sequence number>*
set public-variable *<name>* **header** *<header>* **position last new-value** *<pattern>*
set public-variable *<name>* **header** *<header>* **position last new-value** *<pattern>* *<sequence number>*
set public-variable *<name>* **header** *<header>* **position last new-value** *<pattern>* **match-value** *<pattern>*
set public-variable *<name>* **header** *<header>* **position last new-value** *<pattern>* **match-value** *<pattern>* *<sequence number>*
set public-variable *<name>* **new-value** *<pattern>*
set public-variable *<name>* **new-value** *<pattern>* *<sequence number>*
set public-variable *<name>* **new-value** *<pattern>* **match-value** *<pattern>*
set public-variable *<name>* **new-value** *<pattern>* **match-value** *<pattern>* *<sequence number>*

Syntax Description

<name>	Specifies the name of the variable. Variables are referenced in the format **%public.variablename%**.
body	Optional. Specifies that matching occurs on the body of the SIP message.
header *<header>*	Optional. Specifies whether the optional match pattern applies to the contents of a SIP header or to the existing contents of the variable. Available header types are outlined in the *Functional Notes* below.
position first	Optional. Specifies that the first header of the specified type is used as a data source for the variable.
position first-match	Optional. Specifies that the first matching header of the specified header type, regardless of its position within the message, is used as a data source for the variable.

position last	Optional. Specifies the last header of the specified type is used as a data source for the variable.
match-value <*pattern*>	Optional. Specifies the pattern to be used for matching. This can be a regular expression or a text string, and can reference variable names.
new-value <*pattern*>	Specifies the value to be assigned to the variable. This can be a regular expression or a text string.
<*sequence number*>	Optional. Specifies the sequence number given to the message rule, which determines the order in which the rules are processed. Valid sequence number range is **1** to **99999**. By default, sequence numbering occurs in increments of **10**, and all rules are processed in sequence.

Default Values

By default, no variables are configured.

Command History

Release R10.1.0	Command was introduced.
Release R11.3.0	Command was expanded to include the **body** parameter.
Release R11.6.0	Command was expanded to include variable manipulation in the <*pattern*> parameter.

Functional Notes

Multiple headers of the same type can occur in SIP messages, and therefore, the specified position of the header can determine whether a match occurs. For more information, refer to *Appendix B: Matching Regular Expressions in SIP Messages with Multiples of the Same Header* in the configuration guide *Manipulating SIP Headers and Messages in AOS*, available online at http://supportforums.adtran.com.

SIP headers available for matching include the following:

Accept-Contact	Allow	Allow-Events
Call-Id	Contact	Content-Encoding
Content-Length	Content-Type	Diversion
Event	From	Identity
Identity-info	P-Asserted-Identity	P-Preferred-Identity
Record-Route	Refer-To	Referred-By
Reject-Contact	Replaces	Request-Disposition
Route	Session-Expires	Sip-Req-Uri
Sip-Status-Line	Subject	Supported
To	Via	<*name*> (specifies another header not listed here)

SIP headers can also be expressed in compact form in a SIP message. Compact forms of the header name will match the full SIP header name.

If both the header and a match pattern are specified, the indicated variable is modified if the header is present and contains the match value. If only the match pattern is specified, the match pattern is applied to the variable's current value.

In AOS firmware release R11.6.0, additional manipulation capability is included for both public and private variables. These features allow you to perform additional operations on the content of both public and private variables. These operations include (but are not limited to) appending to, deleting from, or replacing variable content as well as searching or comparing variable content. To perform these operations on variable content, manipulative actions are specified in the variable's pattern definition. When the variable is define with one of these commands, a new value (**new-value** *<pattern>*) or a match value (**match-value** *<pattern>*) can also be defined. These values, specified in the *<pattern>* parameter, are expressed as a regular expressions or text strings. To perform additional operations on the content of the variable, you can specify an action in the *<pattern>* parameter of the new or matched value. In this case, the *<pattern>* parameter is not just a regular expression or text string, but rather a combination of the variable name and the operation you want to perform on the variable's content; it is expressed as *<variable name>.<function>*, so that, for example, **set private-variable %PRIVATEVAR1% match-value MATCH** becomes **set private-variable %PRIVATEVAR1% match-value %PRIVATEVAR1%.add(1)**. The *<variable name>* parameter in this instance is the variable that contains the content to be manipulated, and the *<function>* parameter is the manipulative action to be applied to that content. Function pattern definitions are outlined in the configuration guide *Manipulating SIP Headers and Messages in AOS*, available online at http://supportforums.adtran.com.

Usage Examples

The following example sets a public variable called **paiTest** :

```
(config-rule-set-SET1)#message-rule RULE1 message-type any 5
(config-msg-rule-RULE1)#set public-variable paiTest new-value match
```

The following example manipulates the **inviteCount** public variable:

```
(config)#hmr rule-set INVITECOUNT
(config-rule-set-INVITECOUNT)#message-rule TestAdd1
(config-msg-rule-TestAdd1)#match header sip-req-uri match-value /INVITE/
(config-msg-rule-TestAdd1)#set public-variable inviteCount new-value /%public.inviteCount%.add(1)/
(config-msg-rule-TestAdd1)#exit
(config-rule-set-INVITECOUNT)#message-rule TestAdd2
(config-msg-rule-TestAdd2)#match public-variable match-value /10/
(config-msg-rule-TestAdd2)#add header MyInviteNotification position first new-value "INVITE count
    just hit 10!"
```

HMR INTERCEPT COMMAND SET

Header manipulation rules (HMR) intercept is an AOS feature that allows standard HMR policies to be used to alter the flow of selected SIP requests. HMR intercept policies, when created and enabled, are given first access to inbound SIP requests. These policies can be used to respond to a request, block the processing of a request, or modify a request before other SIP agents within the device gain control of the request. The HMR intercept policy's rules are evaluated to determine whether one or more rules match a given SIP request. If a match occurs, all rules that match within the policy are applied to the traffic in the same way that inbound or outbound HMR policies are applied. In addition, HMR intercept actions assigned to the intercept policy are applied to the SIP request.

Three HMR intercept actions are available: modifying requests, responding to requests, and blocking requests. The respond and block actions, when invoked, take ownership of the SIP request and no other SIP agent within the AOS device is given access to the request. The modify action, when invoked, applies the assigned policy to the request but does not take ownership of the request.

Each HMR intercept action specifies an HMR intercept policy. Respond policies accept a matching request and send the specified response. The configuration of the respond policy can specify the response code as well as any text to be used in the response. The generated responses are modified by applicable rules that are included in the response policy. Block policies accept matching requests and terminate these requests without generating a response. Modify policies apply the rules included in the policy to the request. Requests are modified before other SIP agents within the AOS device gain access to the request; however, once the policy is applied, normal SIP request processing continues.

Multiple actions can be specified for an HMR intercept policy. In addition, multiple policy assignments can be made for a given action. Matching actions are applied in sequence number order. If a respond or block action policy matches a request, ownership of the request is given to that policy and the policy selection is halted. If a modify policy matches a request, the policy is applied and policy selection continues.

For more information about configuring SIP HMR, refer to the *HMR Command Set on page 4762*. For additional SIP HMR and HMR intercept configuration information and examples, refer to the configuration guide *Manipulating SIP Headers and Messages in AOS*, available online at https://supportcommunity.adtran.com.

To enter the HMR Intercept Configuration mode, enter the **hmr intercept** command from the Global Configuration mode as follows:

```
(config)#hmr intercept
(config-hmr-intercept)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

do on page 81

The commands available in the HMR Intercept Configuration mode are listed in alphabetical order below:

block <*policy name*>

Use the **block** <*policy name*> command to specify a header manipulation rules (HMR) intercept block action. Use the **no** form of this command to remove the block action from the HMR intercept configuration. Variations of this command include:

block <*policy name*>
block <*policy name*> <*sequence number*>

Syntax Description

<*policy name*>	Specifies the name of the block action policy.
<*sequence number*>	Optional. Specifies the sequence number given to the policy, which determines the order in which the policy actions are processed. Valid sequence number range is **1** to **99999**. If no sequence number is specified, a sequence number is automatically assigned so that new actions are placed at the end of the list of configured actions.

Default Values

By default, no HMR intercept block policies are configured.

Command History

Release 12.4.0	Command was introduced.

Functional Notes

Block action policies accept matching Session Initiation Protocol (SIP) requests and terminate those requests without generating a response. The rule set for this type of policy should include a message-rule of the **request** type that contains the necessary match rules to match the inbound request. No other rules are necessary because matching causes the request to be ignored.

If any changes are made to an HMR intercept policy, the HMR feature must be shutdown and restarted, using the command *shut on page 4820*, before the changes take effect.

Usage Examples

The following example configures an HMR rule set, **BlockOtherRegisters**, an HMR policy **BlockOtherRegisters** that applies the rule set, and also creates an HMR intercept policy that blocks SIP requests that match the **BlockOtherRegisters** rule set:

(config)**#hmr rule-set BlockOtherRegisters**
(config-rule-set-BlockOtherRegisters)**#message-rule MatchBlock message-type request 10**
(config-msg-rule-MatchBlock)**#match header sip-req-uri match-value REGISTER**
(config-msg-rule-MatchBlock)**#exit**
(config-rule-set-BlockOtherRegisters)**#exit**
(config)**#hmr policy BlockOtherRegisters**
(config-policy-BlockOtherRegisters)**#rule-set BlockOtherRegisters 10**
(config-policy-BlockOtherRegisters)**#exit**

(config)**#hmr intercept**
(config-hmr-intercept)**#block BlockOtherRegisters 30**
(config-hmr-intercept)**#no shut**

modify *<policy name>*

Use the **modify** *<policy name>* command to specify a header manipulation rules (HMR) intercept modify action. Use the **no** form of this command to remove the modify action from the HMR intercept configuration. Variations of this command include:

modify *<policy name>*
modify *<policy name>* *<sequence number>*

Syntax Description

<policy name>	Specifies the name of the modify action policy.
<sequence number>	Optional. Specifies the sequence number given to the policy, which determines the order in which the policy actions are processed. Valid sequence number range is **1** to **99999**. If no sequence number is specified, a sequence number is automatically assigned so that new actions are placed at the end of the list of configured actions.

Default Values

By default, no HMR intercept modify policies are configured.

Command History

Release 12.4.0	Command was introduced.

Functional Notes

Modify action policies apply the rules included in the policy to Session Initiation Protocol (SIP) requests. The rule set for this type of policy should include a message-rule of the **request** type that contains the necessary match rules to match the inbound request as well as the HMR rules necessary to modify the message as needed.

If any changes are made to an HMR intercept policy, the HMR feature must be shutdown and restarted, using the command *shut on page 4820*, before the changes take effect.

Usage Examples

The following example configures an HMR rule set, **ModifyNotify**, an HMR policy **ModifyNotify** that applies the rule set, and also creates an HMR intercept policy that modifies SIP requests that match the **ModifyNotify** rule set:

(config)**#hmr rule-set ModifyNotify**
(config-rule-set-ModifyNotify)**#message-rule ModifyNotify message-type request 10**
(config-msg-rule-ModifyNotify)**#match header sip-req-uri match-value NOTIFY**
(config-msg-rule-ModifyNotify)**#add header MyHeader position first new-value “New Header” 10**
(config-msg-rule-ModifyNotify)**#exit**
(config-rule-set-ModifyNotify)**#exit**
(config)**#hmr policy ModifyNotify**
(config-policy-ModifyNotify)**#rule-set ModifyNotify 10**

(config-policy-ModifyNotify)**#exit**
(config)**#hmr intercept**
(config-hmr-intercept)**#modify ModifyNotify 40**
(config-hmr-intercept)**#no shut**

respond <*policy name*>

Use the **respond** <*policy name*> command to specify a header manipulation rules (HMR) intercept response action. Use the **no** form of this command to remove the response action from the HMR intercept configuration. Variations of this command include:

respond <*policy name*>
respond <*policy name*> <*sequence number*>
respond <*policy name*> **code** <*response code*>
respond <*policy name*> **code** <*response code*> <*sequence number*>
respond <*policy name*> **code** <*response code*> **text** <*"response text"*>
respond <*policy name*> **code** <*response code*> **text** <*"response text"*> <*sequence number*>
respond <*policy name*> **text** <*"response text"*>
respond <*policy name*> **text** <*"response text"*> <*sequence number*>

Syntax Description

<*policy name*>	Specifies the name of the respond action policy.
<*sequence number*>	Optional. Specifies the sequence number given to the policy, which determines the order in which the policy actions are processed. Valid sequence number range is **1** to **99999**. If no sequence number is specified, a sequence number is automatically assigned so that new actions are placed at the end of the list of configured actions.
code <*response code*>	Optional. Specifies a response code to be used in the generated response. Valid range is **1** to **999**.
text <*"response text"*>	Optional. Specifies a response text to be used in the generated response. Enter response text in quotations.

Default Values

By default, no HMR intercept respond policies are configured. When respond policies are configured, if no response code is specified, by default a response code of **200** is used.

Command History

Release 12.4.0	Command was introduced.

Functional Notes

Respond action policies accept Session Initiation Protocol (SIP) requests that match the rules of the policy and send an appropriate response. The configuration of the respond action can include both response code and response text. The generated response can be modified by applicable rules included in the policy. The rule set for this type of policy should include a message-rule of the **request** type that contains the necessary match rules to match the inbound request. A second message-rule can be included if modification of the generated response is necessary.

If any changes are made to an HMR intercept policy, the HMR feature must be shutdown and restarted, using the command *shut on page 4820*, before the changes take effect.

Usage Examples

The following example configures an HMR rule set, **RespondToRegisterFromChicago**, an HMR policy **RespondToRegisterFromChicago** that applies the rule set, and also creates an HMR intercept policy that responds to SIP requests that match the **RespondToRegisterFromChicago** rule set:

(config)**#hmr rule-set RespondToRegisterFromChicago**
(config-rule-set-RespondToRegisterFromChicago)**#message-rule MatchRegister message-type request 10**
(config-msg-rule-MatchRegister)**#match header sip-req-uri match-value REGISTER**
(config-msg-rule-MatchRegister)**#match header contact match-value PlantA**
(config-msg-rule-ModifyRegister)**#exit**
(config-rule-set-RespondToRegisterFromChicago)**#message-rule ModifyResponse message-type response 20**
(config-msg-rule-ModifyResponse)**#add header PlantHeader position first new-value “Plant A” 10**
(config-msg-rule-ModifyResponse)**#exit**
(config-rule-set-RespondToRegisterFromChicago)**#exit**
(config)**#hmr policy RespondToRegisterFromChicago**
(config-policy-RespondToRegisterFromChicago)**#rule-set RespondToRegisterFromChicago 10**
(config-policy-RespondToRegisterFromChicago)**#exit**
(config)**#hmr intercept**
(config-hmr-intercept)**#respond RespondToRegisterFromChicago code 200 10**
(config-hmr-intercept)**#no shut**

shut

Use the **shut** command to disable the header manipulation rules (HMR) intercept feature. Use the **no** form of this command to enable the policy.

Syntax Description

No subcommands.

Default Values

By default, the HMR intercept policy is not active.

Command History

Release 12.4.0	Command was introduced.

Functional Notes

Any time an HMR intercept policy is modified, it must be shut down and then re-enabled for the changes to take effect.

Usage Examples

The following example enables the HMR intercept policy:

```
(config)#hmr intercept
(config-hmr-intercept)#no shut
```

MGCP COMMAND SET

Media Gateway Control Protocol (MGCP) is a protocol that works hand-in-hand with H.323 and Session Initiation Protocol (SIP) in Voice over Internet Protocol (VoIP) services. MGCP works between a call agent or media gateway controller, usually a software switch, and a media gateway with internal endpoints. The call agents create and manage media sessions with endpoints of physical or virtual data sources through the media gateway. The media gateway is the network device that converts voice signals carried by telephone lines into data packets carried over the Internet or other packet networks. In this network structure, AOS products function as a media gateway.

To enable MGCP functionality, enter the **ip mgcp** command from the Global Configuration mode prompt as follows:

```
>enable
#configure terminal
(config)#ip mgcp
(config)#
```

MGCP gateways communicate with internal MGCP endpoints. MGCP endpoints are dedicated foreign exchange station (FXS) ports configured to use MGCP to communicate with a call agent. The endpoints are configured with a few specialized MGCP commands and a large number of commands that are similar to those used for voice user configuration.

To create an MGCP endpoint and access its configuration, enter the **voice mgcp-endpoint** <*index*> command from the Global Configuration mode prompt as follows:

```
>enable
#configure terminal
(config)#voice mgcp-endpoint 1
(config-mgcp-1)#
```

The following configuration command set describes commands associated with configuring MGCP endpoints. For more information about MGCP gateway and endpoint configuration, refer to the *MGCP in AOS* configuration guide available online at https://supportcommunity.adtran.com.

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
exit on page 83
interface on page 84

All other commands in this command set are described in this section in alphabetical order:

alc

Use the **alc** command to enable automatic level control (ALC). ALC reduces Realtime Transport Protocol (RTP) received signals that are out of specification to the predefined levels. It is not necessary to enable ALC on those networks that guarantee signal levels to be within specification. Use the **no** form of this command to disable this feature. Variations of this command include:

alc
alc level -16
alc level -17
alc level -18
alc level -19
alc level -20
alc level -21
alc level -22

Syntax Description

level -16	Optional. Specifies the ALC attenuation level is -16 dBm0.
level -17	Optional. Specifies the ALC attenuation level is -17 dBm0.
level -18	Optional. Specifies the ALC attenuation level is -18 dBm0.
level -19	Optional. Specifies the ALC attenuation level is -19 dBm0.
level -20	Optional. Specifies the ALC attenuation level is -20 dBm0.
level -21	Optional. Specifies the ALC attenuation level is -21 dBm0.
level -22	Optional. Specifies the ALC attenuation level is -22 dBm0.

Default Values

By default, ALC is disabled.

Command History

Release 14.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the Media Gateway Control Protocol (MGCP) endpoint configuration.
Release A2.04	Command was expanded to include the **level** parameters.

Usage Examples

The following example activates the ALC for MGCP endpoint **1**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#alc**

block-caller-id

Use the **block-caller-id** command to block caller ID information included in Media Gateway Control Protocol (MGCP) signaling on the endpoint. Use the **no** form of this command to allow caller ID information to appear.

Syntax Description

No subcommands.

Default Values

By default, caller ID information is allowed.

Command History

Release 10.1	Command was introduced.
Release A2	Command was added to the MGCP endpoint configuration.

Usage Examples

The following example enables caller ID information blocking on MGCP endpoint **1**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#block-caller-id**

codec-group *<name>*

Use the **codec-group** command to specify the coder-decoder (CODEC) list to be used by this account. Use the **no** form of this command to remove the CODEC list from the account.

Syntax Description

<name>	Specifies the CODEC list to be used for this account.

Default Values

By default, no CODEC lists are assigned.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was expanded to include the integrated services digital network (ISDN) trunk.
Release 15.1	Command was added to the Voice Line Configuration command set.
Release A1	Command was included in the Voice Loopback Account Configuration command set.
Release A2	Command was added to the Media Gateway Control Protocol (MGCP) Configuration command set.

Functional Notes

The **codec-group** command applies a previously configured CODEC list to an interface, voice trunk, or voice account. These lists are lists of CODECs used by the interface, trunk, or account in call negotiation, and are arranged in preferred order with the first listed CODEC being the most preferred.

CODEC lists are created using the **codec** command from the Voice CODEC List Configuration mode prompt. For more information about creating CODEC lists, refer to the *Voice CODEC List Command Set on page 4893.*

Usage Examples

The following example applies the CODEC list **List1** to the MGCP endpoint **1**:

```
(config)#voice mgcp-endpoint 1
(config-mgcp-1)#codec-group List1
```

connect fxs <*slot/port*>

Use the **connect fxs** command to connect a Media Gateway Control Protocol (MGCP) endpoint to a physical foreign exchange station (FXS) port. Use the **no** form of this command to disconnect from the physical FXS port.

Syntax Description

<*slot/port*>	Specifies the slot and port to which the MGCP endpoint will connect. Slots and ports are entered as follows: **0/1**.

Default Values

By default, the endpoint is not connected to a physical port.

Command History

Release A2	Command was introduced.

Functional Notes

This command fails if the specified FXS port is already in use on another MGCP endpoint or by a configured voice user.

Usage Examples

The following example connects MGCP endpoint **1** to the physical FXS port **0/1**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#connect fxs 0/1**

description *<text>*

Use the **description** command to give a textual description to a Media Gateway Control Protocol (MGCP) endpoint. Use the **no** form of this command to remove the endpoint's description.

Syntax Description

<text>	Specifies the textual description of the endpoint.

Default Values

By default, no description is given to an endpoint.

Command History

Release A2	Command was introduced.

Usage Examples

The following example gives the description of **farendpoint** to MGCP endpoint **1**:

(config)**#voice mgcp-endpoint1**
(config-mgcp-1)**#description farendpoint**

echo-cancellation

Use the **echo-cancellation** command to improve voice quality for packetized-based voice calls, such as Voice over Internet Protocol (VoIP) or Media Gateway Control Protocol (MGCP). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **echo-cancellation** is enabled.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the MGCP endpoint configuration.

Usage Examples

The following example activates **echo-cancellation** for MGCP endpoint **1**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#echo-cancellation**

forward-disconnect delay

Use the **forward-disconnect delay** command to modify the forward disconnect delay time (in milliseconds) for the Media Gateway Control Protocol (MGCP) endpoint. Use the **no** form of this command to return the delay period to the default value. Variations of this command include:

forward-disconnect delay 250
forward-disconnect delay 500
forward-disconnect delay 750
forward-disconnect delay 900
forward-disconnect delay 1000
forward-disconnect delay 2000
forward-disconnect delay follow-switch

Syntax Description

250	Specifies a 250 ms delay time.
500	Specifies a 500 ms delay time.
750	Specifies a 750 ms delay time.
900	Specifies a 900 ms delay time.
1000	Specifies a 1000 ms delay time.
2000	Specifies a 2000 ms delay time.
follow-switch	Specifies a delay time follows the switch.

Default Values

By default, the forward disconnect delay is set to follow the switch.

Command History

Release A2.04	Command was introduced.
Release A4.01	Command syntax was updated from **fwd-disconnect delay** to **forward-disconnect delay**.

Functional Notes

Although the MGCP endpoint forward disconnect delay is set to follow the switch by default, this delay time varies depending on the endpoint's RFC 2833 signaling specification. If the RFC 2833 signaling is enabled, then the **follow-switch** parameter indicates that the Class 5 switch determines the length of the delay time. If RFC 2833 signaling is disabled, then using **follow-switch** indicates that the battery is removed for the default time of **900** ms.

Usage Examples

The following example specifies the forward disconnect delay for MGCP endpoint **1** is **1000** ms:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)#forward-disconnect delay 1000

modem-passthrough

Use the **modem-passthrough** command to switch to passthrough mode on fax or modem tone detection. This command allows modem and fax calls to maintain a connection without altering the signals with the voice improvement settings, such as echo cancellation and voice activity detection (VAD). Use the **no** form of this command to disable this feature. Variations of this command include:

modem-passthrough
modem-passthrough detection-time <*time*>
modem-passthrough cng-early-detect

Syntax Description

detection-time <*value*>	Optional. Specifies the fax and/or modem detection time length value in seconds. Range is **0** to **8** seconds.
cng-early-detect	Optional. Enables early (first burst) detection of fax calling (CNG) tone.

Default Values

By default, **modem-passthrough** is disabled. By default, the detection time is set to **8** seconds.

Command History

Release 11.1	Command was introduced.
Release 12.1	Command was expanded.
Release A2	Command was added to the Media Gateway Control Protocol (MGCP) endpoint configuration.
Release A4.02	Command was expanded to include the **detection-time** parameter.
Release R10.8.0	Command was expanded to include the **cng-early-detect** parameter.

Usage Examples

The following example disables **modem-passthrough** on MGCP endpoint **1**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#no modem-passthrough**

name *<text>*

Use the **name** command to specify a textual name that the Media Gateway Control Protocol (MGCP) call agent will use to refer to a specific endpoint. Use the **no** form of this command to return to the default naming convention.

Syntax Description

<text>	Specifies the textual name of the MGCP endpoint.

Default Values

By default, when endpoints are created and given an index number, they are named in the following format: **aaln/x**, where **x** is the index number. For example, an endpoint with an index of **4** will by default have the name **aaln/4**.

Command History

Release A2	Command was introduced.

Usage Examples

The following example renames endpoint **1** as **endpoint243**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#name endpoint243**

nls

Use the **nls** command to enable the non-linear suppression (NLS) for the Media Gateway Control Protocol (MGCP) endpoint. This option is a component of echo cancellation. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 14.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the MGCP endpoint configuration.

Usage Examples

The following example enables NLS for MGCP endpoint **1**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#nls**

plc

Use the **plc** command to enable packet loss concealment (PLC). PLC is used to attempt to mask lost or delayed packets by replacing the lost packet with another voice packet in the data stream. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, PLC is disabled.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the Media Gateway Control Protocol (MGCP) endpoint configuration.

Usage Examples

The following example disables PLC for the MGCP endpoint **1**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#no plc**

rtp delay-mode

Use the **rtp delay-mode** command to configure the Realtime Transport Protocol (RTP) jitter buffer mode settings. RTP is used to prevent static on voice connections by enhancing the quality of the packet delivery. Use the **no** form of this command to return to the default setting. Variations of this command include:

rtp delay-mode adaptive
rtp delay-mode fixed

Syntax Description

adaptive	Configures the RTP jitter buffer packet delay to adjust during a call based on network conditions.
fixed	Configures the RTP jitter buffer packet delay to remain constant.

Default Values

By default, the RTP delay mode is set to **adaptive**. This allows for minimal latency by adjusting the average packet delay based on the conditions of the network.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the Media Gateway Control Protocol (MGCP) endpoint configuration.

Usage Examples

The following example configures RTP delay mode as **fixed** on MGCP endpoint **1**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#rtp delay-mode fixed**

rtp dtmf-relay

Use the **rtp dtmf-relay** command to configure the method by which Realtime Transport Protocol (RTP) dual tone multi-frequency (DTMF) events are relayed. The dial digits can be sent inband or out-of-band (OOB) of the voice stream. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp dtmf-relay inband
rtp dtmf-relay nte <*value*>

Syntax Description

inband	Specifies that RTP DTMF events be relayed inband in the RTP stream.
nte <*value*>	Specifies that RTP DTMF events be relayed OOB using named telephone events (NTEs). Enter an NTE value between **96** and **127**.

Default Values

By default, the **rtp dtmf-relay** is set for **NTE 101**.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the Media Gateway Control Protocol (MGCP) endpoint configuration.

Usage Examples

The following example configures RTP DTMF relay events for **inband**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#rtp dtmf-relay inband**

rtp frame-packetization <*value*>

Use the **rtp frame-packetization** command to configure the Realtime Transport Protocol (RTP) frame packetization time in milliseconds for individual Media Gateway Control Protocol (MGCP) endpoints. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Configures the RTP frame packetization time value in milliseconds. Select from **10**, **20**, or **30** milliseconds.

Default Values

By default, the **rtp frame-packetization** time is set to **20** milliseconds on all MGCP endpoints.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the MGCP endpoint configuration.

Usage Examples

The following example sets the frame packetization time for MGCP endpoint **1** to **10** milliseconds:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#rtp frame-packetization 10**

rtp packet-delay

Use the **rtp packet-delay** command to configure the maximum Realtime Transport Protocol (RTP) packet delays. This command is used to set the allowable limits of latency on the network. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp packet-delay fax <*value*>
rtp packet-delay maximum <*value*>
rtp packet-delay nominal <*value*>

Syntax Description

fax <*value*>	Sets the fax delay time value in increments of **10** milliseconds. Range is **0** to **500** milliseconds.
maximum <*value*>	Sets the maximum delay time value in increments of **10** milliseconds. Range is **40** to **320** milliseconds.
nominal <*value*>	Sets the nominal delay time value in increments of **10** milliseconds. Range is **10** to **240** milliseconds.

Default Values

By default, the RTP packet delay for fax is **50**, maximum is **100**, and for nominal is **50**.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the Media Gateway Control Protocol (MGCP) endpoint configuration.

Usage Examples

The following example configures the RTP maximum delay time on MGCP endpoint **1** to **200** milliseconds:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#rtp packet-delay maximum 200**

rtp qos dscp <*value*>

Use the **rtp qos dscp** command to configure the maximum Realtime Transport Protocol (RTP) quality of service (QoS) parameters for differentiated services code point (DSCP). Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Configures the RTP QoS parameter for DSCP. Enter a value between **10** and **63**.

Default Values

By default, the RTP QoS parameter for DSCP on Media Gateway Control Protocol (MGCP) endpoints is **46**.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the MGCP endpoint configuration.

Usage Examples

The following example configures the RTP QoS DSCP for MGCP endpoint **1** to **60**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#rtp qos dscp 60**

t38

Use the **t38** command to enable T.38 fax operation on the Media Gateway Control Protocol (MGCP) endpoint. Use the **no** form of this command to disable this feature.

*The **modem-passthrough** command must be enabled for T.38 operation to work. Refer to modem-passthrough on page 4830 for more information.*

Syntax Description

No subcommands.

Default Values

By default, T.38 is disabled.

Command History

Release 16.1	Command was introduced.
Release A2	Command was added to the MGCP endpoint configuration.

Usage Examples

The following example enables T.38 on MGCP endpoint **1**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#t38**

Technology Review

T.38 is an International Telecommunication Union (ITU) specification that allows Group-3 Fax (T.30) data to be transported over the Internet. It is similar to dual tone multi-frequency (DTMF) relay (RFC 2833) in that the digital signal processor (DSP) decodes tones and demodulated fax data and converts them into packets. A similar device on the other end takes the packets/tones and remodulates them so that an analog fax machine on the other end can receive the fax. AOS's previous support (revisions 12 through 15) for fax/modem signals was simply detecting a tone and forcing the coder-decoder (CODEC) into G.711 and disabling/enabling echo cancellers based on the tones detected. When packet loss becomes high, sending faxes over G.711 becomes problematic, due to dropped messages and timeouts/retrains.

T.38 can be used in conjunction with various call-control schemes, such as H.323, Session Initiation Protocol (SIP), and MGCP. AOS only supports SIP as the call-control method. This is typically referred to T.38/Annex-D. Annex-D describes the Session Initiation Protocol/Session Description Protocol (SIP/SDP) call establishment procedures.

t38 ced auto-generate

Use the **t38 ced auto-generate** command to specify when the digital signal processor (DSP) should regenerate the called station identifier (CED) signal toward the time division multiplexed (TDM) endpoint. If auto-generate is enabled, the DSP generates the CED signal only when it does not receive CED indicator packets from the Voice over IP (VoIP) endpoint. If auto-generate is disabled, the DSP generates the CED signal only when it does receive CED indicator packets from the VoIP endpoint. Using the **no** version of this command disables CED auto-generate.

Syntax Description

No subcommands.

Default Values

By default, CED auto-generate is disabled.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Usage Examples

The following example enables CED auto-generate for the T.38 session on the Media Gateway Control Protocol (MGCP) endpoint:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#t38 ced auto-generate**

t38 ced length <*time*>

Use the **t38 ced length** command to set the maximum duration of a regenerated called station identifier (CED) signal, in milliseconds, from the digital signal processor (DSP) toward the time division multiplexed (TDM) endpoint when a T.38 session is active. Using the **no** form of this command returns the duration to the default value.

Syntax Description

<*time*>	Specifies the maximum duration of a regenerated CED signal in milliseconds. Valid range is **0** to **4000** ms.

Default Values

By default, the maximum duration of a regenerated CED signal is **3000** ms.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Setting the maximum duration of a regenerated CED signal to **0** effectively prevents any CED generation.

Usage Examples

The following example decreases the maximum duration of the CED signal to **2000** ms for the T.38 session on the Media Gateway Control Protocol (MGCP) endpoint:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#t38 ced length 2000**

t38 cng-relay-selective

Use the **t38 cng-relay-selective** command to enable fax calling tones (CNG) relay only when V.21 messages are not being transmitted. Use the **no** version of this command to disable selective CNG relay.

Syntax Description

No subcommands.

Default Values

Selective CNG relay is disabled by default.

Command History

Release R10.4.0	Command was introduced.

Usage Examples

The following example enables T.38 CNG relay:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#t38 cng-relay-selective**

t38 ecm

Use the **t38 ecm** command to enable or disable error correction mode (ECM) during T.38 sessions. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 ecm enable
t38 ecm disable

Syntax Description

enable	Enables ECM during T.38 sessions.
disable	Disables ECM during T.38 sessions.

Default Values

By default, ECM is enabled.

Command History

Release R10.8.0	The command was introduced

Usage Examples

The following example disables ECM for T.38 sessions on MGCP endpoint 1:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#t38 ecm disable**

t38 error-correction

Use the **t38 error-correction** command to specify the type of fax error correction. Use the **no** form of this command to disable this feature. Variations of this command include:

t38 error-correction fec
t38 error-correction redundancy

Syntax Description

fec	Specifies forward error correction (FEC) as the fax error correction. FEC is a system of error control where the sender adds redundant data to its messages, allowing the receiver to detect and correct errors (within certain bounds) without the need to request additional data from the sender.
redundancy	Specifies redundancy as the fax error correction. Redundancy error correction replicates the payload a user-specified number of times to determine if errors are present. The number of redundant packets is set using the command *t38 v21-preamble-timeout <value> on page 4851*).

Default Values

By default, **t38 error-correction** is set to **redundancy** for the Total Access 900(e) Series, the NetVanta 6310/6330 Series, the NetVanta 6355 Series, the NetVanta 6240/6250 Serires, and the NetVanta 640 Series.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default value changed to **fec** for the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 6355 Series products.
Release R10.8.0	The default values for this command were updated.

Usage Examples

The following example sets the **t38 error-correction** to **fec** for the Media Gateway Control Protocol (MGCP) endpoint:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#t38 error-correction fec**

t38 fallback-mode g711

Use the **t38 fallback-mode** command to specify the transmission mode used when T.38 fax relay cannot be successfully negotiated at the time of the fax transfer. Use the **no** form of this command to disable this feature.

Syntax Description

g711	Specifies that fax operation revert back to analog mode (G.711).

Default Values

By default, **t38 fallback-mode** is to **G.711**.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default was changed to **G.711**.

Usage Examples

The following example enables the **t38 fallback-mode** on the Media Gateway Control Protocol (MGCP) endpoint:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#t38 fallback-mode g711**

t38 generate-cng

Use the **t38 generate-cng** command to specify whether the digital signal processor (DSP) will begin a T.38 session by generating the calling signal (CNG) toward the time division multiplexed (TDM) endpoint. Using the **no** version of this command disables CNG generation.

Syntax Description

No subcommands.

Default Values

By default, CNG generation is disabled.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

With the introduction of this command, the CNG generation behavior of the T.38 session is now configurable. In AOS firmware prior to A5.01, this behavior was not configurable, but rather was set to always generate this signal.

Usage Examples

The following example enables CNG generation for the T.38 session on the Media Gateway Control Protocol (MGCP) endpoint:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#t38 generate-cng**

t38 max-buffer <*value*>

Use the **t38 max-buffer** command to set the maximum buffer size for T.38 fax operation. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the value of the **max-buffer** attribute in the Session Description Protocol (SDP) offer when the T.38 session is initiated. Range is **0** to **800** bytes.

Default Values

By default, the maximum buffer size is set to **200**.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example sets the **t38 max-buffer** to **100** on the Media Gateway Control Protocol (MGCP) endpoint:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#t38 max-buffer 100**

t38 max-datagram <*value*>

Use the **t38 max-datagram** command to set the maximum datagram value in this unit. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the value of the **max-datagram** attribute in the Session Description Protocol (SDP) offer when the T.38 session is initiated. Range is **0** to **300** bytes.

Default Values

By default, the maximum datagram value is set to **72** bytes.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default was changed to **72** bytes.

Usage Examples

The following example sets the **t38 max-datagram** to **100** on the Media Gateway Control Protocol (MGCP) endpoint:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#t38 max-datagram 100**

t38 max-rate

Use the **t38 max-rate** command to specify the fax maximum rate. The actual transmission rate could be lower than specified rate if the receiving end cannot support the maximum rate. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 max-rate 14400
t38 max-rate 12000
t38 max-rate 2400
t38 max-rate 4800
t38 max-rate 7200
t38 max-rate 9600

Syntax Description

14400	Specifies 14400 bits per second (bps) as fax maximum rate.
12000	Specifies 12000 bps as fax maximum rate.
2400	Specifies 2400 bps as fax maximum rate.
4800	Specifies 4800 bps as fax maximum rate.
7200	Specifies 7200 bps as fax maximum rate.
9600	Specifies 9600 bps as fax maximum rate.

Default Values

By default, the maximum fax rate is set to **14400** bps.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example sets the **t38 max-rate** to **4800** bps on the Media Gateway Control Protocol (MGCP) endpoint:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#t38 max-rate 4800**

t38 redundancy

Use the **t38 redundancy** command to set the number of redundant packets sent when the **t38 error-correction redundancy** feature is enabled on Media Gateway Control Protocol (MGCP) endpoints. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 redundancy high-speed <*value*>
t38 redundancy low-speed <*value*>

Syntax Description

high-speed <*value*>	Specifies the number of redundant T.38 fax packets to be sent for data messages (high-speed fax machine image data). Range is **0** (no redundancy) to **4** packets.
low-speed <*value*>	Specifies the number of redundant T.38 fax packets to be sent for the signaling messages (low-speed fax machine protocol). Range is **0** (no redundancy) to **7** packets.

Default Values

By default, high-speed and low-speed redundancy values are set to **0** (no redundancy).

Command History

Release 16.1	Command was introduced.
Release A2	Command was added to the MGCP endpoint configuration.

Usage Examples

The following example enables **t38 error-correction redundancy** and sets the number of redundant data messages to **high-speed 3** on MGCP endpoint **1**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#t38 error-correction redundancy**
(config-mgcp-1)**#t38 redundancy high-speed 3**

t38 v21-preamble-timeout *<value>*

Use the **t38 v21-preamble-timeout** command to set the maximum amount of time that the digital signal processor (DSP) waits for peer device activity after starting to transmit a V.21 preamble event before spoofing a response to the time division multiplexed (TDM) endpoint. Using the **no** version of this command returns the timeout value to the default setting.

Syntax Description

<value>	The time, in milliseconds, that the DSP will wait for peer activity. Valid range is **1** to **3000** ms.

Default Values

By default, the V.21 preamble timeout is set to **1700** ms.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Usage Examples

The following example specifies the V.21 preamble timeout value as **2000** ms on the Media Gateway Control Protocol (MGCP) endpoint:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#t38 v21-preamble-timeout 2000**

vad

Use the **vad** command to enable voice activity detection (VAD) on Media Gateway Control Protocol (MGCP) endpoints. VAD blocks out noise categorized as silence during a voice connection. The silent voice packets are not transmitted, allowing bandwidth usage to be reduced. Although VAD saves bandwidth, the quality of the voice call may be compromised. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, VAD is enabled for all MGCP endpoints.

Command History

Release 9.3	Command was introduced.
Release A2	Command was added to the MGCP endpoint configuration.

Usage Examples

The following example disables VAD on MGCP endpoint **1**:

(config)**#voice mgcp-endpoint 1**
(config-mgcp-1)**#no vad**

MUSIC ON HOLD COMMAND SET

Music on hold (MOH) is a feature that allows the user to play hold music internally from a NetVanta 7000 Series unit rather than using an external music player. This feature replaces the CD player or other hardware that would normally be required to generate hold music. The MOH feature can be used for hold music, as well as for call queues and FindMe-FollowMe.

For more information about configuring MOH, refer to the quick configuration guide *Configuring Music on Hold on the NetVanta 7000 Series* available online at https://supportcommunity.adtran.com.

To specify a MOH player and enter the Voice Music on Hold Configuration mode, enter the **voice music-on-hold player** <*name*> command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice music-on-hold player moh1
(config-moh1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the section listed below:

cross-connect on page 76
do on page 81
exit on page 83

All other commands for this command set are described in this section in alphabetical order:

default on page 4854
file <filename> on page 4855

default

Use the **default** command to set the current music on hold (MOH) player as the default player. Use the **no** version of this command to restore the system default.

Default Values

By default, the **system** player is set as the default player.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the player **MOH1** as the default MOH player:

```
(config)#voice music-on-hold player MOH1
(config-moh1)#default
```

file <*filename*>

Use the **file** command to add music files to a music on hold (MOH) player. Use the **no** version of this command to remove the file from the MOH player.

Syntax Description

<*filename*>	Specifies the name of the music file to be added to the MOH player.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example adds the file named **holdmusic1.wav** to the MOH player:

(config)**#voice music-on-hold player moh1**
(config-moh1)**#file holdmusic1.wav**

PROXY USER TEMPLATE COMMAND SET

The proxy user template is an expanded function of the Session Initiation Protocol (SIP) Proxy feature on Adtran Operating System (AOS) products. By creating a proxy user template on the AOS device serving as a SIP Proxy, calls are allowed to route to a private branch exchange (PBX) even if the SIP Proxy has not received a REGISTER request from that user on the PBX. Users are dynamically added to the proxy user database when an INVITE or SUBSCRIBE message is received from the user, allowing SIP messages to be routed for the identified user. The user template makes it possible to route traffic for users not already known by the SIP Proxy. This feature can also direct certain calls to local external public switch telephone network (PSTN) gateways.

The commands in this section help you to create and define a template, as well as explain how calls received by the SIP Proxy respond to these configuration parameters. For more information about SIP Proxy configuration, refer to the configuration guide *Configuring SIP Proxy in AOS* available online at https://supportcommunity.adtran.com.

To create a proxy user template and enter the proxy user template configuration mode, enter the **sip proxy user-template** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#sip proxy user-template Set1
(config-template-Set1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

accept <template> on page 4857
expire-time <seconds> on page 4859
match on page 4860
proxy-mode on page 4861
reject <template> on page 4862
routeback-rejection on page 4864
target <host> on page 4865

accept *<template>*

Use the **accept** command to specify a number pattern to match to a user ID and add the user to the Session Initiation Protocol (SIP) Proxy user database. Once the **accept** entry is added to the proxy user template, SIP messages are permitted and routed on the proxy server for the identified user. Use the **no** form of this command to remove a configured template entry from the proxy user template.

*AOS will process the **reject** patterns before the **accept** patterns, regardless of the order they appear in the configuration of the proxy user template. Refer to reject <template> on page 4862 for additional information.*

Syntax Description

<template>	Specifies the patterns to match to a proxy user and allow the user as an entry to the SIP Proxy user database. You can enter a complete phone number, or use wildcards to define accepted numbers. Refer to *Functional Notes* below for more information on using wildcards.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Functional Notes

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example configures the **Set1** proxy user template to permit SIP messages for users with the 256-555 exchange in their ID:

(config)**#sip proxy user-template Set1**
(config-template-Set1)**#accept 256555XXXX**

expire-time *<seconds>*

Use the **expire-time** command to set the number of seconds before a proxy user entry is removed from the SIP proxy user database. In the Proxy User Template command set, this command applies to a user entry created as a result of matching the specified proxy user template. Use the **no** form of this command to return to the default value of **3600** seconds.

Syntax Description

<seconds>	Specifies the number of seconds until the user entry expires. Valid range is **30** to **86400** seconds. A value of **0** means the entry will never expire.

Default Values

By default, the expiration time is set to **3600**, which means the user entry will be removed from the database after 1 hour.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the expiration time to **7200** seconds (or 2 hours) for the **Set1** proxy user template:

(config)**#sip proxy user-template Set1**
(config-template-Set1)**#expire-time 7200**

match

Use the **match** command to configure the proxy user template match settings for specific traffic patterns. Use the **no** form of this command to disable a match setting. Variations of this command include:

match inbound
match outbound
match outbound source contact
match outbound source from
match outbound source from enable-alternate-identity

Syntax Description

inbound	Specifies that this proxy user template should be used to match against inbound traffic.
outbound	Specifies that this proxy user template should be used to match against outbound traffic.
source	Specifies the Session Initiation Protocol (SIP) header type(s) to use when matching the proxy user template against outbound traffic.
contact	Specifies that the Contact header should be used when matching the proxy user template against outbound traffic.
from	Specifies that the From header should be used when matching the proxy user template against outbound traffic.
enable-alternate-identity	Specifies that the P-Preferred-Indentity, P-Asserted-Identity or Remote-Party-ID header, if present, should be used in place of the From header when matching the proxy user template against outbound traffic.

Default Values

By default, the Contact header is used when matching the proxy user template agains outbound traffic.

Command History

Release A5.01	Command was introduced.

Functional Notes

For more information on the operation and configuration of SIP proxy, refer to the configuration guide *Configuring SIP Proxy in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the Set1 proxy user template should be used to match against outbound traffic and that the From header should be used:

(config)**#sip proxy user-template Set1**
(config-template-Set1)**#match outbound source from**

proxy-mode

Use the **proxy-mode** command to enable the appropriate Session Initiation Protocol (SIP) proxy operation mode for users added to the SIP proxy user database by the specified proxy user template. Use the **no** form of this command to return to the default setting. Variations of this command include:

proxy-mode auto
proxy-mode outbound-proxy
proxy-mode stateful
proxy-mode transparent

Syntax Description

auto	Detects the correct proxy mode automatically.
outbound-proxy	Specifies using outbound proxy mode.
stateful	Specifies using stateful proxy mode.
transparent	Specifies using transparent proxy mode.

Default Values

By default, this feature is set to **auto**. The **auto** setting detects the correct proxy mode for outbound requests based upon how the INVITE is addressed. The correct proxy mode for inbound requests cannot be initially detected until the proxy server has trained using an outbound message from the user. Therefore, in situations where it is essential to correctly identify the proxy mode for inbound messages, it is suggested to specifically configure the **proxy-mode** for **outbound-proxy**, **stateful**, or **transparent**, whichever is most appropriate for your situation.

Command History

Release A4.01	Command was introduced.

Functional Notes

For more information on the operation and configuration of SIP proxy, refer to the configuration guide *Configuring SIP Proxy in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables transparent proxy mode operation for users added by the **Set1** proxy user template:

(config)**#sip proxy user-template Set1**
(config-template-Set1)**#proxy-mode transparent**

reject *<template>*

Use the **reject** command to specify a number pattern to match to a user ID for rejection from the SIP Proxy user database. If a match is successful, SIP messages are rejected for the matching user. Use the **no** form of this command to remove a configured template entry from the proxy user template.

> NOTE *AOS will process the **reject** patterns before the **accept** patterns, regardless of the order they appear in the configuration of the proxy user template. Refer to accept <template> on page 4857 for additional information.*

Syntax Description

<template>	Specifies the patterns to match a proxy user and reject the user as an entry to the SIP proxy user database. You can enter a complete phone number, or wildcards can be used to help define rejected numbers. Refer to *Functional Notes* below for more information on using wildcards.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Functional Notes

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.

2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example configures the **Set1** proxy user template to reject the user matching ID **2565556031** as an entry to the SIP proxy user database:

(config)**#sip proxy user-template Set1**
(config-template-Set1)**#reject 2565556031**

routeback-rejection

Use the routeback-rejection command to specify that during failover the proxy user template should not be used if the Contact header matches the template's target. Use the **no** form of this command to disable routeback rejection.

Syntax Description

No subcommands.

Default Values

By default, routeback-rejection is disabled.

Command History

Release A5.01	Command was introduced.

Usage Examples

The following example enables routeback rejection for proxy user template **Set1**:

(config)**#sip proxy user-template Set1**
(config-template-Set1)**#routeback-rejection**

target <*host*>

Use the **target** command to specify the proxy user's location. This command indicates the host name or IP address, protocol, and port number to use in locating the proxy user. Use the **no** form of this command to remove the target configuration. Variations of this command include:

target <*host*>
target <*host*> **tcp**
target <*host*> **tcp** <*port*>
target <*host*> **udp**
target <*host*> **udp** <*port*>

Syntax Description

<*host*>	Specifies the fully qualified domain name (FQDN) or IP address of the target server. IP addresses should be expressed in dotted decimal notation (for example, 208.61.209.1).
tcp	Optional. Specifies using Transmission Control Protocol (TCP).
udp	Optional. Specifies using User Datagram Protocol (UDP).
<*port*>	Optional. Specifies the TCP or UDP port used by the target host. Range is **1** to **65535**.

Default Values

By default, no target server is configured. If a target is configured with no protocol or port specified, the proxy server operates using UDP on port **5060**. If a protocol is specified, but no port is specified, the proxy server uses port **5060**.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example specifies the users matching the proxy user template **Set1** are located at IP address **10.10.10.3** and to use UDP port **5061**:

(config)**#sip proxy user-template Set1**
(config-template-Set1)**#target 10.10.10.3 udp 5061**

SIP PROXY MONITOR COMMAND SET

The Session Initiation Protocol (SIP) proxy monitor feature provides support for monitored rollover to the SIP proxy in stateful mode. When the currently selected SIP server is unresponsive, the proxy uses a secondary proxy server for future calls. In the event the selected secondary SIP server becomes unresponsive, the proxy will roll over to the next available secondary server. As more preferred servers are returned to service, all future calls are routed to it.

When enabled, the SIP proxy monitor can operate in one of two modes: **continuous** or **on-failure**. In continuous mode, the proxy monitor continues to poll the currently selected SIP proxy server to determine its operational state. In contrast, the on-failure mode only polls SIP proxy servers during a detected failure state. The mode is configured using the **mode** command in this command set.

Additional monitoring behaviors can be configured to specify the poll timeout, intervals, recover response, poll requests grammar, and SNMP traps. Each configuration option is explained in detail in this command set.

For more information about SIP proxy implementation and configuration in AOS, refer to the configuration guide *Configuring SIP Proxy in AOS*, available online at http://supportforums.adtran.com.

To enable the SIP proxy SIP server monitor, and enter the SIP proxy SIP server monitor configuration mode, enter the following command from the Global Configuration mode:

```
(config)#sip proxy sip-server monitor
    Configuring New Proxy Monitor.
(config-proxy-monitor)#
```

Once you have entered the SIP Proxy SIP Server Monitor Configuration mode, you can configure the specific behavior of the proxy monitor feature.

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

grammar from user on page 4867
grammar request-uri user on page 4868
grammar to user on page 4869
mode on page 4870
poll timeout <value> on page 4871
recover on page 4872
trap rollover on page 4874

grammar from user

Use the **grammar from user** command to configure the User field of the From header on Session Initiation Protocol (SIP) proxy monitor poll requests. Use the **no** form of this command to return to the default setting. Variations of this command include:

grammar from user none
grammar from user <*username*>

Syntax Description

none	Specifies the user is not included in the User field of the From header.
<*username*>	Specifies the user name used to format the User field of the From header.

Default Values

By default, the user is not specified in the From header. The default value is set to **none**.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example sets the User field for the From header to **2565555229**:

(config)**#sip proxy sip-server monitor**
Configuring New Proxy Monitor.
(config-proxy-monitor)**#grammar from user 2565555229**

grammar request-uri user

Use the **grammar request-uri user** command to configure the Request uniform resource identifier (URI) header user on Session Initiation Protocol (SIP) proxy monitor poll requests. Use the **no** form of this command to return to the default setting. Variations of this command include:

grammar request-uri user none
grammar request-uri user <*username*>

Syntax Description

none	Specifies the user is not included in the Request-URI header.
<*username*>	Specifies the user name used to format the User field of the Request-URI header.

Default Values

By default, the user is not specified in the Request-URI header. The default value is set to **none**.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example sets the User field for the Request-URI header to **none**:

(config)**#sip proxy sip-server monitor**
Configuring New Proxy Monitor.
(config-proxy-monitor)**#grammar request-uri user none**

grammar to user

Use the **grammar to user** command to configure the User field of the To header on Session Initiation Protocol (SIP) proxy monitor poll requests. Use the **no** form of this command to return to the default setting. Variations of this command include:

grammar to user none
grammar to user <*username*>

Syntax Description

none	Specifies the user is not included in the User field of the To header.
<*username*>	Specifies the user name used to format the User field of the To header.

Default Values

By default, the user is not specified in the To header. The default value is set to **none**.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example sets the User field for the To header to **2565555229**:

(config)**#sip proxy sip-server monitor**
Configuring New Proxy Monitor.
(config-proxy-monitor)**#grammar to user 2565555229**

mode

Use the **mode** command to configure the polling behavior of the Session Initiation Protocol (SIP) proxy monitor. Use the **no** form of this command to return to the default setting. Variations of this command include:

mode continuous
mode continuous interval <*value*>
mode on-failure

Syntax Description

continuous	Specifies proactive polling of the current SIP proxy server. Even if the SIP proxy monitor detects all servers are functioning, the SIP proxy monitor continues to poll them on a continuous basis.
interval <*value*>	Optional. Specifies the continuous polling interval. Valid range is **1** to **84600** seconds. The default value is **30** seconds.
on-failure	Specifies polling SIP proxy servers only when a failed state is detected. Once the server returns to a functioning state, the polling is ceased.

Default Values

By default, the SIP proxy monitor polling mode is set to poll **on-failure**.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example configures the SIP proxy monitor to poll SIP servers continuously at **1200** second intervals:

(config)**#sip proxy sip-server monitor**
Configuring New Proxy Monitor.
(config-proxy-monitor)**#mode continuous interval 1200**

poll timeout *<value>*

Use the **poll timeout** command to configure the poll request timeout for the Session Initiation Protocol (SIP) proxy monitor. This value defines the number of seconds the SIP proxy monitor must wait for a response when issuing poll requests to a SIP server. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the timeout value. Valid range is **1** to **600** seconds.

Default Values

By default, the poll requests are set to timeout after **32** seconds.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example configures the poll timeout to **16** seconds:

(config)**#sip proxy sip-server monitor**
Configuring New Proxy Monitor.
(config-proxy-monitor)**#poll timeout 16**

recover

Use the **recover** command to configure the polling behavior of the Session Initiation Protocol (SIP) proxy monitor. The recover interval only takes affect when the server is down. Use the **no** form of this command to return to the default setting. Variations of this command include:

recover delay <*min*>
recover delay <*min*> <*max*>
recover no-response interval <*value*>
recover no-response interval <*min*> <*max*>
recover responses <*value*> **interval** <*value*>

Syntax Description

delay	Configures the SIP proxy monitor recovery delay. In a failover situation, this delay allows the AOS device to delay communication attempts to a SIP proxy server for a specified amount of time.
<*min*>	Specifies the minimum recovery delay period. Valid range is **0** to **86400** seconds.
<*max*>	Specifies the maximum recover delay period. Valid range is **0** to **86400** seconds. The <*max*> value must be greater than the <*min*> value. When both values are configured, a random selection of the timeout value within the indicated range occurs.
no-response interval	Specifies proxy monitor recovery operation when no response is received from the SIP server.
<*value*>	Specifies the interval at which the proxy monitor will poll the SIP server. Valid range is **1** to **86400** seconds.
<*min*> <*max*>	Specifies a range for the interval at which the proxy monitor will poll the SIP server. Valid range is **1** to **86400** seconds. The first value is the minimum value which is the starting interval. The second value is the maximum value to which the interval works up. The interval time is doubled with each time the SIP server fails to respond until the maximum is reached, which is where the interval setting will stay.
responses	Specifies the number of successful responses necessary to recover service to the SIP server and the interval at which the polls are sent.
<*value*>	Specifies the number of successful responses needed to recover. Valid range is **1** to **255**.
interval <*value*>	Specifies the interval at which polls are sent after a successful response is received from the SIP server. Valid range is **1** to **86400** seconds.

Default Values

By default, the SIP proxy monitor is set to recover after **3** responses to polls sent at **10** second intervals. The **recover no-response interval** is set to a minimum of **5** and a maximum of **60**.

Command History

Release R10.9.0	Command was introduced.
Release R11.7.0	Command was expanded to include the **recover delay** parameter.

Usage Examples

The following example configures the SIP proxy SIP server monitor to recover after **7** successful responses are received at **32** second intervals:

(config)**#sip proxy sip-server monitor**
Configuring New Proxy Monitor.
(config-proxy-monitor)**#recover responses 7 interval 32**

The following example configures the SIP proxy SIP server monitor to send recover poll requests to the SIP server at 60 second intervals:
(config)**#sip proxy sip-server monitor**
Configuring New Proxy Monitor.
(config-proxy-monitor)**#recover no-response interval 60**

trap rollover

Use the **trap rollover** command to enable Simple Network Management Protocol (SNMP) traps when Session Initiation Protocol (SIP) proxy monitor rollover occurs. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, the SNMP traps are disabled for SIP proxy SIP server monitor rollover.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example enables SNMP traps when the SIP proxy SIP server monitor rollover occurs:

```
(config)#sip proxy sip-server monitor
    Configuring New Proxy Monitor.
(config-proxy-monitor)#trap rollover
```

SIP SERVER MONITOR COMMAND SET

The Session Initiation Protocol (SIP) server monitor feature provides support for monitoring the availability of SIP servers for validated SIP trunk failover configurations. When the currently selected SIP server is unresponsive, the SIP server monitor causes the SIP trunk to use a secondary SIP server for future calls through a monitored rollover procedure. In the event the selected secondary SIP server becomes unresponsive, the SIP server monitor will then roll over to the next available secondary server. As a more preferred server is returned to service, all future calls are routed to it.

When enabled, the SIP server monitor can operate in one of two modes: **continuous** or **on-failure**. In continuous mode, the server monitor continues to poll the currently selected SIP server to determine its operational state. In contrast, the on-failure mode only polls SIP servers during a detected failure state. The mode is configured using the **mode** command in this command set.

Additional monitoring behaviors can be configured to specify the poll timeout, intervals, and recovery responses. Each configuration option is explained in detail in this command set.

For more information about SIP server monitor and validated SIP trunk failover configuration in AOS, refer to the configuration guide *Configuring SIP Trunk Failover in AOS*, available online at http://supportcommunity.adtran.com.

To enable the SIP server monitor, and enter the SIP Server Monitor configuration mode, enter the following command from the SIP Trunk Configuration mode:

```
(config)#voice trunk t01 type sip
(config-T01)#sip-server monitor
    Configuring SIP Server Monitor.
(config-sip-server-monitor)#
```

Once you have entered the SIP Server Monitor Configuration mode, you can configure the specific behavior of the SIP server monitor feature.

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

mode on page 4876
poll timeout <value> on page 4877
recover on page 4878

mode

Use the **mode** command to configure the polling behavior of the Session Initiation Protocol (SIP) server monitor. Use the **no** form of this command to return to the default setting. Variations of this command include:

mode continuous
mode continuous interval <*value*>
mode on-failure

Syntax Description

continuous	Specifies proactive polling of the current SIP server. Even if the SIP server monitor detects all servers are functioning, the SIP server monitor continues to poll them on a continuous basis.
interval <*value*>	Optional. Specifies the continuous polling interval. Valid range is **1** to **86400** seconds. The default value is **60** seconds.
on-failure	Specifies polling SIP servers only when a failed state is detected. Once the server returns to a functioning state, the polling is ceased.

Default Values

By default, the SIP server monitor polling mode is set to poll **on-failure**.

Command History

Release R13.11.0	Command was introduced.

Functional Notes

If the continuous polling interval is specified, it should not be less than 64 multiplied by the configured value of the SIP T1 timer (specified using the command *sip timer on page 1772*).

Usage Examples

The following example configures the SIP server monitor to poll SIP servers continuously at **1200** second intervals:

```
(config-T01)#sip-server monitor
    Configuring SIP Server Monitor.
(config-sip-server-monitor)#mode continuous interval 1200
```

poll timeout *<value>*

Use the **poll timeout** command to configure the poll request timeout for the Session Initiation Protocol (SIP) server monitor. This value defines the number of seconds the SIP server monitor must wait for a response when issuing poll requests to a SIP server. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the timeout value. Valid range is **1** to **600** seconds.

Default Values

By default, the poll requests are set to timeout after **32** seconds.

Command History

Release R13.11.0	Command was introduced.

Functional Notes

The **poll timeout** value should not be greater than 64 multiplied by the configured value of the SIP T1 timer (specified using the command *sip timer on page 1772*).

Usage Examples

The following example configures the poll timeout to **16** seconds:

```
(config-T01)#sip-server monitor
    Configuring SIP Server Monitor.
(config-sip-server-monitor)#poll timeout 16
```

recover

Use the **recover** command to configure the recovery polling behavior of the Session Initiation Protocol (SIP) server monitor. The recover interval only takes affect when the server is down. Use the **no** form of this command to return to the default setting. Variations of this command include:

recover delay <*min*>
recover delay <*min*> <*max*>
recover no-response interval <*value*>
recover no-response interval <*initial*> <*max*>
recover responses <*value*> **interval** <*value*>

Syntax Description

delay	Configures the SIP server monitor recovery delay. In a SIP trunk failover situation, this delay allows the AOS device to delay communication attempts to a SIP server for a specified amount of time.
<*min*>	Specifies the minimum recovery delay period. Valid range is **0** to **86400** seconds.
<*max*>	Optional. Specifies the maximum recover delay period. Valid range is **0** to **86400** seconds. The <*max*> value must be greater than the <*min*> value. When both values are configured, a random selection of the timeout value within the indicated range occurs.
no-response interval	Specifies SIP server monitor recovery operation when no response is received from the SIP server.
<*value*>	Specifies the interval at which the SIP server monitor will poll the SIP server. Valid range is **1** to **86400** seconds.
<*initial*> <*max*>	Specifies a range for the interval at which the SIP server monitor will poll the SIP server. Valid range is **1** to **86400** seconds. The first value is the initial value which is the starting interval. The second value is the maximum value to which the interval works up. The interval time is doubled with each time the SIP server fails to respond until the maximum is reached, which is where the interval setting will stay.
responses	Specifies the number of successful responses necessary to recover service to the SIP server and the interval at which the polls are sent.
<*value*>	Specifies the number of successful responses needed to recover. Valid range is **1** to **255**.
interval <*value*>	Specifies the interval at which polls are sent after a successful response is received from the SIP server. Valid range is **1** to **86400** seconds.

Default Values

By default, the SIP server monitor is set to recover after **3** responses to polls sent at **10** second intervals. The **recover no-response interval** is set to an initial interval of **5** and a maximum of **60**.

Command History

Release R10.9.0	Command was introduced.
Release R13.11.0	Command was expanded to include the **no-response** and **responses** parameters.

Usage Examples

The following example configures the SIP server monitor to recover after **7** successful responses are received at **32** second intervals:

```
(config-T01)#sip-server monitor
    Configuring SIP Server Monitor.
(config-sip-server-monitor)#recover responses 7 interval 32
```

The following example configures the SIP server monitor to send recover poll requests to the SIP server at **60** second intervals:

```
(config-T01)#sip-server monitor
    Configuring SIP Server Monitor.
(config-sip-server-monitor)#recover no-response interval 60
```

SIP TLS PROFILE COMMAND SET

Session Initiation Protocol (SIP) Transport Layer Security (TLS) is a cryptographic protocol, intended to replace Secure Socket Layer, that provides communication security over the internet. TLS is used to authenticate communication peers through the exchange of symmetric keys and authentication certificates. The protocol certifies the relation between a certificate and its owner as well as administers the validity of certificates used between communication peers. TLS operates on top of an underlying transport protocol, such as Transport Control Protocol (TCP), which carries the encrypted data. Privacy and security is provided by TLS between media endpoints, particularly in SIP signaling in Voice over IP (VoIP) networks. The certificate authority (CA) profile is responsible for certificate storage and management. Each TLS profile is associated with exactly one CA profile. TLS is configurable on a per-Session Initiation Protocol (SIP) trunk basis by applying a TLS profile. The profile is used by each SIP/TLS entity, and contains the configuration necessary to control TLS usage, such as identity validation, negotiable cipher suites, CA profiles, and server or mutual authentication settings.

Each entity that uses TLS uses a TLS profile. Many TLS profiles can exist and be referenced by many entities using TLS on the AOS device. The same TLS profile can be used by as many entities using TLS as required. The TLS profile essentially operates as a template for TLS operation and is applied on a per-trunk basis.

TLS profiles are created and configured using the **tls-profile** <*profile name*> command from the Global Configuration mode as follows:

```
>enable
#configure terminal
(config)#tls-profile TLSPROFILE1
(config-tls-profile-TLSPROFILE1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
exit on page 83

All other commands for this command set are described in this section in alphabetical order.

allow-self-signed-cert on page 4881
authentication mutual on page 4882
ca-profile <profile name> on page 4883
secure-ciphersuite <name> on page 4884
tls-version on page 4886
validate identity on page 4887

allow-self-signed-cert

Use the **allow-self-signed-cert** command to allow a Transport Layer Security (TLS) communication peer to send a self-signed certificate as its sole identification. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

A trusted copy of the peer's certificate must be specified in the certificate authority (CA) profile associated with the TLS profile in order to validate the certificate provided by the peer in the TLS handshake. If this feature is not enabled, the peer's certificate must be signed by a trusted CA.

Usage Examples

The following example configures the TLS profile to allow a TLS peer to send a self-signed certificate as identification:

(config)**#tls-profile TLSPROFILE1**
(config-tls-profile-TLSPROFILE1)**#allow-self-signed-cert**

authentication mutual

Use the **authentication mutual** command to enable mutual Transport Layer Security (TLS) authentication in the TLS profile. Use the **no** form of this command to disable mutual authentication and return to the default authentication method (server authentication).

Syntax Description

No subcommands.

Default Values

By default, TLS mutual authentication is disabled and server authentication is used.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

If mutual authentication is configured, when the entity using the TLS profile is responding to a TLS negotiation (server role), the server requests the certificate of authentication from the client, and then authenticates the client. If the client does not provide a certificate, or the certificate fails validation, the TLS connection is rejected by the server. If mutual authentication is not configured, the responder (server) does not request or require a certificate from the client. When the entity using the TLS profile is initiating a Session Initiation Protocol (SIP)/TLS negotiation (client role), the client always requests the certificate of authentication and then authenticates the server. If the server does not provide a certificate or the certificate fails validation, the TLS connection is rejected by the client.

Usage Examples

The following example enables mutual authentication in the TLS profile:

(config)**#tls-profile TLSPROFILE1**
(config-tls-profile-TLSPROFILE1)**#authentication mutual**

ca-profile *<profile name>*

Use the **ca-profile** command to apply a previously configured certificate authority (CA) profile to the TLS profile. Use the **no** form of this command to remove the CA profile from the TLS profile.

Syntax Description

<profile name>	Specifies the name of the previously created CA profile.

Default Values

By default, no CA profile is associated with the TLS profile.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

A CA profile must be specified for TLS operation. The TLS profile is not valid until it is associated with a valid CA profile. If the command is entered more than once, the previous instance of the command is overwritten.

TLS authentication modes support both server authentication and mutual authentication. In most Session Initiation Protocol (SIP) applications, a SIP entity using TLS might initiate or respond to a TLS connection at any given time and therefore would be configured to operate as client or server. For example, trunks would typically operate as peers and use mutual authentication and SIP phones would typically be authenticated using server authentication. If the CA profile limits TLS authentication to a single mode of authentication (either server or mutual), the CA profile could omit the trusted or self-signed certificate. This is a rare case, however, since most SIP entities can be servers or clients at any time.

For more information about configuring CA profiles, refer to the *CA Profile Command Set on page 5209*.

Usage Examples

The following example associates the CA profile **MYPROFILE** with the TLS profile:

(config)**#tls-profile TLSPROFILE1**
(config-tls-profile-TLSPROFILE1)**#ca-profile MYPROFILE**

secure-ciphersuite <*name*>

Use the **secure-ciphersuite** command to specify a Transport Layer Security (TLS) cipher suite for the TLS profile. Use the **no** form of this command to remove the cipher suite from the TLS profile. Variations of this command include:

secure-ciphersuite <*name*>
secure-ciphersuite <*name*> <*number*>

Syntax Description

<*name*>	Specifies the name of a supported TLS cipher suite. Supported cipher suites are as follows: **TLS_DHE_RSA_WITH_3DES_EDE_CBC_SHA** **TLS_DHE_RSA_WITH_AES_128_CBC_SHA** **TLS_DHE_RSA_WITH_AES_256_GCM_SHA384** **TLS_DHE_RSA_WITH_AES_256_CBC_SHA256** **TLS_DHE_RSA_WITH_AES_256_CBC_SHA** **TLS_ECDH_ECDSA_WITH_AES_256_CBC_SHA384** **TLS_ECDH_ECDSA_WITH_AES_256_GCM_SHA384** **TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256** **TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384** **TLS_RSA_WITH_3DES_EDE_CBC_SHA** **TLS_RSA_WITH_AES_128_CBC_SHA** **TLS_RSA_WITH_AES_256_CBC_SHA** **TLS_RSA_WITH_NULL_MD5** **TLS_RSA_WITH_NULL_SHA** **TLS_RSA_WITH_RC4_128_MD5** **TLS_RSA_WITH_RC4_128_SHA**
<*number*>	Optional. Specifies an integer that describes the cipher suite's desired relative position among all enabled cipher suites within the profile. Valid range is **1** to **65535**.

Default Values

By default, all strong (high level) cipher suites are individually enabled and all weak cipher suites are individually disabled.

Command History

Release R11.5.0	Command was introduced.
Release R13.1.0	Command was expanded to include the **TLS_DHE_RSA_WITH_AES_256_CBC_SHA256** and **TLS_DHE_RSA_WITH_AES_256_GCM_SHA384** cipher suites.

Functional Notes

If multiple cipher suites have the same number value specified, they are placed in that number position and then subsorted in the order they appear in the configuration. One instance of this command exists for each supported TLS cipher suite.

Usage Examples

The following example enables a cipher suite in the TLS profile:

(config)**#tls-profile TLSPROFILE1**
(config-tls-profile-TLSPROFILE1)**#secure-ciphersuite TLS_RSA_WITH_RC4_128_SHA 150**

tls-version

Use the **tls-version** command to specify the Transport Layer Security (TLS) version used by this TLS profile. Use the **no** form of this command to revert to the default TLS version. Variations of this command include:

tls-version 1.0
tls-version 1.1
tls-version 1.2
tls-version fallback
tls-version fallback 1.0
tls-version fallback 1.1
tls-version fallback 1.2

Syntax Description

1.0	Specifies TLS version 1.0 is used.
1.1	Specifies TLS version 1.1 is used.
1.2	Specifies TLS version 1.2 is used.
fallback	Specifies that fallback from the highest supported TLS version to the lowest supported version is allowed.
fallback 1.0	Specifies that fallback from the highest supported TLS version to 1.0 is allowed.
fallback 1.1	Specifies that fallback from the highest supported TLS version to 1.1 is allowed.
fallback 1.2	Specifies that fallback from the highest supported TLS version to 1.2 is allowed.

Default Values

By default, fallback 1.2 is enabled.

Command History

Release R11.5.0	Command was introduced.
Release R13.8.0	Command was expanded to include the **fallback [1.0 | 1.1 | 1.2]** parameter.

Usage Examples

The following example specifies that the TLS profile uses TLS version **1.2**:

(config)**#tls-profile TLSPROFILE1**
(config-tls-profile-TLSPROFILE1)**#tls-version 1.2**

validate identity

Use the **validate identity** command to control how the identity of the Transport Layer Security (TLS) communication peer's certificate, received during the TLS handshake, is validated. Use the **no** form of this command to remove the identity validation method from the TLS profile. Variations of this command include:

validate identity fqdn configured
validate identity fqdn resolved
validate identity ip-address
validate identity string

Syntax Description

fqdn configured	Specifies that the peer's subject alternative name (SAN) IP domain naming service (DNS) name is used to validate the peer. The name must match the fully qualified domain name (FQDN) configured for the peer at the trunk.
fqdn resolved	Specifies that the peer's SAN IP domain DNS name is used to validate the peer. The name must match the FQDN as resolved by DNS service records (SRVs) from the FQDN as configured for the peer at the trunk.
ip-address	Specifies that the peer's SAN IP address is used to validate the peer. The address must match the IP address configured or resolved by DNS for the peer at the trunk.
string	Specifies that the peer's SAN fields or Subject components are used to identify the peer. The string must match the string configured at the trunk (using the command *peer-certificate-identity <string> on page 5108*).

Default Values

By default, identity validations are disabled and only proper signing is verified.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

Up to one instance of each validation method can be specified in the profile, and each method specified must be matched in order for successful validation. These identity validation methods do not specify the value that must be matched, but rather specify an attribute whose value is related to the current session.

Usage Examples

The following example enables identity validation for the TLS profile based on IP address:

(config)**#tls-profile TLSPROFILE1**
(config-tls-profile-TLSPROFILE1)**#validate identity ip-address**

SRTP PROFILE COMMAND SET

Secure Realtime Transfer Protocol (SRTP) is a protocol used to provide confidentiality, message authentication, and replay protection to Realtime Transfer Protocol (RTP) traffic. This protocol provides a framework for encryption and message authentication of RTP streams between media endpoints. Typically, SRTP uses Transport Layer Security (TLS) for signaling authentication and encryption. Although SRTP protects the media shared between endpoints, it relies on the exchange of Session Description Protocol Security Descriptions (SDES) keys that appear clearly within the SIP message. TLS is used with SRTP to encrypt the signaling and protect against snooping of the SDES keys. TLS is not required for successful SRTP negotiation, but it is strongly recommended. In AOS, SRTP is used for calls when SRTP is enabled and when the capabilities of the communication peer allow it. SRTP configuration in AOS depends on the configuration of an SRTP profile. This profile controls SRTP usage for AOS devices acting as communication servers and is applied on a per-trunk basis in the AOS device.

Each entity that uses SRTP uses an SRTP profile. Many SRTP profiles can exist and be referenced by many entities using SRTP on the AOS device. The same SRTP profile can be used by as many entities using SRTP as required. The SRTP profile essentially operates as a template for SRTP operation and is applied on a per-trunk basis.

SRTP profiles are created and configured using the **srtp-profile** <*profile name*> command from the Global Configuration mode as follows:

```
>enable
#configure terminal
(config)#tls-profile SRTPPROFILE1
(config-srtp-profile-SRTPPROFILE1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
exit on page 83

All other commands for this command set are described in this section in alphabetical order.

crypto-suite <crypto suite> on page 4889
srtcp on page 4890
srtp auth on page 4891
srtp encrypt on page 4892

crypto-suite *<crypto suite>*

Use the **crypto-suite** command to specify a Secure Realtime Transfer Protocol (SRTP) cryptography suite for the SRTP profile. Use the **no** form of this command to remove the crypto suite from the SRTP profile.

Syntax Description

<crypto suite> Specifies the SRTP crypto suite to use in this profile. Supported SRTP crypto suites are as follows:

SRTP Crypto Suites	Associated RFC
AES_CM_128_HMAC_SHA1_80	RFC 4568
AES_CM_128_HMAC_SHA1_32	RFC 4568
AES_256_CM_HMAC_SHA1_80	RFC 6188
AES_256_CM_HMAC_SHA1_32	RFC 6188
SRTP_NULL_HMAC_SHA1_80	RFC 3711
SRTP_NULL_HMAC_SHA1_32	RFC 3711

Default Values

By default, the **AES_CM_128_HMAC_SHA1_80** crypto suite is used.

Command History

Release R11.5.0 Command was introduced.

Usage Examples

The following example specifies the SRTP crypto suite to be used with this profile:

(config)**#srtp-profile SRTPPROFILE1**
(config-srtp-profile-SRTPPROFILE1)**#crypto-suite SRTP_NULL_HMAC_SHA1_80**

srtcp

Use the **srtcp** command to specify the Secure Realtime Transport Control Protocol (SRTCP) encryption method for the Secure Realtime Transport Protocol (SRTP) profile. Variations of this command include:

srtcp encrypt
srtcp offer-no-encrypt
srtcp strict-no-encrypt

Syntax Description

encrypt	Species that the SRTP session must encrypt SRTP.
offer-no-encrypt	Specifies that encryption can be used, but is not required.
strict-no-encrypt	Specifies that session must not encrypt SRTCP.

Default Values

By default, the SRTP session must encrypt SRTCP.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

When **encrypt** is used, as an offerer, the crypto attributes offered do not contain the UNENCRYPTED_SRTCP parameter and answers that contain this parameter are not accepted.

When **offer-no-encrypt** is used, as an offerer, the crypto attributes offered contain the UNENCRYPTED_SRTCP session parameter, and valid answers with or without the parameter are accepted. When enabled as an answerer, a crypto attribute with or without the UNENCRYPTED_SRTCP parameter can be selected.

When **strict-no-encrypt** is used, as an offerer, the crypto attributes offered contain the UNENCRYPTED_SRTCP session parameter and answers not containing the same parameter are not accepted. When enabled as an answerer, the crypto attribute that does not contain the UNENCRYPTED_SRTCP parameter is rejected.

The SRTP authentication and encryption commands (*srtp auth on page 4891* and *srtp encrypt on page 4892*), as well as this SRTCP encryption command, are set once at the SRTP profile but they affect the parameter present in each crypto attribute associated with a media session.

Usage Examples

The following example specifies that the SRTP profile does not encrypt SRTCP:

(config)**#srtp-profile SRTPPROFILE1**
(config-srtp-profile-SRTPPROFILE1)**#srtcp strict-no-encrypt**

srtp auth

Use the **srtp auth** command to specify the Secure Realtime Transfer Protocol (SRTP) authentication method for the SRTP profile. Variations of this command include:

srtp auth
srtp offer-no-auth
srtp strict-no-auth

Syntax Description

auth	Specifies that the SRTP session must authenticate SRTP.
offer-no-auth	Specifies that the SRTP session can authenticate SRTP, but it is not required.
strict-no-auth	Specifies that the SRTP session must not authenticate SRTP.

Default Values

By default, SRTP sessions must authenticate SRTP.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

When **auth** is used, as an offerer, the crypto attributes offered do not contain the UNAUTHENTICATED_SRTP session parameter, and any answers containing that parameter are not accepted. When enabled as an answerer, the crypto attribute containing the same parameter is not accepted.

When **offer-no-auth** is used, as an offerer, crypto attributes offered contain the UNAUTHENTICATED_SRTP parameter, and valid answers with or without that parameter are accepted. When enabled as an answerer, the crypto attribute with or without this parameter can be selected.

When **strict-no-auth** is used, as an offerer, crypto attributes offered contain the session parameter UNAUTHENTICATED_SRTP and answers that do NOT contain this parameter are rejected. When enabled as an answerer, the crypto attribute containing the parameter is not accepted.

The SRTP authentication and encryption commands (*srtp auth on page 4891* and *srtp encrypt on page 4892*), as well as the SRTCP encryption command (*srtcp on page 4890*), are set once at the SRTP profile but they affect the parameter present in each crypto attribute associated with a media session.

Usage Examples

The following example specifies that the SRTP profile authenticates with or without the UNAUTHENTICATED_SRTP parameter:

(config)**#srtp-profile SRTPPROFILE1**
(config-srtp-profile-SRTPPROFILE1)**#srtp offer-no-auth**

srtp encrypt

Use the **srtp encrypt** command to specify the Secure Realtime Transfer Protocol (SRTP) encryption method for the SRTP profile. Variations of this command include:

srtp encrypt
srtp offer-no-encrypt
srtp strict-no-encrypt

Syntax Description

encrypt	Specifies that the SRTP session must encrypt SRTP.
offer-no-encrypt	Specifies that the SRTP session can encrypt SRTP, but it is not required.
strict-no-encrypt	Specifies that the SRTP session must not encrypt SRTP.

Default Values

By default, SRTP sessions must encrypt SRTP.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

When **encrypt** is used, as an offerer, the crypto attributes offered do not contain the UNENCRYPTED_SRTP session parameter, and any answers containing that parameter are not accepted.

When **offer-no-encrypt** is used, as an offerer, crypto attributes offered contain the UNUNENCRYPTED_SRTP parameter, and valid answers with or without that parameter are accepted. When enabled as an answerer, the crypto attribute with or without this parameter can be selected.

When **strict-no-encrypt** is used, as an offerer, crypto attributes offered contain the session parameter UNENCRYPTED_SRTP and answers that do NOT contain this parameter are rejected. When enabled as an answerer, the crypto attribute containing the parameter is not accepted.

The SRTP authentication and encryption commands (*srtp auth on page 4891* and *srtp encrypt on page 4892*), as well as the SRTCP encryption command (*srtcp on page 4890*), are set once at the SRTP profile but they affect the parameter present in each crypto attribute associated with a media session.

Usage Examples

The following example specifies that the SRTP profile is accepted with or without encryption:

(config)**#srtp-profile SRTPPROFILE1**
(config-srtp-profile-SRTPPROFILE1)**#srtp offer-no-encrypt**

VOICE CODEC LIST COMMAND SET

Voice coder-decoder (CODEC) lists are lists of CODECs arranged in preferred order with the first listed CODEC being the most preferred for call negotiation.

The primary reason to create and assign voice CODEC lists is to save time. CODEC lists are created, listing CODECs in the order of preference, and then lists are applied to interfaces using the **codec-group** command (refer to the specific interface configuration command set for more information). Configuring a CODEC list allows the list to be applied to multiple interfaces, such as Media Gateway Control Protocol (MGCP) interfaces, voice trunks, voice accounts, and voice users without having to define the order of CODECs individually. The order of preference is used primarily to conserve bandwidth on wide area network (WAN)-based interfaces.

For example, when a user makes an outbound call from a foreign exchange station (FXS) port to a Session Initiation Protocol (SIP) trunk, the trunk will look at its CODEC list and query the user making the call as to which CODEC is to be used according to its CODEC list. It will query with the first CODEC (for example, G.729). If this CODEC is listed in the CODEC list that is applied to the user (no matter the CODEC preference on the user interface), then G.729 is agreed upon and the call will be converted and sent out the trunk. This is the most bandwidth conservative CODEC in this case.

To activate the Voice CODEC List Configuration mode, enter the **voice codec-list trunk** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice codec-list List1
(config-codec)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

codec on page 4894
default on page 4896

codec

Use the **codec** command to specify the order of preference for coder-decoders (CODECs) used by the CODEC list. Use the **no** form of this command to remove a CODEC from the CODEC list. Variations of this command include:

codec g711alaw
codec g711ulaw
codec g722
codec g729

Syntax Description

g711alaw	Assigns the G.711 A-law CODEC (64000 bps) as the preferred CODEC for negotiation.
g711ulaw	Assigns the G.711 U-law CODEC (64000 bps) as the preferred CODEC for negotiation.
g722	Assigns the G.722 CODEC as the preferred CODEC for negotiation.
g729	Assigns the G.729 CODEC (8000 bps) as the preferred CODEC for negotiation.

Default Values

By default, no CODEC lists are created.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was expanded to include the **g711alaw** parameter.
Release A2.04	Command was expanded to include the **g722** parameter.

Functional Notes

You can enter as many CODECs in the list as necessary by repeating the **codec** command while in the Voice CODEC List Configuration mode (refer to the *Usage Examples* section of this command).

Order is important when creating a CODEC list. The interface attempts to use the first CODEC in the list to negotiate a call. If the first CODEC negotiation is unsuccessful, the interface uses the second CODEC in the list and so on. If this process is unsuccessful, the call will fail.

CODEC lists do not take any action until they are applied to an interface. For information on applying CODEC lists, refer to the **codec-group** <*name*> command in the command section of the interface to which you want to apply the list.

Usage Examples

The following example creates a CODEC list, **List1**, and specifies that the interface to which this list is applied will use **g729** first, **g711ulaw** second, and **g722** third as it negotiates the call:

(config)**#voice codec-list List1**
(config-codec)**#codec g729**
(config-codec)**#codec g711ulaw**
(config-codec)**#codec g722**

default

Use the **default** command to set the coder-decoder (CODEC) list as the default list for call negotiation on the interface to which it is applied. Use the **no** form of this command to remove the CODEC list as the default.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example specifies the CODEC list **List1** is used as the default list for call negotiation on the interfaces to which the list is applied:

(config)**#voice codec-list List1**
(config-codec)**#default**

VOICE COS COMMAND SET

Class of service (CoS) defines the permissions available to a system user for making voice calls, and it is necessary to configure CoS before calls can be made (other than to the operator and 911). Voice CoS permissions include the types of calls and actions a user can perform. There are three default classes of voice CoS: normal users, executive users, and public phones, but you can also create your own class. A maximum of 10 voice CoS types can be defined. The commands in this section help you to define voice CoS classes so they can be applied to voice users. Voice CoS classes created with these commands are applied to users using the **cos** command, detailed in the *Voice User Account Command Set on page 4564*. For more information on configuring voice CoS, refer to the *NetVanta 7000 Series Classes of Service* quick configuration guide available online at https://supportcommunity.adtran.com.

To create a voice CoS and enter the Voice CoS Configuration mode, enter the **voice class-of-service** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

aa-initiate-permit <template> on page 4899
block-caller-id on page 4901
call-privilege on page 4902
camp-on on page 4904
conference on page 4905
default-level on page 4906
deny-template <template> on page 4907
disable-callwaiting on page 4909
dnd on page 4910
door-phone on page 4911
external-fwd on page 4912
forward on page 4913
hold on page 4914

aa-initiate-permit *<template>*

Use the **aa-initiate-permit** command to enable the handsfree auto answer feature. Handsfree voice communication (similar to using a speakerphone or intercom) will be available for the programmed number template. When using **aa-initiate-permit**, the receiving party's phone automatically answers the phone. Use the **no** form of this command to disable this feature.

Syntax Description

<template>	Allows users with the specified number template to initiate auto answer calls. Refer to *Functional Notes* for more information.

Default Values

By default, **aa-initiate-permit** is disabled.

Command History

Release 13.1	Command was introduced.

Functional Notes

In order to place an auto answer call, you must dial ** prior to the number. Users can also program ** as a soft key to dial ** separately before dialing the number to call. Users must dial ***971** to block auto answer calls and ***970** to reactivate the feature.

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example enables the handsfree auto answer for users with the extension range of **4200** to **4299**:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#aa-initiate-permit 42xx**

block-caller-id

Use the **block-caller-id** command to conceal caller ID information for outbound calls. Use the **no** form of this command to allow caller ID for outbound calls.

Syntax Description

No subcommands.

Default Values

By default, the **block-caller-id** feature is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example blocks caller ID for outbound calls in rule set **set1**:

```
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#block-caller-id
```

call-privilege

Use the **call-privilege** command to assign general call privileges for outbound access. This determines what type of calls a user is permitted to make as a member of this class of service (CoS). Use the **no** form of this command to remove general call privileges for outbound access. Variations of this command include:

call-privilege 900-number
call-privilege all
call-privilege extensions
call-privilege international
call-privilege local
call-privilege long-distance
call-privilege operator-assisted
call-privilege specify-carrier
call-privilege toll-free
call-privilege [user1 | user2 | user3]

Syntax Description

900-number	Permits 900 calls in the form 1-900-NXX-XXXX and 976-XXXX.
all	Permits all calls.
extensions	Permits internal calls.
international	Permits international calls in the form 011-number.
local	Permits local calls in the form NXX-XXXX.
long-distance	Permits long distance calls in the form 1-NXX-NXX-XXXX.
operator-assisted	Permits operator-assisted calls.
specify-carrier	Permits calls that specify carrier.
toll-free	Permits toll free calls.
user1	Permits calls that match the first user-defined template.
user2	Permits calls that match the second user-defined template.
user3	Permits calls that match the third user-defined template.
	Valid characters include: 0-9 - Any single digit. X - Any single digit 0 through 9. N - Any single digit 2 through 9.

Default Values

By default, no call privileges are enabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example permits long distance calls in rule set **set1**:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#call-privilege long-distance**

camp-on

Use the **camp-on** command to allow automatic retry of a busy extension. This feature enables a user to reach the busy party as soon as the line is available. Use the **no** form of this command to disable automatic retry.

Syntax Description

No subcommands.

Default Values

By default, the **camp-on** feature is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example enables automatic retry of a busy extension in rule set **set1**:

```
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#camp-on
```

conference

Use the **conference** command to allow the initiation of three-way conference calls. This feature allows multiple parties to communicate at the same time on the same line. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, the three-way conference call feature is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example allows the initiation of three-way conference calls in rule set **set1**:

```
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#conference
```

default-level

Use the **default-level** command to set this class of service (CoS) level as the default. When enabled, new users that are added to the system are assigned this CoS by default. To change the default from this CoS level, use the **no** form of this command.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example sets the rule set **set1** as the default CoS level:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#default-level**

deny-template *<template>*

Use the **deny-template** command to configure a number template that specifies the types of calls that users in this class of service (CoS) are not allowed to make. Use the **no** form of this command to remove a deny template.

Syntax Description

<template>	Specifies a number template. All calls matching this pattern will be denied. Refer to *Functional Notes* for more information.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Functional Notes

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example denies users in rule set **set1** the ability to make any call beginning with **555**:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#deny-template 555-xxxx**

disable-callwaiting

Use the **disable-callwaiting** command to allow users to control the call waiting feature. Disabling call waiting will block the alert of an incoming call while the user is on the phone. Use the **no** form of this command to enable call waiting.

Syntax Description

No subcommands.

Default Values

By default, call waiting is enabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example allows users in rule set **set1** to disable call waiting:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#disable-callwaiting**

dnd

Use the **dnd** command to enable do-not-disturb (DND). Do-not-disturb makes the line appear busy to incoming calls. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, the do-not-disturb feature is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example enables the do-not-disturb feature in rule set **set1**:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#dnd**

door-phone

Use the **door-phone** command to allow the user to call the door phone using a special prefix (SPRE) code. Use the **no** form of this command to deny door phone access.

Syntax Description

No subcommands.

Default Values

By default, door phone access is denied.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example allows door phone access in voice class of service (CoS) rule set named **set1**:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#door-phone**

external-fwd

Use the **external-fwd** command to allow forwarding of calls to an external number. When enabled, the users can forward their phones to lines outside the system, such as their home numbers. Use the **no** form of this command to disable external call forwarding.

Syntax Description

No subcommands.

Default Values

By default, forwarding calls to an external number is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example allows users in rule set **set1** to forward calls to an external number:

```
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#external-fwd
```

forward

Use the **forward** command to allow users to forward calls to another extension. Forwarding calls allows the user to receive incoming calls at a different number. Use the **no** form of this command to end call forwarding.

Syntax Description

No subcommands.

Default Values

By default, internal call forwarding is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example allows users in rule set **set1** to forward calls:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#forward**

hold

Use the **hold** command to allow users to place calls on standby. Use the **no** form of this command to disable the call hold option.

Syntax Description

No subcommands.

Default Values

By default, the call hold option is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example enables users in rule set **set1** to place a call on hold:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#hold**

hotel

Use the **hotel** command to allow extension reassignment to an alternate phone. Use the **no** form of this command to disable extension reassignment.

Syntax Description

No subcommands.

Default Values

By default, the **hotel** feature is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example enables users in rule set **set1** to reassign an extension to an alternate phone:

```
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#hotel
```

logout-group

Use the **logout-group** command to allow a user to issue a special prefix (SPRE) command to log out of a user group. Use the **no** form of this command to deny the ability to log out of a user group.

Syntax Description

No subcommands.

Default Values

By default, the ability to log out of a user group is denied.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example allows the user in rule set **set1** to log out of a user group:

```
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#logout-group
```

message-waiting

Use the **message-waiting** command to allow message waiting indicator control. This allows users to change the manner in which message notification takes place. Use the **no** form of this command to disable message waiting indicator control.

Syntax Description

No subcommands.

Default Values

By default, control of the message waiting indicator is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example allows users in rule set **set1** to manage message waiting indicators:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#message-waiting**

overhead-paging

Use the **overhead-paging** command to allow the user to connect to overhead paging using a special prefix (SPRE) code. Use the **no** form of this command to deny the ability to connect to overhead paging.

Syntax Description

No subcommands.

Default Values

By default, the ability to connect to overhead paging is denied.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example allows the user in rule set **set1** to connect to overhead paging:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#overhead-paging**

override-passcode <*passcode*>

Use the **override-passcode** command to assign an override passcode. This four-digit code is used in conjunction with the class of service (CoS) override feature and enables a user to override an extension's configured CoS with the new CoS as defined by the passcode. Use the **no** form of this command to remove an override passcode.

Syntax Description

<*passcode*>	Specifies a four-digit numerical passcode.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example sets the override passcode to **1234** in rule set **set1**:

(config)**#voice class-of-service set1**
Configuring Existing Level "set1".
(config-cos-set1)**#override-passcode 1234**

park

Use the **park** command to allow users to park calls on the system. Use the **no** form of this command to disable the call parking feature.

Syntax Description

No subcommands.

Default Values

By default, the parking feature is enabled.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example allows users to park calls in rule set **set1**:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#park**

permit template <*number*>

Use the **permit template** command to configure call privilege additions that are permitted access only. This specifically allows an otherwise restricted number to be dialed. Use the **no** form of this command to remove the template.

Syntax Description

<*number*>	Specifies the number that may be dialed. The number is in the form **NXX-XXXX**, where **N** is **2** to **9** and **X** is **0** to **9**.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example allows the number **325-1234** to be dialed in rule set **set1**:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#permit template 325-1234**

pickup

Use the **pickup** command to enable the call pickup feature. If enabled, users with this voice class of service (CoS) applied can enter a special prefix (SPRE) code or group extension to answer calls ringing on another phone. Using the **no** form of this command disabled the call pickup feature on the CoS.

Syntax Description

No subcommands.

Default Values

By default, call pickup is disabled.

Command History

Release A4.01	Command was introduced.

Functional Notes

There are two types of call pickup available: directed call pickup and call pickup groups. Directed call pickup allows a user to answer a ringing phone by dialing a SPRE code in addition to the phone's extension. For example, using directed call pickup, a user would dial ***528509** where ***52** is the call pickup SPRE code and **8509** is the ringing phone's extension. Call pickup groups allow the user to dial the group extension to answer the ringing phone. For more information about configuring call pickup, refer to the *Configuring the Call Pickup Feature on AOS Voice Products* quick configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables the call pickup feature in the CoS **set1**:

```
(config)#voice class-of-service set1
Configuring Existing Level "set1".
(config-cos-set1)#pickup
```

program-user-speed

Use the **program-user-speed** command to allow users to access speed dial functionality through the system. Use the **no** form of this command to disable the speed dialing feature.

Syntax Description

No subcommands.

Default Values

By default, the speed dial feature is disabled.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example enables the speed dial feature for users in rule set **set1**:

```
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#program-user-speed
```

redial

Use the **redial** command to grant users access to the redial functionality, which redials the last outgoing number. Use the **no** form of this command to disable last number redial.

Syntax Description

No subcommands.

Default Values

By default, the last number **redial** feature is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example enables the last number redial feature in rule set **set1**:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#redial**

remote-fwd

Use the **remote-fwd** command to allow a user to control call forwarding from a remote location. Use the **no** form of this command to disable remote forwarding.

Syntax Description

No subcommands.

Default Values

By default, remote forwarding feature is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example allows users in rule set **set1** to enable call forwarding from a remote location:

```
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#remote-fwd
```

rename *<name>*

Use the **rename** command to assign a new name to the class of service (CoS) rule set.

Syntax Description

<name>	Specifies the new name of the CoS rule set.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example changed the name of rule set **set1** to **accounting**:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#rename accounting**
(config-cos-accounting)#

retrieve-park

Use the **retrieve-park** command to allow the retrieval of parked calls. Use the **no** form of this command to disable the retrieve parked calls feature.

Syntax Description

No subcommands.

Default Values

By default, the retrieve parked calls feature is disabled.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example enables retrieval of parked calls in rule set **set1**:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#retrieve-park**

return-last-call

Use the **return-last-call** command to allow users to return the last call received. Use the **no** form of this command to disable the return last call received feature.

Syntax Description

No subcommands.

Default Values

By default, the **return-last-call** feature is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example allows users in rule set **set1** to return the last call received:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#return-last-call**

send-to-vm

Use the **send-to-vm** command to allow users to send calls directly to voicemail. Use the **no** form of this command to disable the ability to send calls to directly to voicemail.

Syntax Description

No subcommands.

Default Values

By default, the ability to send calls directly to voicemail is disabled.

Command History

Release R10.2.0	Command was introduced.

Usage Examples

The following example allows users in rule set **set1** to send calls directly to voicemail:

```
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#send-to-vm
```

station-lock

Use the **station-lock** command to allow users to lock an extension, preventing it from making outbound calls. Use the **no** form of this command to revoke user's ability to disable outbound calling capabilities.

Syntax Description

No subcommands.

Default Values

By default, the **station-lock** feature is disabled. Users are not allowed to block their extension's capability to place outbound calls.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example enables the station-lock feature in rule set **set1**:

(config)**#voice class-of-service set1**
Configuring Existing Level "set1".
(config-cos-set1)**#station-lock**

system-mode

Use the **system-mode** command to enable the system mode feature for this class of service (CoS). Once enabled, users to whom this CoS is applied can activate different system modes on the unit via the command line interface (CLI), special prefix (SPRE) codes, auto attendant, or the Web-based graphical user interface (GUI). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release A1	Command was introduced.

Usage Examples

The following example enables the system mode feature for users with the applied CoS **set1**:

```
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#system-mode
```

system-speed

Use the **system-speed** command to enable system speed dial usage for the system. Use the **no** form of this command to disable the system speed setting.

Syntax Description

No subcommands.

Default Values

By default, **system-speed** is enabled.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example enables configuration of the system speed in rule set **set1**:

```
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#system-speed
```

transfer

Use the **transfer** command to allow users to perform call transfers. Use the **no** form of this command to disable call transfers.

Syntax Description

No subcommands.

Default Values

By default, the call transfer feature is disabled.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example allows users in rule set **set1** to perform call transfers:

(config)**#voice class-of-service set1**
Configuring Existing Level “set1”.
(config-cos-set1)**#transfer**

unlock-door

Use the **unlock-door** command to enable the user to use a special prefix (SPRE) code to control the door contact. Use the **no** form of this command to disable door contact operation.

Syntax Description

No subcommands.

Default Values

By default, door contact operation is disabled.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example enables door contact operation in rule set **set1**:

```
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#unlock-door
```

user-speed

Use the **user-speed** command to allow users to program speed dial numbers. Use the **no** form of this command to deny this privilege.

Syntax Description

No subcommands.

Default Values

By default, user speed dial programming is not allowed.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example allows users in rule set **set1** to program speed dial numbers:

```
(config)#voice class-of-service set1
Configuring Existing Level “set1”.
(config-cos-set1)#user-speed
```

VOICEMAIL COS COMMAND SET

Class of service (CoS) defines the permissions available to a system user, and in this case defines permissions as they relate to user voicemail. By default, users are not assigned a voicemail CoS. When a user's account does not have an assigned voicemail CoS, the user will not have access to a voice mailbox. The commands in this section help you to create a CoS specifically for voice mailboxes. The classes created with these commands are then applied to users using the command *voicemail on page 4646*. For more information about configuring voicemail CoS and voicemail in general, refer to the *NetVanta 7000 Series Voicemail* quick configuration guide available online at https://supportcommunity.adtran.com.

To create a voicemail CoS and enter the Voicemail CoS Configuration mode, enter the **voice mail class-of-service** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice mail class-of-service class1
Configuring Existing Level "class1".
(config-vm-class1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

default-level on page 4937
expire-time <days> on page 4938
greeting-length-max <time> on page 4939
greeting-quota <time> on page 4940
message-length-max <time> on page 4941
message-quota <time> on page 4942
prompt-delete on page 4943
rename <name> on page 4944

default-level

Use the **default-level** command to set the current voicemail class of service (CoS) level as the default level. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example configures the voicemail CoS **class1** as the default CoS:

(config)**#voice mail class-of-service class1**
Configuring Existing Level "class1".
(config-vm-class1)**#default-level**

expire-time *<days>*

Use the **expire-time** command to set the number of days before a voicemail message expires. Use the **no** form of this command to return to the default value.

Syntax Description

<days>	Specifies the number of days until a message expires. Valid range is **5** to **60** days. A value of **0** means messages will never expire.

Default Values

By default, the number of days is set to **0**, which means messages will never expire.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example configures the voicemail class of service (CoS) **class1** to delete voicemail messages after **14** days:

(config)**#voice mail class-of-service class1**
Configuring Existing Level "class1".
(config-vm-class1)**#expire-time 14**

greeting-length-max *<time>*

Use the **greeting-length-max** command to set the maximum length (in seconds) for a voicemail greeting. Use the **no** form of this command to return to the default value.

Syntax Description

<time>	Specifies the length in seconds for a voicemail greeting. Valid range is **20** to **120** seconds.

Default Values

By default, the maximum voicemail greeting time is set to **60** seconds.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example configures the maximum length for a voicemail greeting in rule set **class1** to **60** seconds:

(config)**#voice mail class-of-service class1**
Configuring Existing Level "class1".
(config-vm-class1)**#greeting-length-max 60**

greeting-quota *<time>*

Use the **greeting-quota** command to set the maximum storage time (in minutes) of all greeting messages. Use the **no** form of this command to return to the default value.

Syntax Description

<time>	Specifies the maximum storage time (in minutes) for the storage of all greeting messages. Valid range is **1** to **9** minutes.

Default Values

By default, the maximum storage time for all greeting messages is **3** minutes.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example configures the maximum storage time for all greeting messages in rule set **class1** to **5** minutes:

(config)**#voice mail class-of-service class1**
Configuring Existing Level "class1".
(config-vm-class1)**#greeting-quota 5**

message-length-max *<time>*

Use the **message-length-max** command to set the maximum length (in seconds) for a voicemail message. Use the **no** form of this command to return to the default value.

Syntax Description

<time>	Specifies the maximum length (in seconds) for a voicemail message. Valid range is **30** to **600** seconds.

Default Values

By default, the maximum length for a voicemail message is **120** seconds.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example sets the maximum length a voicemail message in rule set **class1** to **300** seconds:

(config)**#voice mail class-of-service class1**
Configuring Existing Level "class1".
(config-vm-class1)**#message-length-max 300**

message-quota *<time>*

Use the **message-quota** command to set the maximum storage time (in minutes) of all voicemail messages. Use the **no** form of this command to return to the default value.

Syntax Description

<time>	Specifies the maximum storage time (in minutes) of all voicemail messages. Valid range is **1** to **180** minutes.

Default Values

By default, the maximum storage time of all voicemail messages is **10** minutes.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example sets the maximum storage time of all voicemail messages in rule set **class1** to **120** minutes:

(config)**#voice mail class-of-service class1**
Configuring Existing Level "class1".
(config-vm-class1)**#message-quota 120**

prompt-delete

Use the **prompt-delete** command to configure the unit to prompt the user before deleting messages. Use the **no** form of this command to disable the prompt before deleting messages.

Syntax Description

No subcommands.

Default Values

By default, the prompt before deleting messages is disabled.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example configures the unit to prompt the user before deleting voicemail messages:

```
(config)#voice mail class-of-service class1
Configuring Existing Level "class1".
(config-vm-class1)#prompt-delete
```

rename *<name>*

Use the **rename** command to rename the voicemail class of service (CoS) rule set. Use the **no** form of this command to return to the previous name.

Syntax Description

<name>	Specifies the new name of the CoS rule set.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example assigns a new name (**class2**) to the current CoS rule set **class1**:

(config)**#voice mail class-of-service class1**
Configuring Existing Level "class1".
(config-vm-class1)**#rename class2**

VQM REPORTER COMMAND SET

Voice quality monitoring (VQM) allows real time passive Voice over IP (VoIP) quality measurements to be taken on all Realtime Transport Protocol (RTP) voice streams transmitted through an AOS device. The VQM reporter is a feature supported by AOS devices that allows the gathered VQM statistics to be aggregated by third-party collectors, such as the n-Command® managed service provider (MSP) server. Allowing aggregation by the n-Command MSP server provides more flexibility in monitoring voice networks.

VQM should be enabled and configured on the AOS device before configuring the VQM reporter. For information on configuring VQM, refer to the *Voice Quality Monitoring* configuration guide available online at https://supportcommunity.adtran.com. VQM commands are also detailed in the *Global Configuration Mode Command Set on page 1149* beginning with the command *ip rtp quality-monitoring on page 1465*.

To create a VQM reporter and enter the reporter's configuration mode, enter the **ip rtp quality-monitoring reporter** <*name*> command from the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ip rtp quality-monitoring reporter Reporter1
(config-rtp-reporter-Reporter1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the section listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
shutdown on page 93

All other commands in this command set are described in this section in alphabetical order:

collector on page 4946
collector auto-link on page 4948
domain <name> on page 4949
grammar contact host port persistent on page 4950
grammar from on page 4951
grammar request-uri on page 4952
grammar to on page 4953
max-queue-depth <value> on page 4954
max-retries <value> on page 4955
outbound-proxy on page 4956

collector

Use the **collector** command to specify the IP address or host name of the server that will be receiving information from the voice quality monitoring (VQM) reporter. Use the **no** form of this command to remove the server from the reporter's configuration. Variations of this command include:

collector primary <*hostname* | *ip address*>
collector primary <*hostname* | *ip address*> **tcp**
collector primary <*hostname* | *ip address*> **tcp** <*port*>
collector primary <*hostname* | *ip address*> **udp**
collector primary <*hostname* | *ip address*> **udp** <*port*>
collector primary <*hostname* | *ip address*> **tls** <*profile name*>
collector primary <*hostname* | *ip address*> **tls** <*profile name*> **srv**
collector primary <*hostname* | *ip address*> **tls** <*profile name*> **srv** <*service name prefix*>
collector primary <*hostname* | *ip address*> **tls** <*profile name*> **srv** <*service name prefix*> <*transport name prefix*>
collector primary <*hostname* | *ip address*> **tls** <*profile name*> <*port*>
collector primary <*hostname* | *ip address*> **tls** <*profile name*> <*port*> **srv**
collector primary <*hostname* | *ip address*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*>
collector primary <*hostname* | *ip address*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*> <*transport name prefix*>
collector secondary <*hostname* | *ip address*>
collector secondary <*hostname* | *ip address*> **tcp**
collector secondary <*hostname* | *ip address*> **tcp** <*port*>
collector secondary <*hostname* | *ip address*> **udp**
collector secondary <*hostname* | *ip address*> **udp** <*port*>
collector secondary <*hostname* | *ip address*> **tls** <*profile name*>
collector secondary <*hostname* | *ip address*> **tls** <*profile name*> **srv**
collector secondary <*hostname* | *ip address*> **tls** <*profile name*> **srv** <*service name prefix*>
collector secondary <*hostname* | *ip address*> **tls** <*profile name*> **srv** <*service name prefix*> <*transport name prefix*>
collector secondary <*hostname* | *ip address*> **tls** <*profile name*> <*port*>
collector secondary <*hostname* | *ip address*> **tls** <*profile name*> <*port*> **srv**
collector secondary <*hostname* | *ip address*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*>
collector secondary <*hostname* | *ip address*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*> <*transport name prefix*>

Syntax Description

primary	Specifies that the server is the primary contact server for the VQM reporter.
secondary	Specifies that the server is the secondary contact server for the VQM reporter.
<*hostname* | *ip address*>	Specifies the host name or IP address of the server. IP addresses should be expressed in the decimal dotted notation (for example, **10.10.10.1**).
tcp	Optional. Specifies that the reporter and server communicate using Transmission Control Protocol (TCP).

udp	Optional. Specifies that the reporter and server communicate using User Datagram Protocol (UDP).
tls *<profile name>*	Optional. Associates a Transport Layer Security (TLS) profile with the trunk, thus specifying the TLS operation on the trunk.
<port>	Optional. Specifies the port number used for communication between the reporter and the server. Range is **0** to **65535**.
srv	Optional. Specifies that service records (SRV) parameters are enabled. This option is available only when an FQDN has been specified.
<service name prefix>	Optional. Specifies the service name used to format the domain naming service (DNS) SRV request used to resolve the domain name. Underscores are added automatically.
<transport name prefix>	Optional. Specifies the transport name used to format the DNS SRV request used to resolve the domain name. Underscores are added automatically.

Default Values

By default, no server is configured. When configured, by default, the UDP port is set to **5060**, and the TLS port is set to **5061**.

Command History

Release 17.6	Command was introduced.
Release R11.5.0	Command was expanded to include the TLS and SRV configuration options.

Usage Examples

The following example specifies that the VQM reporter uses the server with the IP address of **172.5.67.99** as its **primary** server:

(config)**#ip rtp quality-monitoring reporter Reporter1**
(config-rtp-reporter-Reporter1)**#collector primary 172.5.67.99**

The following example specifies the VQM collector as a primary collection server at IP address **10.10.10.1** using TLS profile **TLSPROFILE1** on the default port:

(config)**#ip rtp quality-monitoring reporter REPORTER1**
(config-rtp-reporter-REPORTER1)**#collector primary 10.10.10.1 tls TLSPROFILE1**

collector auto-link

Use the **collector auto-link** command to specify the auto-link server that will be receiving information from the voice quality monitoring (VQM) reporter. When a failover event occurs, VQM reporters that are configured to use auto-link automatically roll over to the new server for reporting. Use the **no** form of this command to remove the auto-link server from the reporter's configuration. Variations of this command include:

collector auto-link
collector auto-link tcp
collector auto-link tcp *<port>*
collector auto-link udp
collector auto-link udp *<port>*

Syntax Description

tcp	Optional. Specifies that the reporter and server communicate using Transmission Control Protocol (TCP).
udp	Optional. Specifies that the reporter and server communicate using User Datagram Protocol (UDP).
<port>	Optional. Specifies the TCP or UDP port used for communication between the reporter and the server. Range is **0** to **65535**.

Default Values

By default, VQM reporting is not associated with an auto-link server.

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example specifies that the VQM reporter uses the auto-link server and UDP:

(config)**#ip rtp quality-monitoring reporter Reporter1**
(config-rtp-reporter-Reporter1)**#collector auto-link udp**

domain *<name>*

Use the **domain** command to configure the assigned fully qualified domain name (FQDN) for host messages. The domain is a unique identifier for the Session Initiation Protocol (SIP) messages sent by the VQM reporter. Use the no form of this command to disable this feature.

Syntax Description

<name>	Specifies the FQDN for the SIP messages sent by the VQM reporter.

Default Values

By default, no FQDN is configured.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example sets the domain name as **home.com**:

(config)**#ip rtp quality-monitoring reporter Reporter1**
(config-rtp-reporter-Reporter1)**#domain home.com**

grammar contact host port persistent

Use the **grammar contact host port persistent** command to configure the AOS device to use the Transmission Control Protocol (TCP) port from which AOS initiated a Transport Layer Security (TLS) connection in the Contact uniform resource identifier (URI) sent by AOS. Use the **no** form of this command to disable this feature.

Syntax Description

host	Specifies the Contact header Host field setting.
port	Specifies the Contact header host port.
persistent	Specifies that the persistent connection port should be used for the Contact header host port.

Default Values

No default values are necessary for this command.

Command History

Release R11.5.0	Command was introduced

Functional Notes

This configuration is useful when using client-only authentication. With this type of authentication, a persistent connection is established to the SIP server. Many SIP servers and enterprise session border controllers (eSBCs) need to see the TCP port from which AOS initiated the TLS connection in the Contact URI sent by AOS.

Usage Examples

The following example specifies that AOS device should use the TCP port from which AOS initiated the TLS connection in the Contact URI sent by AOS:

(config)**#ip rtp quality-monitoring reporter Reporter1**
(config-rtp-reporter-Reporter1)**#grammar contact host port persistent**

grammar from

Use the **grammar from** command to configure the From header on Session Initiation Protocol (SIP) messages from the VQM reporter. Use the **no** form of this command to return to the default setting. Variations of this command include:

grammar from host collector
grammar from host domain
grammar from host local
grammar from user *<username>*
grammar from user none

Syntax Description

host	Specifies the Host field formatting for the From header.
collector	Specifies the collector's host setting for formatting the Host field of the From header.
domain	Specifies the user defined domain name for formatting the Host field of the From header. The domain name is configure using the command *domain <name> on page 4949*.
local	Specifies the local IP address for formatting the Host field of the From header.
user	Specifies the User field formatting for the From header.
<username>	Specifies the user name used to format the User field of the From header.
none	Specifies that the user is not include in the User field of the From header.

Default Values

By default, the host for formatting messages is **local**, and *<username>* is set to the unit's **serial number.**

Command History

Release A2	Command was introduced.
Release R10.1.0	Command was added to the VQM Reporter command set.

Usage Examples

The following example sets the From header format to use the user defined domain name:

(config)**#ip rtp quality-monitoring reporter Reporter1**
(config-rtp-reporter-Reporter1)**#grammar from host domain**

The following example specifies that the user is not included in the User field of the From header:

(config)**#ip rtp quality-monitoring reporter Reporter1**
(config-rtp-reporter-Reporter1)**#grammar from user none**

grammar request-uri

Use the **grammar request-uri** command to format the Request uniform resource identifier (URI) for Session Initiation Protocol (SIP) messages from the VQM reporter. Use the **no** form of this command to return to the default setting. Variations of this command include:

grammar request-uri host collector
grammar request-uri host domain
grammar request-uri host-resolve
grammar request-uri user follow-to
grammar request-uri user none

Syntax Description

host	Specifies the Host field formatting for the Request-URI header.
collector	Specifies the collector's host setting for formatting the Host field of the Request-URI header.
domain	Specifies the user defined domain name for formatting the Host field of the Request-URI header. The domain name is configure using the command *domain <name> on page 4949*.
host-resolve	Enables the local unit to resolve the domain before resolving the Host field of the Request URI.
user	Specifies the User field formatting for the Request-URI header.
follow-to	Specifies that the current To header user values should be used for formatting the User field formatting of the Request-URI header.
none	Specifies that the user is not included in the Request-URI header.

Default Values

By default, the host for formatting messages is **collector**, **host-resolve** is disabled, and the User field formatting uses the current To header (**follow-to**) user values.

Command History

Release A2	Command was introduced.
Release R10.1.0	Command was added to the VQM Reporter command set.

Usage Examples

The following example enables VQM reporter SIP messages to resolve the Request URI from the host domain:

(config)**#ip rtp quality-monitoring reporter Reporter1**
(config-rtp-reporter-Reporter1)**#grammar request-uri host domain**

The following example specifies that the user is not included in the User field of the Request URI header:

(config)**#ip rtp quality-monitoring reporter Reporter1**
(config-rtp-reporter-Reporter1)**#grammar request-uri user none**

grammar to

Use the **grammar to** command to configure the To header on Session Initiation Protocol (SIP) messages from the VQM reporter. Use the **no** form of this command to return to the default setting. Variations of this command include:

grammar to host collector
grammar to host domain
grammar to user <*username*>
grammar to user none

Syntax Description

host	Specifies the Host field formatting for the To header.
collector	Specifies the collector's host setting for formatting the Host field of the To header.
domain	Specifies the user defined domain name for formatting the Host field of the To header. The domain name is configure using the command *domain <name> on page 4949*.
user	Specifies the User field formatting for the Host field of the To header.
<*username*>	Specifies the user name used to format the User field of the To header.
none	Specifies that the user is not include in the Host field of the To header.

Default Values

By default, the host for formatting messages is **collector**, and the <*username*> is **collector.**

Command History

Release A2	Command was introduced.
Release R10.1.0	Command was added to the VQM Reporter command set.

Usage Examples

The following example sets the To header format to use the user defined domain name for formatting the To header:

(config)**#ip rtp quality-monitoring reporter Reporter1**
(config-rtp-reporter-Reporter1)**#grammar to host domain**

The following example specifies that the user is not included in the User field of the To header:

(config)**#ip rtp quality-monitoring reporter Reporter1**
(config-rtp-reporter-Reporter1)**#grammar to user none**

max-queue-depth *<value>*

Use the **max-queue-depth** command to specify the number of reports held in queue that are waiting to send requests or receive responses. Use the **no** form of this command to return the queue depth to the default value.

Syntax Description

<value>	Specifies the number of reports held in queue. Range is **0** to **2000**.

Default Values

By default, the reporter is configured to hold **512** reports in queue.

Command History

Release 17.6	Command was introduced.

Usage Examples

The following example sets the reporter to hold **700** reports in its queue:

(config)**#ip rtp quality-monitoring reporter Reporter1**
(config-rtp-reporter-Reporter1)**#max-queue-depth 700**

max-retries *<value>*

Use the **max-retries** command to specify the number of times the reporter will attempt to contact the server. Use the **no** form of this command to return the number of attempts to the default value.

Syntax Description

<value>	Specifies the number of connection attempts. Range is **0** to **5**.

Default Values

By default, the voice quality monitoring (VQM) reporter is set to attempt to connect to the server **3** times.

Command History

Release 17.6	Command was introduced.

Functional Notes

After the reporter has attempted the maximum number of times to contact the server, the reports sent to the server are discarded. You can see how many reports have been discarded by using the command *debug ip security monitor on page 389*.

Usage Examples

The following example sets the number of connection attempts to **4**:

(config)**#ip rtp quality-monitoring reporter Reporter1**
(config-rtp-reporter-Reporter1)**#max-retries 4**

outbound-proxy

Use the **outbound-proxy** command to specify the IP address or host name of the device receiving information from the voice quality monitoring (VQM) reporter before the information is sent to the collector. This command allows you to configure additional devices to receive VQM reporters in addition to a single collector. Using the **no** form of this command removes the outbound proxy server from the VQM reporter configuration. Variations of this command include:

outbound-proxy primary <*hostname* | *ip address*>
outbound-proxy primary <*hostname* | *ip address*> **tcp**
outbound-proxy primary <*hostname* | *ip address*> **tcp** <*port*>
outbound-proxy primary <*hostname* | *ip address*> **udp**
outbound-proxy primary <*hostname* | *ip address*> **udp** <*port*>
outbound-proxy primary <*hostname* | *ip address*> **tls** <*profile name*>
outbound-proxy primary <*hostname* | *ip address*> **tls** <*profile name*> **srv**
outbound-proxy primary <*hostname* | *ip address*> **tls** <*profile name*> **srv** <*service name prefix*>
outbound-proxy primary <*hostname* | *ip address*> **tls** <*profile name*> **srv** <*service name prefix*> <*transport name prefix*>
outbound-proxy primary <*hostname* | *ip address*> **tls** <*profile name*> <*port*>
outbound-proxy primary <*hostname* | *ip address*> **tls** <*profile name*> <*port*> **srv**
outbound-proxy primary <*hostname* | *ip address*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*>
outbound-proxy primary <*hostname* | *ip address*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*> <*transport name prefix*>
outbound-proxy secondary <*hostname* | *ip address*>
outbound-proxy secondary <*hostname* | *ip address*> **tcp**
outbound-proxy secondary <*hostname* | *ip address*> **tcp** <*port*>
outbound-proxy secondary <*hostname* | *ip address*> **udp**
outbound-proxy secondary <*hostname* | *ip address*> **udp** <*port*>
outbound-proxy secondary <*hostname* | *ip address*> **tls** <*profile name*>
outbound-proxy secondary <*hostname* | *ip address*> **tls** <*profile name*> **srv**
outbound-proxy secondary <*hostname* | *ip address*> **tls** <*profile name*> **srv** <*service name prefix*>
outbound-proxy secondary <*hostname* | *ip address*> **tls** <*profile name*> **srv** <*service name prefix*> <*transport name prefix*>
outbound-proxy secondary <*hostname* | *ip address*> **tls** <*profile name*> <*port*>
outbound-proxy secondary <*hostname* | *ip address*> **tls** <*profile name*> <*port*> **srv**
outbound-proxy secondary <*hostname* | *ip address*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*>
outbound-proxy secondary <*hostname* | *ip address*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*> <*transport name prefix*>

Syntax Description

primary	Specifies this outbound proxy server as the primary contact server for the VQM reporter.
secondary	Specifies this outbound proxy server as the secondary contact server for the VQM reporter.

<hostname | ip address>	Specifies the host name or IP address of the outbound proxy. IP addresses should be expressed in the decimal dotted notation (for example, **10.10.10.1**).
tcp	Optional. Specifies that the reporter and outbound proxy server communicate using Transmission Control Protocol (TCP).
udp	Optional. Specifies that the reporter and outbound proxy server communicate using User Datagram Protocol (UDP).
tls *<profile name>*	Optional. Associates a Transport Layer Security (TLS) profile with the trunk, thus specifying the TLS operation on the trunk.
<port>	Optional. Specifies the port number used for communication between the reporter and the server. Range is **0** to **65535**.
srv	Optional. Specifies that service records (SRV) parameters are enabled. This option is available only when an FQDN has been specified.
<service name prefix>	Optional. Specifies the service name used to format the domain naming service (DNS) SRV request used to resolve the domain name. Underscores are added automatically.
<transport name prefix>	Optional. Specifies the transport name used to format the DNS SRV request used to resolve the domain name. Underscores are added automatically.

Default Values

By default, no server is configured. When configured, by default, the UDP port is set to **5060**, and the TLS port is set to **5061**.

Command History

Release A4.03	Command was introduced.
Release R11.5.0	Command was expanded to include the TLS and SRV configuration options.

Usage Examples

The following example specifies that the VQM reporter uses the outbound proxy server with the IP address of **172.5.67.99** as its **primary** server:

(config)**#ip rtp quality-monitoring reporter Reporter1**
(config-rtp-reporter-Reporter1)**#outbound-proxy primary 172.5.67.99**

The following example specifies the VQM collector as an outbound-proxy server at IP address **10.10.10.1** using TLS profile **TLSPROFILE1** on the default port:

(config)**#ip rtp quality-monitoring reporter REPORTER1**
(config-rtp-reporter-REPORTER1)**#outbound-proxy primary 10.10.10.1 tls TLSPROFILE1**

VOICE TRUNKS COMMAND SETS

This section includes the following command sets:

VOICE ANALOG TRUNK COMMAND SET

Voice analog trunks are analog subscriber lines delivered by service providers that allow communication devices to connect to the outside world. To configure analog trunks, you must first configure the foreign exchange office (FXO) physical interface. By default, FXO interfaces are enabled, but their status must be verified before creating an analog trunk. For more information on configuring and verifying FXO interfaces, refer to the *FXO Interface Command Set on page 2364*.

Once the FXO interface is configured, a trunk account must be created for the analog trunk to make and receive calls. When creating trunk accounts, you must assign an FXO port to the trunk, and make sure the analog FXO settings (trunk number, supervision, etc.) match the parameters set by your service provider.

There are three main types of analog trunks supported by AOS. The first type is a dial pulse terminate (DPT) analog trunk, the second type is a loop start (LS) analog trunk, and the third is a ground start (GS) analog trunk. Configuration commands for all three analog trunk types are included in this section. For more information about configuring analog trunks, refer to the *NetVanta 7000 Series Trunk Accounts* configuration guide available online at https://supportcommunity.adtran.com.

To enter the Voice Analog Trunk DPT Configuration mode, enter the following command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice trunk t01 type analog supervision dpt
(config-t01)#
```

To enter the Voice Analog Trunk LS Configuration mode, enter the following command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice trunk t01 type analog supervision loop-start
(config-t01)#
```

To enter the Voice Analog Trunk GS Configuration mode, enter the following command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice trunk t01 type analog supervision ground-start
(config-t01)#
```

NOTE

*Not all Voice Analog Trunk commands apply to all analog trunk types. Use the **?** command to display a list of valid commands.*

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

alc on page 4962
anlp on page 4963
blind-dial on page 4964
busy all on page 4965
busy fxo <slot/port> on page 4966
busy-out monitor track <name> on page 4967
busy range fxo <range> on page 4968
caller-id on page 4969
caller-id-override on page 4970
codec-list <name> on page 4972
connect fxo <slot/port> on page 4974
connect range fxo <range> on page 4975
dialtone timeout <value> on page 4976
did digits-transferred <value> on page 4977
disconnect-supervision on page 4978
echo-cancellation on page 4979
loop-disconnect time <value> on page 4980
modem-passthrough on page 4981
plc on page 4982
prefer trunk-routing on page 4983
reject-external on page 4984
resource-selection on page 4985
rtp delay-mode on page 4986
rtp dtmf-relay on page 4987
rtp frame-packetization <value> on page 4988
rtp packet-delay on page 4989
rtp qos dscp <value> on page 4990
rtp rx-gain <value> on page 4991
rtp tx-gain <value> on page 4992
trunk-number <number> on page 4993

alc

Use the **alc** command to enable automatic level control (ALC). ALC reduces Realtime Transport Protocol (RTP) received signals that are out of specification to the predefined levels. It is not necessary to enable ALC on those networks that guarantee signal levels to be within specification. Use the **no** form of this command to disable this feature. Variations of this command include:

alc
alc level -16
alc level -17
alc level -18
alc level -19
alc level -20
alc level -21
alc level -22

Syntax Description

level -16	Optional. Specifies the ALC attenuation level is -16 dBm0.
level -17	Optional. Specifies the ALC attenuation level is -17 dBm0.
level -18	Optional. Specifies the ALC attenuation level is -18 dBm0.
level -19	Optional. Specifies the ALC attenuation level is -19 dBm0.
level -20	Optional. Specifies the ALC attenuation level is -20 dBm0.
level -21	Optional. Specifies the ALC attenuation level is -21 dBm0.
level -22	Optional. Specifies the ALC attenuation level is -22 dBm0.

Default Values

By default, ALC is disabled.

Command History

Release 14.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the Media Gateway Control Protocol (MGCP) endpoint configuration.
Release A2.04	Command was expanded to include the **level** parameters.

Usage Examples

The following example activates ALC on trunk **T01**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#alc**

anlp

Use the **anlp** command to enable advanced nonlinear processing which adds attenuation of residual echo level by way of a nonlinear processor (NLP) placed in the send path of an echo canceller. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **blind-dial** is disabled.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example enables anlp:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#anlp**

blind-dial

Use the **blind-dial** command to allow calls to be placed without the presence of dial tone. Use the **no** form of this command to disable blind dialing.

Syntax Description

No subcommands.

Default Values

By default, **blind-dial** is disabled.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example enables blind dialing:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#blind-dial**

busy all

Use the **busy all** command to set all level zero digital signals (DS0s) to busy so that no calls are allowed inbound or outbound. If any calls are active at the time this command is issued, the calls will stay active until either party terminates the call. Once terminated, the DS0s are busied out. Use the **no** form of this command to return to the default setting. Variations of this command include:

busy all
busy all now

Syntax Description

now	Optional. Immediately terminates calls that are active at the time the command is issued (for example, in the middle of a conversation).

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was expanded to include the analog voice trunk.

Usage Examples

The following example sets all DS0s on trunk **T01** to busy and terminates calls that are active at the time the command is issued:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#busy all now**

busy fxo <*slot/port*>

Use the **busy fxo** command to set a DS0 to busy so that no calls are allowed inbound or outbound. If a call is active at the time this command is issued, the call will stay active until either party terminates the call. Once terminated, the DS0 is set to busy. Use the **no** form of this command to disable this feature. Variations of this command include:

busy fxo <*slot/port*>
busy fxo <*slot/port*> **now**

Syntax Description

<*slot/port*>	Specifies the slot/port for the foreign exchange office (FXO).
now	Optional. Immediately terminates active call at the time the command is issued (for example, in the middle of a conversation).

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was expanded to include the analog voice trunk.

Usage Examples

The following example sets FXO 0/1 to busy and terminates an active call when the command is issued:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#busy fxo 0/1 now**

busy-out monitor track *<name>*

Use the **busy-out monitor track** command to automatically take a voice trunk out of service based on one or more conditions. The primary application of this feature is to signal to an attached private branch exchange (PBX) that because calls routed to the integrated access device (IAD) could fail due to loss of Session Initiation Protocoal (SIP) trunk connectivity, it should attempt to route the call via another interface. For more information on creating tracks, refer to *track <name> on page 1886* and the *Network Monitor Track Command Set on page 4098*. Use the no form of this command to remove a track from busy-out monitoring.

Syntax Description

<name>	Specifies the name of the track to monitor.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example shuts down trunk **T01** when the **on_fail** track fails:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#busy-out monitor track on_fail**

busy range fxo <*range*>

Use the **busy range fxo** command to set a particular set of level zero digital signals (DS0s) to busy so that no calls are allowed inbound or outbound. If any calls are active at the time this command is issued, the calls will stay active until either party terminates the call. Once terminated, the DS0s are set to busy. Use the **no** form of this command to return to the default setting. Variations of this command include:

busy range fxo <*range*>
busy range fxo <*range*> **now**

Syntax Description

<*range*>	Specifies a range of ports in the format <*slot/begin port range-end port range*> (for example, **0/1-4**).
now	Optional. Terminates calls that are active at the time the command is issued (for example, in the middle of a conversation).

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets DS0s to busy and terminates calls assigned to port range **fxo 0/1** through **fxo 0/4** when the command is issued:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#busy range fxo 0/1-4 now**

caller-id

Use the **caller-id** command to interpret and pass caller identification (ID) on this trunk. This information usually displays the name, number, time, and date of the calling party. Use the **no** form of this command to cancel the setting.

Syntax Description

No subcommands.

Default Values

By default, caller ID is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example enables caller ID:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#caller-id**

caller-id-override

Use the **caller-id-override** command to replace the calling party information for this trunk with a specific number. This command is used to conceal a user's name and number or to display a different name and number for internal or external caller ID. Use the **no** form of this command to cancel the setting. Variations of this command include:

caller-id-override emergency-outbound <*number*>
caller-id-override emergency-outbound match-substitute
caller-id-override name-inbound <*name*>
caller-id-override name-inbound <*name*> **if-unavailable**
caller-id-override number-inbound <*number*>
caller-id-override number-inbound <*number*> **if-no-cpn**
caller-id-override number-inbound <*number*> <*trunk id*>
caller-id-override privacy-outbound match-substitute

Syntax Description

emergency-outbound	Replaces the calling party number for outbound emergency calls.
<*number*>	Specifies the number to replace the calling party number for outbound emergency calls.
match-substitute	Specifies that the configured automatic number identification (ANI) match substitution is used for outbound emergency calls.
name-inbound <*name*>	Specifies the name to replace the calling party name for inbound calls.
if-unavailable	Specifies that the calling party name is replaced only if the calling party name is unavailable.
number-inbound <*number*>	Specifies the number to replace the calling party number for inbound calls.
<*trunk id*>	Optional. Specifies the trunk ID (**Txx**) for outbound calls.
if-no-cpn	Optional. Specifies that the calling party number is replaced only if the calling party number is unavailable.
privacy-outbound	Replaces the calling party number on anonymous outbound calls.
match-substitute	Specifies that the configured ANI match substitution is used for anonymous outbound calls.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.
Release 15.1	Command was expanded.
Release 16.1	Command was expanded to include the **if-no-cpn** parameter.
Release A4.01	Command was expanded to include the **match-substitute** parameter.
Release R11.8.0	Command was expanded to include the **privacy-outbound** parameter.

Usage Examples

The following example sets the caller ID override number on the trunk where the command is issued:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#caller-id-override number-inbound 555-8000**

codec-list *<name>*

Use the **codec-list** command to specify the coder-decoder (CODEC) list to be used by this account. This CODEC can be used for normal voice traffic or for Session Border Controller (SBC) transcoding. Use the **no** form of this command to remove the CODEC list from the account. Variations of this command include:

codec-list *<name>*
codec-list *<name>* **both**
codec-list *<name>* **in**
codec-list *<name>* **out**
codec-list any
codec-list any both
codec-list any in
codec-list any out

Syntax Description

<name>	Specifies the CODEC list to be used for this account.
any	Specifies that any possible CODEC is allowed on this account.
both	Optional. Specifies that the CODEC list is applied to both transmitted and received Session Description Protocol (SDP) transmissions.
in	Optional. Specifies that the CODEC list is applied to received SDP only.
out	Optional. Specifies that the CODEC list is applied to transmitted SDP only.

Default Values

By default, no CODEC lists are assigned.

Command History

Release R10.4.0	Command was introduced and replaced the **codec-group** command.

Functional Notes

The **codec-list** command applies a previously configured CODEC list to an interface, voice trunk, or voice account. These lists are lists of CODECs used by the interface, trunk, or account in call negotiation and are arranged in preferred order with the first listed CODEC being the most preferred.

CODEC lists are created using the **codec** command from the Voice CODEC List Configuration mode prompt. For more information about creating CODEC lists, refer to the *Voice CODEC List Command Set on page 4893***.**

In addition, CODEC lists can be used for the SBC transcoding feature. For more information about this feature, its uses, and its configuration, refer to the configuration guide *Configuring Transcoding in AOS*, available online at https://supportcommunity.adtran.com.

> NOTE *Because you can choose to specify that any CODEC is used by a Session Initiation Protocol (SIP) endpoint with the **any** keyword, do not create a CODEC list with the name of **any**.*

Usage Examples

The following example applies the CODEC list **LIST1** to incoming SDP traffic on trunk **T01**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#codec-list LIST1 in**

connect fxo *<slot/port>*

Use the **connect fxo** command to specify the physical interface this trunk will use for voice calls. Use the **no** form of this command to remove this association.

Syntax Description

<slot/port>	Specifies the slot/port for the foreign exchange office (FXO) trunk.

Default Values

By default, no physical interface is assigned.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was expanded to include the analog voice trunk.

Usage Examples

The following example specifies this trunk to use port **fxo 0/1**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#connect fxo 0/1**

connect range fxo <*range*>

Use the **connect range fxo** command to specify the range of physical interfaces for this trunk group usage. Use the **no** form of this command to return to the default setting.

Syntax Description

<*range*>	Specifies a range of ports in the format <*slot/begin port range-end port range*> (for example, **0/1-4**).

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example specifies that this analog loop start (LS) trunk will use the contiguous port range **fxo 0/1** through **fxo 0/4**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#connect range fxo 0/1-4**

dialtone timeout *<value>*

Use the **dialtone timeout** command to specify the dial tone detection timeout period (in milliseconds) for dial tone detection.

Syntax Description

<value>	Specifies the dial tone detection timeout period in milliseconds. Valid rage is **1500** to **60000** milliseconds.

Default Values

By default, the dial tone detection timeout period is **2000** milliseconds for the United States, Puerto Rico, and Canada and is **4000** milliseconds for all other supported countries.

Command History

Release A4.05	Command was introduced.

Usage Examples

The following example specifies that analog loop start trunk **t01** will use a **3000** milliseconds dial tone detection timeout period:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#dialtone timeout 3000**

did digits-transferred <*value*>

Use the **did digits-transferred** command to define how many of the received digits should be sent to the internal switchboard from an incoming call on a user role trunk. The number of digits transferred are the least significant digits received. Direct inward dialing (DID) should be used if a Telco provider is providing digits to the unit on inbound calls or if the unit needs to provide DID information to a piece of customer premises equipment (CPE). Use the **no** form of this command to disable this feature. Variations of this command include:

did digits-transferred <*value*>
did digits-transferred <*value*> **prefix** <*number*>

Syntax Description

<*value*>	Specifies the number of digits to be transferred. Range is **1** to **16** digits.
prefix <*number*>	Optional. Specifies a sequence of digits to be prepended to the digits that will be transmitted. For example, if seven digits will be transferred via DID, then prefix the seven digits with 256. Thus, **555-8000** would be prefixed with **256**, transmitting out the string of digits **256-555-8000**.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Functional Notes

User Role Example:

555-1000 is an incoming call on the trunk. With **did digits-transferred** <*value*> set to 4, the number 1000 will be sent to the switchboard. On a network role trunk, the **did digits-transferred** command allows you to define how many of the digits from the Accept criteria should be sent externally from a call that was routed by the switchboard. The number of digits transferred are the least significant digits received.

Network Role Example:

555-1000 is accepted on the universal time (UT) interface. With **did digits-transferred** <*value*> set to 4, the number of 1000 will be sent to the device connected to the UT interface. This command cannot be specified if and when **trunk-number** is being used. Conversely, if DID is used, **trunk-number** will not be allowed.

Usage Examples

The following example transfers the digits **555-8000** and adds the prefix **256**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#did digits-transferred 5558000 prefix 256**

disconnect-supervision

Use the **disconnect-supervision** command to configure disconnect supervision for calls on the analog voice trunk. Use the **no** version of this command to disable this feature. Variations of this command include:

disconnect-supervision release-delay <*seconds*>
disconnect-supervision tone busy
disconnect-supervision tone busy <*seconds*>

Syntax Description

release-delay <*seconds*>	Specifies the time delay (in seconds) between when the call is terminated and when the unit places the FXO port in an idle state. Range is **1** to **120** seconds.
tone busy	Specifies that the voice trunk be monitored for busy tone. Upon detection of busy tone, the call will be disconnected after **10** seconds.
<*seconds*>	Specifies the time delay (in seconds) between the busy tone detection and the termination of the call. Range is **1** to **120** seconds.

Default Values

By default, **disconnect-supervision** is disabled.

Command History

Release A4.05	Command was introduced.
Release R10.2.0	Command was expanded to include the **release-delay** parameter.

Functional Notes

Disconnect supervision monitors a foreign exchange office (FXO) port for a specific condition to determine when the line should be released. Disconnect supervision is used in auto attendant, fax, and modem applications to ensure that a connection is not maintained indefinitely when a call has ended or could not be completed.

Usage Examples

The following example enables disconnect supervision for busy tone:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#disconnect-supervision tone busy**

echo-cancellation

Use the **echo-cancellation** command to improve voice quality for packetized-based voice calls, such as Voice over Internet Protocol (VoIP) or Media Gateway Control Protocol (MGCP). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **echo-cancellation** is enabled.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example activates **echo-cancellation**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#echo-cancellation**

loop-disconnect time <*value*>

Use the **loop-disconnect time** command to specify the length of time a line must maintain a loop current feed open (LCFO) state to qualify as a valid disconnection. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

The default loop-disconnect time is determined using the command *voice system-country <name> on page 1970*. The list below shows the default loop disconnect time (in milliseconds) for fully-supported countries:

Australia	500 ms	Mexico	500 ms
Belgium	200 ms	Puerto Rico	500 ms
Canada	500 ms	United Arab Emirates	200 ms
ETSI	200 ms	United Kingdom	200 ms
Ireland	200 ms	United States	500 ms

Command History

Release A5.01	Command was introduced.

Functional Notes

Loop disconnect time is only configurable on ground start and loop start analog trunks.

Usage Examples

The following example configures the loop disconnect time for loop start trunk T01 as **500** ms:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#loop-disconnect time 500**

modem-passthrough

Use the **modem-passthrough** command to switch to passthrough mode on fax or modem tone detection. This command allows modem and fax calls to maintain a connection without altering the signals with the voice improvement settings, such as echo cancellation and voice activity detection (VAD). Use the **no** form of this command to disable this feature. Variations of this command include:

modem-passthrough
modem-passthrough detection-time <*value*>
modem-passthrough cng-early-detect

Syntax Description

detection-time <*value*>	Optional. Specifies the fax and/or modem detection time length value in seconds. Range is **0** to **8** seconds.
cng-early-detect	Optional. Enables early (first burst) detection of fax calling (CNG) tone.

Default Values

By default, **modem-passthrough** is enabled.

Command History

Release 11.1	Command was introduced.
Release 12.1	Command was expanded.
Release R10.8.0	Command was expanded to include the **cng-early-detect** parameter.

Usage Examples

The following example disables **modem-passthrough**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#no modem-passthrough**

plc

Use the **plc** command to enable packet loss concealment (PLC). PLC is used to prevent choppy connections by concealing a packet loss by replacing the lost packet with another voice packet in the data stream. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, PLC is enabled on this interface.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example disables PLC on trunk **T01**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#no plc**

prefer trunk-routing

Use the **prefer trunk-routing** command to add a trunk to a list of trunks that are considered first for call routing, regardless of system routing mode or locally configured extensions. Use the **no** form of this command to remove the trunk from the list.

Syntax Description

No subcommands.

Default Values

By default, **prefer trunk-routing** is disabled.

Command History

Release A2	Command was introduced.

Functional Notes

Trunk routing can be specified as a preference for specific trunks, allowing the trunk to be considered first for routing rather than relying on the internal or external nature of the call to dictate whether the trunk or voice station is the first choice routing path. The **prefer trunk-routing** command, executed from a specific trunk's configuration mode, adds the trunk to a list of trunks that are considered first for routing.

By default, no trunk routing preference is set, so that each trunk operates as dictated by normal call routing modes. Adding the trunk routing preference only affects how inbound calls from the specific trunk are handled.

Usage Examples

The following example specifies that trunk routing is preferred on the trunk **T01**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#prefer trunk-routing**

reject-external

Use the **reject-external** command to prevent inbound calls on the trunk from being routed back out of the same trunk. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **reject-external** is enabled on this interface.

Command History

Release 9.3	Command was introduced.

Functional Notes

In general, trunks are assigned to the user role, which means they terminate lines from a Telco provider. If this is the case, **reject-external** should be enabled so that inbound calls on the trunk cannot be routed back out of the same trunk. If the configuration is poor, inbound long distance calls could be routed back out the same trunk, causing the owner of the unit to be charged for long distance calls without his knowledge. For network-role trunks and Session Initiation Protocol (SIP) based trunks, this command should be disabled to allow calls to be properly routed in the unit.

Usage Examples

The following example disables **reject-external**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#no reject-external**

resource-selection

Use the **resource-selection** command to determine how the switchboard uses outbound call resources contained within a time division multiplexing (TDM) based trunk group. Use the **no** form of this command to disable this feature. Variations of this command include:

resource-selection circular
resource-selection circular ascending
resource-selection circular descending
resource-selection linear
resource-selection linear ascending
resource-selection linear descending

Syntax Description

circular	Performs call load balancing among available DS0s/B-channels in this trunk. Subsequent calls will be delivered to the next available DS0/B-channel in a round-robin fashion.
linear	Specifies that a call being delivered to this trunk will be accepted out the first available DS0/B-channel available at the time the call is received.
ascending	Optional. Distributes calls in an order from the lowest to the highest channel (DS0 1, 2, 3 through 24).
descending	Optional. Distributes calls in an order from the highest to the lowest channel (DS0 24, 23, 22 through 1).

Default Values

By default, resource selection is set to **linear**.

Command History

Release 9.3	Command was introduced.
Release 13.1	Command was expanded to include the **ascending** and **descending** subcommands.

Usage Examples

The following example specifies circular resource selection:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#resource-selection circular**

rtp delay-mode

Use the **rtp delay-mode** command to configure the Realtime Transport Protocol (RTP) jitter buffer packet delay mode settings. RTP is used to prevent static on voice connections by enhancing the quality of the packet delivery. Use the **no** form of this command to return to the default setting. Variations of this command include:

rtp delay-mode adaptive
rtp delay-mode fixed

Syntax Description

adaptive	Configures the RTP jitter buffer packet delay to adjust during a call based on network conditions.
fixed	Configures the RTP jitter buffer packet delay to remain constant.

Default Values

By default, the RTP delay mode is set to **adaptive**. This allows for minimal latency by adjusting the average packet delay based on the conditions of the network.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures RTP delay mode as **fixed**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#rtp delay-mode fixed**

rtp dtmf-relay

Use the **rtp dtmf-relay** command to configure the method by which Realtime Transport Protocol (RTP) dual tone multi-frequency (DTMF) events are relayed. The dial digits can be sent inband or out-of-band (OOB) of the voice stream. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp dtmf-relay inband
rtp dtmf-relay nte <*value*>

Syntax Description

inband	Specifies that RTP DTMF events be relayed inband in the RTP stream.
nte <*value*>	Specifies that RTP DTMF events be relayed OOB using named telephone event (NTE). Enter an NTE value between **96** and **127**.

Default Values

By default, the **rtp dtmf-relay** is set for **NTE 101**.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example configures RTP DTMF relay events for **inband**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#rtp dtmf-relay inband**

rtp frame-packetization <*value*>

Use the **rtp frame-packetization** command to configure the Realtime Transport Protocol (RTP) frame packetization time in milliseconds for individual trunks and users. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Configures the RTP frame packetization time value in milliseconds. Select from **10**, **20**, **30**, or **40** milliseconds.

Default Values

By default, the **rtp frame-packetization** time is set to **20** milliseconds on all trunks and users.

Command History

Release 9.3	Command was introduced.
Release R10.8.0	Command was expanded to include **40** milliseconds.

Usage Examples

The following example sets the frame packetization time for trunk **T01** to **10** milliseconds:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#rtp frame-packetization 10**

rtp packet-delay

Use the **rtp packet-delay** command to configure the maximum Realtime Transport Protocol (RTP) packet delays. This command is used to set the allowable limits of latency on the network. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp packet-delay fax <*value*>
rtp packet-delay maximum <*value*>
rtp packet-delay nominal <*value*>

Syntax Description

fax <*value*>	Sets the fax delay time value. Range is **0** to **500** milliseconds.
maximum <*value*>	Sets the maximum delay time value in increments of **10** milliseconds. Range is **40** to **320** milliseconds.
nominal <*value*>	Sets the nominal delay time value in increments of **10** milliseconds. Range is **10** to **240** milliseconds.

Default Values

By default, the RTP packet delay for fax is **300**, maximum is **100**, and nominal is **50**.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures the RTP fax delay time on trunk **T01** to **200** milliseconds:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#rtp packet-delay fax 200**

rtp qos dscp <*value*>

Use the **rtp qos dscp** command to configure the maximum Realtime Transport Protocol (RTP) quality of service (QoS) parameters for differentiated services code point (DSCP). Use the **no** form of this command to return to the default global value.

Syntax Description

<*value*>	Configures the RTP QoS parameter for DSCP. Enter a value between **0** and **63**.

Default Values

By setting the **rtp qos dscp** value on an individual trunk or user, you will override the global **rtp qos dscp** setting for RTP packets. The default global DSCP value for RTP is **46**.

Command History

Release 9.3	Command was introduced.

Functional Notes

By setting the **rtp qos dscp** value on an individual trunk or user, you will override the global **rtp qos dscp** setting for RTP packets. QoS is set using a DSCP value. Valid DSCP values are **0** to **63**, and a higher DSCP value has a higher priority. The default global DSCP value for RTP is **46**. Remember that if you are using a public IP connection, such as the Internet, for Voice over Internet Protocol (VoIP), end-to-end QoS may not be guaranteed. The default DSCP value for Session Initiation Protocol (SIP) is **26**. To configure QoS for the RTP traffic that carries the voice conversation, use the command **ip rtp qos dscp** followed by the desired DSCP value.

Usage Examples

The following example configures the RTP QoS DSCP for trunk **T02** to **60**:

(config)**#voice trunk t02 type analog supervision loop-start**
(config-t02)**#rtp qos dscp 60**

rtp rx-gain *<value>*

Use the **rtp rx-gain** command to specify the Realtime Transport Protocol (RTP) receive (RX) gain or attenuation. RTP is used to prevent static on voice connections by enhancing the quality of the packet delivery. Using the **no** form of this command returns the RTP RX gain or attenuation to the default value.

Syntax Description

<value>	Specifies the RTP RX gain or attenuation in the RTP to time division multiplexing (TDM) direction. Range is **6** to **-14**. Negative values specify attenuation. Positive values specify gain in decibels (dB).

Default Values

By default, RTP RX gain is set to **0** dB.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example specifies the RTP RX gain for trunk **T01** is **4** dB:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#rtp rx-gain 4**

rtp tx-gain <*value*>

Use the **rtp tx-gain** command to specify the Realtime Transport Protocol (RTP) transmit (TX) gain or attentuation. RTP is used to prevent static on voice connections by enhancing the quality of the packet delivery. Using the **no** form of this command returns the RTP TX gain or attenuation to the default value.

Syntax Description

<*value*>	Specifies the RTP TX gain or attenuation in the time division multiplexing (TDM) to RTP direction. Range is **6** to **-14**. Negative values specify attenuation. Positive values specify gain in decibels (dB).

Default Values

By default, RTP TX gain is set to **0** dB.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example specifies the RTP TX gain for trunk **T01** is **4** dB:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#rtp tx-gain 4**

trunk-number <*number*>

Use the **trunk-number** command to define the call routing when direct inward dialing (DID) is disabled. This feature directs incoming calls to the specified number when DID is not present. This command also allows users to activate different system modes of operation that redirect incoming calls to a different number depending on the specified mode. Use the **no** form of this command to disable this feature. Variations of this command include:

trunk-number <*number*>
trunk-number no-number
trunk-number <*system mode*> <*number*>
trunk-number <*system mode*> **no-number**
trunk-number override <*number*>
trunk-number override no-number

Syntax Description

<*number*>	Specifies the number used for call routing when DID is disabled.
<*system mode*>	Optional. Specifies the system mode to configure. Choose from **custom1**, **custom2**, **custom3**, **lunch**, **night**, or **weekend**. Refer to the command *voice system-mode on page 1971* for more information on system modes.
no-number	Specifies no inbound calls are allowed on this trunk.
override	Ignores the programmed system mode schedule.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was added to the feature group D (FGD) trunk options.
Release A1	Command was expanded to include the new subcommands.

Usage Examples

The following example defines call routing on trunk **T03**:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#trunk-number 4000**

t38

Use the **t38** command to enable T.38 fax operation. Use the **no** form of this command to disable this feature.

The command modem-passthrough on page 4981 must be enabled for T.38 operation to work.

Syntax Description

No subcommands.

Default Values

By default, T.38 is disabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables T.38 on trunk **T01**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#t38**

Technology Review

T.38 is an International Telecommunication Union (ITU) specification that allows Group-3 Fax (T.30) data to be transported over the Internet. It is similar to dual tone multi-frequency (DTMF) relay (RFC 2833) in that the digital signal processor (DSP) decodes tones and demodulated fax data and converts them into packets. A similar device on the other end takes the packets/tones and remodulates them so that an analog fax machine on the other end can receive the fax. AOS's previous support (revisions 12 through 15) for fax/modem signals was simply detecting a tone and forcing the coder-decoder (CODEC) into G.711 and disabling/enabling echo cancellers based on the tones detected. When packet loss becomes high, sending faxes over G.711 becomes problematic, due to dropped messages and timeouts/retrains.

T.38 can be used in conjunction with various call-control schemes, such as H.323, Session Initiation Protocol (SIP), and Media Gateway Control Protocol (MGCP). AOS only supports SIP as the call-control method. This is typically referred to T.38/Annex-D. Annex-D describes the Session Initiation Protocol/Session Description Protocol (SIP/SDP) call establishment procedures.

t38 ced auto-generate

Use the **t38 ced auto-generate** command to specify when the digital signal processor (DSP) should regenerate the called station identifier (CED) signal toward the time division multiplexed (TDM) endpoint. If auto-generate is enabled, the DSP generates the CED signal only when it does not receive CED indicator packets from the Voice over IP (VoIP) endpoint. If auto-generate is disabled, the DSP generates the CED signal only when it does receive CED indicator packets from the VoIP endpoint. Using the **no** version of this command disables CED auto-generate.

Syntax Description

No subcommands.

Default Values

By default, CED auto-generate is disabled.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Usage Examples

The following example enables CED auto-generate for the T.38 session on the trunk:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#t38 ced auto-generate**

t38 ced length <*time*>

Use the **t38 ced length** command to set the maximum duration of a regenerated called station identifier (CED) signal, in milliseconds, from the digital signal processor (DSP) toward the time division multiplexed (TDM) endpoint when a T.38 session is active. Using the **no** form of this command returns the duration to the default value.

Syntax Description

<time>	Specifies the maximum duration of a regenerated CED signal in milliseconds. Valid range is **0** to **4000** ms.

Default Values

By default, the maximum duration of a regenerated CED signal is **3000** ms.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Setting the maximum duration of a regenerated CED signal to **0** effectively prevents any CED generation.

Usage Examples

The following example decreases the maximum duration of the CED signal to **2000** ms for the T.38 session:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#t38 ced length 2000**

t38 cng-relay-selective

Use the **t38 cng-relay-selective** command to enable fax calling tones (CNG) relay only when V.21 messages are not being transmitted. Use the **no** version of this command to disable selective CNG relay.

Syntax Description

No subcommands.

Default Values

Selective CNG relay is disabled by default.

Command History

Release R10.4.0	Command was introduced.

Usage Examples

The following example enables T.38 CNG relay:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#t38 cng-relay-selective**

t38 ecm

Use the **t38 ecm** command to enable or disable error correction mode (ECM) during T.38 sessions. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 ecm enable
t38 ecm disable

Syntax Description

enable	Enables ECM during T.38 sessions.
disable	Disables ECM during T.38 sessions.

Default Values

By default, ECM is enabled.

Command History

Release R10.8.0	The command was introduced

Usage Examples

The following example disables ECM for T.38 sessions on trunk T01:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#t38 ecm disable**

t38 error-correction

Use the **t38 error-correction** command to specify the type of fax error correction. Use the **no** form of this command to disable this feature. Variations of this command include:

t38 error-correction fec
t38 error-correction redundancy

Syntax Description

fec	Specifies forward error correction (FEC) as the fax error correction. FEC is a system of error control where the sender adds redundant data to its messages, allowing the receiver to detect and correct errors (within certain bounds) without the need to request additional data from the sender.
redundancy	Specifies redundancy as the fax error correction. Redundancy error correction replicates the payload a user-specified number of times to determine if errors are present. The number of redundant packets is set using the command *t38 v21-preamble-timeout <value> on page 5006*).

Default Values

By default, **t38 error-correction** is set to **redundancy** for the Total Access 900(e) Series, the NetVanta 6310/6330 Series, the NetVanta 6355 Series, the NetVanta 6240/6250 Serires, and the NetVanta 640 Series.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default value changed to **fec** for the Total Access 900(e) Series, the NetVanta 6310/6330 Series, the NetVanta 6355 Series, and the NetVanta 7000 Series products.
Release R10.8.0	The default values for this command were updated.

Usage Examples

The following example sets the **t38 error-correction** to **fec**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#t38 error-correction fec**

t38 fallback-mode g711

Use the **t38 fallback-mode** command to specify the transmission mode used when T.38 fax relay cannot be successfully negotiated at the time of the fax transfer. Use the **no** form of this command to disable this feature.

Syntax Description

g711	Specifies that fax operation revert back to analog mode (G.711).

Default Values

By default, **t38 fallback-mode** is to **G.711**.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default was changed to **G.711**.

Usage Examples

The following example enables the **t38 fallback-mode** on trunk **T02**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#t38 fallback-mode g711**

t38 generate-cng

Use the **t38 generate-cng** command to specify whether the digital signal processor (DSP) will begin a T.38 session by generating the calling signal (CNG) toward the time division multiplexed (TDM) endpoint. Using the **no** version of this command disables CNG generation.

Syntax Description

No subcommands.

Default Values

By default, CNG generation is disabled.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

With the introduction of this command, the CNG generation behavior of the T.38 session is now configurable. In AOS firmware prior to A5.01, this behavior was not configurable, but rather was set to always generate this signal.

Usage Examples

The following example enables CNG generation for the T.38 session:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#t38 generate-cng**

t38 max-buffer <*value*>

Use the **t38 max-buffer** command to set the maximum buffer size for T.38 fax operation. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the value of the **max-buffer** attribute in the Session Description Protocol (SDP) offer when the T.38 session is initiated. Range is **0** to **800** bytes.

Default Values

By default, the maximum buffer size is set to **200**.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example sets the **t38 max-buffer** to **100**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#t38 max-buffer 100**

t38 max-datagram <*value*>

Use the **t38 max-datagram** command to set the maximum datagram value in this unit. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the value of the **max-datagram** attribute in the Session Description Protocol (SDP) offer when the T.38 session is initiated. Range is **0** to **300** bytes.

Default Values

By default, the maximum datagram value is set to **72** bytes.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default was changed to **72** bytes.

Usage Examples

The following example sets the **t38 max-datagram** to **100**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#t38 max-datagram 100**

t38 max-rate

Use the **t38 max-rate** command to specify the fax maximum rate. The actual transmission rate could be lower than specified rate if the receiving end cannot support the maximum rate. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 max-rate 14400
t38 max-rate 12000
t38 max-rate 2400
t38 max-rate 4800
t38 max-rate 7200
t38 max-rate 9600

Syntax Description

14400	Specifies 14400 bits per second (bps) as fax maximum rate.
12000	Specifies 12000 bps as fax maximum rate.
2400	Specifies 2400 bps as fax maximum rate.
4800	Specifies 4800 bps as fax maximum rate.
7200	Specifies 7200 bps as fax maximum rate.
9600	Specifies 9600 bps as fax maximum rate.

Default Values

By default, the maximum fax rate is set to **14400** bps.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example sets the **t38 max-rate** to **4800** bps:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#t38 max-rate 4800**

t38 redundancy

Use the **t38 redundancy** command to set the number of redundant packets sent when the **t38 error-correction redundancy** feature is enabled. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 redundancy high-speed <*value*>
t38 redundancy low-speed <*value*>

Syntax Description

high-speed <*value*>	Specifies the number of redundant T.38 fax packets to be sent for data messages (high-speed fax machine image data). Range is **0** (no redundancy) to **4** packets.
low-speed <*value*>	Specifies the number of redundant T.38 fax packets to be sent for the signaling messages (low-speed fax machine protocol). Range is **0** (no redundancy) to **7** packets.

Default Values

By default, high-speed and low-speed redundancy values are set to **0** (no redundancy).

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables **t38 error-correction redundancy** and sets the number of redundant data messages to **3** on trunk **T01**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#t38 error-correction redundancy**
(config-t01)**#t38 redundancy high-speed 3**

t38 v21-preamble-timeout *<value>*

Use the **t38 v21-preamble-timeout** command to set the maximum amount of time that the digital signal processor (DSP) waits for peer device activity after starting to transmit a V.21 preamble event before spoofing a response to the time division multiplexed (TDM) endpoint. Using the **no** version of this command returns the timeout value to the default setting.

Syntax Description

<value>	The time, in milliseconds, that the DSP will wait for peer activity. Valid range is **1** to **3000** ms.

Default Values

By default, the V.21 preamble timeout is set to **1700** ms.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Usage Examples

The following example specifies the V.21 preamble timeout value as **2000** ms:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#t38 v21-preamble-timeout 2000**

vad

Use the **vad** command to enable voice activity detection (VAD). VAD blocks out noise categorized as silence during a voice connection. The silent voice packets are not transmitted, allowing bandwidth usage to be reduced. Although VAD saves bandwidth, the quality of the voice call may be compromised. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, VAD is enabled for all T1 robbed bit signaling (RBS) trunks and users.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example disables VAD on trunk **T01**:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#no vad**

VOICE ISDN TRUNK COMMAND SET

The integrated services digital network (ISDN) primary rate interface (PRI) is a circuit composed of 23 bearer (B) channels and 1 data (D) channel. ISDN PRI is an international standard for digital communications, allowing a full range of enhanced services supporting voice and data. The 23 B channels are used to transmit voice or data over an all-digital public switched telephone network (PSTN). The D channel is used to transmit out-of-band (OOB) signaling for the B channels and controls dialing numbers and features such as call waiting.

Voice ISDN trunks are digital subscriber lines delivered by service providers that connect communication devices through the PRI interface to the outside world. In order to configure ISDN trunks, you must configure a trunk account to make and receive calls. To do this, you create a trunk account (using the command *voice trunk <trunk id> type on page 1980*) and assign the PRI interface (using the command *cross-connect on page 76*). When you configure the trunk account, make sure the PRI settings (trunk number, caller ID, etc.) match the parameters set by your service provider. For more information about the creation and use of ISDN trunks, refer to the *Total Access 900 Series ISDN PRI Interface* quick configuration guide or the *NetVanta 7000 Series Trunk Accounts* configuration guide available online at https://supportcommunity.adtran.com.

To create an ISDN trunk account and enter the Voice ISDN Trunk Configuration mode, enter **voice trunk** *<trunk id>* **type isdn** at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice trunk t01 type isdn
(config-t01)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

alc on page 5010
caller-id-override on page 5011
codec-list <name> on page 5013
connect isdn-group <number> on page 5015
early-cut-through on page 5016
echo-cancellation on page 5017
match ani <template> substitute <template> on page 5018
match dnis <template> replace ani <number> on page 5020

alc

Use the **alc** command to enable automatic level control (ALC). ALC reduces Realtime Transport Protocol (RTP) received signals that are out of specification to the predefined levels. It is not necessary to enable ALC on those networks that guarantee signal levels to be within specification. Use the **no** form of this command to disable this feature. Variations of this command include:

alc
alc level -16
alc level -17
alc level -18
alc level -19
alc level -20
alc level -21
alc level -22

Syntax Description

level -16	Optional. Specifies the ALC attenuation level is -16 dBm0.
level -17	Optional. Specifies the ALC attenuation level is -17 dBm0.
level -18	Optional. Specifies the ALC attenuation level is -18 dBm0.
level -19	Optional. Specifies the ALC attenuation level is -19 dBm0.
level -20	Optional. Specifies the ALC attenuation level is -20 dBm0.
level -21	Optional. Specifies the ALC attenuation level is -21 dBm0.
level -22	Optional. Specifies the ALC attenuation level is -22 dBm0.

Default Values

By default, ALC is disabled.

Command History

Release 14.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the Media Gateway Control Protocol (MGCP) endpoint configuration.
Release A2.04	Command was expanded to include the **level** parameters.

Usage Examples

The following example activates the ALC for the trunk:

(config)**#voice trunk t01 type isdn**
(config-t01)**#alc**

caller-id-override

Use the **caller-id-override** command to replace the calling party information for this trunk with a specific number. This command is used to conceal a user's name and number or to display a different name and number for internal or external caller ID. Use the **no** form of this command to cancel the setting. Variations of this command include:

caller-id-override emergency-outbound <*number*>
caller-id-override emergency-outbound match-substitute
caller-id-override name-inbound <*name*>
caller-id-override name-inbound <*name*> **if-unavailable**
caller-id-override number-inbound <*number*>
caller-id-override number-inbound <*number*> **if-no-cpn**
caller-id-override number-inbound <*number*> <*trunk id*>
caller-id-override privacy-outbound match-substitute

Syntax Description

emergency-outbound	Replaces the calling party number for outbound emergency calls.
<*number*>	Specifies the number to replace the calling party number for outbound emergency calls.
match-substitute	Specifies that the configured automatic number identification (ANI) match substitution is used for outbound emergency calls.
name-inbound <*name*>	Specifies the name to replace the calling party name for inbound calls.
if-unavailable	Specifies that the calling party name is replaced only if the calling party name is unavailable.
number-inbound <*number*>	Specifies the number to replace the calling party number for inbound calls.
<*trunk id*>	Optional. Specifies the trunk ID (**Txx**) for outbound calls.
if-no-cpn	Optional. Specifies that the calling party number is replaced only if the calling party number is unavailable.
privacy-outbound	Replaces the calling party number on anonymous outbound calls.
match-substitute	Specifies that the configured ANI match substitution is used for anonymous outbound calls.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.
Release 15.1	Command was expanded.
Release 16.1	Command was expanded to include the **if-no-cpn** parameter.
Release A4.01	Command was expanded to include the **match-substitute** parameter.
Release R11.8.0	Command was expanded to include the **privacy-outbound** parameter.

Usage Examples

The following example sets the caller ID override number on the trunk where the command is issued:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#caller-id-override number-inbound 555-8000**

codec-list *<name>*

Use the **codec-list** command to specify the coder-decoder (CODEC) list to be used by this account. This CODEC can be used for normal voice traffic or for Session Border Controller (SBC) transcoding. Use the **no** form of this command to remove the CODEC list from the account. Variations of this command include:

codec-list *<name>*
codec-list *<name>* **both**
codec-list *<name>* **in**
codec-list *<name>* **out**
codec-list any
codec-list any both
codec-list any in
codec-list any out

Syntax Description

<name>	Specifies the CODEC list to be used for this account.
any	Specifies that any possible CODEC is allowed on this account.
both	Optional. Specifies that the CODEC list is applied to both transmitted and received Session Description Protocol (SDP) transmissions.
in	Optional. Specifies that the CODEC list is applied to received SDP only.
out	Optional. Specifies that the CODEC list is applied to transmitted SDP only.

Default Values

By default, no CODEC lists are assigned.

Command History

Release R10.4.0	Command was introduced and replaced the **codec-group** command.

Functional Notes

The **codec-list** command applies a previously configured CODEC list to an interface, voice trunk, or voice account. These lists are lists of CODECs used by the interface, trunk, or account in call negotiation and are arranged in preferred order with the first listed CODEC being the most preferred.

CODEC lists are created using the **codec** command from the Voice CODEC List Configuration mode prompt. For more information about creating CODEC lists, refer to the *Voice CODEC List Command Set on page 4893***.**

In addition, CODEC lists can be used for the SBC transcoding feature. For more information about this feature, its uses, and its configuration, refer to the configuration guide *Configuring Transcoding in AOS*, available online at https://supportcommunity.adtran.com.

> NOTE *Because you can choose to specify that any CODEC is used by a Session Initiation Protocol (SIP) endpoint with the **any** keyword, do not create a CODEC list with the name of **any**.*

Usage Examples

The following example applies the CODEC list **LIST1** to incoming SDP traffic on trunk **T01**:

(config)**#voice trunk t01 type isdn**
(config-t01)**#codec-list LIST1 in**

connect isdn-group <*number*>

Use the **connect isdn-group** command to associate a trunk with an integrated services digital network (ISDN) group. The ISDN group number uniquely identifies an ISDN trunk group. Use the **no** form of this command to remove this association.

Syntax Description

<*number*>	Specifies the ISDN group number. Range is **1** to **255**.

Default Values

By default, no group is defined.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was expanded to include the ISDN trunk.

Usage Examples

The following example specifies that this trunk will use the ISDN group **1**:

(config)**#voice trunk t01 type isdn**
(config-t01)**#connect isdn-group 1**

early-cut-through

Use the **early-cut-through** command to provide the caller with inband ringback and other call progress signals. This command should not be issued if the connected equipment does not provide inband ringback and other call progress signals. This option is only valid for voice trunks in the network role. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **early-cut-through** is enabled.

Command History

Release A5.02	Command was introduced.

Usage Examples

The following example disables early-cut-through:

```
(config)#voice trunk t01 type isdn
(config-t01)#no early-cut-through
```

echo-cancellation

Use the **echo-cancellation** command to improve voice quality for packetized-based voice calls, such as Voice over IP (VoIP) or Media Gateway Control Protocol (MGCP). Enabling this command may significantly improve the voice quality in calls across the telephone network. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **echo-cancellation** is enabled.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was expanded to include the integrated services digital network (ISDN) trunk.

Usage Examples

The following example activates **echo-cancellation**:

(config)**#voice trunk t01 type isdn**
(config-t01)**#echo-cancellation**

match ani <*template*> substitute <*template*>

Use the **match ani substitute** command to configure automatic number identification (ANI) substitution for outbound voice trunks. Use the **no** form of this command to remove the substitution. Variations of this command include:

match ani <*template*> **substitute** <*template*>
match ani <*template*> **substitute** <*template*> **name** <*name*>

Syntax Description

ani <*template*>	Specifies the ANI information to be substituted. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
substitute <*template*>	Specifies the ANI information that is substituted for the original ANI information. This information is entered using wildcards and numerical digits. When using wildcards in the **match** and **substitute** template, both must be of the same type and position in the number template or AOS will not allow the substitution. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
name <*name*>	Optional. Specifies the name associated with the ANI information. This option is only available on trunks that support ANI name information (integrated services digital network (ISDN) trunks, Session Initiation Protocol (SIP) trunks, T1 loop start (LS) network trunks, and T1 ground start (GS) network trunks).

Default Values

By default, no ANI substitution is configured.

Command History

Release A2	Command was introduced.

Functional Notes

The convention for ANI templates is very similar to dial plan entries. Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example specifies that the ANI information from numbers **555-8111** to **555-8115** will be substituted by **555-8110** for outbound calls on the trunk **T03**:

(config)**#voice trunk t03 type isdn**
(config-t03)**#match ani 555-811[125] substitute 555-8110**

match dnis <*template*> replace ani <*number*>

Use the **match dnis replace ani** command to replace dialed number identification service (DNIS) information with automatic number identification (ANI) information on outbound voice trunks. Use the **no** form of this command to remove the replacement. Variations of this command include:

match dnis <*template*> **replace ani** <*number*>
match dnis <*template*> **replace ani** <*number*> **name** <*name*>

Syntax Description

dnis <*template*>	Specifies the DNIS information to be replaced. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
replace ani <*number*>	Specifies the ANI information that replaces the original DNIS information. This information is entered using numerical digits. Enter the number without punctuation.
name <*name*>	Optional. Specifies the name associated with the ANI information. This option is only available on trunks that support ANI name information (integrated services digital network (ISDN) trunks, Session Initiation Protocol (SIP) trunks, T1 loop start (LS) network trunks, and T1 ground start (GS) network trunks).

Default Values

By default, no DNIS replacement is configured.

Command History

Release A2	Command was introduced.

Functional Notes

The convention for DNIS templates is very similar to dial plan entries. Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits

3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example specifies that the DNIS information for dialed numbers on trunk **T03** that match **1-256-524-8600** are replaced with **882-6467**:

(config)**#voice trunk t03 type isdn**
(config-t03)**#match dnis 1-256-524-8600 replace ani 8826467**

match dnis <*template*> substitute <*template*>

Use the **match dnis substitute** command to configure dialed number identification service (DNIS) substitution for outbound voice trunks. Use the **no** form of this command to remove the substitution. Variations of this command include:

match dnis <*template*> **substitute** <*template*>
match dnis <*template*> **substitute** <*template*> **name** <*name*>

Syntax Description

dnis <*template*>	Specifies the DNIS information to be substituted. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
substitute <*template*>	Specifies the DNIS information that is substituted for the original DNIS information. This information is entered using wildcards and numerical digits. When using wildcards in the **match** and **substitute** template, both must be of the same type and position in the number template or AOS will not allow the substitution. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
name <*name*>	Optional. Specifies the name associated with the DNIS information. This option is only available on trunks that support DNIS name information (integrated services digital network (ISDN) trunks, Session Initiation Protocol (SIP) trunks, T1 loop start (LS) network trunks, and T1 ground start (GS) network trunks).

Default Values

By default, no DNIS substitution is configured.

Command History

Release A2	Command was introduced.

Functional Notes

The convention for DNIS templates is very similar to dial plan entries. Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example specifies that the DNIS information for dialed numbers on trunk **T03** that match **1-334-NXX-XXXX** are substituted with **1-800-557-4500**:

(config)**#voice trunk t03 type isdn**
(config-t03)**#match dnis 1-334-NXX-XXXX substitute 1-800-557-4500**

modem-passthrough

Use the **modem-passthrough** command to switch to passthrough mode on fax or modem tone detection. This command allows modem and fax calls to maintain a connection without altering the signals with the voice improvement settings, such as echo cancellation and voice activity detection (VAD). Use the **no** form of this command to disable this feature. Variations of this command include:

modem-passthrough
modem-passthrough detection-time <*value*>
modem-passthrough cng-early-detect

Syntax Description

detection-time <*value*>	Optional. Specifies the fax and/or modem detection time length value in seconds. Range is **0** to **8** seconds.
cng-early-detect	Optional. Enables early (first burst) detection of fax calling (CNG) tone.

Default Values

By default, **modem-passthrough** is enabled.

Command History

Release 11.1	Command was introduced.
Release 12.1	Command was expanded.
Release R10.8.0	Command was expanded to include the **cng-early-detect** parameter.

Usage Examples

The following example enables **modem-passthrough**:

(config)**#voice trunk t01 type isdn**
(config-t01)**#modem-passthrough**

plc

Use the **plc** command to enable packet loss concealment (PLC). PLC is used to prevent choppy connections by concealing a packet loss by replacing the lost packet with another voice packet in the data stream. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, PLC is enabled.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example enables PLC on trunk **T01**:

```
(config)#voice trunk t01 type isdn
(config-t01)#plc
```

prefer trunk-routing

Use the **prefer trunk-routing** command to add a trunk to a list of trunks that are considered first for call routing, regardless of system routing mode or locally configured extensions. Use the **no** form of this command to remove the trunk from the list.

Syntax Description

No subcommands.

Default Values

By default, **prefer trunk-routing** is disabled.

Command History

Release A2	Command was introduced.

Functional Notes

Trunk routing can be specified as a preference for specific trunks, allowing the trunk to be considered first for routing rather than relying on the internal or external nature of the call to dictate whether the trunk or voice station is the first choice routing path. The **prefer trunk-routing** command, executed from a specific trunk's configuration mode, adds the trunk to a list of trunks that are considered first for routing.

By default, no trunk routing preference is set, so that each trunk operates as dictated by normal call routing modes. Adding the trunk routing preference only affects how inbound calls from the specific trunk are handled.

Usage Examples

The following example specifies that trunk routing is preferred on the trunk **T01**:

(config)**#voice trunk t01 type isdn**
(config-t01)**#prefer trunk-routing**

reject-external

Use the **reject-external** command to blocked outbound (external) call attempts. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is enabled.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example enables packet loss concealment (PLC) on trunk **T01**:

(config)**#voice trunk t01 type isdn**
(config-t01)**#reject-external**

resource-selection

Use the **resource-selection** command to determine how the switchboard uses outbound call resources contained within a time division multiplexing (TDM) based trunk group. Use the **no** form of this command to disable this feature. Variations of this command include:

resource-selection circular
resource-selection circular ascending
resource-selection circular descending
resource-selection linear
resource-selection linear ascending
resource-selection linear descending

Syntax Description

circular	Performs call load balancing among available DS0s/B-channels in this trunk. Subsequent calls will be delivered to the next available DS0/B-channel in a round-robin fashion.
linear	Specifies that a call being delivered to this trunk will be accepted out the first available DS0/B-channel available at the time the call is received.
ascending	Optional. Distributes calls in an order from the lowest to the highest channel (DS0 1, 2, 3 through 24).
descending	Optional. Distributes calls in an order from the highest to the lowest channel (DS0 24, 23, 22 through 1).

Default Values

By default, resource selection is set to **linear**.

Command History

Release 9.3	Command was introduced.
Release 13.1	Command was expanded to include the **ascending** and **descending** subcommands.

Usage Examples

The following example specifies **circular** resource selection:

(config)**#voice trunk t01 type isdn**
(config-t01)**#resource-selection circular**

rtp delay-mode

Use the **rtp delay-mode** command to configure the Realtime Transport Protocol (RTP) jitter buffer packet delay mode settings. RTP is used to prevent static on voice connections by enhancing the quality of the packet delivery. Use the **no** form of this command to return to the default setting. Variations of this command include:

rtp delay-mode adaptive
rtp delay-mode fixed

Syntax Description

adaptive	Configures RTP jitter buffer packet delay to adjust during a call based on network conditions.
fixed	Configures the RTP jitter buffer packet delay to remain constant.

Default Values

By default, this command is set to **adaptive**.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures RTP delay mode as **fixed**:

(config)**#voice trunk t01 type isdn**
(config-t01)**#rtp delay-mode fixed**

rtp dtmf-relay

Use the **rtp dtmf-relay** command to configure the method by which Realtime Transport Protocol (RTP) dual tone multi-frequency (DTMF) events are relayed, either inband in the RTP stream or out-of-band (OOB) using named telephone events (NTEs). RTP DTMF relay is used to prevent the tone (dialed digits) from being corrupted. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp dtmf-relay inband
rtp dtmf-relay nte <*value*>

Syntax Description

inband	Configures RTP DTMF relay events for **inband**.
nte <*value*>	Configures RTP DTMF relay events for NTE. Enter a value between **96** and **127**.

Default Values

By default, the **rtp dtmf-relay** is set for **NTE 101**.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was expanded to include the integrated services digital network (ISDN) trunk.

Usage Examples

The following example configures RTP DTMF relay events for **NTE** with an event value of **101**:

(config)**#voice trunk t01 type isdn**
(config-t01)**#rtp dtmf-relay nte 101**

rtp frame-packetization <*value*>

Use the **rtp frame-packetization** command to configure the Realtime Transport Protocol (RTP) frame packetization time in milliseconds for individual trunks and users. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Configures the RTP frame packetization time value in milliseconds. Select from **10**, **20**, **30**, or **40** milliseconds.

Default Values

By default, the **rtp frame-packetization** time is set to **20** milliseconds on all trunks and users.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was expanded to include the integrated services digital network (ISDN) trunk.
Release R10.8.0	Command was expanded to include **40** milliseconds.

Usage Examples

The following example sets the frame packetization time for trunk **T01** to **20** milliseconds:

(config)**#voice trunk t01 type isdn**
(config-t01)**#rtp frame-packetization 20**

rtp packet-delay

Use the **rtp packet-delay** command to configure the maximum Realtime Transport Protocol (RTP) packet delays. This command is used to set the allowable limits of latency on the network. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp packet-delay fax <*value*>
rtp packet-delay maximum <*value*>
rtp packet-delay nominal <*value*>

Syntax Description

fax <*value*>	Sets the fax delay time in milliseconds. Range is **0** to **500** milliseconds.
maximum <*value*>	Sets the maximum delay time in increments of **10** milliseconds. Range is **40** to **320** milliseconds.
nominal <*value*>	Sets the nominal delay time in increments of **10** milliseconds. Range is **10** to **240** milliseconds.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures the RTP fax delay time on trunk **T01** to **10** milliseconds:

(config)**#voice trunk t01 type isdn**
(config-t01)**#rtp packet-delay fax 10**

rtp qos dscp <*value*>

Use the **rtp qos dscp** command to configure the maximum Realtime Transport Protocol (RTP) quality of service (QoS) parameters for differentiated services code point (DSCP).

Syntax Description

<*value*>	Configures the RTP QoS parameter for DSCP. Enter a value between **10** and **63**.

Default Values

By default, no RTP QoS DSCP is configured for this interface.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was expanded to include the integrated services digital network (ISDN) trunk.

Functional Notes

By setting the **rtp qos dscp** value on an individual trunk or user, you will override the global **rtp qos dscp** setting for RTP packets. QoS is set using a DSCP value. Valid DSCP values are **10** to **63**, and a higher DSCP value has a higher priority. The default DSCP value for RTP is **46**. Remember that if you are using a public IP connection, such as the Internet, for Voice over Internet Protocol (VoIP), end-to-end QoS may not be guaranteed. The default DSCP value for Session Initiation Protocol (SIP) is **26**. To configure QoS for the RTP traffic that carries the voice conversation, use the command **ip rtp qos dscp** followed by the desired DSCP value.

Usage Examples

By setting the **rtp qos dscp** value on an individual trunk or user, you will override the global **rtp qos dscp** setting for RTP packets. The following example sets the DSCP value for RTP packets that trunk **T02** generates to **60**.

(config)**#voice trunk t02 type isdn**
(config-t02)**#rtp qos dscp 60**

rtp rx-gain *<value>*

Use the **rtp rx-gain** command to specify the Realtime Transport Protocol (RTP) receive (RX) gain or attenuation. RTP is used to prevent static on voice connections by enhancing the quality of the packet delivery. Using the **no** form of this command returns the RTP RX gain or attenuation to the default value.

Syntax Description

<value>	Specifies the RTP RX gain or attenuation in the RTP to time division multiplexing (TDM) direction. Range is **6** to **-14**. Negative values specify attenuation. Positive values specify gain in decibels (dB).

Default Values

By default, RTP RX gain is set to **0** dB.

Command History

Release A2.04	Command was introduced.

Usage Examples

The following example specifies the RTP RX gain for integrated services digital network (ISDN) trunk **T01** is **4** dB:

(config)**#voice trunk t01 type isdn**
(config-t01)**#rtp rx-gain 4**

rtp tx-gain <*value*>

Use the **rtp tx-gain** command to specify the Realtime Transport Protocol (RTP) transmit (TX) gain or attentuation. RTP is used to prevent static on voice connections by enhancing the quality of the packet delivery. Using the **no** form of this command returns the RTP TX gain or attenuation to the default value.

Syntax Description

<*value*>	Specifies the RTP TX gain or attenuation in the time division multiplexing (TDM) to RTP direction. Range is **6** to **-14**. Negative values specify attenuation. Positive values specify gain in decibels (dB).

Default Values

By default, RTP TX gain is set to **0** dB.

Command History

Release A2.04	Command was introduced.

Usage Examples

The following example specifies the RTP TX gain for integrated services digital network (ISDN) trunk **T01** is **4** dB:

(config)**#voice trunk t01 type isdn**
(config-t01)**#rtp tx-gain 4**

supplementary-service trunk *<trunk id>*

Use the **supplementary-service trunk** command to configure a Session Initiation Protocol (SIP) trunk to provide supplementary services to the integrated services digital network (ISDN) trunk. Use the **no** form of this command to remove the SIP trunk.

Syntax Description

<trunk id>	Specifies a specific voice trunk using the trunk's two-digit identifier following T (for example, T01).

Default Values

By default, there are no trunks configured for supplementary services.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example configures trunk **T01** to be a SIP trunk that provides supplementary services to the ISDN trunk:

(config)**#voice trunk t01 type isdn**
(config-t01)**#supplementary-service trunk T01**

trunk-number <*number*>

Use the **trunk-number** command to define the call routing when direct inward dialing (DID) is disabled. This feature directs incoming calls to the specified number when DID is not present. This command also allows users to activate different system modes of operation that redirect incoming calls to a different number depending on the specified mode. Use the **no** form of this command to disable this feature. Variations of this command include:

trunk-number <*number*>
trunk-number no-number
trunk-number <*system mode*> <*number*>
trunk-number <*system mode*> **no-number**
trunk-number override <*number*>
trunk-number override no-number

Syntax Description

<*number*>	Specifies the number used for call routing when DID is disabled.
<*system mode*>	Optional. Specifies the system mode to configure. Choose from **custom1**, **custom2**, **custom3**, **lunch**, **night**, or **weekend**. Refer to the command *voice system-mode on page 1971* for more information on system modes.
no-number	Specifies no inbound calls are allowed on this trunk.
override	Ignores the programmed system mode schedule.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was added to the feature group D (FGD) trunk options.
Release A1	Command was expanded to include the new subcommands.

Usage Examples

The following example defines call routing on trunk **T02**:

(config)**#voice trunk t02 type isdn**
(config-t02)**#trunk-number 4000**

t38

Use the **t38** command to enable T.38 fax operation. Use the **no** form of this command to disable this feature.

> *The command modem-passthrough on page 5024 must be enabled for T.38 operation to work.*

Syntax Description

No subcommands.

Default Values

By default, T.38 is disabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables T.38:

(config)**#voice trunk t02 type isdn**
(config-t02)**#t38**

Technology Review

T.38 is an International Telecommunication Union (ITU) specification that allows Group-3 Fax (T.30) data to be transported over the Internet. It is similar to dual tone multi-frequency (DTMF) relay (RFC 2833) in that the digital signal processor (DSP) decodes tones and demodulated fax data and converts them into packets. A similar device on the other end takes the packets/tones and remodulates them so that an analog fax machine on the other end can receive the fax. AOS's previous support (revisions 12 through 15) for fax/modem signals was simply detecting a tone and forcing the coder-decoder (CODEC) into G.711 and disabling/enabling echo cancellers based on the tones detected. When packet loss becomes high, sending faxes over G.711 becomes problematic, due to dropped messages and timeouts/retrains.

T.38 can be used in conjunction with various call-control schemes, such as H.323, Session Initiation Protocol (SIP), and Media Gateway Control Protocol (MGCP). AOS only supports SIP as the call-control method. This is typically referred to T.38/Annex-D. Annex-D describes the Session Initiation Protocol/Session Description Protocol (SIP/SDP) call establishment procedures.

t38 ced auto-generate

Use the **t38 ced auto-generate** command to specify when the digital signal processor (DSP) should regenerate the called station identifier (CED) signal toward the time division multiplexed (TDM) endpoint. If auto-generate is enabled, the DSP generates the CED signal only when it does not receive CED indicator packets from the Voice over IP (VoIP) endpoint. If auto-generate is disabled, the DSP generates the CED signal only when it does receive CED indicator packets from the VoIP endpoint. Using the **no** version of this command disables CED auto-generate.

Syntax Description

No subcommands.

Default Values

By default, CED auto-generate is disabled.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Usage Examples

The following example enables CED auto-generate for the T.38 session on the trunk:

(config)**#voice trunk t02 type isdn**
(config-t02)**#t38 ced auto-generate**

t38 ced length <*time*>

Use the **t38 ced length** command to set the maximum duration of a regenerated called station identifier (CED) signal, in milliseconds, from the digital signal processor (DSP) toward the time division multiplexed (TDM) endpoint when a T.38 session is active. Using the **no** form of this command returns the duration to the default value.

Syntax Description

<*time*>	Specifies the maximum duration of a regenerated CED signal in milliseconds. Valid range is **0** to **4000** ms.

Default Values

By default, the maximum duration of a regenerated CED signal is **3000** ms.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Setting the maximum duration of a regenerated CED signal to **0** effectively prevents any CED generation.

Usage Examples

The following example decreases the maximum duration of the CED signal to **2000** ms for the T.38 session:

(config)**#voice trunk t02 type isdn**
(config-t02)**#t38 ced length 2000**

t38 cng-relay-selective

Use the **t38 cng-relay-selective** command to enable fax calling tones (CNG) relay only when V.21 messages are not being transmitted. Use the **no** version of this command to disable selective CNG relay.

Syntax Description

No subcommands.

Default Values

Selective CNG relay is disabled by default.

Command History

Release R10.4.0	Command was introduced.

Usage Examples

The following example enables T.38 CNG relay:

(config)**#voice trunk t02 type isdn**
(config-t02)**#t38 cng-relay-selective**

t38 ecm

Use the **t38 ecm** command to enable or disable error correction mode (ECM) during T.38 sessions. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 ecm enable
t38 ecm disable

Syntax Description

enable	Enables ECM during T.38 sessions.
disable	Disables ECM during T.38 sessions.

Default Values

By default, ECM is enabled.

Command History

Release R10.8.0	The command was introduced

Usage Examples

The following example disables ECM for T.38 sessions on trunk T01:

((config)**#voice trunk t02 type isdn**
(config-t02)**#t38 ecm disable**

t38 error-correction

Use the **t38 error-correction** command to specify the type of fax error correction. Use the **no** form of this command to disable this feature. Variations of this command include:

t38 error-correction fec
t38 error-correction redundancy

Syntax Description

fec	Specifies forward error correction (FEC) as the fax error correction. FEC is a system of error control where the sender adds redundant data to its messages, allowing the receiver to detect and correct errors (within certain bounds) without the need to request additional data from the sender.
redundancy	Specifies redundancy as the fax error correction. Redundancy error correction replicates the payload a user-specified number of times to determine if errors are present. The number of redundant packets is set using the command *t38 redundancy on page 5049*).

Default Values

By default, **t38 error-correction** is set to **redundancy** for the Total Access 900(e) Series, the NetVanta 6310/6330 Series, the NetVanta 6355 Series, the NetVanta 6240/6250 Serires, and the NetVanta 640 Series.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default value changed to **fec** for the Total Access 900(e) Series, the NetVanta 6310/6330 Series, the NetVanta 6355 Series, and the NetVanta 7000 Series products.
Release R10.8.0	The default values for this command were updated.

Usage Examples

The following example sets the **t38 error-correction** to **fec**:

(config)**#voice trunk t02 type isdn**
(config-t02)**#t38 error-correction fec**

t38 fallback-mode g711

Use the **t38 fallback-mode** command to specify the transmission mode used when T.38 fax relay cannot be successfully negotiated at the time of the fax transfer. Use the **no** form of this command to disable this feature.

Syntax Description

g711	Specifies that fax operation revert back to analog mode (G.711).

Default Values

By default, **t38 fallback-mode** is to **G.711**.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default was changed to **G.711**.

Usage Examples

The following example enables the **t38 fallback-mode** on trunk **T02**:

(config)**#voice trunk t02 type isdn**
(config-t02)**#t38 fallback-mode g711**

t38 generate-cng

Use the **t38 generate-cng** command to specify whether the digital signal processor (DSP) will begin a T.38 session by generating the calling signal (CNG) toward the time division multiplexed (TDM) endpoint. Using the **no** version of this command disables CNG generation.

Syntax Description

No subcommands.

Default Values

By default, CNG generation is disabled.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

With the introduction of this command, the CNG generation behavior of the T.38 session is now configurable. In AOS firmware prior to A5.01, this behavior was not configurable, but rather was set to always generate this signal.

Usage Examples

The following example enables CNG generation for the T.38 session:

(config)**#voice trunk t02 type isdn**
(config-t02)**#t38 generate-cng**

t38 max-buffer <*value*>

Use the **t38 max-buffer** command to set the maximum buffer size for T.38 fax operation. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the value of the **max-buffer** attribute in the Session Description Protocol (SDP) offer when the T.38 session is initiated. Range is **0** to **800** bytes.

Default Values

By default, the maximum buffer size is set to **200**.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example sets the **t38 max-buffer** to **100**:

(config)**#voice trunk t02 type isdn**
(config-t02)**#t38 max-buffer 100**

t38 max-datagram <*value*>

Use the **t38 max-datagram** command to set the maximum datagram value in this unit. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the value of the **max-datagram** attribute in the Session Description Protocol (SDP) offer when the T.38 session is initiated. Range is **0** to **300** bytes.

Default Values

By default, the maximum datagram value is set to **72** bytes.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default was changed to **72** bytes.

Usage Examples

The following example sets the **t38 max-datagram** to **100**:

(config)**#voice trunk t02 type isdn**
(config-t02)**#t38 max-datagram 100**

t38 max-rate

Use the **t38 max-rate** command to specify the fax maximum rate. The actual transmission rate could be lower than specified rate if the receiving end cannot support the maximum rate. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 max-rate 14400
t38 max-rate 12000
t38 max-rate 2400
t38 max-rate 4800
t38 max-rate 7200
t38 max-rate 9600

Syntax Description

14400	Specifies 14400 bits per second (bps) as fax maximum rate.
12000	Specifies 12000 bps as fax maximum rate.
2400	Specifies 2400 bps as fax maximum rate.
4800	Specifies 4800 bps as fax maximum rate.
7200	Specifies 7200 bps as fax maximum rate.
9600	Specifies 9600 bps as fax maximum rate.

Default Values

By default, the maximum fax rate is set to **14400** bps.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example sets the **t38 max-rate** to **4800** bps:

(config)**#voice trunk t02 type isdn**
(config-t02)**#t38 max-rate 4800**

t38 redundancy

Use the **t38 redundancy** command to set the number of redundant packets sent when the **t38 error-correction redundancy** feature is enabled. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 redundancy high-speed <*value*>
t38 redundancy low-speed <*value*>

Syntax Description

high-speed <*value*>	Specifies the number of redundant T.38 fax packets to be sent for data messages (high-speed fax machine image data). Range is **0** (no redundancy) to **4** packets.
low-speed <*value*>	Specifies the number of redundant T.38 fax packets to be sent for the signaling messages (low-speed fax machine protocol). Range is **0** (no redundancy) to **7** packets.

Default Values

By default, high-speed and low-speed redundancy values are set to **0** (no redundancy).

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables **t38 error-correction redundancy** and sets the number of redundant data messages to **3**:

(config)**#voice trunk t02 type isdn**
(config-t02)**#t38 error-correction redundancy**
(config-t02)**#t38 redundancy high-speed 3**

t38 v21-preamble-timeout *<value>*

Use the **t38 v21-preamble-timeout** command to set the maximum amount of time that the digital signal processor (DSP) waits for peer device activity after starting to transmit a V.21 preamble event before spoofing a response to the time division multiplexed (TDM) endpoint. Using the **no** version of this command returns the timeout value to the default setting.

Syntax Description

<value>	The time, in milliseconds, that the DSP will wait for peer activity. Valid range is **1** to **3000** ms.

Default Values

By default, the V.21 preamble timeout is set to **1700** ms.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Usage Examples

The following example specifies the V.21 preamble timeout value as **2000** ms:

(config)**#voice trunk t02 type isdn**
(config-t02)**#t38 v21-preamble-timeout 2000**

vad

Use the **vad** command to enable voice activity detection (VAD). VAD blocks out noise categorized as silence during a voice connection. The silent voice packets are not transmitted, allowing bandwidth usage to be reduced. Although VAD saves bandwidth, the quality of the voice call may be compromised. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, VAD is enabled for all T1 robbed-bit signaling RBS trunks and users.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was expanded to include the integrated services digital network (ISDN) trunk.

Usage Examples

The following example enables voice activation detection on trunk **T01**:

(config)**#voice trunk t01 type isdn**
(config-t01)**#vad**

VOICE SIP TRUNK COMMAND SET

Session Initiation Protocol (SIP) trunking is a packet-based voice service that routes calls over an IP network to an IP-compatible private branch exchange (PBX) or voice switch using SIP signaling to place and receive calls. The typical SIP trunk service provider offers extensive cost savings, compared to conventional trunk services. The IP connection to the provider carries all traffic, such as local, long distance, and toll free calls, video, email, Internet, data, and other media over a single circuit. Calls into public switched telephone networks (PSTNs) are also handled by the SIP service provider by passing the calls off to a media gateway that connects to the PSTN for users not using Voice over Internet Protocol (VoIP) service.

SIP trunks are configured over data connections. Thus, they can be configured over an Ethernet connection or a T1 connection.

To create a SIP trunk and enter the Voice SIP Trunk Configuration mode, enter the **voice trunk type sip** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice trunk t01 type sip
(config-t01)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

alc on page 5055
alert-info on page 5056
authentication username <username> password <password> on page 5057
busy all on page 5058
busy-out monitor track <name> on page 5059
caller-id-override on page 5060
check-supported replaces on page 5062
codec-list <name> on page 5063
conferencing-uri <value> on page 5065
default-ring-cadence on page 5066
dial-string source on page 5067

alc

Use the **alc** command to enable automatic level control (ALC). ALC reduces Realtime Transport Protocol (RTP) received signals that are out of specification to the predefined levels. It is not necessary to enable ALC on those networks that guarantee signal levels to be within specification. Use the **no** form of this command to disable this feature. Variations of this command include:

alc
alc level -16
alc level -17
alc level -18
alc level -19
alc level -20
alc level -21
alc level -22

Syntax Description

level -16	Optional. Specifies the ALC attenuation level is -16 dBm0.
level -17	Optional. Specifies the ALC attenuation level is -17 dBm0.
level -18	Optional. Specifies the ALC attenuation level is -18 dBm0.
level -19	Optional. Specifies the ALC attenuation level is -19 dBm0.
level -20	Optional. Specifies the ALC attenuation level is -20 dBm0.
level -21	Optional. Specifies the ALC attenuation level is -21 dBm0.
level -22	Optional. Specifies the ALC attenuation level is -22 dBm0.

Default Values

By default, ALC is disabled.

Command History

Release 14.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the Media Gateway Control Protocol (MGCP) endpoint configuration.
Release A2.04	Command was expanded to include the **level** parameters.

Usage Examples

The following example activates the ALC on trunk **T01**:

(config)**#voice trunk t01 type sip**
(config-t01)**#alc**

alert-info

Use the **alert-info** command to allow the alert information attribute on incoming and/or outgoing auto answer alert information. Use the **no** form of this command to cancel the setting. Variations of this command include:

alert-info incoming auto-answer
alert-info outgoing auto-answer

Syntax Description

incoming auto-answer	Specifies processing incoming ALERT-INFO attribute.
outgoing auto-answer	Specifies allowing the outgoing ALERT-INFO auto-answer attribute.

Default Values

By default, both incoming and outgoing auto answer alert information is allowed on the NetVanta 7000 Series in the ALERT-INFO messages. However, both are disabled by default in the IP business gateways (IPBGs). The IPBGs will ignore incoming auto answer in the ALERT-INFO messages, and will not send the information on outgoing trunks.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example blocks outgoing alert-info auto-answer attribute on trunk **T01**:

(config)**#voice trunk t01 type sip**
(config-t01)**#alert-info outgoing auto-answer**

authentication username <*username*> password <*password*>

Use the **authentication username password** command to enable authentication security between the Session Initiation Protocol (SIP) server and the unit. Each port that registers with the SIP server will use the defined **username** and **password**. Use the **no** form of this command to return to the default setting.

Syntax Description

username <*username*>	Specifies a string to be sent as the user name in authentication.
password <*password*>	Specifies a string to be sent as the password in authentication.

Default Values

By default, authentication is not enabled.

Command History

Release 9.3	Command was introduced.

Functional Notes

If all users on the trunk use the same user name/password, enter the user name and password for authentication under the trunk. Otherwise, enter authentication information for each user individually in the Voice User command set that overrides the setting of this command. Refer to *Voice User Account Command Set on page 4564* for more information.

Usage Examples

The following example configures a user name of **iaduser** and password of **totalaccess** at the trunk level:

(config)**#voice trunk t01 type sip**
(config-t01)**#authentication username iaduser password totalaccess**

busy all

Use the **busy all** command to set all level zero digital signals (DS0s) to busy so that no calls are allowed inbound or outbound. If any calls are active at the time this command is issued, the calls will stay active until either party terminates the call. Once terminated, the DS0s are busied out. Use the **no** form of this command to disable this feature. Variations of this command include:

busy all
busy all now

Syntax Description

now	Optional. Immediately terminates calls that are active at the time the command is issued.

Default Values

By default, this command is disabled.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was added to the Voice Trunk Session Initiation Protocol (SIP) command set.

Usage Examples

The following example sets all DS0s on trunk **T01** to busy and terminates calls that are active at the time the command is issued:

(config)**#voice trunk t01 type sip**
(config-t01)**#busy all now**

busy-out monitor track <*name*>

Use the **busy-out monitor track** command to automatically take a voice trunk out of service based on one or more conditions. The primary application of this feature is to signal to an attached private branch exchange (PBX) that because calls routed to the integrated access device (IAD) could fail due to loss of Session Initiation Protocoal (SIP) trunk connectivity, it should attempt to route the call via another interface. For more information on creating tracks, refer to *track <name> on page 1886* and the *Network Monitor Track Command Set on page 4098*. Use the no form of this command to remove a track from busy-out monitoring.

Syntax Description

<name>	Specifies the name of the track to monitor.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example shuts down trunk **T01** when the **on_fail** track fails:

(config)**#voice trunk t01 type sip**
(config-t01)**#busy-out monitor track on_fail**

caller-id-override

Use the **caller-id-override** command to replace the calling party information for this trunk with a specific number. This command is used to conceal a user's name and number or to display a different name and number for internal or external caller ID. Use the **no** form of this command to cancel the setting. Variations of this command include:

caller-id-override emergency-outbound <*number*>
caller-id-override emergency-outbound match-substitute
caller-id-override name-inbound <*name*>
caller-id-override name-inbound <*name*> **if-unavailable**
caller-id-override number-inbound <*number*>
caller-id-override number-inbound <*number*> **if-no-cpn**
caller-id-override number-inbound <*number*> <*trunk id*>
caller-id-override privacy-outbound match-substitute

Syntax Description

emergency-outbound	Replaces the calling party number for outbound emergency calls.
<*number*>	Specifies the number to replace the calling party number for outbound emergency calls.
match-substitute	Specifies that the configured automatic number identification (ANI) match substitution is used for outbound emergency calls.
name-inbound <*name*>	Specifies the name to replace the calling party name for inbound calls.
if-unavailable	Specifies that the calling party name is replaced only if the calling party name is unavailable.
number-inbound <*number*>	Specifies the number to replace the calling party number for inbound calls.
<*trunk id*>	Optional. Specifies the trunk ID (**Txx**) for outbound calls.
if-no-cpn	Optional. Specifies that the calling party number is replaced only if the calling party number is unavailable.
privacy-outbound	Replaces the calling party number on anonymous outbound calls.
match-substitute	Specifies that the configured ANI match substitution is used for anonymous outbound calls.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.
Release 15.1	Command was expanded.
Release 16.1	Command was expanded to include the **if-no-cpn** parameter.
Release A4.01	Command was expanded to include the **match-substitute** parameter.
Release R11.8.0	Command was expanded to include the **privacy-outbound** parameter.

Usage Examples

The following example sets the caller ID override number on the trunk where the command is issued:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#caller-id-override number-inbound 555-8000**

check-supported replaces

Use the **check-supported replaces** command to check all support extensions on outbound messages and only send replaces when supported by the far-end device. Otherwise, replaces are automatically sent regardless of the far-end capabilities. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example sets all DS0s on trunk **T01** to busy and terminates calls that are active at the time the command is issued:

(config)**#voice trunk t01 type sip**
(config-t01)**#check-supported replaces**

codec-list *<name>*

Use the **codec-list** command to specify the coder-decoder (CODEC) list to be used by this account. This CODEC can be used for normal voice traffic or for Session Border Controller (SBC) transcoding. Use the **no** form of this command to remove the CODEC list from the account. Variations of this command include:

codec-list *<name>*
codec-list *<name>* **both**
codec-list *<name>* **in**
codec-list *<name>* **out**
codec-list any
codec-list any both
codec-list any in
codec-list any out

Syntax Description

<name>	Specifies the CODEC list to be used for this account.
any	Specifies that any possible CODEC is allowed on this account.
both	Optional. Specifies that the CODEC list is applied to both transmitted and received Session Description Protocol (SDP) transmissions.
in	Optional. Specifies that the CODEC list is applied to received SDP only.
out	Optional. Specifies that the CODEC list is applied to transmitted SDP only.

Default Values

By default, no CODEC lists are assigned.

Command History

Release R10.4.0	Command was introduced and replaced the **codec-group** command.

Functional Notes

The **codec-list** command applies a previously configured CODEC list to an interface, voice trunk, or voice account. These lists are lists of CODECs used by the interface, trunk, or account in call negotiation and are arranged in preferred order with the first listed CODEC being the most preferred.

CODEC lists are created using the **codec** command from the Voice CODEC List Configuration mode prompt. For more information about creating CODEC lists, refer to the *Voice CODEC List Command Set on page 4893***.**

In addition, CODEC lists can be used for the SBC transcoding feature. For more information about this feature, its uses, and its configuration, refer to the configuration guide *Configuring Transcoding in AOS*, available online at https://supportcommunity.adtran.com.

> NOTE *Because you can choose to specify that any CODEC is used by a Session Initiation Protocol (SIP) endpoint with the **any** keyword, do not create a CODEC list with the name of **any**.*

Usage Examples

The following example applies the CODEC list **LIST1** to incoming SDP traffic on trunk **T01**:

(config)**#voice trunk t01 type sip**
(config-t01)**#codec-list LIST1 in**

conferencing-uri *<value>*

Use the **conferencing-uri** command to configure a conference application server uniform resource identifier (URI) that controls and uniquely identifies a conference. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the extension or complete URI of the conference application server.

Default Values

By default, **conferencing-uri** is not configured.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the **conferencing-uri** to **0606**:

(config)**#voice trunk t01 type sip**
(config-t01)**#conferencing-uri 0606**

default-ring-cadence

Use the **default-ring-cadence** to set the default ring cadence for incoming Session Initiation Protocol (SIP) calls that do not contain an Alert-Info header preference. Use the **no** form of this command to return to the default setting. Variations of this command include:

default-ring-cadence external
default-ring-cadence internal

Syntax Description

external	Sets the default ring cadence for incoming calls to external.
internal	Sets the default ring cadence for incoming calls to internal.

Default Values

By default, the inbound ring cadence is set to external.

Command History

Release A5.01	Command was introduced.

Usage Examples

The following example sets the **default-ring-cadence** to **internal**:

(config)**#voice trunk t01 type sip**
(config-t01)**#default-ring-cadence internal**

dial-string source

Use the **dial-string source** command to set the Session Initiation Protocol (SIP) dialing string field of your choice. Use the **no** form of this command to remove the specified setting. Variations of this command include the following:

dial-string source request-uri
dial-string source to

Syntax Description

request-uri	Specifies the Request URI user field as the dialing string source.
to	Specifies the To header field as the dialing string source.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example enables the To header user field as the **dial-string** for this trunk:

(config)**#voice trunk t01 type sip**
(config-t01)**#dial-string source to**

diversion-supported

Use the **diversion-supported** command to apply a Session Initiation Protocol (SIP) Diversion header to redirected calls on the trunk. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled on the NetVanta 7000 Series products. By default, this feature is enabled on the Total Access 900(e) Series products and NetVanta 6000 Series products.

Command History

Release A2.03	Command was introduced.

Functional Notes

This feature retains the originating number when a call is processed through an auto attendant, transferred from a user extension, or is forwarded by a user phone to an external number. For these calls, the number included in the From field of the SIP messages are subject to the automatic number identification (ANI) substitution and a SIP Diversion header is added with the original caller ID number. Calls from internal extensions are subject to the ANI substitution configured on the trunk without the addition of a SIP Diversion header.

Usage Examples

The following example enables **diversion-supported**:

(config)**#voice trunk t01 type sip**
(config-t01)**#diversion-supported**

domain *<name>*

Use the **domain** command to configure the assigned domain name for host messages. The domain is an unique identifier for the Session Initiation Protocol (SIP) users on the trunk. Use the **no** form of this command to disable this feature.

Syntax Description

<name>	Specifies the domain name for the SIP trunk commands.

Default Values

By default, no domain is configured.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the domain name as **home.com**:

(config)**#voice trunk t01 type sip**
(config-t01)**#domain home.com**

grammar alert-info url <*url*>

Use the **grammar alert-info url** command to specify the Alert-Info header construction for Session Initiation Protocol (SIP) trunk messages. Use the **no** form of this command to return to the default setting.

Syntax Description

<*url*>	Specifies the Alert-Info Hypertext Transfer Protocol (HTTP) universal resource locator (URL) header format.

Default Values

By default, the local loopback address is the host in the Alert-Info header (**127.0.0.1**).

Command History

Release A2	Command was introduced.

Usage Examples

The following example sets the Alert-Info header to use a specific URL as shown in the sample header below:

(config)**#voice trunk t01 type sip**
(config-t01)**#grammar alert-info url www.notused.com**

Sample header:

Alert-Info:<http://www.notused.com>;info=alert-internal

grammar contact host local

Use the **grammar contact host local** command to configure the Contact header on Session Initiation Protocol (SIP) messages. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip grammar contact host local
sip grammar contact host local fqdn

Syntax Description

host local	Specifies that the local IP is used in the SIP Contact header.
fqdn	Optional. Specifies that a fully qualified domain name (FQDN) is used in the SIP Contact header.

Default Values

By default, SIP Contact headers use a local IP.

Command History

Release R13.11.0	Command was introduced.

Usage Examples

The following example sets the Contact header format to use an FQDN:

(config)**#voice trunk t01 type sip**
(config-t01)**#grammar contact host local fqdn**

grammar contact host port persistent

Use the **grammar contact host port persistent** command to configure the AOS device to use the Transmission Control Protocol (TCP) port from which AOS initiated a Transport Layer Security (TLS) connection in the Contact uniform resource identifier (URI) sent by AOS. Use the **no** form of this command to disable this feature.

Syntax Description

host	Specifies the Contact header Host field setting.
port	Specifies the Contact header host port.
persistent	Specifies that the persistent connection port should be used for the Contact header host port.

Default Values

No default values are necessary for this command.

Command History

Release R11.5.0	Command was introduced

Functional Notes

This configuration is useful when using client-only authentication. With this type of authentication, a persistent connection is established to the SIP server. Many SIP servers and enterprise session border controllers (eSBCs) need to see the TCP port from which AOS initiated the TLS connection in the Contact URI sent by AOS.

Usage Examples

The following example specifies that AOS device should use the TCP port from which AOS initiated the TLS connection in the Contact URI sent by AOS:

(config)**#voice trunk t01 type sip**
(config-t01)**#grammar contact host port persistent**

grammar from

Use the **grammar from** command to configure the From header on Session Initiation Protocol (SIP) messages. Use the **no** form of this command to return to the default setting. Variations of this command include:

grammar from host domain
grammar from host local
grammar from host local fqdn
grammar from host override registered-users domain
grammar from host override registered-users local
grammar from host override registered-users sip-server
grammar from host sip-server
grammar from user domestic
grammar from user domestic <*Txx*>
grammar from user international
grammar from user international <*Txx*>

Syntax Description

host	Specifies the Host field formatting for the From header.
domain	Specifies the trunk domain setting for formatting the From header.
local	Specifies the local IP address for formatting the From header.
fqdn	Optional. Specifies a fully qualified domain name (FQDN) is used for formatting the From header.
override registered-users	Overrides the current **grammar from host** setting for SIP messages originating from registered users.
sip-server	Specifies the SIP server settings for formatting the From header.
user	Specifies the User field formatting for the From header.
domestic	Specifies domestic formatting for the From user header.
international	Specifies international formatting for the From user header.
<*Txx*>	Optional. Indicates a two-digit trunk identifier (for example, **T01**).

Default Values

By default, the host for formatting messages is **sip-server**, and the default for the user format is **domestic**.

Command History

Release A2	Command was introduced.
Release A5.01	Command was expanded to include the **override registered-users** parameter.
Release R10.1.0	Command was introduced.
Release R13.11.0	Command was expanded to include the **fqdn** parameter.

Functional Notes

Omitting the trunk identifier when issuing the **grammar from user** command specifies the User header globally.

Usage Examples

The following example sets the From header format to use an FQDN:

(config)**#voice trunk t01 type sip**
(config-t01)**#grammar from host local fqdn**

The following example sets the From header format to use calling party format on trunk **T02**:

(config)**#voice trunk t01 type sip**
(config-t01)**#grammar from user domestic T02**

Technology Review

This technology review provides information about the E.164 recommendation for international numbering plans and telephone number formats.

A fully specified telephone number can have a maximum of 15 digits, including country code, area code, and the subscriber's number. These numbers usually consist of a + prefix. E.164 numbers exclude dialing prefixes. The most familiar prefixes are international direct dialing (IDD) and national direct dialing (NDD). In countries other than the United States, the IDD and NDD are represented by different numbers.

Additionally, E.123 describes the use of + to indicate a fully specified international number. The + is used in SIP headers to provide consistency across national and international phone calls.

AOS products provide support for E.164 by being able to specify a country code and an IDD prefix. Nationally formatted telephone numbers are converted to international format by prefixing them with + and the country code. On outbound international calls, + is substituted for the IDD. On incoming international calls, the + is removed. If the country code matches the configured value, it too is removed.

*Setting the From header to **international** will cause phone numbers to be formatted as indicated by E.164. The country code must be configured, and the number must be of type **national** for this feature to work successfully.*

grammar p-asserted-identity host

Use the **grammar p-asserted-identity host** command to configure the P-Asserted Identity header host format for the Session Initiation Protocol (SIP) trunk. Use the **no** form of this command to return to the default setting. Variations of this command include:

grammar p-asserted-identity host domain
grammar p-asserted-identity host local
grammar p-asserted-identity host local fqdn
grammar p-asserted-identity host sip-server

Syntax Description

domain	Specifies the domain host for formatting the header.
local	Specifies the local IP as host for formatting the header.
fqdn	Optional. Specifies that a fully qualified domain name (FQDN) is used for formatting the header.
sip-server	Specifies the SIP server as host for formatting the header.

Default Values

By default, the host for formatting messages is **sip-server**.

Command History

Release A2	Command was introduced.
Release R13.11.0	Command was expanded to include the **fqdn** parameter.

Usage Examples

The following example sets the p-asserted-identity header host format to use an FQDN for constructing the header:

(config)**#voice trunk t01 type sip**
(config-t01)**#grammar p-asserted-identity host local fqdn**

grammar p-early-media supported

Use the **grammar p-early-media supported** command to enable sending a P-Early-Media header with a value of "supported" in INVITE, PRACK, and UPDATE requests sent on the Session Initiation Protocol (SIP) trunk. Use the **no** form of this command to disable support for the early media detection feature.

Syntax Description

No subcommands.

Default Values

By default, sending of the P-Early-Media header is disabled.

Command History

Release 13.6.0	Command was introduced.

Functional Notes

Support for sending the P-Early-Media header can be configured on a per-trunk basis, using the **grammar p-early-media supported** command as described here, or it can be configured globally, using the command *sip grammar p-early-media supported on page 1715*. The trunk setting will always take precedence over the globally configured setting.

Usage Examples

The following example configures a trusted domain on the trunk and enables sending the P-Early-Media header:

(config)**#voice trunk t01 type sip**
(config-t01)**#trust-domain**
(config-t01)**#grammar p-early-media supported**

grammar proxy-require privacy

Use the **grammar proxy-require privacy** command to add privacy to Proxy-Require header format for Session Initiation Protocol (SIP) trunk. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release A2	Command was introduced.

Usage Examples

The following example allows a Proxy-Require header to be added to packets containing a privacy header:

(config)**#voice trunk t01 type sip**
(config-t01)**#grammar proxy-require privacy**

grammar refer-to

Use the **grammar refer-to** command to configure the Session Initiation Protocol (SIP) Refer-To header on intratrunk attended transfers. Use the **no** form of this command to return to the default setting. Variations of this command include:

grammar refer-to intratrunk-attended-transfer source contact
grammar refer-to intratrunk-attended-transfer source to-from

Syntax Description

intratrunk-attended-transfer source	Specifies the source for Refer-To header of an intratrunk attended transfer.
contact	Specifies the Contact header as the source for the Refer-To header.
to-from	Specifies either the To or From header as the source for Refer-To header.

Default Values

By default, the To or From header is the source for the Refer-To header on intratrunk attended transfers.

Command History

Release A5.01	Command was introduced.

Usage Examples

The following example specifies the Contact header as the source for the Refer-To header of an intratrunk attended transfer:

(config)**#voice trunk t01 type sip**
(config-T01)**#grammar refer-to intratrunk-attended-transfer source contact**

grammar request-uri

Use the **grammar request-uri** command to format the Request uniform resource identifier (URI) for Session Initiation Protocol (SIP) trunk messages. Use the **no** form of this command to return to the default setting. Variations of this command include:

grammar request-uri host domain
grammar request-uri host sip-server
grammar request-uri host-resolve
grammar request-uri transmit-network-selection <*parameter name*>

Syntax Description

host domain	Specifies the trunk domain setting for formatting the Request-URI header.
host sip-server	Specifies the trunk SIP server setting for formatting the Request-URI header.
host-resolve	Enables the local unit to resolve the domain before constructing the Request-URI header.
transmit-network-selection <*parameter name*>	Specifies that Transmit Network Selection is included in the Request URI.

Default Values

By default, the host for formatting messages is **sip server**, and **host-resolve** is disabled.

Command History

Release A2	Command was introduced.
Release R10.1.0	Command was added to the VQM Reporter command set.
Release R13.8.0	Command was expanded to include the **transmit-network-selection** parameter.

Usage Examples

The following example enables SIP trunk messages to resolve the Request URI from the host domain:

(config)**#voice trunk t01 type sip**
(config-t01)**#grammar request-uri host domain**

The following example enables SIP trunk messages to resolve the Request URI from the local unit:

(config)**#voice trunk t01 type sip**
(config-t01)**#grammar request-uri host-resolve**

grammar require 100rel

Use the **grammar require 100rel** command to add **100rel** to the Require header format. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, **grammar require 100rel** is disabled.

Command History

Release A2	Command was introduced.

Functional Notes

This command enables or disables the sending of reliable provisional responses to clients that *support* 100rel. Reliable provisional responses will always be sent to clients that *require* 100rel even with **grammar require 100rel** disabled.

Usage Examples

The following example enables **grammar require 100rel**:

(config)**#voice trunk t01 type sip**
(config-t01)**#grammar require 100rel**

Technology Review

There are two Require headers that may use the 100rel tag, one in the initial request, and one in the provisional response.

The user agent client (UAC) is used to initiate Session Initiation Protocol (SIP) requests. When the UAC creates a new request, it can require reliable provisional responses for that request by adding the option tag 100rel to the Require header of that request.

The user agent server (UAS) contacts the user when SIP requests are received, and returns responses on behalf of the user, using provisional responses for request progress information. Provisional responses (100 to 199) are transmitted on a best-effort basis. By using reliable provisional responses, responses are sent by the UAS until they are acknowledged as received. This is especially beneficial when sending provisional responses over an unreliable transport, such as User Datagram Protocol (UDP).

The UAS must send any non-100rel provisional responses reliably if the initial request contained a Require header field with the option tag 100rel. If the UAS is unwilling to do so, it must reject the initial request with a Bad Extension message and include an Unsupported header field containing the option tag 100rel. If the client *supports* 100rel, the UAS has the *option* of sending provisional responses with or without the Require 100rel tag as instructed by the **grammar require 100rel** command.

grammar supported 100rel

Use the **grammar supported 100rel** command to include 100rel in the supported header of the Session Initiation Protocol (SIP) trunk message. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, **grammar supported 100rel** is disabled.

Command History

Release A2	Command was introduced.

Usage Examples

The following example enables **grammar supported 100rel**:

(config)**#voice trunk t01 type sip**
(config-t01)**#grammar supported 100rel**

grammar to

Use the **grammar to** command to configure the To header host format of Session Initiation Protocol (SIP) trunk messages. Use the **no** form of this command to return to the default setting. Variations of this command include:

grammar to host domain
grammar to host sip-server

Syntax Description

host domain	Specifies using the trunk domain setting to format the To header.
host sip-server	Specifies using the trunk SIP server settings to format the To header.

Default Values

By default, the host for formatting messages is **sip server**.

Command History

Release A2	Command was introduced.
Release R10.1.0	Command was added to the VQM Reporter command set.

Usage Examples

The following example configures the To header format construction to use the trunk domain:

(config)**#voice trunk t01 type sip**
(config-t01)**#grammar to host domain**

grammar user-agent

Use the **grammar user-agent** command to configure the user agent (UA) header format in Session Initiation Protocol (SIP) messages for the trunk. The UA header can be given the default value for the product, a user-defined value, or no value at all, in which case the UA header is not sent in SIP messages. In addition, other specific values can be included in the UA header. Use the **no** form of this command to return to the configured system value. Variations of this command include the following:

grammar user-agent <*word*>
grammar user-agent default
grammar user-agent include custom-text <*word*>
grammar user-agent include firmware-version
grammar user-agent include hostname
grammar user-agent include serial-number
grammar user-agent none

Syntax Description

<*word*>	Specifies a word as a user-defined value to replace the default UA value. Maximum 128 letters.
default	Returns the UA header field to the default value.
include	Specifies that additional information is included in the UA header.
custom-text <*word*>	Specifies that a user-defined value is included in the UA header. Maximum 128 letters.
firmware-version	Specifies that the firmware version is included in the UA header.
hostname	Specifies that the host name is included in the UA header.
serial-number	Specifies that the serial number is included in the UA header.
none	Disables the UA header field resulting in no UA header sent in SIP messages.

Default Values

By default, the UA value is set to the system value of the product specified by the Global Configuration mode command *sip grammar user-agent on page 1722*.

Command History

Release R10.3.0	Command was expanded to include the **include** parameters.

Usage Examples

The following example removes the UA header field from SIP messages on the trunk:

(config)**#voice trunk t01 type sip**
(config-t01)**#grammar user-agent none**

hmr

Use the **hmr** command to apply a Session Initiation Protocol (SIP) header manipulation rule (HMR) policy to the SIP traffic on a specific SIP trunk. Use the **no** form of this command to remove the HMR policy. Variations of this command include:

hmr <*name*> **in**
hmr <*name*> **out**

Syntax Description

<*name*>	Specifies the name of the HMR policy to apply to SIP messaging on the trunk.
in	Specifies the HMR policy is applied to inbound SIP messaging received on the trunk.
out	Specifies the HMR policy is applied to outbound SIP messaging transmitted on the trunk.

Default Values

By default, there are no configured HMR options.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

For more information about SIP HMR, its uses and configuration, refer to the configuration guide *Manipulating SIP Headers and Messages in AOS,* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example adds the HMR policy **MYPOLICY1** to the T01 SIP trunk for inbound SIP traffic:

(config)**#voice trunk t01 type sip**
(config-t01)**#hmr MYPOLICY1 in**

incoming-music-on-hold

Use the **incoming-music-on-hold** command to activate music on hold for hold re-invites on Session Initiation Protocol (SIP) trunk calls. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example activates music on hold for hold re-invites on SIP trunk calls:

(config)**#voice trunk t01 type sip**
(config-t01)**#incoming-music-on-hold**

match ani <*template*> add diversion <*template*>

Use the **match ani add diversion** command to add Session Initiation Protocol (SIP) Diversion headers to outgoing SIP messages. Use the **no** form of this command to remove the Diversion header from the SIP message. Variations of this command include:

match ani <*template*> **add diversion** <*template*>
match ani <*template*> **add diversion** <*template*> <*diversion type*> <*screening type*> <*privacy setting*>

Syntax Description

ani <*template*>	Specifies the source automatic number identification (ANI) information to be matched. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
add	Specifies that when the match source matches the match source template, SIP Diversion headers are added to the SIP trunk messages.
diversion <*template*>	Specifies the match target and match target template used to execute the command action when adding SIP Diversion headers to SIP messages. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
<*diversion type*>	Optional. Specifies the reason for the diversion. If you specify the diversion type, you must also specify whether or not the diversion is screened by the network, and whether diversion privacy is used. Diversion reasons include the following:

away	Diverts the message if the receiving SIP agent is away.
deflection	Diverts the message if the receiving SIP agent is deflecting calls.
do-not-disturb	Diverts the message if the receiving SIP agent has do-not-disturb enabled.
follow-me	Diverts the message if the receiving SIP agent has FindMe-FollowMe enabled.
no-answer	Diverts the message if the receiving SIP agent does not answer.
out-of-service	Diverts the message if the receiving SIP agent is out-of-service.
time-of-day	Diverts the message if the message is sent at a particular time of day.
unavailable	Diverts the message if the receiving SIP agent is unavailable.
unconditional	Diverts the message on an unconditional basis.
unknown	Diverts the message if an unknown error occurs.
user-busy	Diverts the message if the receiving SIP agent is busy.

<screening type>	Optional. Specifies whether the diversion is screened by the network. Screening types include:	
	no	Specifies that the diversion used is not screened by the network.
	yes	Specifies that the diversion used is screened by the network.
<privacy setting>	Optional. Specifies whether privacy is used when SIP Diversion headers are added to the SIP messages. Privacy settings include:	
	full	Specifies that the diversion uses full privacy.
	off	Specifies that the diversion does not use privacy.

Default Values

By default, SIP diversions are specified as unconditional (**unconditional**), do not use network screening (**no**), and do not use privacy (**off**).

This command can get very lengthy. To shorten the length of the command, you must elect to use all default values for the diversion options, or you must override all options.

Command History

Release A4.01	Command was introduced.

Functional Notes

Both match source and match target templates are defined in the same way as dial plan entries.

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8

6) 1234 Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

In the following example command, the match source template is in **bold**:

match ani **!2565558XXX** add diversion 2565558000 unconditional yes full

*In this example, the template includes a **!** at the beginning. The **!** indicates that the inverse of the template is matched. Inverse matching can only be used with the match source template and requires a static target template (the target template cannot contain wildcards).*

For additional information about configuring SIP Diversion headers in SIP messaging, refer to the quick configuration guide, *Modifying SIP Headers to SIP Trunks in AOS Voice Products* available online at https://supportcommunity.adtran.com.

Usage Examples

In the following example, the SIP trunk (**t01**) is configured so that when the ANI source template (**2565558XXX**) is matched, an unconditional SIP Diversion header with a target template of **2565558000** and network screening and full privacy are added to the message.

(config)**#voice trunk t01**
(config-T01)**#match ani 2565558XXX add diversion 2565558000 unconditional yes full**

match ani <*template*> add p-asserted-identity <*template*>

Use the **match ani add p-asserted-identity** command to add a P-Asserted-Identity header to an outgoing Session Initiation Protocol (SIP) message. Use the **no** form of this command to remove the P-Asserted-Identity header.

Syntax Description

ani <*template*>	Specifies the source ANI information to be matched. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
add	Specifies that when the match source matches the match source template, SIP headers are added to the SIP trunk messages.
p-asserted-identity <*template*>	Specifies that it is a P-Asserted-Identity header that is added to the SIP message and specifies the match target template. Templates are entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.

Default Values

By default, P-Asserted-Identity headers are not added to SIP messages.

Command History

Release A4.01	Command was introduced.

Functional Notes

Both match source and match target templates are defined in the same way as dial plan entries.

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits

5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

In the following example command, the match source template is in **bold**:

match ani **!2565558XXX** add diversion 2565558000 unconditional yes full

*In this example, the template includes a **!** at the beginning. The **!** indicates that the inverse of the template is matched. Inverse matching can only be used with the match source template and requires a static target template (the target template cannot contain wildcards).*

For additional information about configuring SIP Diversion headers in SIP messaging, refer to the quick configuration guide, *Modifying SIP Headers to SIP Trunks in AOS Voice Products* available online at https://supportcommunity.adtran.com.

Usage Examples

In the following example, a P-Asserted-Identity header is adding to a SIP message when the ANI source template of **2565558XXX** is matched with the target template of **2565558000**:

(config)**#voice trunk t01**
(config-T01)**#match ani 2565558XXX add p-asserted-identity 2565558000**

match ani <*template*> replace diversion <*template*>

Use the **match ani replace diversion** command to replace Session Initiation Protocol (SIP) Diversion headers on outgoing SIP messages. Use the **no** form of this command to revert to the original header on the SIP message. Variations of this command include:

match ani <*template*> **replace diversion** <*template*>
match ani <*template*> **replace diversion** <*template*> <*diversion type*> <*screening type*> <*privacy setting*>

Syntax Description

ani <*template*>	Specifies the source automatic number identification (ANI) information to be matched. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
replace	Specifies that when the match source matches the match source template, SIP Diversion headers are replaced on the SIP trunk messages.
diversion <*template*>	Specifies the match target and match target template used to execute the command action when replacing SIP Diversion headers in SIP messages. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
<*diversion type*>	Optional. Specifies the reason for the diversion. If you specify the diversion type, you must also specify whether or not the diversion is screened by the network, and whether diversion privacy is used. Diversion reasons include the following:

away	Diverts the message if the receiving SIP agent is away.
deflection	Diverts the message if the receiving SIP agent is deflecting calls.
do-not-disturb	Diverts the message if the receiving SIP agent has do-not-disturb enabled.
follow-me	Diverts the message if the receiving SIP agent has FindMe-FollowMe enabled.
no-answer	Diverts the message if the receiving SIP agent does not answer.
out-of-service	Diverts the message if the receiving SIP agent is out-of-service.
time-of-day	Diverts the message if the message is sent at a particular time of day.
unavailable	Diverts the message if the receiving SIP agent is unavailable.
unconditional	Diverts the message on an unconditional basis.
unknown	Diverts the message if an unknown error occurs.
user-busy	Diverts the message if the receiving SIP agent is busy.

<screening type>	Optional. Specifies whether the diversion is screened by the network. Screening types include:	
	no	Specifies that the diversion used is not screened by the network.
	yes	Specifies that the diversion used is screened by the network.
<privacy setting>	Optional. Specifies whether privacy is used when SIP Diversion headers are added to the SIP messages. Privacy settings include:	
	full	Specifies that the diversion uses full privacy.
	off	Specifies that the diversion does not use privacy.

Default Values

By default, SIP diversions are specified as unconditional (**unconditional**), do not use network screening (**no**), and do not use privacy (**off**).

This command can get very lengthy. To shorten the length of the command, you must elect to use all default values for the diversion options, or you must override all options.

Command History

Release A4.05	Command was introduced.

Functional Notes

The following are example template entries using wildcards:

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8

6) 1234 Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

In the following example command, the match source template is in **bold**:

match ani **!2565558XXX** replace diversion 2565558000 unconditional yes full

*In this example, the template includes a **!** at the beginning. The **!** indicates that the inverse of the template is matched. Inverse matching can only be used with the match source template and requires a static target template (the target template cannot contain wildcards).*

For additional information about configuring SIP Diversion headers in SIP messaging, refer to the configuration guide, *Modifying SIP Headers on SIP Trunks in AOS Voice Products* available online at https://supportcommunity.adtran.com.

Usage Examples

In the following example, the SIP trunk (**t01**) is configured so that when the ANI source template (**2565558XXX**) is matched, an unconditional SIP Diversion header with a target template of **2565558000** and network screening and full privacy replaces the original SIP header.

(config)**#voice trunk t01**
(config-T01)**#match ani 2565558XXX replace diversion 2565558000 unconditional yes full**

match ani <*template*> substitute <*template*>

Use the **match ani substitute** command to configure automatic number identification (ANI) substitution for outbound voice trunks. Use the **no** form of this command to remove the substitution. Variations of this command include:

match ani <*template*> **substitute** <*template*>
match ani <*template*> **substitute** <*template*> **name** <*name*>

Syntax Description

ani <*template*>	Specifies the ANI information to be substituted. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
substitute <*template*>	Specifies the ANI information that is substituted for the original ANI information. This information is entered using wildcards and numerical digits. When using wildcards in the **match** and **substitute** template, both must be of the same type and position in the number template or AOS will not allow the substitution. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
name <*name*>	Optional. Specifies the name associated with the ANI information. This option is only available on trunks that support ANI name information (integrated services digital network (ISDN) trunks, Session Initiation Protocol (SIP) trunks, T1 loop start (LS) network trunks, and T1 ground start (GS) network trunks).

Default Values

By default, no ANI substitution is configured.

Command History

Release A2	Command was introduced.

Functional Notes

The convention for ANI templates is very similar to dial plan entries. Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example specifies that the ANI information from numbers **555-8111** to **555-8115** will be substituted by **555-8110** for outbound calls on the trunk **T03**:

(config)**#voice trunk t03 type sip**
(config-t03)**#match ani 555-811[125] substitute 555-8110**

match dnis <*template*> replace ani <*number*>

Use the **match dnis replace ani** command to replace dialed number identification service (DNIS) information with automatic number identification (ANI) information on outbound voice trunks. Use the **no** form of this command to remove the replacement. Variations of this command include:

match dnis <*template*> **replace ani** <*number*>
match dnis <*template*> **replace ani** <*number*> **name** <*name*>

Syntax Description

dnis <*template*>	Specifies the DNIS information to be replaced. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
replace ani <*number*>	Specifies the ANI information that replaces the original DNIS information. This information is entered using numerical digits. Enter the number without punctuation.
name <*name*>	Optional. Specifies the name associated with the ANI information. This option is only available on trunks that support ANI name information (integrated services digital network (ISDN) trunks, Session Initiation Protocol (SIP) trunks, T1 loop start (LS) network trunks, and T1 ground start (GS) network trunks).

Default Values

By default, no DNIS replacement is configured.

Command History

Release A2	Command was introduced.

Functional Notes

The convention for DNIS templates is very similar to dial plan entries. Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits

3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example specifies that the DNIS information for dialed numbers on trunk **T03** that match **1-256-524-8600** are replaced with **882-6467**:

(config)**#voice trunk t03 type sip**
(config-t03)**#match dnis 1-256-524-8600 replace ani 8826467**

match dnis <*template*> substitute <*template*>

Use the **match dnis substitute** command to configure dialed number identification service (DNIS) substitution for outbound voice trunks. Use the **no** form of this command to remove the substitution. Variations of this command include:

match dnis <*template*> **substitute** <*template*>
match dnis <*template*> **substitute** <*template*> **name** <*name*>

Syntax Description

dnis <*template*>	Specifies the DNIS information to be substituted. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
substitute <*template*>	Specifies the DNIS information that is substituted for the original DNIS information. This information is entered using wildcards and numerical digits. When using wildcards in the **match** and **substitute** template, both must be of the same type and position in the number template or AOS will not allow the substitution. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
name <*name*>	Optional. Specifies the name associated with the DNIS information. This option is only available on trunks that support DNIS name information (integrated services digital network (ISDN) trunks, Session Initiation Protocol (SIP) trunks, T1 loop start (LS) network trunks, and T1 ground start (GS) network trunks).

Default Values

By default, no DNIS substitution is configured.

Command History

Release A2	Command was introduced.

Functional Notes

The convention for DNIS templates is very similar to dial plan entries. Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example specifies that the DNIS information for dialed numbers on trunk **T03** that match **1-334-NXX-XXXX** are substituted with **1-800-557-4500**:

(config)**#voice trunk t03 type sip**
(config-t03)**#match dnis 1-334-NXX-XXXX substitute 1-800-557-4500**

max-number-calls <*value*>

Use the **max-number-calls** command to configure the maximum number of calls allowed on this trunk. This command is useful in controlling the call usage of the trunk. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the maximum number of calls allowed on this trunk. Range is **1** to **64** calls.

Default Values

By default, no maximum number of calls is specified.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the maximum number of calls allowed to **25**:

(config)**#voice trunk t01 type sip**
(config-t01)**#max-number-calls 25**

media-loopback

Use the **media-loopback** command to configure a Session Initiation Protocol (SIP) trunk to allow media loopback calls to be placed on the trunk. Media loopback enables media sessions to be established where the media is looped back to the transmitter. This is typically referred to as active monitoring of services. This command allows media loopback sessions on some SIP trunks while disallowing media-loopback on others. Use the **no** form of this command do disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **media-loopback** is enabled on SIP trunks.

Command History

Release A4.03	Command was introduced.

Usage Examples

The following example enables media loopback on trunk **T01**:

(config)**#voice trunk t01 type sip**
(config-t01)**#media-loopback**

options-supported

Use the **options-supported** command to enable support for the OPTIONS message for calls on the trunk. Use the **no** form of this command to return to the default setting. Variations of this command include:

options-supported
options-supported forward

Syntax Description

forward	Optional. Enables support for forwarding in-dialog OPTIONS requests to the other trunk involved in a call.

Default Values

By default, this feature is enabled.

Command History

Release R13.8.0	Command was introduced.

Usage Examples

The following example enables support for OPTIONS messages for calls on SIP trunk T01:

(config)**#voice trunk t01 type sip**
(config-t01)**#options-supported**

outbound-proxy primary <*value*>

Use the **outbound-proxy primary** command to define the primary name/address of the Session Initiation Protocol (SIP) proxy server to which the trunk will send all SIP messages. Use the **no** form of this command to return to the default setting. Variations of this command include:

outbound-proxy primary <*value*>
outbound-proxy primary <*value*> **tcp**
outbound-proxy primary <*value*> **tcp** <*port*>
outbound-proxy primary <*value*> **udp**
outbound-proxy primary <*value*> **udp** <*number*>
outbound-proxy primary <*value*> **tls** <*profile name*>
outbound-proxy primary <*value*> **tls** <*profile name*> **srv**
outbound-proxy primary <*value*> **tls** <*profile name*> **srv** <*service name prefix*>
outbound-proxy primary <*value*> **tls** <*profile name*> **srv** <*service name prefix*> <*transport name prefix*>
outbound-proxy primary <*value*> **tls** <*profile name*> <*port*>
outbound-proxy primary <*value*> **tls** <*profile name*> <*port*> **srv**
outbound-proxy primary <*value*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*>
outbound-proxy primary <*value*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*>
<*transport name prefix*>

Syntax Description

<*value*>	Specifies the fully qualified domain name (FQDN) or IP address of the outbound proxy server.
tcp	Optional. Sets the Transmission Control Protocol (TCP) port of the outbound proxy server.
udp	Optional. Sets the User Datagram Protocol (UDP) port of the outbound proxy server.
tls <*profile name*>	Optional. Associates a Transport Layer Security (TLS) profile with the trunk, thus specifying the TLS operation on the trunk.
<*port*>	Optional. Specifies the port number. Range is **0** to **65535**.
srv	Optional. Specifies that service records (SRV) parameters are enabled. This option is available only when an FQDN has been specified.
<*service name prefix*>	Optional. Specifies the service name used to format the domain naming service (DNS) SRV request used to resolve the domain name. Underscores are added automatically.
<*transport name prefix*>	Optional. Specifies the transport name used to format the DNS SRV request used to resolve the domain name. Underscores are added automatically.

Default Values

By default, the IP address is set to **0.0.0.0**, the UDP port is set to **5060**, and the TLS port is set to **5061**.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was expanded.
Release R11.5.0	Command was expanded to include the TLS and SRV configuration options.

Functional Notes

The configured value must resolve to a valid IP address.

Usage Examples

The following example sets the outbound proxy server to **sip-proxy.adtran.com** with a UDP port of **2222**:

(config)**#voice trunk t01 type sip**
(config-t01)**#outbound-proxy primary sip-proxy.adtran.com udp 2222**

The following example specifies the SIP trunk as a primary SIP server at IP address **10.10.10.1** using TLS profile **TLSPROFILE1** on the default port:

(config)**#voice trunk t01 type sip**
(config-t01)**#outbound-proxy primary 10.10.10.1 tls TLSPROFILE1**

outbound-proxy secondary <*value*>

Use the **outbound-proxy secondary** command to define the secondary name/address of the Session Initiation Protocol (SIP) proxy server to which the trunk will send all SIP messages. Use the **no** form of this command to return to the default setting. Variations of this command include:

outbound-proxy secondary <*value*>
outbound-proxy secondary <*value*> **tcp**
outbound-proxy secondary <*value*> **tcp** <*port*>
outbound-proxy secondary <*value*> **udp**
outbound-proxy secondary <*value*> **udp** <*port*>
outbound-proxy secondary <*value*> **tls** <*profile name*>
outbound-proxy secondary <*value*> **tls** <*profile name*> **srv**
outbound-proxy secondary <*value*> **tls** <*profile name*> **srv** <*service name prefix*>
outbound-proxy secondary <*value*> **tls** <*profile name*> **srv** <*service name prefix*> <*transport name prefix*>
outbound-proxy secondary <*value*> **tls** <*profile name*> <*port*>
outbound-proxy secondary <*value*> **tls** <*profile name*> <*port*> **srv**
outbound-proxy secondary <*value*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*>
outbound-proxy secondary <*value*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*> <*transport name prefix*>

Syntax Description

<*value*>	Specifies the fully qualified domain name (FQDN) or IP address of the outbound proxy server.
tcp	Optional. Sets the Transmission Control Protocol (TCP) port of the outbound proxy server.
udp	Optional. Sets the User Datagram Protocol (UDP) port of the outbound proxy server.
tls <*profile name*>	Optional. Associates a Transport Layer Security (TLS) profile with the trunk, thus specifying the TLS operation on the trunk.
<*port*>	Optional. Specifies the port number. Range is **0** to **65535**.
srv	Optional. Specifies that service records (SRV) parameters are enabled. This option is available only when an FQDN has been specified.
<*service name prefix*>	Optional. Specifies the service name used to format the domain naming service (DNS) SRV request used to resolve the domain name. Underscores are added automatically.
<*transport name prefix*>	Optional. Specifies the transport name used to format the DNS SRV request used to resolve the domain name. Underscores are added automatically.

Default Values

By default, the IP address is set to **0.0.0.0**, the UDP port is set to **5060**, and the TLS port is set to **5061**.

Command History

Release 15.1	Command was introduced.
Release R11.5.0	Command was expanded to include the TLS and SRV configuration options.

Functional Notes

The configured value must resolve to a valid IP address.

Usage Examples

The following example sets the outbound proxy server to **sip-proxy.adtran.com** with a UDP port of **2244**:

(config)**#voice trunk t01 type sip**
(config-t01)**#outbound-proxy secondary sip-proxy.adtran.com udp 2244**

The following example specifies the SIP trunk as a secondary SIP server at IP address **10.10.10.1** using TLS profile **TLSPROFILE1** on the default port:

(config)**#voice trunk t01 type sip**
(config-t01)**#outbound-proxy secondary 10.10.10.1 tls TLSPROFILE1**

p-assert-diversion

Use the **p-assert-diversion** command to enable sending P-Asserted-Identity in place of the Session Initiation Protocol (SIP) diversion header. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example enables P-Asserted-Identity in place of the SIP diversion header:

(config)**#voice trunk t01 type sip**
(config-t01)**#p-assert-diversion**

peer-certificate-identity *<string>*

Use the **peer-certificate-identity** command to configure a static string used in peer validation for Transport Layer Security (TLS). The value specified at the trunk is used by the TLS profile to match for validation (refer to the TLS profile command *validate identity on page 4887*). Use the **no** form of this command to remove the string from the trunk's configuration.

Syntax Description

<string>	Specifies, in text, the static string for the trunk to use in TLS peer identity validation.

Default Values

By default, no peer identity string is defined.

Command History

Release R11.5.0	Command was introduced.

Usage Examples

The following example defines a static string for use in TLS validation:

(config)**#voice trunk t01 type sip**
(config-t01)**#peer-certificate-identity PEER1VALID**

phone-context

Use the **phone-context** command to create an entry in the phone-context map. The phone-context map allows call context information to be preserved between the Session Initiation Protocol (SIP) server and the primary rate interface (PRI). Use the **no** form of this command to delete the configured entry. Variations of this command include the following:

phone-context <*string*> **plan** <*indicator*> **type** <*number*>
phone-context <*string*> **plan** <*indicator*> **type abbreviated**
phone-context <*string*> **plan** <*indicator*> **type international**
phone-context <*string*> **plan** <*indicator*> **type level0**
phone-context <*string*> **plan** <*indicator*> **type level1**
phone-context <*string*> **plan** <*indicator*> **type level2**
phone-context <*string*> **plan** <*indicator*> **type national**
phone-context <*string*> **plan** <*indicator*> **type network-specific**
phone-context <*string*> **plan** <*indicator*> **type subscriber**
phone-context <*string*> **plan** <*indicator*> **type unknown**
phone-context <*string*> **plan e164 type** <*number*>
phone-context <*string*> **plan e164 type abbreviated**
phone-context <*string*> **plan e164 type international**
phone-context <*string*> **plan e164 type level0**
phone-context <*string*> **plan e164 type level1**
phone-context <*string*> **plan e164 type level2**
phone-context <*string*> **plan e164 type national**
phone-context <*string*> **plan e164 type network-specific**
phone-context <*string*> **plan e164 type subscriber**
phone-context <*string*> **plan e164 type unknown**
phone-context <*string*> **plan private type** <*number*>
phone-context <*string*> **plan private type abbreviated**
phone-context <*string*> **plan private type international**
phone-context <*string*> **plan private type level0**
phone-context <*string*> **plan private type level1**
phone-context <*string*> **plan private type level2**
phone-context <*string*> **plan private type national**
phone-context <*string*> **plan private type network-specific**
phone-context <*string*> **plan private type subscriber**
phone-context <*string*> **plan private type unknown**
phone-context <*string*> **plan unknown type** <*number*>
phone-context <*string*> **plan unknown type abbreviated**
phone-context <*string*> **plan unknown type international**
phone-context <*string*> **plan unknown type level0**
phone-context <*string*> **plan unknown type level1**
phone-context <*string*> **plan unknown type level2**
phone-context <*string*> **plan unknown type national**
phone-context <*string*> **plan unknown type network-specific**
phone-context <*string*> **plan unknown type subscriber**

phone-context <*string*> **plan unknown type unknown**

Syntax Description

<*string*>		Specifies a string of text for the phone-context map entry. This is used to convert between phone-context and NPI/TON values.
plan		Specifies the NPI to associate with the phone-context map entry.
	<*number*>	Specifies the NPI value. Valid range is **0** to **15**.
	e164	Specifies using the ISDN/telephone numbering plan (E.164) value (0001) for the NPI bits of the Type-of-Address octet.
	private	Specifies using the **private** numbering plan value (1001) for the NPI bits of the Type-of-Address octet.
	unkown	Specifies using the **unknown** numbering plan value (0000) for the NPI bits of the Type-of-Address octet.
type		Specifies the TON to associate with the phone-context map entry.
	<*number*>	Specifies the TON value. Valid range is **0** to **7**.
	abbreviated	Specifies using the **abbreviated** value (110) for the TON bits of the Type-of-Address octet. Abbreviated is used mainly in private ISDN network applications and the implementation is network dependent.
	international	Specifies using the **international** value (001) for the TON bits of the Type-of-Address octet. International is used for calls destined outside the national calling area. International calls have the international direct dialing (IDD) prefix removed. For example, consider an international call of 011-N$, where the IDD prefix is 011 and the N$ represents the digits necessary for routing the call at the destination. When the called party information element (IE) is created for this call, the prefix is stripped and the N$ digits are placed in the number digits field.
	level0	Specifies using the level 0 local number type in a Private Numbering Plan (PNP). The value of the TON bits of the Type-of-Address octet is identical to the **subscriber** value (100) in E.164 format.
	level1	Specifies using the level 1 regional number type in a PNP. The value of the TON bits of the Type-of-Address octet is identical to the **national** value (010) in E.164 format.
	level2	Specifies using the level 2 local number type in a PNP. The value of the TON bits of the Type-of-Address octet is identical to the **international** value (001) in E.164 format.
	national	Specifies using the **national** value (010) for the TON bits of the Type-of-Address octet. National is used for calls destined for inside the national calling area (calls that do not cross into an international local access and transport area (LATA)). National calls have the direct dialing prefix removed. For example, consider a national call with a direct dialing prefix of 1 and NXX-NXX-XXXX to represent the ten-digit number necessary for routing the call. When the called party IE is created for this call, the prefix (1) is stripped and the NXX-NXX-XXXX digits are placed in the number digits field.

network-specific	Specifies using the **network-specific** value (011) for the TON bits of the Type-of-Address octet. Network specific is used for calls that require special access to a private network, which requires the use of a prefix that should be stripped once access to the network has been gained. Network-specific calls have the dialing prefix removed. For example, a call to a private network with the prefix 700 consists of 700-N$, where 700 is the dialing prefix and N$ represents the digits necessary for routing the call at the destination. When the called party IE is created for this call, the prefix is stripped and the N$ is placed in the Number Digits field.
subscriber	Specifies using the **subscriber** value (100) for the TON bits of the Type-of-Address octet. Subscriber is used for local calls (not long distance). Subscriber calls, by default, have the area code removed. For example, a subscriber call to 916-555-1212 would have the prefix 916 stripped and 555-1212 in the number digits field. For areas with mandatory ten-digit dialing, a blank prefix should be entered to ensure that all ten digits are passed to the number digits field.
unknown	Specifies using the **unknown** value (000) for the TON bits of the Type-of-Address octet. Unknown is used when the number type is not known. Unknown numbers are presumed to have no prefix, and the entire dialed number is presented in the number digits field.

Default Values

By default, no phone-context map entries are configured.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

During ISDN call establishment on a PRI, each phone number in the SETUP message is qualified with a pair of identifiers, TON and NPI, which determine how the phone number is to be treated. The mechanism by which a SIP server communicates information about phone numbers is the SIP URI phone-context field.

The **phone-context** command allows a table to be configured that stores associations between the SIP URI phone-context strings and NPI/TON value pairs. This map allows the SIP trunk to convert between numerical NPI/TON value pairs and a phone-context text string. Consequently, phone number information is preserved during interworking between SIP and ISDN PRI.

In the PRI to SIP direction, the received NPI/TON values are passed through the switchboard to the SIP trunk. The SIP trunk then uses the phone-context table to find the corresponding phone-context text string, and the string is inserted as a **phone-context=** parameter into the outgoing SIP URI.

In the SIP to PRI direction, the SIP trunk uses the phone-context table to convert the string received in the **phone-context=** parameter to the corresponding NPI/TON values. The values are then passed through the switchboard to the PRI trunk and on to the connected equipment.

Usage Examples

The following example creates an entry in the phone-context map that associates the phone-context string **phonesystem.adtran.com** with the **private** NPI and **level0** TON:

(config)**#voice trunk t01 type sip**
(config-t01)**#phone-context phonesystem.adtran.com plan private type level0**

prefer double-reinvite

Use the **prefer double-reinvite** command to specify that Session Initiation Protocol (SIP) double reInvite messages are included in calls involving the trunk. Calls that typically require a double reInvite are forwarded calls from call overage and any attended transfer, and when these calls connect, a double reInvite message is initiated when the feature is enabled. Using the **no** form of this command indicates that double reInvites are not preferred on the trunk. Use the command *sip prefer double-reinvite on page 1726* to specify the global setting for this feature. Variations of this command include:

prefer double-reinvite
prefer double-reinvite system

This command should only be issued by advanced users or at the direction of Adtran technical support.

Syntax Description

system	Optional. Specifies that the system double reInvite setting is used. The system setting is specified using the command *prefer double-reinvite on page 5113*.

Default Values

By default, all trunk accounts prefer a double re-Invite.

Command History

Release A5.01	Command was introduced.

Functional Notes

The **prefer double-reinvite** command is used in the trunk's configuration to determine whether a double reInvite is preferred in calls involving the trunk. By default, the system is configured so that double reInvites are preferred, and all trunk accounts prefer a double reInvite. Double reInvites are used, for example, when a SIP trunk in local transfer mode is providing ring-back during a blind transfer. In this scenario, a double reInvite must occur in order to establish a talk path after the transfer target answers.

You can also specify whether Session Description Protocol (SDP) is used in the double reInvite message. To send a double reInvite without SDP, refer to the command *prefer reinvite-without-sdp on page 5114*. This command helps determine which endpoint receives SDP in the double reInvite call flow.

Usage Examples

The following example specifies that SIP double reInvites are not preferred on this trunk:

(config)**#voice trunk t01 type sip**
(config-t01)**#no prefer double-reinvite**

prefer reinvite-without-sdp

Use the **prefer reinvite-without-sdp** command to specify that Session Initiation Protocol (SIP) double reInvite messages are included in calls involving the trunk, but that these messages do not include Session Description Protocol (SDP). This command helps to determine which endpoint receives the SDP in the double reInvite call flow. Using the **no** form of this command indicates that reInvite messages without SDP are not preferred. Use the command *sip prefer double-reinvite on page 1726* to specify the global setting for this feature.

This command should only be issued by advanced users or at the direction of Adtran technical support.

Syntax Description

No subcommands.

Default Values

By default, all trunk accounts prefer a double reInvite with SDP.

Command History

Release A5.01	Command was introduced.

Functional Notes

When a double reInvite is initiated, the first reInvite without SDP is not sent to the account that does not require it. When both accounts do not require a reInvite with SDP, the target account sends the initial reInvite message.

You can specify whether a re-Invite is preferred on the trunk using the command *prefer double-reinvite on page 5113*. This command is used in the trunk's configuration to determine whether a double reInvite is preferred in calls involving the trunk. By default, the system is configured so that double reInvites are preferred, and all trunk accounts prefer a double reInvite. Double reInvites are used, for example, when a SIP trunk in local transfer mode is providing ring-back during a blind transfer. In this scenario, a double reInvite must occur in order to establish a talk path after the transfer target answers.

Usage Examples

The following example specifies that SIP double reInvites with SDP are preferred on this trunk:

(config)**#voice trunk t01 type sip**
(config-t01)**#no prefer reinvite-without-sdp**

prefer trunk-routing

Use the **prefer trunk-routing** command to add a trunk to a list of trunks that are considered first for call routing, regardless of system routing mode or locally configured extensions. Use the **no** form of this command to remove the trunk from the list.

Syntax Description

No subcommands.

Default Values

By default, **prefer trunk-routing** is disabled.

Command History

Release A2	Command was introduced.

Functional Notes

Trunk routing can be specified as a preference for specific trunks, allowing the trunk to be considered first for routing rather than relying on the internal or external nature of the call to dictate whether the trunk or voice station is the first choice routing path. The **prefer trunk-routing** command, executed from a specific trunk's configuration mode, adds the trunk to a list of trunks that are considered first for routing.

By default, no trunk routing preference is set, so that each trunk operates as dictated by normal call routing modes. Adding the trunk routing preference only affects how inbound calls from the specific trunk are handled.

Usage Examples

The following example specifies that trunk routing is preferred on the trunk **T01**:

(config)**#voice trunk t01 type sip**
(config-t01)**#prefer trunk-routing**

reason-supported

Use the **reason-supported** command to enable support for the addition of Session Initiation Protocol (SIP) Reason headers to outgoing SIP requests on the trunk. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release R13.8.0	Command was introduced.

Usage Examples

The following example enables the addition of SIP Reason headers to outgoing SIP requests on SIP trunk T01:

(config)**#voice trunk t01 type sip**
(config-t01)**#reason-supported**

register

Use the **register** command to define the Session Initiation Protocol (SIP) name for registration of the authorization name(s) and password(s). Use the **no** form of this command to remove a registration. Variations of this command include the following:

register <*name*>
register <*name*> **auth-name** <*username*> **password** <*word*>
register range <*begin*> <*end*>
register range <*begin*> <*end*> **auth-name** <*username*> **password** <*word*>
register range <*begin*> <*end*> **auth-name range** <*begin*> <*end*> **password range** <*begin*> <*end*>
register range <*begin*> <*end*> **auth-name range** <*begin*> <*end*> **password** <*word*>

When using the range option, there must be the same number of elements in each related range. In other words, each SIP user in a range must have one authentication name and/or one password.

Syntax Description

<*name*>	Specifies the name of the SIP trunk to register.
range <*begin*> <*end*>	Specifies the beginning and ending of the range to register SIP users, authentication names, and/or passwords.
auth-name <*username*>	Optional. Specifies the user name for authentication.
password <*word*>	Optional. Specifies the password for authentication.

Default Values

By default, no registration range is programmed.

Command History

Release 12.1	Command was introduced.
Release 15.1	Command was expanded.

Functional Notes

Using the **range** option reduces the time required to program individual user registration and authentication settings. The range configuration option allows multiple users to be configured in one step for example:

register range 2565553000 2565553100 auth-name range Adtran3000 Adtran3100 password range adtn3000 adtn3100

In this example, 100 users in the range (256) 555-3000 to (256) 555-3100 are registered with authentication names ranging from **Adtran3000** to **Adtran3100** and passwords ranging from **adtn3000** to **adtn3100**.

The user may enter an authentication name range, password range, or both. An error will be returned if the provided authentication name and/or password range values are not large enough for the SIP identity range provided (i.e., in the example, if the user had entered Adtran3000 Adtran3099 for the authentication name range, an error would have been returned because the specified SIP identity range is 100 users (not 99)).

Usage Examples

The following example registers trunk **T01** under the name of **MainOffice**:

(config)**#voice trunk t01 type sip**
(config-t01)**#register MainOffice**

The following example sets the authorization name and password range for a group of SIP users:

(config)**#voice trunk t01 type sip**
(config-t01)**#register range 2565554000 2565554100 auth-name range Adtran4000 Adtran4100 password range adtn8000 adtn8100**

registrar expire-time <*value*>

Use the **registrar expire-time** command to define the Session Initiation Protocol (SIP) expiration time for requested registration. This command specifies the duration of the registration that is requested in the REGISTER sent to the SIP server. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies expiration time (in seconds) for a registration. Valid range depends on whether the command *registrar threshold on page 5126* is configured for **absolute** or **percentage**. If the threshold is set to **percentage**, the range is **0** to **4294967295**. If the threshold is set to **absolute**, the range is <*absolute threshold value*> **+ 6** to **4294967295**.

Default Values

By default, this value is set to **3600** seconds.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example specifies the registration expiration time for the SIP trunk as **1800** seconds:

(config)**#voice trunk t01 type sip**
(config-t01)**#registrar expire-time 1800**

registrar max-concurrent-reg <*value*>

Use the **registrar max-concurrent-reg** command to control the maximum number of simultaneous registration requests that are allowed for the trunk. This value can be adjusted to help eliminate congestion caused by too many concurrent registration requests. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the maximum number of concurrent registrations. Valid range is **1** to **32** registrations.

Default Values

By default, the maximum number of concurrent registrations is set to **32**.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example sets the maximum number on concurrent registrations to **12**:

(config)**#voice trunk t01 type sip**
(config-t01)**#registrar max-concurrent-reg 12**

registrar primary <*value*>

Use the **registrar primary** command to define the primary Session Initiation Protocol (SIP) registrar fully qualified domain name (FQDN) or IP address that is based on the domain naming system (DNS) suffix. Use the **no** form of this command to return to the default setting. Variations of this command include:

registrar primary <*value*>
registrar primary <*value*> **tcp**
registrar primary <*value*> **tcp** <*port*>
registrar primary <*value*> **udp**
registrar primary <*value*> **udp** <*port*>
registrar primary <*value*> **tls** <*profile name*>
registrar primary <*value*> **tls** <*profile name*> **srv**
registrar primary <*value*> **tls** <*profile name*> **srv** <*service name prefix*>
registrar primary <*value*> **tls** <*profile name*> **srv** <*service name prefix*> <*transport name prefix*>
registrar primary <*value*> **tls** <*profile name*> <*port*>
registrar primary <*value*> **tls** <*profile name*> <*port*> **srv**
registrar primary <*value*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*>
registrar primary <*value*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*> <*transport name prefix*>

A secondary SIP registrar can be set using the command *registrar secondary <value> on page 5124*.

Syntax Description

<*value*>	Specifies the FQDN or IP address of the registrar server. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
tcp	Optional. Sets the Transmission Control Protocol (TCP) port of the registrar server.
udp	Optional. Sets the User Datagram Protocol (UDP) port of the registrar server.
tls <*profile name*>	Optional. Associates a Transport Layer Security (TLS) profile with the trunk, thus specifying the TLS operation on the trunk.
<*port*>	Optional. Specifies the port number. Range is **0** to **65535**.
srv	Optional. Specifies that service records (SRV) parameters are enabled. This option is available only when an FQDN has been specified.
<*service name prefix*>	Optional. Specifies the service name used to format the domain naming service (DNS) SRV request used to resolve the domain name. Underscores are added automatically.
<*transport name prefix*>	Optional. Specifies the transport name used to format the DNS SRV request used to resolve the domain name. Underscores are added automatically.

Default Values

By default, the IP address is set to **0.0.0.0**, the UDP port is set to **5060**, and the TLS port is set to **5061**.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was expanded.
Release R11.5.0	Command was expanded to include the TLS and SRV configuration options.

Functional Notes

This command specifies which trunk will send SIP register messages. The configured value must resolve to a valid IP address.

Usage Examples

The following example sets the registrar server to **as1.adtran.com** with a UDP port of **9060**:

(config)**#voice trunk t01 type sip**
(config-t01)**#registrar primary as1.adtran.com udp 9060**

The following example specifies the SIP trunk as a primary SIP registrar server at IP address **10.10.10.1** using TLS profile **TLSPROFILE1** on the default port:

(config)**#voice trunk t01 type sip**
(config-t01)**#registrar primary 10.10.10.1 tls TLSPROFILE1**

registrar require-expires

Use the **registrar require-expires** command to define the Session Initiation Protocol (SIP) expiration time for registration. A successful response to a register contains an expires header or the response is considered a failure. When disabled, a successful response does not require an expires header to be considered successful. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies expiration time (in seconds) for a response to a registration request.

Default Values

By default, the registration expiration time is enabled.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example disables registration expiration time for the SIP trunk:

(config)**#voice trunk t01 type sip**
(config-t01)**#no registrar require-expires**

registrar secondary <*value*>

Use the **registrar secondary** command to define the primary Session Initiation Protocol (SIP) registrar fully qualified domain name (FQDN) or IP address that is based on the domain naming system (DNS) suffix. Use the **no** form of this command to return to the default setting. Variations of this command include:

registrar secondary <*value*>
registrar secondary <*value*> **tcp**
registrar secondary <*value*> **tcp** <*port*>
registrar secondary <*value*> **udp**
registrar secondary <*value*> **udp** <*port*>
registrar secondary <*value*> **tls** <*profile name*>
registrar secondary <*value*> **tls** <*profile name*> **srv**
registrar secondary <*value*> **tls** <*profile name*> **srv** <*service name prefix*>
registrar secondary <*value*> **tls** <*profile name*> **srv** <*service name prefix*> <*transport name prefix*>
registrar secondary <*value*> **tls** <*profile name*> <*port*>
registrar secondary <*value*> **tls** <*profile name*> <*port*> **srv**
registrar secondary <*value*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*>
registrar secondary <*value*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*> <*transport name prefix*>

Syntax Description

<*value*>	Specifies the FQDN or IP address of the registrar server. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
tcp	Optional. Sets the Transmission Control Protocol (TCP) port of the registrar server.
udp	Optional. Sets the User Datagram Protocol (UDP) port of the registrar server.
tls <*profile name*>	Optional. Associates a Transport Layer Security (TLS) profile with the trunk, thus specifying the TLS operation on the trunk.
<*port*>	Optional. Specifies the port number. Range is **0** to **65535**.
srv	Optional. Specifies that service records (SRV) parameters are enabled. This option is available only when an FQDN has been specified.
<*service name prefix*>	Optional. Specifies the service name used to format the domain naming service (DNS) SRV request used to resolve the domain name. Underscores are added automatically.
<*transport name prefix*>	Optional. Specifies the transport name used to format the DNS SRV request used to resolve the domain name. Underscores are added automatically.

Default Values

By default, the IP address is set to **0.0.0.0**, the UDP port is set to **5060**, and the TLS port is set to **5061**.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was expanded.
Release R11.5.0	Command was expanded to include the TLS and SRV configuration options.

Functional Notes

This command specifies which trunk will send SIP register messages. The configured value must resolve to a valid IP address.

Usage Examples

The following example sets the secondary registrar server to **as1.adtran.com** with a UDP port of **9060**:

(config)**#voice trunk t01 type sip**
(config-t01)**#registrar secondary as1.adtran.com udp 9060**

The following example specifies the SIP trunk as a secondary SIP registrar server at IP address **10.10.10.1** using TLS profile **TLSPROFILE1** on the default port:

(config)**#voice trunk t01 type sip**
(config-t01)**#registrar secondary 10.10.10.1 tls TLSPROFILE1**

registrar threshold

Use the **registrar threshold** command to specify the Session Initiation Protocol (SIP) trunk registration renewal threshold. Use the **no** form of this command to return to the default value. Variations of this command include:

registrar threshold absolute <*value*>
registrar threshold percentage <*percent*>

Syntax Description

absolute <*value*>	Specifies that the registration renewal occurs when the remaining amount of time on the registration coincides with this value. Valid range is **5** to **604800** seconds (1 week).
percentage <*percent*>	Specifies that the renewal occurs at a certain remaining percentage of the registration time. Valid range is **1** to **90** percent.

Default Values

By default, the registrar threshold is set at **absolute 300** seconds.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example sets the registrar renewal threshold time at **50** percent of the returned valid registration time:

(config)**#voice trunk t01 type sip**
(config-t01)**#registrar threshold percentage 50**

reject-external

Use the **reject-external** command to prevent inbound calls on the trunk from being routed back out of the same trunk. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Functional Notes

In general, trunks are assigned to the user role, which means they terminate lines from a Telco provider. If this is the case, **reject-external** should be enabled so that inbound calls on the trunk cannot be routed back out of the same trunk. If the configuration is poor, inbound long distance calls could be routed back out of the same trunk, causing the owner of the unit to be charged for long distance calls without his knowledge. For network-role trunks and SIP-based trunks, this command should be disabled to allow calls to be properly routed in the unit.

Usage Examples

The following example activates **reject-external**:

(config)**#voice trunk t01 type sip**
(config-t01)**#reject-external**

require-registration *<identity>*

Use the **require-registration** command to allow registration for one Private Branch Exchange (PBX) on the Session Initiation Protocol (SIP) trunk. Use the **no** form of this command to disable the feature. Variations of this command include:

require-registration *<identity>*
require-registration *<server>* **auth-name** *<username>* **password** *<password>*

Syntax Description

<identity>	Specifies the identity of the SIP user used for registration.
auth-name *<username>* **password** *<password>*	Optional. Specifies a user name and password for registration authentication.

Default Values

By default, this feature is disabled.

Command History

Release R13.8.0	Command was introduced.

Functional Notes

When PBX registration is enabled on the trunk, the following conditions occur:

- INVITE requests received from an unregistered PBX result in a response code of 403.
- When enabled in tandem with the SIP Reason header addition feature (refer to the command *reason-supported on page 5116*), INVITE requests from the WAN interface to an unregistered PBX result in a response code of 480 and a Reason header containing Q.850 Cause number 18.
- Failure of PBX to register before the expires time sent by the AOS registrar elapses will result in the PBX being considered unregistered.
- A valid registration request from a registered PBX will renew the registration time period.
- SIP registrar authentication must also be enabled for PBX registration requests to be issued an authentication challenge. If the specified user name or password contained in the Authorization header of the PBX registration request do not match what is specified in the SIP registrar authentication configuration, the registration request is rejected.

Usage Examples

The following example enables PBX registration on SIP trunk T01:

(config)**#voice trunk t01 type sip**
(config-t01)**#require-registration 2565551234**

ringback override

Use the **ringback** command to specify ringback options for calls on the trunk. Use the **no** form of this command to return to the default setting. Variations of this command include:

ringback override 180
ringback override 183

Syntax Description

180	Specifies override a 180 and send 183 with local ringback.
183	Specifies override a 183 and send 183 with local ringback.

Default Values

By default, no ringback override is specified.

Command History

Release A5.03	Command was introduced.

Usage Examples

The following example enables ringback override 180 and 183 on SIP trunk T01:

(config)**#voice trunk t01 type sip**
(config-t01)**#ringback override 180**
(config-t01)**#ringback override 183**

rtp dtmf-relay offer

Use the **rtp dtmf-relay offer** command to specify which dualtone multifrequency (DTMF) relay mode to offer to a particular Session Initiation Protocol (SIP) endpoint when using DTMF transcoding. Use the **no** form of this command to return the DTMF method to default value. Variations of this command include:

rtp dtmf-relay offer inband
rtp dtmf-relay offer nte <*value*>

Syntax Description

inband	Specifies that the DTMF relay method is in-band.
nte <*value*>	Specifies that the DTMF relay method is an RFC 2833 named telephone events (NTE). Valid NTE value range is **96** to **127**.

Default Values

By default, there is no preferred DTMF relay mode on the SIP endpoint, and the Session Border Controller (SBC) can choose a DTMF value that does not require transcoding to complete a call.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

The **rtp dtmf-relay offer** command is used to enable and configure DTMF transcoding on the AOS device when it is acting as an SBC. Transcoding is a method of translating media types in which the SBC operates as a translator for SIP devices using different media types that are attempting a connection. The AOS device translates one media type to another to allow the communication to succeed. For more information about transcoding and its configuration, refer to the configuration guide *Configuring Transcoding in AOS*, available online at https://supportcommunity.adtran.com.

Before you can configure the DTMF relay method for transcoding, you must enable media anchoring using the command *ip rtp media-anchoring on page 1458*.

Usage Examples

The following example specifies the NTE 101 DTMF relay method for transcoding on the SIP trunk:

(config)**#ip rtp media-anchoring transcoding dtmf**
(config)**#voice trunk T01 type sip**
(config-T01)**#rtp dtmf-relay offer nte 101**

rtp media video filter

Use the **rtp media video filter** command to filter out video media attributes from transmitted or received Session Description Protocol (SDP) messages on an AOS device acting as a session border controller (SBC). You can filter out video media on a Session Initiation Protocol (SIP) endpoint by entering the command from the SIP endpoint's configuration mode. Use the **no** form of this command to disable the media filtering feature.

Syntax Description

No subcommands.

Default Values

By default, media filtering is disabled and all video SDP media attributes are passed through the SBC device.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

Media filtering is a part of the transcoding feature that is available when the AOS device is acting as an SBC. For more information about transcoding and the media filtering feature, refer to the configuration guide *Configuring Transcoding in AOS*, available online at https://supportofurms.adtran.com.

Usage Examples

The following example enables media filtering on the voice trunk:

(config)**#voice trunk T01 type sip**
(config-T01)**#rtp media video filter**

sip-header-passthrough

Use the **sip-header-passthrough** command to enable and configure Session Initiation Protocol (SIP) header transparency on the trunk. Use the **no** form of this command to disable the feature. Variations of this command include:

sip-header-passthrough both
sip-header-passthrough in
sip-header-passthrough out

Syntax Description

both	Enables support for SIP header transparency for both inbound and outbound messages.
in	Enables support for SIP header transparency for inbound messages.
out	Enables support for SIP header transparency for outbound messages.

Default Values

By default, this feature is disabled.

Command History

Release R13.8.0	Command was introduced.

Usage Examples

The following example enables support for SIP header transparency for inbound messages on SIP trunk T01:

(config)**#voice trunk t01 type sip**
(config-t01)**#sip-header-passthrough in**

sip-keep-alive

Use the **sip-keep-alive** command to configure the type of keep-alive method for this Session Initiation Protocol (SIP) trunk. Keep-alive messages must be sent between SIP device and the registrar to keep the connected channel open for communication. Use the **no** form of this command to return to disable this feature. Variations of this command include the following:

sip-keep-alive info
sip-keep-alive info <*value*>
sip-keep-alive options
sip-keep-alive options <*value*>

Syntax Description

info	Specifies the INFO method to be used for the keep-alives on the trunk.
options	Specifies the OPTIONS method to be used for the keep-alives on the trunk.
<*value*>	Optional. Specifies the amount of time in seconds between the type of SIP keep-alive messages being sent during a call. Range is **30** to **3600** seconds.

Default Values

By default, **sip-keep-alive** is set to **info 60** on NetVanta 7000 Series products. For IP business gateways (Total Access 900(e) Series and NetVanta 6000 Series) **sip-keep-alive** is disabled by default.

Command History

Release 13.1	Command was introduced
Release A2.04	Command was added to the Voice Line and Voice User command sets.

Usage Examples

The following example sets the keep-alive method to **info**:

(config)**#voice trunk t01 type sip**
(config-t01)**#sip-keep-alive info**

sip-server primary <*value*>

Use the **sip-server primary** command to define the primary name/address of the Session Initiation Protocol (SIP) server to which the trunk will send call-related SIP messages. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip-server primary <*value*>
sip-server primary <*value*> **tcp**
sip-server primary <*value*> **tcp** <*port*>
sip-server primary <*value*> **udp**
sip-server primary <*value*> **udp** <*port*>
sip-server primary <*value*> **tls** <*profile name*>
sip-server primary <*value*> **tls** <*profile name*> **srv**
sip-server primary <*value*> **tls** <*profile name*> **srv** <*service name prefix*>
sip-server primary <*value*> **tls** <*profile name*> **srv** <*service name prefix*> <*transport name prefix*>
sip-server primary <*value*> **tls** <*profile name*> <*port*>
sip-server primary <*value*> **tls** <*profile name*> <*port*> **srv**
sip-server primary <*value*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*>
sip-server primary <*value*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*>
<*transport name prefix*>

Syntax Description

<*value*>	Specifies the FQDN or IP address of the server. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
tcp	Optional. Sets the Transmission Control Protocol (TCP) port of the server.
udp	Optional. Sets the User Datagram Protocol (UDP) port of the server.
tls <*profile name*>	Optional. Associates a Transport Layer Security (TLS) profile with the trunk, thus specifying the TLS operation on the trunk.
<*port*>	Optional. Specifies the port number. Range is **0** to **65535**.
srv	Optional. Specifies that service records (SRV) parameters are enabled. This option is available only when an FQDN has been specified.
<*service name prefix*>	Optional. Specifies the service name used to format the domain naming service (DNS) SRV request used to resolve the domain name. Underscores are added automatically.
<*transport name prefix*>	Optional. Specifies the transport name used to format the DNS SRV request used to resolve the domain name. Underscores are added automatically.

Default Values

By default, the IP address is set to **0.0.0.0**, the UDP port is set to **5060**, and the TLS port is set to **5061**.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was expanded.
Release R11.5.0	Command was expanded to include the TLS and SRV configuration options.

Usage Examples

The following example sets the SIP proxy server to **as1.adtran.com** with a UDP port of **9060**:

(config)**#voice trunk t01 type sip**
(config-t01)**#sip-server primary as1.adtran.com udp 9060**

The following example specifies the SIP trunk as a primary SIP server at IP address **10.10.10.1** using TLS profile **TLSPROFILE1** on the default port:

(config)**#voice trunk t01 type sip**
(config-t01)**#sip-server primary 10.10.10.1 tls TLSPROFILE1**

sip-server rollover

Use the **sip-server rollover** command to configure the rollover behavior of the Session Initiation Protocol (SIP) server. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip-server rollover service-unavailable-or-timeout
sip-server rollover timeout-only

Syntax Description

service-unavailable-or-timeout	Specifies the rollover to the next SIP server to occur after receiving a 503 Service Unavailable message or no response.
timeout-only	Specifies the rollover to the next SIP server to occur only after no response is received.

Default Values

By default, the **sip-server rollover** is set to **timeout-only**.

Command History

Release A2.03	Command was introduced.

Usage Examples

The following example sets the SIP server rollover to **timeout-only**:

(config)**#voice trunk t01 type sip**
(config-t01)**#sip-server rollover timeout-only**

sip-server secondary <*value*>

Use the **sip-server secondary** command to define the secondary name/address of the Session Initiation Protocol (SIP) server to which the trunk will send call-related SIP messages. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip-server secondary <*value*>
sip-server secondary <*value*> **tcp**
sip-server secondary <*value*> **tcp** <*port*>
sip-server secondary <*value*> **udp**
sip-server secondary <*value*> **udp** <*port*>
sip-server secondary <*value*> **tls** <*profile name*>
sip-server secondary <*value*> **tls** <*profile name*> **srv**
sip-server secondary <*value*> **tls** <*profile name*> **srv** <*service name prefix*>
sip-server secondary <*value*> **tls** <*profile name*> **srv** <*service name prefix*> <*transport name prefix*>
sip-server secondary <*value*> **tls** <*profile name*> <*port*>
sip-server secondary <*value*> **tls** <*profile name*> <*port*> **srv**
sip-server secondary <*value*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*>
sip-server secondary <*value*> **tls** <*profile name*> <*port*> **srv** <*service name prefix*>
<*transport name prefix*>

Syntax Description

<*value*>	Specifies the FQDN or IP address of the registrar server. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
tcp	Optional. Sets the Transmission Control Protocol (TCP) port of the server.
udp	Optional. Sets the User Datagram Protocol (UDP) port of the server.
tls <*profile name*>	Optional. Associates a Transport Layer Security (TLS) profile with the trunk, thus specifying the TLS operation on the trunk.
<*port*>	Optional. Specifies the port number. Range is **0** to **65535**.
srv	Optional. Specifies that service records (SRV) parameters are enabled. This option is available only when an FQDN has been specified.
<*service name prefix*>	Optional. Specifies the service name used to format the domain naming service (DNS) SRV request used to resolve the domain name. Underscores are added automatically.
<*transport name prefix*>	Optional. Specifies the transport name used to format the DNS SRV request used to resolve the domain name. Underscores are added automatically.

Default Values

By default, the IP address is set to **0.0.0.0**, the UDP port is set to **5060**, and the TLS port is set to **5061**.

Command History

Release 9.3	Command was introduced.
Release 15.1	Command was expanded.
Release R11.5.0	Command was expanded to include the TLS and SRV configuration options.

Usage Examples

The following example sets the SIP proxy server to **as1.adtran.com** with a UDP port of **9070**:

(config)**#voice trunk t01 type sip**
(config-t01)**#sip-server secondary as1.adtran.com udp 9070**

The following example specifies the SIP trunk as a secondary SIP server at IP address **10.10.10.1** using TLS profile **TLSPROFILE1** on the default port:

(config)**#voice trunk t01 type sip**
(config-t01)**#sip-server secondary 10.10.10.1 tls TLSPROFILE1**

sip-server triggered-registration

Use the **sip-server triggered-registration** command to enable the Session Initiation Protocol (SIP) triggered registration feature on the trunk. Use the **no** form of this command to disable the feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release R13.8.0	Command was introduced.

Usage Examples

The following example enables the SIP triggered registration feature on SIP trunk T01:

(config)**#voice trunk t01 type sip**
(config-t01)**#sip-server triggered-registration**

sip-server validation register

Use the **sip-server validation register** command to enable Session Initiation Protocol (SIP) server validation on the trunk for use in SIP trunk failover. When this feature is enabled, new REGISTER requests are only sent to valid servers, or the highest priority server to which the SIP trunk can register. Use the **no** form of this command to disable the validation feature.

Syntax Description

No subcommands.

Default Values

By default, SIP server validation is disabled.

Command History

Release A5.01	Command was introduced.

Functional Notes

Enabling this feature configures the trunk to use the validated form of SIP trunk failover. This method of SIP trunk failover works in this manner:

When the AOS unit first boots, it establishes a prioritized list of SIP server addresses, using DNS as necessary. It uses the highest priority server as the destination of outbound trunk registrations. As long as these registrations are successful, the unit continues to use that server. If a failover condition occurs (if a request times out or there is no response from the server), the unit unregisters the specific registration to that server. The unit then iterates through the prioritized list of servers to find a valid one. A server is valid if it accepts the trunk registration request. All other trunk registrations remain unchanged. When the registration expires, the new REGISTER request is always sent to the highest priority server address in the list.

Usage Examples

The following example enables SIP server validation for the trunk:

```
(config)#voice trunk t01 type sip
(config-t01)#sip-server validation register
```

snmp trap registration failures <*value*> interval <*value*>

Use the **snmp trap registration** command to specify that Simple Network Management Protocol (SNMP) traps are enabled for the trunk, and that these traps are sent for Session Initiation Protocol (SIP) registration events. In addition, this command specifies how many registration failures can occur before an SNMP trap is sent, and at what interval the traps are sent. Use the **no** form of this command to disable SNMP traps for the trunk.

Syntax Description

failures <*value*>	Specifies the number of failures that occur before a trap is sent. Valid range is **1** to **128** failures.
interval <*value*>	Specifies the time (in seconds) that elapses between traps. Valid range is **30** to **86400** seconds.

Default Values

By default, SNMP traps are disabled on the trunk.

Command History

Release A5.01	Command was introduced.

Usage Examples

The following example enables SNMP traps on the trunk, and specifies that traps are sent for every **3** registration failures and every **3600** seconds:

(config)**#voice trunk t01 type sip**
(config-t01)**#snmp trap registration failures 3 interval 3600**

srtp *<profile name>*

Use the **srtp** *<profile name>* command to enable Secure Realtime Transfer Protocol (SRTP) on the Session Initiation Protocol (SIP) trunk and to associate an SRTP profile with the trunk. Use the **no** form of this command to disable SRTP on the trunk. Variations of this command include:

srtp *<profile name>*
srtp allow-non-rtp-media *<profile name>*
srtp allow-non-rtp-media reduced-rekeying roc-reset-on-reinvite *<profile name>*
srtp allow-non-rtp-media tls-optional *<profile name>*
srtp allow-non-rtp-media tls-optional reduced-rekeying roc-reset-on-reinvite *<profile name>*
srtp optional avp *<profile name>*
srtp optional avp reduced-rekeying roc-reset-on-reinvite *<profile name>*
srtp optional avp tls-optional *<profile name>*
srtp optional avp tls-optional reduced-rekeying roc-reset-on-reinvite *<profile name>*
srtp optional avp-savp *<profile name>*
srtp optional avp-savp reduced-rekeying roc-reset-on-reinvite *<profile name>*
srtp optional avp-savp tls-optional *<profile name>*
srtp optional avp-savp tls-optional reduced-rekeying roc-reset-on-reinvite *<profile name>*
srtp reduced-rekeying roc-reset-on-reinvite *<profile name>*
srtp tls-optional *<profile name>*
srtp tls-optional reduced-rekeying roc-reset-on-reinvite *<profile name>*

Syntax Description

<profile name>	Specifies the name of the SRTP profile to associate with the trunk. This profile must be specified as it sets the rules for SRTP use on the trunk.
allow-non-rtp-media	Optional. Configures SRTP to allow non-Realtime Transport Protocol (RTP) media, such as T.38 over UDPTL, that cannot be protected by SRTP. When this option is specified, RTP media is secured by SRTP, but any non-RTP media is forwarded unsecured.
reduced-rekeying	Optional. Specifies that SRTP rekeying on reINVITES will be disabled if the received SDP offer is unchanged.
roc-reset-on-reinvite	Optional. Specifies that AOS will reset the outbound rollover counter (ROC) when it sends a reINVITE.
tls-optional	Optional. Specifies that Session Description Protocol Security Descriptions (SDES) negotiation of SRTP is permitted over an unsecure control channel (NOT RECOMMENDED). If this option is not set, the control channel must be secured by Transport Layer Security (TLS) in order to perform SDES negotiation.
optional avp	Optional. Specifies that if negotiation permits, fall back to RTP audio video profile (AVP) is allowed. If this option is not specified, SRTP must be used for negotiation or the call fails.
optional avp-savp	Optional. Specifies that if negotiation permits, fall back to RTP AVP or secure AVP (SAVP) is allowed. If this option is not specified, SRTP must be used for negotiation or the call fails.

Default Values

By default, SRTP is not enabled on the trunk. If SRTP is enabled on the trunk, then by default, SRTP re-keying is enabled.

Command History

Release R11.5.0	Command was introduced.
Release R13.1.0	Command was expanded to include the **allow-non-rtp-media** parameter.
Release R13.4.0	Command was expanded to include the **reduced-rekeying** parameter.
Release R13.7.0	Command was expanded to include the **roc-reset-on-reinvite** parameter.

Functional Notes

Media anchoring must be enabled for SRTP to function.

Usage Examples

The following example specifies the trunk uses SRTP negotiation and TLS control channel security with SRTP profile **SRTPPROFILE1**:

(config)**#voice trunk t01 type sip**
(config-t01)**#srtp SRTPPROFILE1**

subscribe message-summary

Use the **subscribe** command to enable delivery of message-summary for successful registrations on the trunk. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example enables sending the message-summary for successful registrations on SIP trunk T01:

(config)**#voice trunk t01 type sip**
(config-t01)**#subscribe message-summary**

subscribe rfc-3680-event-package

Use the **subscribe rfc-3680-event-package** command to enable subscription to RFC 3680 event packages for successful registrations on the trunk. Use the **no** form of this command to return to the default setting. Variations of this command include:

subscribe rfc-3680-event-package deregister-on-termination
subscribe rfc-3680-event-package expire-time <*value*>
subscribe rfc-3680-event-package threshold absolute <*value*>
subscribe rfc-3680-event-package threshold percentage <*value*>

Syntax Description

deregister-on-termination	Specifies that deregistration occurs when subscription terminates.
expire-time <*value*>	Specifies the expiration time, in seconds, for the RFC 3680 event package subscription. Valid range is **60** to **86400** seconds.
threshold	Specifies the threshold for RFC 3680 event package subscription expiration.
absolute <*value*>	Specifies the expiration threshold as an absolute value. Valid range is **5** to **604800** seconds, and must be less than the specified expiration time.
percentage <*value*>	Specifies the expiration threshold as a percentage. Valid range is **1** to **100** percent.

Default Values

By default, this feature is disabled.

Command History

Release R13.8.0	Command was introduced.

Usage Examples

The following example enables subscription to RFC 3680 event packages for successful registrations on SIP trunk T01, and specifies that the trunk is deregistered when the subscription terminates:

(config)**#voice trunk t01 type sip**
(config-t01)**#subscribe rfc-3680-event-package deregister-on-termination**

transfer-mode

Use the **transfer-mode** command to specify the behavior of the Session Initiation Protocol (SIP) trunk when configured in a network with a Netvanta Unified Communications product. This feature determines whether transferred calls will be controlled by the unit locally, or by the network. Use the **no** form of this command to return to the default setting. Variations of this command include:

transfer-mode local
transfer-mode network

Syntax Description

local	Specifies that call transferring is controlled locally by the unit.
network	Specifies that call transferring is controlled by the network.

Default Values

By default, the network controls call transfers.

Command History

Release A4.05	Command was introduced for the NetVanta 7000 Series products.

Functional Notes

When this command is issued on a specific SIP trunk, it overrides the **voice transfer-mode** configuration (if previously set in the Global Configuration mode) but only applies the new configuration setting to the SIP trunk on which it was issued. Refer to *voice transfer-mode on page 1975* for more information on using the Global command.

Usage Examples

The following example configures the network to handle call transfers:

(config)**#voice trunk t01 type sip**
(config-t01)**#transfer-mode network**

trunk-group-id *<label> <context>*

Use the **trunk-group-id** command to specify an RFC 4904 trunk group identifier in outbound SIP INVITEs on the specified trunk. Use the **no** form of this command to return to the default setting. Variations of this command include:

trunk-group-id *<label> <context>*
trunk-group-id *<label> <context>* **always**

Syntax Description

<label>	Specifies the label for the trunk group identifier. Valid entries consist of any alphanumeric characters with a maximum length of 20 characters.
<context>	Specifies the context for the trunk group identifier. Valid entries consist of any alphanumeric characters with a maximum length of 50 characters.
always	Optional. Specifies to add the trunk group identifier even if no caller ID information is present.

Default Values

By default, there no trunk group id is defined.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example specifies a trunk-group-id with the label **2565550100** and context **voip.example**:

(config)**#voice trunk t01 type sip**
(config-t01)**#trunk-group-id 2565550100 voip.example**

trust-domain

Use the **trust-domain** command to add security measures for users' identity and privacy by connecting the trunk to a trusted domain. Using the trusted domain adds another level of privacy from participating service providers. The system supports RFC 3323 and RFC 3325. Use the **no** form of this command to return to the default setting. Variations of this command include the following:

trust-domain
trust-domain p-asserted-identity-required

Syntax Description

p-asserted-identity-required	Requires the use of P-Asserted-Identity SIP privacy for this trusted domain.

Default Values

By default, the **trust-domain** is disabled.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example enables the **trust-domain**:

(config)**#voice trunk t01 type sip**
(config-t01)**#trust-domain**

update-supported

Use the **update-supported** command to enable support for the UPDATE message for calls on the trunk. UPDATE messages containing SDP will only be accepted for SIP to TDM calls. Use the **no** form of this command to return to the default setting. Variations of this command include:

update-supported
update-supported forward-no-sdp

Syntax Description

forward-no-sdp	Optional. Allows the forwarding of in-dialog UPDATE requests that do not contain SDP to the other trunk involved in a call.

Default Values

By default, this feature is disabled.

Command History

Release A5.01	Command was introduced.
Release R13.8.0	Command was expanded to include the f**orward-no-sdp** parameter.

Usage Examples

The following example enables support for UPDATE messages for calls on SIP trunk T01:

(config)**#voice trunk t01 type sip**
(config-t01)**#update-supported**

vm-diversion

Use the **vm-diversion** command to apply a Session Initiation Protocol (SIP) Diversion header to calls forwarded to the external voice mail server. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example enables **vm-diversion**:

(config)**#voice trunk t01 type sip**
(config-t01)**#vm-diversion**

VOICE T1 TRUNK COMMAND SET

Voice T1 trunks are trunks that use T1 circuits and robbed-bit signaling (RBS) to connect communication devices to the outside world. The T1 RBS trunk can terminate a line from the service provider, or be a termination point acting as the network to a private branch exchange (PBX) or key system requiring a T1 circuit. The term T1 circuit is commonly used to identify a multiplexed 24-channel, 1.544 Mbps digital data circuit, providing communications between two facilities or from a local service provider. T1 refers to the transport of a DS1-formatted signal onto a copper, fiber, or wireless medium for deploying voice, data, or video conferencing services. T1 connections provide up to 24 DSO channels of 64kbps, and use the RBS scheme to pass call signaling status information.

RBS is the process where the least significant bit in the sixth and twelfth frame (of a superframe (SF) T1) and the sixteenth and twentieth frame (of an extended superframe (ESF) T1) is *robbed* for voice A, B, C, and D signaling bits. These signaling bits indicate on-hook or off-hook conditions, as well as other signaling states.

Before configuring a T1 voice trunk, the T1 interface must be configured. For more information on configuring the T1 interface, refer to the *T1 Interface Command Set on page 2463*. Once the T1 interface is configured, you must create a T1 trunk account in order to make and receive calls. When creating the T1 trunk account, it is important to make sure the T1 RBS settings (supervision, type, etc.) match the parameters set by your service providers.

There are six main types of T1 trunks supported by AOS. The first is a T1 trunk without RBS, the second is a T1 RBS trunk using feature group D (FGD), the third is a T1 RBS trunk using ground start (GS), the fourth is a T1 RBS trunk using loop start (LS), the fifth is a T1 RBS trunk using wink, and the sixth is a T1 RBS trunk using immediate supervision.

To create a T1 trunk account without RBS and enter the Trunk Account Configuration mode, enter the following command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice trunk t01
(config-t01)#
```

To create a T1 RBS trunk account using FGD and enter the Trunk Account Configuration mode, enter the following command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice trunk t01 type t1-rbs supervision fgd role user
(config-t01)#
```

To create a T1 RBS trunk account using GS and enter the Trunk Account Configuration mode, enter the following command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice trunk t01 type t1-rbs supervision ground-start role user
(config-t01)#
```

To create a T1 RBS trunk using LS and enter the Trunk Account Configuration mode, enter the following command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice trunk t01 type t1-rbs supervision loop-start role user
(config-t01)#
```

To create a T1 RBS trunk account using wink and enter the Trunk Account Configuration mode, enter the following command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice trunk t01 type t1-rbs supervision wink role [network | user]
(config-t01)#
```

To create a T1 RBS trunk using immediate supervision and enter the Trunk Account Configuration mode, enter the following command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#voice trunk t01 type t1-rbs supervision immediate role [network | user]
(config-t01)#
```

*Not all T1 Trunk commands apply to all T1 trunk types. Use the **?** command to display a list of valid commands.*

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

alc

Use the **alc** command to enable automatic level control (ALC). ALC reduces Realtime Transport Protocol (RTP) received signals that are out of specification to the predefined levels. It is not necessary to enable ALC on those networks that guarantee signal levels to be within specification. Use the **no** form of this command to disable this feature. Variations of this command include:

alc
alc level -16
alc level -17
alc level -18
alc level -19
alc level -20
alc level -21
alc level -22

Syntax Description

level -16	Optional. Specifies the ALC attenuation level is -16 dBm0.
level -17	Optional. Specifies the ALC attenuation level is -17 dBm0.
level -18	Optional. Specifies the ALC attenuation level is -18 dBm0.
level -19	Optional. Specifies the ALC attenuation level is -19 dBm0.
level -20	Optional. Specifies the ALC attenuation level is -20 dBm0.
level -21	Optional. Specifies the ALC attenuation level is -21 dBm0.
level -22	Optional. Specifies the ALC attenuation level is -22 dBm0.

Default Values

By default, ALC is disabled.

Command History

Release 14.1	Command was introduced.
Release 15.1	Command was added to the Voice Line Interface.
Release A2	Command was added to the Media Gateway Control Protocol (MGCP) endpoint configuration.
Release A2.04	Command was expanded to include the **level** parameters.

Usage Examples

The following example activates the ALC on trunk **T01**:

(config)**#voice trunk t01 type t1-rbs supervision loop-start role user**
(config-t01)**#alc**

blind-dial

Use the **blind-dial** command to allow calls to be placed without the presence of dial tone. Use the **no** form of this command to disable blind dialing.

Syntax Description

No subcommands.

Default Values

By default, **blind-dial** is disabled.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example enables blind dialing:

```
(config)#voice trunk t01 type t1-rbs supervision loop-start role user
(config-t01)#blind-dial
```

busy all

Use the **busy all** command to set all level zero digital signals (DS0s) to busy so that no calls are allowed inbound or outbound. If any calls are active at the time this command is issued, the calls will stay active until either party terminates the call. Once terminated, the DS0s are busied out. Use the **no** form of this command to disable this feature. Variations of this command include:

busy all
busy all now

Syntax Description

now	Optional. Immediately terminates calls that are active at the time the command is issued.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example sets all DS0s on trunk **T01** to busy and terminates calls that are active at the time the command is issued:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#busy all now**

busy t1 <*slot/port*> tdm-group <*number*>

Use the **busy t1 tdm-group** command to set a particular set of level zero digital signals (DS0s) (defined in a time division multiplexing (TDM) group) to busy so that no calls are allowed inbound or outbound the interface. If any calls are active at the time this command is issued, the calls will stay active until either party terminates the call. Once terminated, the DS0s are set to busy. Use the **no** form of this command to disable this feature. Variations of this command include:

busy t1 <*slot/port*> **tdm-group** <*number*>
busy t1 <*slot/port*> **tdm-group** <*number*> **now**

Syntax Description

<*slot/port*>	Specifies the slot/port for the T1.
<*number*>	Specifies the TDM group ID number.
now	Optional. Terminates calls that are active at the time the command is issued (for example, in the middle of a conversation).

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example sets DS0s in TDM group **2** to **busy** and terminates calls that are active when the command is issued:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#busy t1 0/1 tdm-group 2 now**

caller-id

Use the **caller-id** number command to interpret and pass caller identification (ID) on this trunk. This information usually displays the name, number, time, and date of the calling party. Use the **no** form of this command to cancel the setting.

Syntax Description

No subcommands.

Default Values

By default, caller ID is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example enables caller ID:

(config)**#voice trunk t01 type t1-rbs supervision fgd role user**
(config-t01)**#caller-id**

caller-id-override

Use the **caller-id-override** command to replace the calling party information for this trunk with a specific number. This command is used to conceal a user's name and number or to display a different name and number for internal or external caller ID. Use the **no** form of this command to cancel the setting. Variations of this command include:

caller-id-override emergency-outbound <*number*>
caller-id-override emergency-outbound match-substitute
caller-id-override name-inbound <*name*>
caller-id-override name-inbound <*name*> **if-unavailable**
caller-id-override number-inbound <*number*>
caller-id-override number-inbound <*number*> **if-no-cpn**
caller-id-override number-inbound <*number*> <*trunk id*>
caller-id-override privacy-outbound match-substitute

Syntax Description

emergency-outbound	Replaces the calling party number for outbound emergency calls.
<*number*>	Specifies the number to replace the calling party number for outbound emergency calls.
match-substitute	Specifies that the configured automatic number identification (ANI) match substitution is used for outbound emergency calls.
name-inbound <*name*>	Specifies the name to replace the calling party name for inbound calls.
if-unavailable	Specifies that the calling party name is replaced only if the calling party name is unavailable.
number-inbound <*number*>	Specifies the number to replace the calling party number for inbound calls.
<*trunk id*>	Optional. Specifies the trunk ID (**Txx**) for outbound calls.
if-no-cpn	Optional. Specifies that the calling party number is replaced only if the calling party number is unavailable.
privacy-outbound	Replaces the calling party number on anonymous outbound calls.
match-substitute	Specifies that the configured ANI match substitution is used for anonymous outbound calls.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.
Release 15.1	Command was expanded.
Release 16.1	Command was expanded to include the **if-no-cpn** parameter.
Release A4.01	Command was expanded to include the **match-substitute** parameter.
Release R11.8.0	Command was expanded to include the **privacy-outbound** parameter.

Usage Examples

The following example sets the caller ID override number on the trunk where the command is issued:

(config)**#voice trunk t01 type analog supervision loop-start**
(config-t01)**#caller-id-override number-inbound 555-8000**

codec-list *<name>*

Use the **codec-list** command to specify the coder-decoder (CODEC) list to be used by this account. This CODEC can be used for normal voice traffic or for Session Border Controller (SBC) transcoding. Use the **no** form of this command to remove the CODEC list from the account. Variations of this command include:

codec-list *<name>*
codec-list *<name>* **both**
codec-list *<name>* **in**
codec-list *<name>* **out**
codec-list any
codec-list any both
codec-list any in
codec-list any out

Syntax Description

<name>	Specifies the CODEC list to be used for this account.
any	Specifies that any possible CODEC is allowed on this account.
both	Optional. Specifies that the CODEC list is applied to both transmitted and received Session Description Protocol (SDP) transmissions.
in	Optional. Specifies that the CODEC list is applied to received SDP only.
out	Optional. Specifies that the CODEC list is applied to transmitted SDP only.

Default Values

By default, no CODEC lists are assigned.

Command History

Release R10.4.0	Command was introduced and replaced the **codec-group** command.

Functional Notes

The **codec-list** command applies a previously configured CODEC list to an interface, voice trunk, or voice account. These lists are lists of CODECs used by the interface, trunk, or account in call negotiation and are arranged in preferred order with the first listed CODEC being the most preferred.

CODEC lists are created using the **codec** command from the Voice CODEC List Configuration mode prompt. For more information about creating CODEC lists, refer to the *Voice CODEC List Command Set on page 4893***.**

In addition, CODEC lists can be used for the SBC transcoding feature. For more information about this feature, its uses, and its configuration, refer to the configuration guide *Configuring Transcoding in AOS*, available online at https://supportcommunity.adtran.com.

*Because you can choose to specify that any CODEC is used by a Session Initiation Protocol (SIP) endpoint with the **any** keyword, do not create a CODEC list with the name of **any**.*

Usage Examples

The following example applies the CODEC list **LIST1** to incoming SDP traffic on trunk **T01**:

(config)**#voice trunk t1-rbs supervision wink role network**
(config-t01)**#codec-list LIST1 in**

connect t1 <*slot/port*> tdm-group <*number*>

Use the **connect t1 tdm-group** command to specify the physical interfaces this trunk group will use for voice connections. Refer to *tdm-group <number> on page 2478* for more information on creating time division multiplexing (TDM) groups. Use the **no** form of this command to remove this association.

Syntax Description

<slot/port>	Specifies the slot/port for the T1.
<number>	Specifies the TDM group ID number.

Default Values

By default, no physical interface is assigned.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example specifies that this trunk will use the level zero digital signals (DS0s) in TDM group **3** (on T1 interface **0/1**):

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#connect t1 0/1 tdm-group 3**

dialtone

Use the **dialtone** command to enable dial tone generation. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, the dial tone is enabled.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example disables dial tone on trunk **T01**:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#no dialtone**

did digits-transferred

Use the **did digits-transferred** command to define how many of the received digits should be sent to the internal switchboard from an incoming call on a user role trunk. The number of digits transferred are the least significant digits received. Direct inward dialing (DID) should be used if a Telco provider is providing digits to the unit on inbound calls or if the unit needs to provide DID information to a piece of customer premises equipment (CPE). Use the **no** form of this command to disable this feature. Variations of this command include:

did digits-transferred <*value*>
did digits-transferred <*value*> **prefix** <*number*>

Syntax Description

<*value*>	Specifies the number of digits to be transferred. Range is **1** to **16** digits.
prefix <*number*>	Optional. Specifies a sequence of digits to be prepended to the digits that will be transmitted. For example, if seven digits will be transferred via DID, then prefix the seven digits with 256. Thus, **555-8000** would be prefixed with **256**, transmitting out the string of digits **256-555-8000**.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Functional Notes

User Role Example:

555-1000 is an incoming call on the trunk. With **did digits-transferred** <*value*> set to 4, the number 1000 will be sent to the switchboard. On a network role trunk, the **did digits-transferred** command allows you to define how many of the digits from the Accept criteria should be sent externally from a call that was routed by the switchboard. The number of digits transferred are the least significant digits received.

Network Role Example:

555-1000 is accepted on the universal time (UT) interface. With **did digits-transferred** <*value*> set to 4, the number of 1000 will be sent to the device connected to the UT interface. This command cannot be specified if and when **trunk-number** is being used. Conversely, if DID is used, **trunk-number** will not be allowed.

Usage Examples

The following example transfers the digits **555-8000** and adds the prefix **256**:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#did digits-transferred 5558000 prefix 256**

dnis-digits <*value*> prefix <*number*>

Use the **dnis-digits prefix** command to program the number of digits to be transferred inbound on the specific trunk. Use the **no** form of this command to cancel the setting.

Syntax Description

<*value*>	Specifies the number of digits to be transferred.
<*number*>	Specifies the number prefix to prepend to the transferred digits.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example sets the number of transferred dialed number identification service (DNIS) digits to **4** on trunk **T01** and sets the prefix **555**:

(config)**#voice trunk t01 type t1-rbs supervision fgd role user**
(config-t01)**#dnis-digits 4 prefix 555**

early-cut-through

Use the **early-cut-through** command to provide the caller with inband ringback and other call progress signals. This command should not be issued if the connected equipment does not provide inband ringback and other call progress signals. This option is only valid for voice trunks in the network role. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **early-cut-through** is enabled.

Command History

Release A1	Command was introduced.

Usage Examples

The following example disables early-cut-through:

```
(config)#voice trunk t01 type t1-rbs supervision wink role network
(config-t01)#no early-cut-through
```

echo-cancellation

Use the **echo-cancellation** command to improve voice quality for packetized-based voice calls, such as Voice over Internet Protocol (VoIP) or Media Gateway Control Protocol (MGCP). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **echo-cancellation** is enabled.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example activates **echo-cancellation**:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#echo-cancellation**

match ani <*template*> substitute <*template*>

Use the **match ani substitute** command to configure automatic number identification (ANI) substitution for outbound voice trunks. Use the **no** form of this command to remove the substitution. Variations of this command include:

match ani <*template*> **substitute** <*template*>
match ani <*template*> **substitute** <*template*> **name** <*name*>

Syntax Description

ani <*template*>	Specifies the ANI information to be substituted. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
substitute <*template*>	Specifies the ANI information that is substituted for the original ANI information. This information is entered using wildcards and numerical digits. When using wildcards in the **match** and **substitute** template, both must be of the same type and position in the number template or AOS will not allow the substitution. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
name <*name*>	Optional. Specifies the name associated with the ANI information. This option is only available on trunks that support ANI name information (integrated services digital network (ISDN) trunks, Session Initiation Protocol (SIP) trunks, T1 loop start (LS) network trunks, and T1 ground start (GS) network trunks).

Default Values

By default, no ANI substitution is configured.

Command History

Release A2	Command was introduced.

Functional Notes

The convention for ANI templates is very similar to dial plan entries. Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example specifies that the ANI information from numbers **555-8111** to **555-8115** will be substituted by **555-8110** for outbound calls on the trunk **T03**:

(config)**#voice trunk t03 type t1-rbs supervision wink role network**
(config-t03)**#match ani 555-811[125] substitute 555-8110**

match dnis <*template*> replace ani <*number*>

Use the **match dnis replace ani** command to replace dialed number identification service (DNIS) information with automatic number identification (ANI) information on outbound voice trunks. Use the **no** form of this command to remove the replacement. Variations of this command include:

match dnis <*template*> **replace ani** <*number*>
match dnis <*template*> **replace ani** <*number*> **name** <*name*>

Syntax Description

dnis <*template*>	Specifies the DNIS information to be replaced. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
replace ani <*number*>	Specifies the ANI information that replaces the original DNIS information. This information is entered using numerical digits. Enter the number without punctuation.
name <*name*>	Optional. Specifies the name associated with the ANI information. This option is only available on trunks that support ANI name information (integrated services digital network (ISDN) trunks, Session Initiation Protocol (SIP) trunks, T1 loop start (LS) network trunks, and T1 ground start (GS) network trunks).

Default Values

By default, no DNIS replacement is configured.

Command History

Release A2	Command was introduced.

Functional Notes

The convention for DNIS templates is very similar to dial plan entries. Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits

3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example specifies that the DNIS information for dialed numbers on trunk **T03** that match **1-256-524-8600** are replaced with **882-6467**:

(config)**#voice trunk t03 type t1-rbs supervision wink role network**
(config-t03)**#match dnis 1-256-524-8600 replace ani 8826467**

match dnis <*template*> substitute <*template*>

Use the **match dnis substitute** command to configure dialed number identification service (DNIS) substitution for outbound voice trunks. Use the **no** form of this command to remove the substitution. Variations of this command include:

match dnis <*template*> **substitute** <*template*>
match dnis <*template*> **substitute** <*template*> **name** <*name*>

Syntax Description

dnis <*template*>	Specifies the DNIS information to be substituted. This information is entered using wildcards and numerical digits.Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
substitute <*template*>	Specifies the DNIS information that is substituted for the original DNIS information. This information is entered using wildcards and numerical digits. When using wildcards in the **match** and **substitute** template, both must be of the same type and position in the number template or AOS will not allow the substitution. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
name <*name*>	Optional. Specifies the name associated with the DNIS information. This option is only available on trunks that support DNIS name information (integrated services digital network (ISDN) trunks, Session Initiation Protocol (SIP) trunks, T1 loop start (LS) network trunks, and T1 ground start (GS) network trunks).

Default Values

By default, no DNIS substitution is configured.

Command History

Release A2	Command was introduced.

Functional Notes

The convention for DNIS templates is very similar to dial plan entries. Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example specifies that the DNIS information for dialed numbers on trunk **T03** that match **1-334-NXX-XXXX** are substituted with **1-800-557-4500**:

(config)**#voice trunk t03 type t1-rbs supervision wink role network**
(config-t03)**#match dnis 1-334-NXX-XXXX substitute 1-800-557-4500**

modem-passthrough

Use the **modem-passthrough** command to switch to passthrough mode on fax or modem tone detection. This command allows modem and fax calls to maintain a connection without altering the signals with the voice improvement settings, such as echo cancellation and voice activity detection (VAD). Use the **no** form of this command to disable this feature. Variations of this command include:

modem-passthrough
modem-passthrough detection-time <*value*>
modem-passthrough cng-early-detect

Syntax Description

detection-time <*value*>	Optional. Specifies the fax and/or modem detection time length value in seconds. Range is **0** to **8** seconds.
cng-early-detect	Optional. Enables early (first burst) detection of fax calling (CNG) tone.

Default Values

By default, **modem-passthrough** is enabled.

Command History

Release 11.1	Command was introduced.
Release 12.1	Command was expanded.
Release R10.8.0	Command was expanded to include the **cng-early-detect** parameter.

Usage Examples

The following example disables **modem-passthrough**:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#no modem-passthrough**

nls

Use the **nls** command to enable the non-linear suppression (NLS) option for the user. This option sets the echo canceller to reduce acoustic echo. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 14.1	Command was introduced.
Release 15.1	Command was added to the Voice Trunk T1 command set.

Usage Examples

The following example enables NLS on trunk **T01**:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#nls**

plc

Use the **plc** command to enable packet loss concealment (PLC). PLC is used to prevent choppy connections by concealing a packet loss by replacing the lost packet with another voice packet in the data stream. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, PLC is enabled.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example disables PLC on trunk **T01**:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#no plc**

prefer trunk-routing

Use the **prefer trunk-routing** command to add a trunk to a list of trunks that are considered first for call routing, regardless of system routing mode or locally configured extensions. Use the **no** form of this command to remove the trunk from the list.

Syntax Description

No subcommands.

Default Values

By default, **prefer trunk-routing** is disabled.

Command History

Release A2	Command was introduced.

Functional Notes

Trunk routing can be specified as a preference for specific trunks, allowing the trunk to be considered first for routing rather than relying on the internal or external nature of the call to dictate whether the trunk or voice station is the first choice routing path. The **prefer trunk-routing** command, executed from a specific trunk's configuration mode, adds the trunk to a list of trunks that are considered first for routing.

By default, no trunk routing preference is set, so that each trunk operates as dictated by normal call routing modes. Adding the trunk routing preference only affects how inbound calls from the specific trunk are handled.

Usage Examples

The following example specifies that trunk routing is preferred on the trunk **T01**:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#prefer trunk-routing**

reject-external

Use the **reject-external** command to prevent inbound calls on the trunk from being routed back out of the same trunk. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **reject-external** is enabled on this interface.

Command History

Release 9.3	Command was introduced.

Functional Notes

In general, trunks are assigned to the user role, which means they terminate lines from a Telco provider. If this is the case, **reject-external** should be enabled so that inbound calls on the trunk cannot be routed back out of the same trunk. If the configuration is poor, inbound long distance calls could be routed back out of the same trunk, causing the owner of the unit to be charged for long distance calls without his knowledge. For network-role trunks and Session Initiation Protocol (SIP) based trunks, this command should be disabled to allow calls to be properly routed in the unit.

Usage Examples

The following example disables **reject-external**:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#no reject-external**

resource-selection

Use the **resource-selection** command to determine how the switchboard uses outbound call resources contained within a time division multiplexing (TDM) based trunk group. Use the **no** form of this command to disable this feature. Variations of this command include:

resource-selection circular
resource-selection circular ascending
resource-selection circular descending
resource-selection linear
resource-selection linear ascending
resource-selection linear descending

Syntax Description

circular	Performs call load balancing among available DS0s/B-channels in this trunk. Subsequent calls will be delivered to the next available DS0/B-channel in a round-robin fashion.
linear	Specifies that a call being delivered to this trunk will be accepted out the first available DS0/B-channel available at the time the call is received.
ascending	Optional. Distributes calls in an order from the lowest to the highest channel (DS0 1, 2, 3 through 24).
descending	Optional. Distributes calls in an order from the highest to the lowest channel (DS0 24, 23, 22 through 1).

Default Values

By default, resource selection is set to **linear**.

Command History

Release 9.3	Command was introduced.
Release 13.1	Command was expanded to include the **ascending** and **descending** subcommands.

Usage Examples

The following example specifies **circular** resource selection:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#resource-selection circular**

rtp delay-mode

Use the **rtp delay-mode** command to configure the Realtime Transport Protocol (RTP) jitter buffer packet delay mode settings. RTP is used to prevent static on voice connections by enhancing the quality of the packet delivery. Use the **no** form of this command to return to the default setting. Variations of this command include:

rtp delay-mode adaptive
rtp delay-mode fixed

Syntax Description

adaptive	Configures the RTP jitter buffer packet delay to adjust during a call based on network conditions.
fixed	Configures the RTP jitter buffer packet delay to remain constant.

Default Values

By default, the RTP delay mode is set to **adaptive**.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures RTP delay mode as **fixed**:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#rtp delay-mode fixed**

rtp dtmf-relay

Use the **rtp dtmf-relay** command to configure the method by which Realtime Transport Protocol (RTP) dual tone multi-frequency (DTMF) events are relayed. The dial digits can be sent inband or out-of-band (OOB) of the voice stream. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp dtmf-relay inband
rtp dtmf-relay nte <*value*>

Syntax Description

inband	Specifies that RTP DTMF events be relayed inband in the RTP stream.
nte <*value*>	Specifies that RTP DTMF events be relayed OOB using named telephone event (NTE). Enter an NTE value between **96** and **127**.

Default Values

By default, the **rtp dtmf-relay** is set for **NTE 101**.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example configures RTP DTMF relay events for **inband**:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#rtp dtmf-relay inband**

rtp frame-packetization <*value*>

Use the **rtp frame-packetization** command to configure the Realtime Transport Protocol (RTP) frame packetization time in milliseconds for individual trunks and users. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Configures the RTP frame packetization time value in milliseconds. Select from **10**, **20**, **30**, or **40** milliseconds.

Default Values

By default, the **rtp frame-packetization** time is set to **20** milliseconds on all trunks and users.

Command History

Release 9.3	Command was introduced.
Release R10.8.0	Command was expanded to include **40** milliseconds.

Usage Examples

The following example sets the frame packetization time for trunk **T01** to **10** milliseconds:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#rtp frame-packetization 10**

rtp packet-delay

Use the **rtp packet-delay** command to configure the maximum Realtime Transport Protocol (RTP) packet delays. This command is used to set the allowable limits of latency on the network. Use the **no** form of this command to return to the default value. Variations of this command include:

rtp packet-delay fax <*value*>
rtp packet-delay maximum <*value*>
rtp packet-delay nominal <*value*>

Syntax Description

fax <*value*>	Sets the fax delay time value. Range is **0** to **500** milliseconds.
maximum <*value*>	Sets the maximum delay time value in increments of **10** milliseconds. Range is **40** to **320** milliseconds.
nominal <*value*>	Sets the nominal delay time value in increments of **10** milliseconds. Range is **10** to **240** milliseconds.

Default Values

By default, the RTP packet delay for fax is **300**, maximum is **100**, and nominal is **50**.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures the RTP fax delay time on trunk **T01** to **200** milliseconds:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#rtp packet-delay fax 200**

rtp qos dscp <*value*>

Use the **rtp qos dscp** command to configure the maximum Realtime Transport Protocol (RTP) quality of service (QoS) parameters for differentiated services code point (DSCP). Use the **no** form of this command to return to the default global value.

Syntax Description

<*value*>	Configures the RTP QoS parameter for DSCP. Enter a value between **0** and **63**.

Default Values

By setting the **rtp qos dscp** value on an individual trunk or user, you will override the global **rtp qos dscp** setting for RTP packets. QoS is set using a DSCP value. The default global DSCP value for RTP is **46**.

Command History

Release 9.3	Command was introduced.

Functional Notes

By setting the **rtp qos dscp** value on an individual trunk or user, you will override the global **rtp qos dscp** setting for RTP packets. QoS is set using a DSCP value. Valid DSCP values are **0** to **63**, and a higher DSCP value has a higher priority. The default global DSCP value for RTP is **46**. Remember that if you are using a public IP connection, such as the Internet, for Voice over Internet Protocol (VoIP), end-to-end QoS may not be guaranteed. The default DSCP value for Session Initiation Protocol (SIP) is **26**. To configure QoS for the RTP traffic that carries the voice conversation, use the command **ip rtp qos dscp** followed by the desired DSCP value.

Usage Examples

The following example configures the RTP QoS DSCP for trunk **T01** to **60**:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#rtp qos dscp 60**

rtp rx-gain *<value>*

Use the **rtp rx-gain** command to specify the Realtime Transport Protocol (RTP) receive (RX) gain or attenuation. RTP is used to prevent static on voice connections by enhancing the quality of the packet delivery. Using the **no** form of this command returns the RTP RX gain or attenuation to the default value.

Syntax Description

<value>	Specifies the RTP RX gain or attenuation in the RTP to time division multiplexing (TDM) direction. Range is **6** to **-14**. Negative values specify attenuation. Positive values specify gain in decibels (dB).

Default Values

By default, RTP RX gain is set to **0** dB.

Command History

Release A2.04	Command was introduced.

Command History

Release A2.04	Command was introduced.

Usage Examples

The following example specifies the RTP RX gain for trunk **T01** is **4** dB:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t01)**#rtp rx-gain 4**

rtp tx-gain *<value>*

Use the **rtp tx-gain** command to specify the Realtime Transport Protocol (RTP) transmit (TX) gain or attentuation. RTP is used to prevent static on voice connections by enhancing the quality of the packet delivery. Using the **no** form of this command returns the RTP TX gain or attenuation to the default value.

Syntax Description

<value>	Specifies the RTP TX gain or attenuation in the time division multiplexing (TDM) to RTP direction. Range is **6** to **-14**. Negative values specify attenuation. Positive values specify gain in decibels (dB).

Default Values

By default, RTP TX gain is set to **0** dB.

Command History

Release A2.04	Command was introduced.

Usage Examples

The following example specifies the RTP TX gain for trunk **T01** is **4** dB:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t01)**#rtp tx-gain 4**

treat-inbound-as-internal

Use the **treat-inbound-as-internal** command to make incoming trunk calls appear as internal calls. Use the **no** form of this command to cancel the setting.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example configures the unit to treat inbound calls on trunk **T03** as internal calls:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#treat-inbound-as-internal**

trunk-number <*number*>

Use the **trunk-number** command to define the call routing when direct inward dialing (DID) is disabled. This feature directs incoming calls to the specified number when DID is not present. This command also allows users to activate different system modes of operation that redirect incoming calls to a different number depending on the specified mode. Use the **no** form of this command to disable this feature. Variations of this command include:

trunk-number <*number*>
trunk-number custom1 <*number*>
trunk-number custom1 no-number
trunk-number custom2 <*number*>
trunk-number custom2 no-number
trunk-number custom3 <*number*>
trunk-number custom3 no-number
trunk-number lunch <*number*>
trunk-number lunch no-number
trunk-number night <*number*>
trunk-number night no-number
trunk-number no-number
trunk-number override <*number*>
trunk-number override no-number
trunk-number weekend <*number*>
trunk-number weekend no-number

Syntax Description

<*number*>	Specifies the number used for call routing when DID is disabled.
custom1 - custom3	Specifies the custom mode to use.
lunch	Specifies the lunch-time mode.
night	Specifies the night-time mode.
no-number	Specifies no inbound calls are allowed on this trunk.
override	Specifies the override mode.
weekend	Specifies the weekend mode.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was added to the feature group D (FGD) trunk options.
Release 16.1	Command was expanded to include the new subcommands.

Usage Examples

The following example defines call routing on trunk **T03**:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#trunk-number 4000**

t38

Use the **t38** command to enable T.38 fax operation. Use the **no** form of this command to disable this feature.

> NOTE *The **modem-passthrough** command must be enabled for T.38 operation to work. Refer to modem-passthrough on page 5176.*

Syntax Description

No subcommands.

Default Values

By default, T.38 is disabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables T.38 for trunk **T03**:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#t38**

Technology Review

T.38 is an International Telecommunication Union (ITU) specification that allows Group-3 Fax (T.30) data to be transported over the Internet. It is similar to dual tone multi-frequency (DTMF) relay (RFC 2833) in that the digital signal processor (DSP) decodes tones and demodulated fax data and converts them into packets. A similar device on the other end takes the packets/tones and remodulates them so that an analog fax machine on the other end can receive the fax. AOS's previous support (revisions 12 through 15) for fax/modem signals was simply detecting a tone and forcing the coder-decoder (CODEC) into G.711 and disabling/enabling echo cancellers based on the tones detected. When packet loss becomes high, sending faxes over G.711 becomes problematic, due to dropped messages and timeouts/retrains.

T.38 can be used in conjunction with various call-control schemes, such as H.323, Session Initiation Protocol (SIP), and Media Gateway Control Protocol (MGCP). AOS only supports SIP as the call-control method. This is typically referred to T.38/Annex-D. Annex-D describes the Session Initiation Protocol/Session Description Protocol (SIP/SDP) call establishment procedures.

t38 ced auto-generate

Use the **t38 ced auto-generate** command to specify when the digital signal processor (DSP) should regenerate the called station identifier (CED) signal toward the time division multiplexed (TDM) endpoint. If auto-generate is enabled, the DSP generates the CED signal only when it does not receive CED indicator packets from the Voice over IP (VoIP) endpoint. If auto-generate is disabled, the DSP generates the CED signal only when it does receive CED indicator packets from the VoIP endpoint. Using the **no** version of this command disables CED auto-generate.

Syntax Description

No subcommands.

Default Values

By default, CED auto-generate is disabled.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Usage Examples

The following example enables CED auto-generate for the T.38 session on the trunk:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#t38 ced auto-generate**

t38 ced length <*time*>

Use the **t38 ced length** command to set the maximum duration of a regenerated called station identifier (CED) signal, in milliseconds, from the digital signal processor (DSP) toward the time division multiplexed (TDM) endpoint when a T.38 session is active. Using the **no** form of this command returns the duration to the default value.

Syntax Description

<*time*>	Specifies the maximum duration of a regenerated CED signal in milliseconds. Valid range is **0** to **4000** ms.

Default Values

By default, the maximum duration of a regenerated CED signal is **3000** ms.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Setting the maximum duration of a regenerated CED signal to **0** effectively prevents any CED generation.

Usage Examples

The following example decreases the maximum duration of the CED signal to **2000** ms for the T.38 session:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#t38 ced length 2000**

t38 cng-relay-selective

Use the **t38 cng-relay-selective** command to enable fax calling tones (CNG) relay only when V.21 messages are not being transmitted. Use the **no** version of this command to disable selective CNG relay.

Syntax Description

No subcommands.

Default Values

Selective CNG relay is disabled by default.

Command History

Release R10.4.0	Command was introduced.

Usage Examples

The following example enables T.38 CNG relay:

(config)**#voice trunk t01 type t1-rbs supervision fgd role user**
(config-t03)**#t38 cng-relay-selective**

t38 ecm

Use the **t38 ecm** command to enable or disable error correction mode (ECM) during T.38 sessions. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 ecm enable
t38 ecm disable

Syntax Description

enable	Enables ECM during T.38 sessions.
disable	Disables ECM during T.38 sessions.

Default Values

By default, ECM is enabled.

Command History

Release R10.8.0	The command was introduced

Usage Examples

The following example disables ECM for T.38 sessions on trunk T03:

(config)**#voice trunk t01 type t1-rbs supervision fgd role user**
(config-t03)**#t38 ecm disable**

t38 error-correction

Use the **t38 error-correction** command to specify the type of fax error correction. Use the **no** form of this command to disable this feature. Variations of this command include:

t38 error-correction fec
t38 error-correction redundancy

Syntax Description

fec	Specifies forward error correction (FEC) as the fax error correction. FEC is a system of error control where the sender adds redundant data to its messages, allowing the receiver to detect and correct errors (within certain bounds) without the need to request additional data from the sender.
redundancy	Specifies redundancy as the fax error correction. Redundancy error correction replicates the payload a user-specified number of times to determine if errors are present. The number of redundant packets is set using the command *t38 v21-preamble-timeout <value> on page 5204*).

Default Values

By default, **t38 error-correction** is set to **redundancy** for the Total Access 900(e) Series, the NetVanta 6310/6330 Series, the NetVanta 6355 Series, the NetVanta 6240/6250 Serires, and the NetVanta 640 Series.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default value changed to **fec** for the Total Access 900(e) Series, the NetVanta 6310/6330 Series, the NetVanta 6355 Series, and the NetVanta 7000 Series products.
Release R10.8.0	The default values for this command were updated.

Usage Examples

The following example sets the **t38 error-correction** to **fec**:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#t38 error-correction fec**

t38 fallback-mode g711

Use the **t38 fallback-mode** command to specify the transmission mode used when T.38 fax relay cannot be successfully negotiated at the time of the fax transfer. Use the **no** form of this command to disable this feature.

Syntax Description

g711	Specifies that fax operation revert back to analog mode (G.711).

Default Values

By default, **t38 fallback-mode** is to **G.711**.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default was changed to **G.711**.

Usage Examples

The following example enables the **t38 fallback-mode** on trunk **T02**:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#t38 fallback-mode g711**

t38 generate-cng

Use the **t38 generate-cng** command to specify whether the digital signal processor (DSP) will begin a T.38 session by generating the calling signal (CNG) toward the time division multiplexed (TDM) endpoint. Using the **no** version of this command disables CNG generation.

Syntax Description

No subcommands.

Default Values

By default, CNG generation is disabled.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

With the introduction of this command, the CNG generation behavior of the T.38 session is now configurable. In AOS firmware prior to A5.01, this behavior was not configurable, but rather was set to always generate this signal.

Usage Examples

The following example enables CNG generation for the T.38 session:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#t38 generate-cng**

t38 max-buffer <*value*>

Use the **t38 max-buffer** command to set the maximum buffer size for T.38 fax operation. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the value of the **max-buffer** attribute in the Session Description Protocol (SDP) offer when the T.38 session is initiated. Range is **0** to **800** bytes.

Default Values

By default, the maximum buffer size is set to **200**.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example sets the **t38 max-buffer** to **100**:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#t38 max-buffer 100**

t38 max-datagram <*value*>

Use the **t38 max-datagram** command to set the maximum datagram value in this unit. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the value of the **max-datagram** attribute in the Session Description Protocol (SDP) offer when the T.38 session is initiated. Range is **0** to **300** bytes.

Default Values

By default, the maximum datagram value is set to **72** bytes.

Command History

Release 16.1	Command was introduced.
Release A5.01	Command default was changed to **72** bytes.

Usage Examples

The following example sets the **t38 max-datagram** to **100**:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#t38 max-datagram 100**

t38 max-rate

Use the **t38 max-rate** command to specify the fax maximum rate. The actual transmission rate could be lower than specified rate if the receiving end cannot support the maximum rate. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 max-rate 14400
t38 max-rate 12000
t38 max-rate 2400
t38 max-rate 4800
t38 max-rate 7200
t38 max-rate 9600

Syntax Description

14400	Specifies 14400 bits per second (bps) as fax maximum rate.
12000	Specifies 12000 bps as fax maximum rate.
2400	Specifies 2400 bps as fax maximum rate.
4800	Specifies 4800 bps as fax maximum rate.
7200	Specifies 7200 bps as fax maximum rate.
9600	Specifies 9600 bps as fax maximum rate.

Default Values

By default, the maximum fax rate is set to **14400** bps.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example sets the **t38 max-rate** to **4800** bps:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#t38 max-rate 4800**

t38 redundancy

Use the **t38 redundancy** command to set the number of redundant packets sent when the **t38 error-correction redundancy** feature is enabled. Use the **no** form of this command to return to the default value. Variations of this command include:

t38 redundancy high-speed <*value*>
t38 redundancy low-speed <*value*>

Syntax Description

high-speed <*value*>	Specifies the number of redundant T.38 fax packets to be sent for data messages (high-speed fax machine image data). Range is **0** (no redundancy) to **4** packets.
low-speed <*value*>	Specifies the number of redundant T.38 fax packets to be sent for the signaling messages (low-speed fax machine protocol). Range is **0** (no redundancy) to **7** packets.

Default Values

By default, high-speed and low-speed redundancy values are set to **0** (no redundancy).

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables **t38 error-correction redundancy** and sets the number of redundant data messages to **3** for trunk **T01**:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#t38 error-correction redundancy**
(config-t01)**#t38 redundancy high-speed 3**

t38 v21-preamble-timeout *<value>*

Use the **t38 v21-preamble-timeout** command to set the maximum amount of time that the digital signal processor (DSP) waits for peer device activity after starting to transmit a V.21 preamble event before spoofing a response to the time division multiplexed (TDM) endpoint. Using the **no** version of this command returns the timeout value to the default setting.

Syntax Description

<value>	The time, in milliseconds, that the DSP will wait for peer activity. Valid range is **1** to **3000** ms.

Default Values

By default, the V.21 preamble timeout is set to **1700** ms.

Command History

Release A5.01	Command was introduced.

Functional Notes

This command is only available on AOS voice products that have Freescale DSP. This includes the Total Access 900(e) Series, the NetVanta 6310/6330 Series, and the NetVanta 7000 Series products.

This command is used to help in troubleshooting T.38 interoperability issues. This command should only be issued by advanced users or at the direction of Adtran technical support.

Usage Examples

The following example specifies the V.21 preamble timeout value as **2000** ms:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#t38 v21-preamble-timeout 2000**

tx-ani

Use the **tx-ani** command to transmit automatic number identification (ANI) (calling-party number) and dialed number identification service (DNIS) (called-party number) for outbound feature group D (FGD) calls. This command is only valid on a trunk configured for FGD supervision. Use the **no** form of this command to cancel the setting.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.
Release 15.1	Command was added to the FGD command set.

Usage Examples

The following example configures the system to transmit ANI/DNIS information on the outbound FGD trunk:

(config)**#voice trunk t03 type t1-rbs supervision fgd role user**
(config-t03)**#tx-ani**

vad

Use the **vad** command to enable voice activity detection (VAD). VAD blocks out noise categorized as silence during a voice connection. The silent voice packets are not transmitted, allowing bandwidth usage to be reduced. Although VAD saves bandwidth, the quality of the voice call may be compromised. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, VAD is enabled for all T1 robbed-bit signaling (RBS) trunks and users.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example disables VAD on trunk **T01**:

(config)**#voice trunk t01 type t1-rbs supervision wink role network**
(config-t01)**#no vad**

VPN PARAMETER COMMAND SETS

The VPN parameter command sets are divided into the following sections:

CERTIFICATE COMMAND SETS

This section includes the following command sets:

CA PROFILE COMMAND SET

To activate the Certificate Authority (CA) Profile Configuration mode, enter the **crypto ca profile** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#crypto ca profile MyProfile
Configuring New CA Profile MyProfile
(ca-profile)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

crl optional on page 5210
email address <address> on page 5211
enrollment retry on page 5212
enrollment terminal on page 5213
enrollment url <url> on page 5214
fqdn <name> on page 5215
ip-address <ipv4 address> on page 5216
password <password> on page 5217
serial-number on page 5218
subject-name <name> on page 5219
uri <uri> on page 5220

crl optional

Use the **crl optional** command to make certificate revocation list (CRL) verification optional.

Syntax Description

No subcommands.

Default Values

By default, CRL optional is enabled.

Command History

Release 5.1	Command was introduced.

Functional Notes

If enabled, AOS is able to accept certificates even if no CRL is loaded into the configuration. Currently, this is the only mode supported by AOS for CRL negotiations.

Usage Examples

The following example sets CRL verification as optional:

(config)**#crypto ca profile MyProfile**
Configuring New CA Profile MyProfile
(ca-profile)**#crl optional**

email address <*address*>

Use the **email address** command to specify that an email address should be included in the certificate request. Use the **no** form of this command to remove an email address.

Syntax Description

<*address*>	Specifies the complete email address to use when sending certificate requests. This field allows up to 51 characters.

Default Values

No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.

Functional Notes

Configuring this setting simplifies the **crypto ca enroll** dialog, allowing you to enter the email address only once rather than every time you go through the enrollment process. Refer to *crypto ca enroll <profile name> on page 1241*.

Usage Examples

The following example specifies **joesmith@company.com** as the email address to be sent in certificate requests:

(config)**#crypto ca profile MyProfile**
Configuring New CA Profile MyProfile
(ca-profile)**#email address joesmith@company.com**

enrollment retry

Use the **enrollment retry** command to determine how AOS handles certificate requests. Use the **no** form of this command to return to the default setting. Variations of this command include:

enrollment retry count <*number*>
enrollment retry period <*value*>

Syntax Description

count <*number*>	Specifies the number of times AOS re-sends a certificate request when it does not receive a response from the previous request. Range is **1** to **100**.
period <*value*>	Specifies the time period between certificate request retries. The default is **1** minute between retries. Range is **1** to **60** minutes.

Default Values

By default, period is set to **5** minutes, and count is set to **12** retries.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example configures AOS to send certificate requests every **2** minutes, stopping after **50** retries (if no response is received):

(config)**#crypto ca profile MyProfile**
Configuring New CA Profile MyProfile
(ca-profile)**#enrollment retry count 50**
(ca-profile)**#enrollment retry period 2**

enrollment terminal

Use the **enrollment terminal** command to specify manual (i.e., cut-and-paste) certificate enrollment. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is enabled.

Command History

Release 5.1	Command was introduced.

Functional Notes

This mode is overridden if the **enrollment url** command specifies the certificate authority (CA) to which automatic certificate requests are to be sent via Simple Certificate Exchange Protocol (SCEP). Issuing an **enrollment terminal** command after using the **enrollment url** command deletes the uniform resource locator (URL) and forces the unit to use manual enrollment. Refer to *enrollment url <url> on page 5214* for more information.

Usage Examples

The following example configures AOS to accept manual certificate enrollment input:

(config)**#crypto ca profile MyProfile**
Configuring New CA Profile MyProfile
(ca-profile)**#enrollment terminal**

enrollment url <*url*>

Use the **enrollment url** command to specify the uniform resource locator (URL) of the certificate authority (CA) to which AOS should send certificate requests. Use the **no** form of this command to remove a URL.

Syntax Description

<*url*>	Specifies the certificate authority's URL (for example, **http://10.10.10.1:400/abcdefg/pkiclient.exe**).

Default Values

No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.

Functional Notes

When entering the URL, **http://** is required followed by the IP address or domain naming system (DNS) of the CA. If the port number is something other than 80, include it after the IP address or DNS name separated with a colon (**:**).

The CA may have other necessary information to include in the common gateway interface (CGI) path before ending with the actual CGI program. An example template to follow is **http://hostname:port/path/to/program.exe**.

Use the default program **pkiclient.exe** without specifying it, end the URL with a slash (**/**). Otherwise, you must enter the program name to use. For example, **http://10.10.10.1:400/abcdefg/** will assume **pkiclient.exe** as the program (but not including the terminating slash is a configuration error).

Specifying this command will override the **enrollment terminal** setting as described previously (refer to *enrollment terminal on page 5213*).

Usage Examples

The following example specifies **http://CAserver/certsrv/mscep/mscep.dll** as the URL to which AOS will send certificate requests:

(config)**#crypto ca profile MyProfile**
Configuring New CA Profile MyProfile
(ca-profile)**#enrollment url http://CAserver/certsrv/mscep/mscep.dll**

fqdn *<name>*

Use the **fqdn** command to specify a fully qualified domain name (FQDN) to be included in the certificate requests. Use the **no** form of this command to remove an FQDN.

Syntax Description

<name>	Specifies the FQDN (e.g., **company.com**) to be included in requests.

Default Values

No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.

Functional Notes

Configuring this setting simplifies the **crypto ca enroll** dialog, allowing you to enter the FQDN only once rather than every time you go through the enrollment process. Refer to *crypto ca enroll <profile name> on page 1241*.

Usage Examples

The following example specifies **company.com** as the FQDN to be sent in certificate requests:

(config)**#crypto ca profile MyProfile**
Configuring New CA Profile MyProfile
(ca-profile)**#fqdn company.com**

ip-address *<ipv4 address>*

Use the **ip-address** command to specify an Internet Protocol version 4 (IPv4) address to be included in the certificate requests. Use the **no** form of this command to remove a defined IPv4 address.

Syntax Description

<ipv4 address>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.

Functional Notes

Configuring this setting simplifies the **crypto ca enroll** dialog, allowing you to enter the IPv4 address only once rather than every time you go through the enrollment process. Refer to *crypto ca enroll <profile name> on page 1241*.

Usage Examples

The following example specifies **66.203.52.193** as the IPv4 address to be sent in certificate requests:

(config)**#crypto ca profile MyProfile**
Configuring New CA Profile MyProfile
(ca-profile)**#ip-address 66.203.52.193**

password *<password>*

Use the **password** command to specify the challenge password for Simple Certificate Exchange Protocol (SCEP). Use the **no** form of this command to allow certificate authority (CA) requests to be sent automatically (using SCEP) without requiring a password.

Syntax Description

<password>	Specifies the SCEP password (up to **80** characters).

Default Values

By default, no password is required.

Command History

Release 5.1	Command was introduced.

Functional Notes

There are two places for configuring a SCEP password:

- At the (ca-profile)# prompt.
- If it is not configured at the (ca-profile)# prompt, you are prompted to enter one when going through the certificate enrollment process.

The password is sent to the CA from which you are requesting a certificate. The CA may then ask for the password later before a certificate can be revoked. Refer to *crypto ca enroll <profile name> on page 1241*.

Usage Examples

The following example sets the SCEP challenge password to **adtran**:

(config)#**crypto ca profile MyProfile**
Configuring New CA Profile MyProfile
(ca-profile)#**password adtran**

serial-number

Use the **serial-number** command to specify that a serial number will be included in the certificate request. Use the **no** form of this command to prevent a serial number from being included in the certificate request.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 5.1	Command was introduced.

Functional Notes

By default, this command is set to **no serial-number**, which means that the serial number is not included in the certificate requests.

Usage Examples

The following example configures AOS to include a serial number in the certificate request:

(config)**#crypto ca profile MyProfile**
Configuring New CA Profile MyProfile
(ca-profile)**#serial-number**

subject-name *<name>*

Use the **subject-name** command to specify the subject name used in the certificate request. Use the **no** form of this command to remove a configured subject name.

Syntax Description

<name>	Specifies a subject name string using up to **256** characters entered in X.500 Lightweight Directory Access Protocol (LDAP) format.

Default Values

By default, there is no subject name configured.

Command History

Release 5.1	Command was introduced.

Functional Notes

Configuring this setting simplifies the **crypto ca enroll** dialog, allowing you to enter the subject name only once rather than every time you go through the enrollment process. Refer to *crypto ca enroll <profile name> on page 1241*.

Usage Examples

The following example assigns a subject name of **Adtran-cert** to certificate requests:

(config)**#crypto ca profile MyProfile**
Configuring New CA Profile MyProfile
(ca-profile)**#subject-name Adtran-cert**

uri *<uri>*

Use the **uri** command to configure a Uniform Resource Identifier (URI) value to be added to the certificate request at enrollment. The specified URI is included in the resulting certificate request and can be used for certificate validation. This option is useful when using features like SIPConnect. Use the **no** form of this command to remove the value from the certificate authority (CA) profile.

Syntax Description

<uri>	Specifies the URI in the format **x@y:port**.

Default Values

By default, no URI value is specified for the certificate.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

Specifying the certificate URI is used in conjunction with the command *crypto ca enroll <profile name> on page 1241*.

Usage Examples

The following example configures a URI value to include in the certificate request:

(config)**#crypto ca enroll MYPROFILE**
(config-ca-profile-MYPROFILE)**#uri joesmith@example.com:5060**

CERTIFICATE COMMAND SET

To activate the Certificate Configuration mode, enter the **crypto ca certificate chain** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#crypto ca certificate chain MyProfile
(config-cert-chain)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

certificate <serial number> on page 5222
certificate ca <serial number> on page 5223
crl on page 5224

certificate *<serial number>*

Use the **certificate** command to restore a certificate. Use the **no** form of this command to remove a specific certificate from the certificate chain.

Syntax Description

<serial number>	Specifies the certificate's serial number (up to **51** characters). This value can be found for existing certificates by using the **show run** command.

Default Values

No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.

Functional Notes

The user typically does not enter this command. It is primarily used to restore certificates from the startup configuration when the product is powered up.

Usage Examples

The following example removes the certificate with the serial number **73f0bfe5ed8391a54d1214390a36cee7**:

(config)**#crypto ca certificate chain MyProfile**
(config-cert-chain)**#no certificate 73f0bfe5ed8391a54d1214390a36cee7**

certificate ca *<serial number>*

Use the **certificate ca** command to restore a certificate authority (CA) certificate. Use the **no** form of this command to remove a specific certificate from the certificate chain for a CA.

Syntax Description

<serial number>	Specifies the certificate's serial number (up to **51** characters). This value can be found for existing certificates by using the **show run** command.

Default Values

No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.

Functional Notes

The user typically does not enter this command. It is primarily used to restore certificates from the startup configuration when the product is powered up.

Usage Examples

The following example removes the CA certificate with the serial number **0712**:

(config)**#crypto ca certificate chain MyProfile**
(config-cert-chain)**#no certificate ca 0712**

crl

Use the **crl** command to restore a certificate revocation list (CRL). Use the **no** form of this command to remove the CRL for the specific certificate authority (CA).

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.

Functional Notes

The user typically does not enter this command. It is primarily used to restore CRLs from the startup configuration when the product is powered up.

Usage Examples

The following example removes the CRL for the current CA:

(config)**#crypto ca certificate chain MyProfile**
(config-cert-chain)**#no crl**

CRYPTO MAP COMMAND SETS

This section includes the following command sets:

CRYPTO MAP IKE COMMAND SET

To activate the Crypto Map Internet Key Exchange (IKE) mode, enter a valid version of the **crypto map ipsec-ike** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#crypto map MyMap 100 ipsec-ike
(config-crypto-map)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

antireplay on page 5227
commit-bit on page 5228
ike-policy <number> on page 5230
match address ip <ipv4 acl name> on page 5231
match track<name> on page 5233
reverse-route on page 5235
set peer on page 5237
set pfs on page 5239
set security-association idle-time <value> on page 5240
set security-association level per-host on page 5241
set security-association lifetime on page 5242
set transform-set on page 5243

For virtual private network (VPN) configuration example scripts, refer to the Virtual Private Network configuration guide available online at https://supportcommunity.adtran.com.

antireplay

Use the **antireplay** command to enable anti-replay sequence number checking for all security associations (SAs) created on this crypto map. Use the **no** form of this command to disable this feature. Variations of this command include:

antireplay
antireplay <*value*>

Syntax Description

<*value*>	Optional. Specifies the anti-replay window size in bytes. Select from **64**,**128**, **256**, **512**, or **1024** bytes.

Default Values

By default, the window size is set to **64** bytes.

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example enables anti-replay sequence checking on crypto map **VPN 100**:

(config)**#crypto map MyMap 100 ipsec-ike**
(config-crypto-map)**#antireplay**

commit-bit

Use the **commit-bit** command to set the commit-bit in the Internet Security Association and Key Management Protocol (ISAKMP) header when sending the second message of quick mode on an IPsec tunnel negotiation. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, the **commit-bit** will be used.

Command History

Release 12.1	Command was introduced.

Functional Notes

As an extra security measure, the commit-bit can be set by the responder of a quick mode negotiation to force the initiator to wait for the fourth message of quick mode before bringing up its IPsec security associations (SAs). By default, this feature is enabled on all AOS products with virtual private network (VPN) capabilities. Some vendors, however, may have incorrect implementations of the commit-bit that do not interoperate well with AOS products. In that case, the commit-bit should be disabled on all crypto maps that have a peer that does not support the commit-bit.

Usage Examples

The following example disables the use of commit-bit:

```
(config)#crypto map MyMap 100 ipsec-ike
(config-crypto-map)#no commit-bit
```

The following example displays a configuration with the commit-bit disabled:

```
ip crypto
!
crypto ike-policy 100
  initiate main
  respond main
  local-id address 10.10.10.1
  peer 192.168.1.1
  attribute 2
   encryption aes-256-cbc
   authentication pre-share
   lifetime 3600
!
```

```
crypto ike remote-id address 10.10.10.1 preshared-key adtran ike-policy 100 crypto map VPN 10
     no-mode-config no-xauth
!
crypto ipsec transform-set esp-aes-256-cbc-esp-sha-hmac esp-aes-256-cbc esp-sha-hmac mode tunnel
!
crypto map VPN 10 ipsec-ike
  description VPN to Main Site
  match address VPN-10-vpn-selectors
  set peer 192.168.1.1
  set transform-set esp-aes-256-cbc-esp-sha-hmac
  set security-association lifetime seconds 3600
  no commit-bit
  ike-policy 100
```

ike-policy *<number>*

Use the **ike-policy** command to ensure that only a specified Internet key exchange (IKE) policy is used to establish the IPsec tunnel. This prevents any mobile virtual private network (VPN) policies from using IPsec policies that are configured for static VPN peer policies. Use the **no** form of this command to remove a configured policy.

Syntax Description

<number>	Specifies the policy number of the policy to assign to this crypto map.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.

Usage Examples

The following example sets the IKE policy **100** for crypto map **MyMap**:

(config)**#crypto map MyMap 100 ipsec-ike**
(config-crypto-map)**#ike-policy 100**

match address ip *<ipv4 acl name>*

Use the **match address ip** command to assign an Internet Protocol version 4 (IPv4) access control list (ACL) to a crypto map definition. The IPv4 ACL designates which IPv4 packets are to be encrypted by this crypto map. Use the **no** form of this command to delete an IPv4 ACL. Refer to *ip access-list extended <ipv4 acl name> on page 1344* for more information on creating ACLs.

Syntax Description

<ipv4 acl name>	Specifies the name of the IPv4 ACL you wish to assign to this crypto map.

Default Values

By default, no IPv4 ACLs are defined.

Command History

Release 4.1	Command was introduced.
Release R10.7.0	Command syntax was changed to require the **ip** keyword.

Functional Notes

Crypto map entries do not directly contain the selectors used to determine which data to secure. Instead, the crypto map entry refers to an IPv4 ACL. An IPv4 ACL is assigned to the crypto map using the **match address** command. If no IPv4 ACL is configured for a crypto map, then the entry is incomplete and will have no effect on the system.

For a complete list of all extended ACL configuration commands, refer to the IPv4 Access Control List Command Set on page 4252.

The entries of the IPv4 ACL used in a crypto map should be created with respect to traffic sent by the Adtran product. The source information must be the local Adtran product and the destination must be the peer.

Only extended IPv4 ACLs can be used in crypto maps.

Usage Examples

The following example shows setting up an IPv4 ACL (called **NewList**) and then assigning the new list to a crypto map (called **NewMap**):

(config)**#ip access-list extended NewList**
(config-ext-nacl)**#exit**
(config)**#crypto map NewMap 10 ipsec-ike**
(config-crypto-map)**#match address ip NewList**

Technology Review

A crypto map entry is a single policy that describes how certain traffic is to be secured. There are two types of crypto map entries: **ipsec-manual** and **ipsec-ike**. Each entry is given an index, which is used to sort the ordered list.

When a nonsecured packet arrives on an interface, the crypto map set associated with that interface is processed in order. If a crypto map entry matches the nonsecured traffic, the traffic is discarded.

When a packet is to be transmitted on an interface, the crypto map set associated with that interface is processed in order. The first crypto map entry that matches the packet will be used to secure the packet. If a suitable security association (SA) exists, that is used for transmission. Otherwise, an SA is established based on the manual key configuration.

When a secured packet arrives on an interface, its security parameter index (SPI) is used to look up an SA. If an SA does not exist, or if the packet fails any of the security checks (bad authentication, traffic does not match SA selectors, etc.), it is discarded. If all checks pass, the packet is forwarded normally.

match track<*name*>

Use the **match track** command to assign a network monitoring track to enable or disable the indicated crypto map policy. Use the **no** form of this command to remove this capability. Refer to *track <name> on page 1886* and *Network Monitor Track Command Set on page 4098* for more information on creating and using tracks.

Syntax Description

<name>	Specifies the name of the network monitoring track to assign to this crypto map.

Default Values

By default, there are no network monitoring tracks assigned.

Command History

Release 14.1	Command was introduced.

Functional Notes

To increase availability of a network with two virtual private network (VPN) gateways, a track can be assigned to a primary crypto map policy. This track will ensure connectivity to the primary VPN gateway. If the track detects connectivity problems on this gateway, the primary crypto map policy is disabled. Network traffic is then allowed to flow over the backup VPN gateway using the backup crypto map policy (which would have a similar **match address** access control list (ACL) as the primary crypto map policy). Once the track detects connectivity with the primary VPN gateway again, it will re-enable the primary crypto map policy.

Network monitoring tracks must be created first with the **track** command executed from the Global Configuration mode command prompt. Once created, further configuration is accomplished through the commands available in the *Network Monitor Track Command Set on page 4098*.

Usage Examples

The following example shows the preliminary steps necessary before assigning a track to a crypto map policy, as well as configuring the track to disable the primary VPN gateway if connectivity issues are detected.

Define a probe named **primaryping** to ping the primary VPN gateway (**10.22.156.251**):

```
(config)#probe primaryping icmp-echo
(config-probe-primaryping)#destination 10.22.156.251
(config-probe-primaryping)#period 10
(config-probe-primaryping)#tolerance consecutive fail 3
(config-probe-primaryping)#no shutdown
```

Create a track named **track1** to test the probe defined above:
(config)**#track track1**
(config-track-track1)**#test probe primaryping**
(config-track-track1)**#no shutdown**
(config-track-track1)**#exit**

Configure the crypto map (**NewMap**) to create a VPN tunnel to the primary VPN gateway (**10.22.156.251**):
(config)**#crypto map NewMap 10 ipsec-ike**
(config-crypto-map)**#description Primary VPN policy**
(config-crypto-map)**#match track track1**
(config-crypto-map)**#match address VPN-selectors**
(config-crypto-map)**#set peer 10.22.156.251**

Configure the crypto map (**NewMap**) to create a VPN tunnel to the backup VPN gateway (**10.22.156.240**):
(config)**#crypto map NewMap 20 ipsec-ike**
(config-crypto-map)**#description Backup VPN policy**
(config-crypto-map)**#match address VPN-selectors**
(config-crypto-map)**#set peer 10.22.156.240**

reverse-route

Use the **reverse-route** command to enable virtual private network (VPN) reverse route injection for a particular crypto map. Use the **no** form of this command to disable reverse route injection. Variations of this command include the following:

reverse-route
reverse-route <*number*>
reverse-route <*number*> **tag** <*value*>
reverse-route tag <*value*>

Syntax Description

<*number*>	Optional. Specifies the administrative distance for the static route. Range is **1** to **255**.
tag <*value*>	Optional. Specifies that a tag will be added to the static route in the route table. Range from **1** to **65535**.

Default Values

By default, reverse routing is disabled.

Command History

Release 15.1	Command was introduced.

Functional Notes

Reverse route injection automatically inserts a static route to a peer's remote network into the route table of a VPN gateway.

The tags used in reverse route injection allow the routes to be individuated from other static routes.

Usage Examples

The following example enables reverse route injection for crypto map **MyMap** with an administrative distance of **20** and a **tag** value of **10**:

(config)**#crypto map MyMap 100 ispec-ike**
(config-crypto-map)**#reverse-route 20 tag 10**

Technology Review

The reverse route injection allows a crypto IPsec policy to inject static routes to a remote network into its own route table, leaving it to the configuration of routing protocols to propagate the routes within the network. Reverse route injection serves as a method of updating routing tables when using a backup VPN server. In case one VPN is taken down or is unreachable, the VPN peer's route is removed out of the VPN gateway's route table and other route tables within the network.

Administrative distance is a feature that routers employ in order to select the most reliable path when there are two or more routes to the same destination from two different routing protocols. Administrative distance defines the reliability of a routing protocol by assigning a value (the smaller the value, the more trustworthy the protocol) that is then used by the router to organize routing protocols according to reliability.

set peer

Use the **set peer** command to set the IP address or host name of the peer device. Use the **no** form of this command to remove a peer device. Variations of this command include:

set peer <*ip address*>
set peer hostname <*hostname*>

Syntax Description

<*ip address*>	Specifies the IP address of the peer device. If this is not configured, it implies responder only to any peer. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
hostname <*hostname*>	Specifies the host name of the peer device expressed in the format <*host.example.com*> (for example, **vpn.somecompany.com**).

Default Values

No default values are necessary for this command.

Command History

Release 4.1	Command was introduced.
Release 16.1	Command was expanded to include the host name parameters.

Functional Notes

If no peer IP address or host name is configured, the entry will only be used to respond to IPsec requests; it cannot initiate the requests (since it doesn't know which IP address to which to send the packet). When a peer IP address is configured, the crypto map entry can be used to both initiate and respond to security associations (SAs). The peer address or host name is not checked when a tunnel is initiated from a remote unit; this address only serves as the virtual private network (VPN) peer to which to initiate a tunnel.

The peer IP address is the public IP address of the device that will terminate the IPsec tunnel. If the peer IP address is not static, or the peer’s address cannot be attained through the domain naming system (DNS) host name, the Adtran product cannot initiate the VPN tunnel. There are many Dynamic DNS services that can serve DNS for hosts that are dynamically addressed. By setting no peer IP address, the Adtran product can respond to an IPsec tunnel request.

Only one peer IP address or host name can be set.

When using DNS host names for peer IP addresses, the crypto map is not able to initiate a tunnel until the DNS host name resolves. This DNS host name is checked every 10 minutes.

Usage Examples

The following example sets the peer IP address of **10.100.23.64**:

(config)**#crypto map MyMap 100 ipsec-ike**
(config-crypto-map)**#set peer 10.100.23.64**

The following example sets the peer host name to **vpn.examplehost.com**:

(config)**#crypto map MyMap 100 ipsec-ike**
(config-crypto-map)**#set peer hostname vpn.examplehost.com**

set pfs

Use the **set pfs** command to choose the type of perfect forward secrecy (PFS), if any, that will be required during the IPsec negotiation of security associations (SAs) for this crypto map. Use the **no** form of this command to return to the default setting. Variations of this command include:

set pfs group1
set pfs group1 legacy-peer
set pfs group2
set pfs group2 legacy-peer
set pfs group5
set pfs group5 legacy-peer

Syntax Description

group1	Requires IPsec to use Diffie-Hellman Group 1 (768-bit modulus) exchange during IPsec security association (SA) key generation.
group2	Requires IPsec to use Diffie-Hellman Group 2 (1024-bit modulus) exchange during IPsec SA key generation.
group5	Requires IPsec to use Diffie-Hellman Group 5 (1536-bit modulus) exchange during IPsec SA key generation.
legacy-peer	Optional. Specifies using the Diffie-Hellman secret generation for legacy peers (running AOS versions prior to A1.08 for voice products or 17.6.1 for data products).

Default Values

By default, no PFS will be used during IPsec SA key generation.

Command History

Release 4.1	Command was introduced.
Release 15.1	Command was expanded to include the **group5** parameter.
Release 17.6/A2.04	Command was expanded to include **legacy-peer** option.

Functional Notes

If left at the default setting, no PFS will be used during IPsec SA key generation. If PFS is specified, then the specified Diffie-Hellman Group exchange will be used for the initial and all subsequent key generation, thus providing no data linkage between prior keys and future keys.

Usage Examples

The following example specifies use of the Diffie-Hellman Group 1 exchange during IPsec SA key generation:

(config)**#crypto map MyMap 100 ipsec-ike**
(config-crypto-map)**#set pfs group1**

set security-association idle-time *<value>*

Use the **set security-association idle-time** command to set the receive idle timeout in seconds. This is the maximum amount of time for which the current virtual private network (VPN) peer can be idle. Once the timeout has occurred, the VPN tunnel will be brought down. Use the **no** form of this command to disable the timeout feature.

Syntax Description

<value>	Specifies the idle timeout in seconds. Valid range is **1** to **4294967294**.

Default Values

By default, the idle timeout is not defined.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example sets the receive idle timeout to **60** seconds:

(config)**#crypto map MyMap 100 ipsec-ike**
(config-crypto-map)**#set security-association idle-time 60**

set security-association level per-host

Use the **set security-association level per-host** command to enable per-host Internet Protocol (IP) security (IPsec) selector negotiation for the crypto map entry. When enabled, per-host mode specifies that the source and destination IP addresses of the packet requiring IPsec protection are placed in the virtual private network (VPN) selectors used in Quick Mode IPsec security association (SA) generation. Use the **no** form of this command to disable the per-host mode.

Exercise caution when enabling the per-host command. If many host-to-host conversations are being protected by the crypto map entry, a large number of IPsec SAs can be created, which can consume significant memory and processor resources on the device.

Syntax Description

No subcommands.

Default Values

By default, per-host mode is disabled.

Command History

Release R11.7.0	Command was introduced.

Functional Notes

Per-host mode applies only to crypto map entries keyed by Internet Key Exchange (IKE). This feature is not available in crypto maps keyed manually.

When per-host mode is enabled, and the device initiates Quick Mode, it replaces the source and destination networks in the crypto map entry access control list (ACL) line with the source and destination IP address of the packet requiring IPsec protection. Protocols and ports, if specified in the ACL, are negotiated as they are specified in the ACL line. This feature allows the hub in a Dynamic Multipoint VPN (DMVPN) network to select the appropriate outbound IPsec SA to protect traffic as it travels from the hub to a spoke.

The per-host setting does not apply when the device is responding to Quick Mode negotiations.

Usage Examples

The following example enables per-host mode on the crypto map:

(config)**#crypto map MyMap 100 ipsec-ike**
(config-crypto-map)**#set security-association level per-host**

set security-association lifetime

Use the **set security-association lifetime** command to define the lifetime (in kilobytes and/or seconds) of the IPsec security associations (SAs) created by this crypto map. Use the **no** form of this command to return to the default setting. Variations of this command include:

set security-association lifetime kilobytes <*value*>
set security-association lifetime seconds <*value*>

Syntax Description

kilobytes <*value*>	Specifies the SA lifetime limit in kilobytes.
seconds <*value*>	Specifies the SA lifetime limit in seconds.

Default Values

By default, the **security-association lifetime** is set to **28800** seconds, and there is no default for the kilobytes' lifetime.

Command History

Release 4.1	Command was introduced.

Functional Notes

Values can be entered for this command in both kilobytes and seconds. Whichever limit is reached first will end the SA.

Usage Examples

The following example sets the SA lifetime to **300** kilobytes and 2 hours (**7200** seconds):

(config)**#crypto map MyMap 100 ipsec-ike**
(config-crypto-map)**#set security-association lifetime kilobytes 300**
(config-crypto-map)**#set security-association lifetime seconds 7200**

set transform-set

Use the **set transform-set** command to assign up to six transform sets to a crypto map. Use the **no** form of this command to return to the default setting. Refer to *data-call on page 1254* for information on defining transform sets. Variations of this command include:

set transform-set *<name>*
set transform-set *<name> <name>*
set transform-set *<name> <name> <name>*
set transform-set *<name> <name> <name> <name>*
set transform-set *<name> <name> <name> <name> <name>*
set transform-set *<name> <name> <name> <name> <name> <name>*

Syntax Description

<name>	Assigns up to six transform sets to this crypto map by listing the set names, separated by a space.

Default Values

By default, there is no transform set assigned to the crypto map.

Command History

Release 4.1	Command was introduced.

Functional Notes

Crypto map entries do not directly contain the transform configuration for securing data. Instead, the crypto map is associated with transform sets that contain specific security algorithms (refer to *data-call on page 1254*).

If no transform set is configured for a crypto map, then the entry is incomplete and will have no effect on the system.

Usage Examples

The following example first creates a transform set (**Set1**) consisting of two security algorithms (up to three may be defined), and then assigns the transform set to a crypto map (**MyMap**):

(config)**#crypto ipsec transform-set Set1 esp-3des esp-sha-hmac**
(cfg-crypto-trans)**#exit**
(config)**#crypto map MyMap 100 ipsec-ike**
(config-crypto-map)**#set transform-set Set1**

IPv4 Crypto Map Manual Command Set

To activate the Internet Protocol version 4 (IPv4) Crypto Map Manual mode, enter a valid version of the **ip crypto map ipsec-manual** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ip crypto map Map-Name 10 ipsec-manual
(config-crypto-map)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

antireplay on page 5245
match address <name> on page 5246
set peer <ipv4 address> on page 5248
set session-key on page 5249
set transform-set <name> on page 5253

antireplay

Use the **antireplay** command to enable anti-replay sequence number checking for all security associations (SAs) created on this Internet Protocol version 4 (IPv4) crypto map. Use the **no** form of this command to disable this feature. Variations of this command include:

antireplay
antireplay <*value*>

Syntax Description

<*value*>	Optional. Specifies the anti-replay window size in bytes. Select from **64**, **128**, **256**, **512**, or **1024** bytes.

Default Values

By default, the window size is set to **64** bytes.

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example enables anti-replay sequence checking on crypto map **VPN 100**:

(config)**#ip crypto map VPN 100 ipsec-manual**
(config-crypto-map)**#antireplay**

match address <*name*>

Use the **match address** command to assign an Internet Protocol version 4 (IPv4) access control list (ACL) to a crypto map definition. The IPv4 ACL designates the IPv4 packets to be encrypted by this crypto map. Use the **no** form of this command to remove a defined IPv4 ACL. Refer to *ip access-list extended <ipv4 acl name> on page 1344* for more information on creating ACLs.

Syntax Description

<name>	Specifies the name of the IPv4 ACL you wish to assign to this crypto map.

Default Values

By default, no IPv4 ACLs are defined.

Command History

Release 4.1	Command was introduced.

Functional Notes

IPv4 crypto map entries do not directly contain the selectors used to determine which data to secure. Instead, the crypto map entry refers to an ACL. An ACL is assigned to the crypto map using the **match address** command. If no ACL is configured for a crypto map, then the entry is incomplete and will have no effect on the system.

For a complete list of all extended ACL configuration commands, refer to the *IPv4 Access Control List Command Set on page 4252*.

The entries of the ACL used in a crypto map should be created with respect to traffic sent by the Adtran product. The source information must be the local Adtran product, and the destination must be the peer.

Only extended ACLs can be used in crypto maps.

Usage Examples

The following example configures an IPv4 ACL (called **NewList**) and then assigning the new list to a crypto map (called **NewMap**):

(config)**#ip access-list extended NewList**

Configuring New Extended ACL "NewList"

(config-ext-nacl)**#exit**
(config)**#ip crypto map NewMap 10 ipsec-manual**
(config-crypto-map)**#match address NewList**

Technology Review

A crypto map entry is a single policy that describes how certain traffic is to be secured. There are two types of IPv4 crypto map entries: **ipsec-manual** and **ipsec-ike**. Each entry is given an index, which is used to sort the ordered list.

When a nonsecured packet arrives on an interface, the crypto map set associated with that interface is processed in order. If a crypto map entry matches the nonsecured traffic, the traffic is discarded.

When a packet is to be transmitted on an interface, the crypto map set associated with that interface is processed in order. The first crypto map entry that matches the packet will be used to secure the packet. If a suitable security association (SA) exists, that is used for transmission. Otherwise, an SA is established based on the manual key configuration.

When a secured packet arrives on an interface, its security parameter index (SPI) is used to look up an SA. If an SA does not exist, or if the packet fails any of the security checks (bad authentication, traffic does not match SA selectors, etc.), it is discarded. If all checks pass, the packet is forwarded normally.

set peer *<ipv4 address>*

Use the **set peer** command to set the Internet Protocol version 4 (IPv4) address of the peer device. Use the **no** form of this command to remove a peer device.

Syntax Description

<ipv4 address>	Specifies the IPv4 address of the peer device. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

No default values are necessary for this command.

Command History

Release 4.1	Command was introduced.

Functional Notes

If no peer IPv4 address is configured, the manual crypto map is not valid and not complete. A peer IPv4 address is required for manual crypto maps. To change the peer IPv4 address, the **no set peer** command must be issued first; then the new peer IP address can be configured.

Usage Examples

The following example sets the peer IPv4 address of **10.100.23.64**:

(config)**#ip crypto map NewMap 10 ipsec-manual**
(config-crypto-map)**#set peer 10.100.23.64**

set session-key

Use the **set session-key** command to define the encryption and authentication keys for this Internet Protocol version 4 (IPv4) crypto map. Use the **no** form of this command to remove defined encryption and authentication keys. Variations of this command include the following:

set session-key inbound ah <*SPI*> <*key*>
set session-key inbound esp <*SPI*> **authenticator** <*key*>
set session-key inbound esp <*SPI*> **cipher** <*key*>
set session-key inbound esp <*SPI*> **cipher** <*key*> **authenticator** <*key*>
set session-key outbound ah <*SPI*> <*key*>
set session-key outbound esp <*SPI*> **authenticator** <*key*>
set session-key outbound esp <*SPI*> **cipher** <*key*>
set session-key outbound esp <*SPI*> **cipher** <*key*> **authenticator** <*key*>

Syntax Description

inbound	Defines encryption keys for inbound traffic.
outbound	Defines encryption keys for outbound traffic.
ah <*SPI*>	Specifies Authentication Header (AH) Protocol and security parameter index (SPI).
esp <*SPI*>	Specifies Encapsulating Security Payload (ESP) Protocol and SPI.
cipher <*key*>	Optional. Specifies encryption/decryption key.
authenticator <*key*>	Optional. Specifies authentication key.

Default Values

No default values are necessary for this command.

Command History

Release 4.1	Command was introduced.

Functional Notes

The inbound local SPI must equal the outbound remote SPI. The outbound local SPI must equal the inbound remote SPI. The key values are the hexadecimal representations of the keys.

Refer to the following list for key length requirements.

Algorithm:	Minimum key length required:
DES	64 bits in length; 8 hexadecimal bytes
3DES	192 bits in length; 24 hexadecimal bytes
AES-128-CBC	128 bits in length; 16 hexadecimal bytes
AES-192-CBC	192 bits in length; 24 hexadecimal bytes
AES-256-CBC	256 bits in length; 32 hexadecimal bytes
MD5	128 bits in length; 16 hexadecimal bytes
SHA1	160 bits in length; 20 hexadecimal bytes

Usage Examples

The following example configures an AOS product for virtual private network (VPN) using IPv4 IPSec manual keys. This example assumes that the AOS product has been configured with a wide area network (WAN) IPv4 address of **63.97.45.57** on interface **ppp 1** and a local area network (LAN) IPv4 address of **10.10.10.254** on interface **ethernet 0/1**. The peer private IPv4 subnet is **10.10.20.0**.

Step 1:
Enter the Global Configuration mode (i.e., config terminal mode).

>**enable**
#configure terminal

Step 2:
Enable VPN support using the **ip crypto** command. This command allows crypto maps to be applied to interfaces, and enables the Internet key exchange (IKE) server to listen for IKE negotiation sessions on User Datagram Protocol (UDP) port 500.

(config)**#ip crypto**

Step 3:
Define the transform set. A transform set defines the encryption and/or authentication algorithms to be used to secure the data transmitted over the VPN tunnel. Multiple transform sets may be defined in a system. Once a transform set is defined, many different crypto maps within the system can reference it. In this example, a transform set named **highly_secure** has been created. This transform set defines ESP with authentication implemented using 3DES encryption and SHA1 authentication.

(config)**#ip crypto ipsec transform-set highly_secure esp-3des esp-sha-hmac**
(cfg-crypto-trans)**#mode tunnel**

Step 4:
Define an IP access control list (ACL). An extended ACL is used to specify which traffic needs to be sent securely over the VPN tunnel. The entries in the list are defined with respect to the local system. The source IP address will be the source of the traffic to be encrypted. The destination IP address will be the receiver of the data on the other side of the VPN tunnel.

(config)**#ip access-list extended corporate_traffic**
(config-ext-nacl)**#permit ip 10.10.10.0 0.0.0.255 10.10.20.0 0.0.0.255 log**
deny ip any any

Step 5:
Create crypto map and define manual keys. A crypto map is used to define a set of encryption schemes to be used for a given interface. A crypto map entry has a unique index within the crypto map set. The crypto map entry will specify whether IKE is used to generate encryption keys, or if manually specified keys will be used. The crypto map entry will also specify who will be terminating the VPN tunnel, as well as which transform set or sets will be used to encrypt and/or authenticate the traffic on that VPN tunnel. It also specifies the lifetime of all created IPSec security associations (SAs).

The keys for the algorithms defined in the transform set associated with the crypto map will be defined by using the **set session-key** command. A separate key is needed for both inbound and outbound traffic. The key format consists of a string of hexadecimal values without the leading **0x** for each character. For example, a cipher key of **this is my cipher key** would be entered as:

7468697320697320D7920636970686572206B6579.

A unique SPI is needed for both inbound and outbound traffic. The local system's inbound SPI and keys will be the peer's outbound SPI and keys. The local system's outbound SPI and keys will be the peer's inbound SPI and keys. In this example, the following keys and SPIs are used:

Inbound cipher SPI: 300 Inbound cipher key: "2te$#g89jnr(j!@4rvnfhg5e"

Outbound cipher SPI: 400 Outbound cipher key: "8564hgjelrign*&(gnb#1$d3"

Inbound authenticator key:"r5%^ughembkdhj34$x.<"

Outbound authenticator key:"io78*7gner#4(mgnsd!3"

(config)**#ip crypto map corporate_vpn 1 ipsec-ike**
(config-crypto-map)**#match address corporate_traffic**
(config-crypto-map)**#set peer 63.105.15.129**
(config-crypto-map)**#set transform-set highly_secure**
(config-crypto-map)**#set session-key inbound esp 300 cipher**
32746524236738396A6E72286A21403472766E6668673565 authenticator
7235255E756768656D626B64686A333424782E3C
(config-crypto-map)**#set session-key outbound esp 400 cipher**
3835363468676A656C7269676E2A2628676E622331246433 authenticator
696F37382A37676E65722334286D676E73642133

Step 6:
Configure public interface. This process includes configuring the IPv4 address for the interface and applying the appropriate crypto map to the interface. Crypto maps are applied to the interface on which encrypted traffic will be transmitted.

(config)**#interface ppp 1**
(config-ppp 1)**#ip address 63.97.45.57 255.255.255.248**
(config-ppp 1)**#ip crypto map corporate_vpn**
(config-ppp 1)**#no shutdown**

Step 7:
Configure private interface to allow all traffic destined for the VPN tunnel to be routed to the appropriate gateway.

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip address 10.10.10.254 255.255.255.0**
(config-eth 0/1)**#no shutdown**
(config-eth 0/1)**#exit**

set transform-set *<name>*

Use the **set transform-set** command to assign a transform set to an Internet Protocol version 4 (IPv4) crypto map. Use the **no** form of this command to remove assigned transform sets. Refer to *ip crypto ipsec transform-set <name> <parameters> on page 1352* for information on defining transform sets.

Syntax Description

<name>	Assigns a transform set to this crypto map by entering the set name.

Default Values

By default, no transform set is assigned to the crypto map.

Command History

Release 4.1	Command was introduced.

Functional Notes

Crypto map entries do not directly contain the transform configuration for securing data. Instead, the crypto map is associated with transform sets that contain specific security algorithms (refer to *ip crypto ipsec transform-set <name> <parameters> on page 1352*).

If no transform set is configured for a crypto map, then the entry is incomplete and will have no effect on the system. For manual key crypto maps, only one transform set can be specified.

Usage Examples

The following example first creates a transform set (**Set1**) consisting of two security algorithms (up to three may be defined), and then assigns the transform set to a crypto map (**Map1**):

(config)**#ip crypto ipsec transform-set Set1 esp-3des esp-sha-hmac**
(cfg-crypto-trans)**#exit**

(config)**#ip crypto map Map1 1 ipsec-manual**
(config-crypto-map)**#set transform-set Set1**

IPV6 CRYPTO MAP MANUAL COMMAND SET

To activate the Internet Protocol version 6 (IPv6) Crypto Map Manual mode, enter a valid version of the **ipv6 crypto map ipsec-manual** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ipv6 crypto map Map-Name 10 ipsec-manual
(config-crypto6-map)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83

All other commands for this command set are described in this section in alphabetical order.

match address ipv6 <name> on page 5255
set peer <ipv6 address> on page 5256
set session-key on page 5257
set transform-set <name> on page 5259

match address ipv6 <*name*>

Use the **match address ipv6** command to assign an Internet Protocol version 6 (IPv6) access control list (ACL) to a crypto map definition. The IPv6 ACL designates the IPv6 packets to be encrypted by this crypto map. Use the **no** form of this command to remove a defined IPv6 ACL. Refer to *ipv6 access-list extended <ipv6 acl name> on page 1500* for more information on creating ACLs.

Syntax Description

<name>	Specifies the name of the IPv6 ACL you wish to assign to this crypto map.

Default Values

By default, no IPv6 ACLs are defined.

Command History

Release 4.1	Command was introduced.
Release 10.7.0	Command was expanded to include the **ipv6** keyword and IPv6 support.

Functional Notes

IPv6 crypto map entries do not directly contain the selectors used to determine which data to secure. Instead, the crypto map entry refers to an IPv6 ACL. An ACL is assigned to the crypto map using the **match address** command. If no ACL is configured for a crypto map, then the entry is incomplete and will have no effect on the system.

For a complete list of all extended ACL configuration commands, refer to the IPv6 Access Control List Command Set on page 4296.

The entries of the IPv6 ACL used in a crypto map should be created with respect to traffic sent by the Adtran product. The source information must be the local Adtran product, and the destination must be the peer.

Only extended IPv6 ACLs can be used in crypto maps.

Usage Examples

The following example creates the IPv6 ACL (**NewList**) and applies it to the IPv6 crypto map **NewMap**:

(config)**#ipv6 access-list extended NewList**
(config-ext6-nacl)**#exit**
(config)**#ipv6 crypto map NewMap 10 ipsec-manual**
(config-crypto6-map)**#match address NewList**

set peer *<ipv6 address>*

Use the **set peer** command to set the Internet Protocol version 6 (IPv6) address of the peer device. Use the **no** form of this command to remove a peer device.

Syntax Description

<ipv6 address>	Specifies the IPv6 address of the peer device. IPv6 addresses should be expressed in colon hexadecimal format **X:X:X:X::X**, for example, **2001:DB8:1::1**.

Default Values

No default values are necessary for this command.

Command History

Release 4.1	Command was introduced.
Release R10.7.0	Command was expanded to include IPv6 support.

Functional Notes

If no peer IPv6 address is configured, the manual crypto map is not complete and not valid. A peer IPv6 address is required for manual crypto maps. To change the peer IPv6 address, the **no set peer** command must be issued first; then the new peer IPv6 address can be configured.

If the peer address is link-local, the interface is assumed to be the interface having the crypto map assigned, and is the destination to which the protected packet is routed.

Usage Examples

The following example creates a peer on the crypto map to use for IPsec tunneling:

(config)**#ipv6 crypto map MAP1 10 ipsec-manual**
(config-crypto6-map)**#set peer 2001:DB8:1::1**

set session-key

Use the **set session-key** command to define the encryption and authentication keys for this Internet Protocol version 6 (IPv6) crypto map. Use the **no** form of this command to remove defined encryption and authentication keys. Variations of this command include the following:

set session-key inbound ah <*SPI*> <*key*>
set session-key inbound esp <*SPI*> **authenticator** <*key*>
set session-key inbound esp <*SPI*> **cipher** <*key*>
set session-key inbound esp <*SPI*> **cipher** <*key*> **authenticator** <*key*>
set session-key outbound ah <*SPI*> <*key*>
set session-key outbound esp <*SPI*> **authenticator** <*key*>
set session-key outbound esp <*SPI*> **cipher** <*key*>
set session-key outbound esp <*SPI*> **cipher** <*key*> **authenticator** <*key*>

Syntax Description

inbound	Defines encryption keys for inbound traffic.
outbound	Defines encryption keys for outbound traffic.
ah <*SPI*>	Specifies Authentication Header (AH) Protocol and security parameter index (SPI). Valid SPI range is **256** to **4294967295**.
esp <*SPI*>	Specifies Encapsulating Security Payload (ESP) Protocol and SPI. Valid SPI range is **256** to **4294967295**.
cipher <*key*>	Optional. Specifies encryption/decryption key. Keys are specified in hexadecimal format without the leading **0x**.
authenticator <*key*>	Optional. Specifies authentication key. Keys are specified in hexadecimal format without the leading **0x**.

Default Values

No default values are necessary for this command.

Command History

Release 4.1	Command was introduced.
Release R10.7.0	Command was expanded to include IPv6 support.

Functional Notes

The inbound local SPI must equal the outbound remote SPI. The outbound local SPI must equal the inbound remote SPI. The key values are the hexadecimal representations of the keys.

Refer to the following list for key length requirements.

Algorithm:	Minimum key length required:
DES	64 bits in length; 8 hexadecimal bytes
3DES	192 bits in length; 24 hexadecimal bytes
AES-128-CBC	128 bits in length; 16 hexadecimal bytes
AES-192-CBC	192 bits in length; 24 hexadecimal bytes
AES-256-CBC	256 bits in length; 32 hexadecimal bytes
MD5	128 bits in length; 16 hexadecimal bytes
SHA1	160 bits in length; 20 hexadecimal bytes

Both the inbound and outbound keys must be set for the crypto map.

Usage Examples

The following example defines the inbound and outbound authentication and encryption keys for the IPv6 crypto map **MAP1**:

(config)**#ipv6 crypto map MAP1 10 ipsec-manual**
(config-crypto6-map)**#set session-key inbound esp 300 cipher**
32746524236738396A6E72286A21403472766E6668673565 authenticator
7235255E756768656D626B64686A333424782E3C
(config-crypto6-map)**#set session-key outbound esp 400 cipher**
3835363468676A656C7269676E2A2628676E622331246433 authenticator
696F37382A37676E65722334286D676E73642133

set transform-set *<name>*

Use the **set transform-set** command to assign a transform set to an Internet Protocol version 6 (IPv6) crypto map. Use the **no** form of this command to remove assigned transform sets. Refer to *ipv6 crypto ipsec transform-set <name> <parameters> on page 1505* for information on defining transform sets.

Syntax Description

<name>	Assigns a transform set to this crypto map by entering the set name.

Default Values

By default, no transform set is assigned to the crypto map.

Command History

Release 4.1	Command was introduced.
Release R10.7.0	Command was expanded to include IPv6 support.

Functional Notes

Crypto map entries do not directly contain the transform configuration for securing data. Instead, the crypto map is associated with transform sets that contain specific security algorithms (refer to *data-call on page 1254*).

If no transform set is configured for a crypto map, then the entry is incomplete and will have no effect on the system. For manual key crypto maps, only one transform set can be specified.

Usage Examples

The following example assigns the transform set **SET1** to crypto map **MAP1**:

(config)**#ipv6 crypto map MAP1 1 ipsec-manual**
(config-crypto6-map)**#set transform-set SET1**

IPSEC PROFILE COMMAND SET

The Internet Protocol Security (IPsec) Profile command set is used to configure a crypto IPsec profile to use in Dynamic Multipoint Virtual Private Network (DMVPN) configurations. This profile is used to simplify the configuration of VPN tunnels in a spoke-to-spoke or partial mesh DMVPN network by eliminating the need to define a crypto map entry and access control list (ACL) for each peer, as well as the traffic selectors in the ACLs for each remote or local network combination that requires IPsec protection. Instead, the profile provides protection to traffic traversing a tunnel interface by inferring a VPN peer address from the tunnel destination, the traffic selectors from the tunnel type, and the source and destination addresses of the tunnel interface. Once these parameters are known by the profile, protection is granted to traffic routed through the tunnel interface with the IPsec profile applied.

To activate the IPsec Profile Configuration mode, enter the **ip crypto ipsec profile** <*name*> command from the Global Configuration mode prompt as follows:

```
>enable
#configure terminal
(config)#ip crypto ipsec profile PROFILE1
(config-crypto-profile)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

description <text> on page 80
do on page 81
end on page 82
exit on page 83

All other commands for this command set are described in this section in alphabetical order.

antireplay <value> on page 5261
commit-bit on page 5262
ike-policy <number> on page 5263
rpf-check on page 5264
set pfs on page 5265
set security-association idle-time <value> on page 5266
set security-association lifetime on page 5267
set transform-set on page 5268

antireplay <*value*>

Use the **antireplay** command to enable anti-replay sequence number checking for all security associations (SAs) using this profile. Use the **no** form of this command to disable this feature. Variations of this command include:

antireplay
antireplay <*value*>

Syntax Description

<*value*>	Optional. Specifies the anti-replay window size in bytes. Select from **64**,**128**, **256**, **512**, or **1024** bytes.

Default Values

By default, the window size is set to **64** bytes.

Command History

Release 7.1	Command was introduced.
Release R11.9.0	Command was added to the IPsec Profile command set.

Functional Notes

When this setting is modified, all IPsec SAs created from this IPsec profile are deleted and delete payloads are sent to the peer(s) so that new IPsec SAs are negotiated using the modified setting.

Usage Examples

The following example enables anti-replay sequence checking for SAs using IPsec profile **PROFILE1** and sets the window size to **128** bytes:

(config)**#ip crypto ipsec profile PROFILE1**
(config-crypto-profile)**#antireplay 128**

commit-bit

Use the **commit-bit** command to set the commit-bit in the Internet Security Association and Key Management Protocol (ISAKMP) header when sending the second message of quick mode on an IPsec tunnel negotiation. This feature verifies that encrypted payloads are not received until an SA is completely established. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, the **commit-bit** will be used.

Command History

Release 12.1	Command was introduced.
Release R11.9.0	Command was added to the IPsec Profile command set.

Functional Notes

As an extra security measure, the commit-bit can be set by the responder of a quick mode negotiation to force the initiator to wait for the fourth message of quick mode before bringing up its IPsec security associations (SAs). By default, this feature is enabled on all AOS products with virtual private network (VPN) capabilities.

When this setting is modified, all IPsec SAs created from this IPsec profile are deleted and delete payloads are sent to the peer(s) so that new IPsec SAs are negotiated using the modified setting.

Usage Examples

The following example disables the use of commit-bit on the SAs associated with IPsec profile **PROFILE1**:

(config)**#ip crypto ipsec profile PROFILE1**
(config-crypto-profile)**#no commit-bit**

ike-policy *<number>*

Use the **ike-policy** command to ensure that only a specified Internet key exchange (IKE) policy is used to establish the IPsec tunnel for this profile. This prevents any mobile virtual private network (VPN) policies from using IPsec policies that are configured for static VPN peer policies. Use the **no** form of this command to remove a configured policy.

Syntax Description

<number>	Specifies the policy number of the policy to assign to this IPsec profile. Valid range is **1** to **10000**.

Default Values

By default, the IPsec profile is not assigned a specific IKE policy.

Command History

Release 6.1	Command was introduced.
Release R11.9.0	Command was added to the IPsec Profile command set.

Functional Notes

If an IKE policy is removed, references to that IKE policy in the IPsec profile must be removed manually to prevent an invalid configuration.

When this setting is modified, all IPsec SAs created from this IPsec profile are deleted and delete payloads are sent to the peer(s) so that new IPsec SAs are negotiated using the modified setting.

Usage Examples

The following example specifies that IPsec profile **PROFILE1** must use the IKE policy **100** to establish a tunnel:

(config)**#ip crypto ipsec profile PROFILE1**
(config-crypto-profile)**#ike-policy 100**

rpf-check

Use the **rpf-check** command to enable reverse path forward (RPF) checking on the IPsec profile. This check refuses traffic on the tunnel if the tunnel's source and destination indicate the source of the traffic can be reached through a different tunnel or interface. Use the **no** form of this command to disable RFP checking on the profile.

Syntax Description

No subcommands.

Default Values

By default, RPF checking is enabled on the profile.

Command History

Release R11.9.0	Command was introduced.

Functional Notes

When this setting is modified, all IPsec SAs created from this IPsec profile are deleted and delete payloads are sent to the peer(s) so that new IPsec SAs are negotiated using the modified setting.

Usage Examples

The following example disables RPF checking on the IPsec profile **PROFILE1**:

(config)**#ip crypto ipsec profile PROFILE1**
(config-crypto-profile)**#no rpf-check**

set pfs

Use the **set pfs** command to choose the type of perfect forward secrecy (PFS), if any, that will be required during the IPsec negotiation of security associations (SAs) for this IPsec profile. Use the **no** form of this command to return to the default setting. Variations of this command include:

set pfs group1
set pfs group2
set pfs group5

Syntax Description

group1	Requires IPsec to use Diffie-Hellman Group 1 (768-bit modulus) exchange during IPsec security association (SA) key generation.
group2	Requires IPsec to use Diffie-Hellman Group 2 (1024-bit modulus) exchange during IPsec SA key generation.
group5	Requires IPsec to use Diffie-Hellman Group 5 (1536-bit modulus) exchange during IPsec SA key generation.

Default Values

By default, no PFS will be used during IPsec SA key generation.

Command History

Release 4.1	Command was introduced.
Release 15.1	Command was expanded to include the **group5** parameter.
Release 17.6/A2.04	Command was expanded to include **legacy-peer** option.
Release R11.9.0	Command was added to the IPsec Profile command set. This command set does not support the **legacy-peer** option.

Functional Notes

If left at the default setting, no PFS will be used during IPsec SA key generation. If PFS is specified, then the specified Diffie-Hellman Group exchange will be used for the initial and all subsequent key generation, thus providing no data linkage between prior keys and future keys.

When this setting is modified, all IPsec SAs created from this IPsec profile are deleted and delete payloads are sent to the peer(s) so that new IPsec SAs are negotiated using the modified setting.

Usage Examples

The following example specifies use of the Diffie-Hellman Group 1 exchange during IPsec SA key generation on the profile:

(config)**#ip crypto ipsec profile PROFILE1**
(config-crypto-profile)**#set pfs group1**

set security-association idle-time *<value>*

Use the **set security-association idle-time** command to set the receive idle timeout in seconds. This is the maximum amount of time for which a security association (SA) pair associated with this IPsec profile can be idle. Once the timeout has occurred, the SA pair is removed. Use the **no** form of this command to disable the timeout feature.

Syntax Description

<value>	Specifies the idle timeout in seconds. Valid range is **20** to **1209600**.

Default Values

By default, the idle timeout is disabled.

Command History

Release 15.1	Command was introduced.
Release R11.9.0	Command was added to the IPsec Profile command set.

Functional Notes

When this setting is modified, all IPsec SAs created from this IPsec profile are deleted and delete payloads are sent to the peer(s) so that new IPsec SAs are negotiated using the modified setting.

Usage Examples

The following example sets the receive idle timeout for SA pairs associated with this profile to **60** seconds:

(config)**#ip crypto ipsec profile PROFILE1**
(config-crypto-profile)**#set security-association idle-time 60**

set security-association lifetime

Use the **set security-association lifetime** command to define the lifetime (in kilobytes and/or seconds) of the IPsec security associations (SAs) associated to this IPsec profile. Use the **no** form of this command to return to the default setting. Variations of this command include:

set security-association lifetime kilobytes <*value*>
set security-association lifetime seconds <*value*>

Syntax Description

kilobytes <*value*>	Specifies the SA lifetime limit in kilobytes. Valid range is **2560** to **536870911** kilobytes.
seconds <*value*>	Specifies the SA lifetime limit in seconds. Valid range is **120** to **1209600** seconds.

Default Values

By default, the **security-association lifetime** is set to **28800** seconds.

Command History

Release 4.1	Command was introduced.
Release R11.9.0	Command was added to the IPsec Profile command set.

Functional Notes

Values can be entered for this command in both kilobytes and seconds. Whichever limit is reached first will end the SA.

When this setting is modified, all IPsec SAs created from this IPsec profile are deleted and delete payloads are sent to the peer(s) so that new IPsec SAs are negotiated using the modified setting.

Usage Examples

The following example sets the SA lifetime to **300** kilobytes and 2 hours (**7200** seconds) for SAs associated with IPsec profile **PROFILE1**:

(config)**#ip crypto ipsec profile PROFILE1**
(config-crypto-profile)**#set security-association lifetime kilobytes 300**
(config-crypto-profile)**#set security-association lifetime seconds 7200**

set transform-set

Use the **set transform-set** command to assign up to six transform sets to the IPsec profile. Use the **no** form of this command to return to the default setting. Variations of this command include:

set transform-set *<name>*
set transform-set *<name> <name>*
set transform-set *<name> <name> <name>*
set transform-set *<name> <name> <name> <name>*
set transform-set *<name> <name> <name> <name> <name>*
set transform-set *<name> <name> <name> <name> <name> <name>*

Syntax Description

<name>	Assigns up to six transform sets to this IPsec profile by listing the set names, separated by a space.

Default Values

By default, there is no transform set assigned to the IPsec profile.

Command History

Release 4.1	Command was introduced.
Release R11.9.0	Command was added to the IPsec Profile command set.

Functional Notes

IPsec profiles do not directly contain the transform configuration for securing data. Instead, the profile is associated with transform sets that contain specific security algorithms (refer to the command *ip crypto ipsec transform-set <name> <parameters> on page 1352* for information about configuring transform sets). The parameters defined in one or more of the transform sets' peer(s) must match.

If no transform set is configured for an IPsec profile, then the profile is incomplete and will not function. This setting is required for an IPsec profile to operate.

When this setting is modified, all IPsec SAs created from this IPsec profile are deleted and delete payloads are sent to the peer(s) so that new IPsec SAs are negotiated using the modified setting.

Usage Examples

The following example assigns the transform set **SET1** to the IPsec profile **PROFILE1**:

(config)**#ip crypto ipsec profile PROFILE1**
(config-crypto-profile)**#set transform-set SET1**

IKE COMMAND SETS

This section includes the following command sets:

IKE CLIENT COMMAND SET

To activate the Internet Key Exchange (IKE) Client mode, enter the **crypto ike client** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#crypto ike client configuration pool ConfigPool1
(config-ike-client-pool)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

dns-server on page 5271
ip-range <start ip address> <end ip address> on page 5272
netbios-name-server <ip address> <secondary> on page 5273

dns-server

Use the **dns-server** command to specify the default primary and secondary domain naming system (DNS) servers to use for the Dynamic Host Configuration Protocol (DHCP) client. Use the **no** form of this command to remove the configured DNS server. Variations of this command include:

dns-server <*ip address*>
dns-server <*ip address*> <*secondary*>

Syntax Description

<*ip address*>	Specifies the IP address of the preferred DNS server on the network.
<*secondary*>	Optional. Specifies the IP address of the second preferred DNS server on the network. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, there are no specified default DNS servers.

Command History

Release 2.1	Command was introduced.
Release 4.1	Command was expanded to include the Internet key exchange (IKE) client configuration pool.

Usage Examples

The following example specifies a default DNS server with address **192.72.3.254** and a secondary DNS server with address **192.100.4.253**:

(config)**#crypto ike client configuration pool ConfigPool1**
(config-ike-client-pool)**#dns-server 192.72.3.254 192.100.4.253**

ip-range *<start ip address> <end ip address>*

Use the **ip-range** command to specify the range of addresses from which the router draws when assigning an IP address to a client. Use the **no** form of this command to remove defined IP ranges.

Syntax Description

<start ip address>	Specifies the first IP address in the range for this pool.
<end ip address>	Specifies the last IP address in the range for this pool. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no IP address range is defined.

Command History

Release 4.1	Command was introduced.

Usage Examples

The following example defines an IP address range for this configuration pool:

(config)**#crypto ike client configuration pool ConfigPool1**
(config-ike-client-pool)**#ip-range 172.1.1.1 172.1.1.25**

netbios-name-server *<ip address> <secondary>*

Use the **netbios-name-server** command to specify the network basic input/output system (NetBIOS) Windows Internet Naming Service (WINS) name servers to assign to a client. Use the **no** form of this command to remove assigned name servers. Variations of this command include:

netbios-name-server *<ip address>*
netbios-name-server *<ip address> <secondary>*

Syntax Description

<ip address>	Specifies the primary WINS server IP address to assign.
<secondary>	Optional. Specifies the secondary WINS server IP address to assign.

Default Values

By default, no WINS server address is defined.

Command History

Release 4.1	Command was introduced.

Usage Examples

The following example defines two WINS server addresses for this configuration pool:

(config)**#crypto ike client configuration pool ConfigPool1**
(config-ike-client-pool)**#netbios-name-server 172.1.17.1 172.1.17.25**

IKE POLICY ATTRIBUTES COMMAND SET

To activate the Internet Key Exchange (IKE) Policy Attributes mode, enter the **attribute** command at the IKE Policy prompt. For example:

```
>enable
#configure terminal
(config)#crypto ike policy 1
(config-ike)#attribute 10
(config-ike-attribute)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

authentication on page 5275
encryption on page 5276
group on page 5277
hash on page 5278
lifetime <value> on page 5279

authentication

Use the **authentication** command to configure this Internet key exchange (IKE) policy's use of preshared secrets and signed certificates during IKE negotiation. Use the **no** form of this command to disable this feature. Variations of this command include:

authentication dss-sig
authentication pre-share
authentication rsa-sig

Syntax Description

dss-sig	Specifies to use DSS-signed certificates during IKE negotiation to validate the peer.
pre-share	Specifies the use of preshared secrets during IKE negotiation to validate the peer.
rsa-sig	Specifies to use RSA-signed certificates during IKE negotiation to validate the peer.

Default Values

By default, authentication is set to **pre-share**.

Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the signed certificates.

Functional Notes

Both sides must share the same preshared secret in order for the negotiation to be successful.

Usage Examples

The following example enables preshared secrets for this IKE policy:

(config-ike)**#attribute 10**
(config-ike-attribute)**#authentication pre-share**

encryption

Use the **encryption** command to specify which encryption algorithm this Internet key exchange (IKE) policy will use to transmit data over the IKE-generated security association (SA). Use the **no** form of this command to return to the default value. Variations of this command include:

encryption aes-128-cbc
encryption aes-192-cbc
encryption aes-256-cbc
encryption des
encryption 3des

Syntax Description

aes-128-cbc	Specifies the AES-128-CBC encryption algorithm.
aes-192-cbc	Specifies the AES-192-CBC encryption algorithm.
aes-256-cbc	Specifies the AES-256-CBC encryption algorithm.
des	Specifies the DES encryption algorithm.
3des	Specifies the 3DES encryption algorithm.

Default Values

By default, encryption is set to **DES**.

Command History

Release 4.1	Command was introduced.

Usage Examples

The following example selects **3DES** as the encryption algorithm for this IKE policy:

(config-ike)**#attribute 10**
(config-ike-attribute)**#encryption 3des**

group

Use the **group** command to specify the Diffie-Hellman Group (1, 2, or 5) to be used by this Internet key exchange (IKE) policy to generate the keys (which are then used to create the IPSec security association (SA)). Use the **no** form of this command to return to the default setting. Variations of this command include:

group 1
group 2
group 5

Syntax Description

1	Requires the IKE policy to use Diffie-Hellman Group 1 (768-bit modulus) exchange during IPSec SA key generation.
2	Requires the IKE policy to use Diffie-Hellman Group 2 (1024-bit modulus) exchange during IPSec SA key generation.
5	Requires the IKE policy to use Diffie-Hellman Group 5 (1536-bit modulus) exchange during IPSec SA key generation.

Default Values

By default, group is set to **1**.

Command History

Release 4.1	Command was introduced.
Release 15.1	Command was expanded to include the **group 5** parameter.

Functional Notes

The local IKE policy and the peer IKE policy must have matching group settings in order for negotiation to be successful.

Usage Examples

The following example sets this IKE policy to use Diffie-Hellman Group **2**:

(config-ike)**#attribute 10**
(config-ike-attribute)**#group 2**

hash

Use the **hash** command to specify the hash algorithm to be used to authenticate the data transmitted over the Internet key exchange (IKE) security association (SA). Use the **no** form of this command to return to the default setting. Variations of this command include:

hash md5
hash sha

Syntax Description

md5	Choose the message digest 5 (MD5) hash algorithm.
sha	Choose the SHA hash algorithm.

Default Values

By default, hash is set to **sha**.

Command History

Release 4.1	Command was introduced.

Usage Examples

The following example specifies **md5** as the hash algorithm:

(config-ike)**#attribute 10**
(config-ike-attribute)**#hash md5**

lifetime <*value*>

Use the **lifetime** command to specify how long an Internet key exchange (IKE) security association (SA) is valid before expiring. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specify how many seconds an IKE SA will last before expiring. The valid range is **60** to **1209600**.

Default Values

By default, **lifetime** is set to **28800** seconds.

Command History

Release 4.1	Command was introduced.

Usage Examples

The following example sets a lifetime of two hours:

(config-ike)**#attribute 10**
(config-ike-attribute)**#lifetime 7200**

IKE POLICY COMMAND SET

To activate the Internet Key Exchange (IKE) Policy mode, enter the **crypto ike policy** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#crypto ike policy 1
(config-ike)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

attribute <number> on page 5281
client authentication host on page 5282
client authentication host xauth-type on page 5283
client authentication server list <listname> on page 5284
client configuration pool <name> on page 5285
initiate on page 5286
local-id on page 5287
nat-traversal on page 5289
peer on page 5290
respond on page 5292

attribute *<number>*

Use the **attribute** command to define attributes for the associated Internet key exchange (IKE) policy. Multiple attributes can be created for a single IKE policy. Once you enter this command, you are in the IKE Policy Attribute mode. Refer to *IKE Policy Attributes Command Set on page 5274* for more information. Use the **no** form of this command to remove a defined attribute.

Syntax Description

<number>	Assigns a number (range: **1** to **65535**) to the attribute policy. The number is the attribute's priority number and specifies the order in which the resulting virtual private network (VPN) proposals get sent to the far end. This command takes you to the (config-ike-attribute)# prompt. From here, you can configure the settings for the attribute as outlined in the section *IKE Policy Attributes Command Set on page 5274*.

Default Values

By default, no **attribute** is defined.

Command History

Release 4.1	Command was introduced.

Functional Notes

Multiple attributes on an IKE policy are ordered by number (with the lowest number representing the highest priority).

Usage Examples

The following example defines a policy attribute (**10**) and takes you into the IKE policy attributes:

```
(config)#crypto ike policy 1
(config-ike)#attribute 10
(config-ike-attribute)#
```

client authentication host

Use the **client authentication host** command to enable the unit to act as an Xauth host when this Internet key exchange (IKE) policy is negotiated with a peer. Use the **no** form of this command to disable this feature. Variations of this command include the following:

client authentication host username <*username*>
client authentication host username <*username*> **password** <*password*>
client authentication host username <*username*> **password** <*password*> **passphrase** <*phrase*>

Syntax Description

password <*password*>	Specifies the value sent via Xauth as the password.
username <*username*>	Specifies the value sent via Xauth as the user name.
passphrase <*phrase*>	Optional. Specifies the value sent via Xauth as the passphrase. This is only used with authentication type one time password (OTP).

Default Values

By default, if this command is not present in the IKE policy, the unit does not act as an Xauth host.

Command History

Release 5.1	Command was introduced.

Functional Notes

The specified credentials are programmed into the unit, and there is no prompt for entering values real time. Therefore, schemes requiring real-time input or additional responses (e.g., SecureID) are not supported. The **client authentication host** and the **client authentication server** commands are mutually exclusive. Refer to *client authentication server list <listname> on page 5284* for more information.

Usage Examples

The following example specifies the login credentials to be sent:

(config)**#crypto ike policy 1**
(config-ike)**#client authentication host username jsmith password password1 passphrase phrase**

client authentication host xauth-type

Use the **client authentication host xauth-type** command to allow the user to specify the Xauth authentication type if a type other than **generic** is desired. Use the **no** form of this command to return to the default setting. Variations of this command include:

client authentication host xauth-type generic
client authentication host xauth-type otp
client authentication host xauth-type radius

Syntax Description

generic	Specifies generic authentication type.
otp	Specifies one time password (OTP) authentication type.
radius	Specifies remote authentication dial-in user service (RADIUS) authentication type.

Default Values

By default, authentication is set to **generic**.

Command History

Release 5.1	Command was introduced.

Functional Notes

This command is used along with the **client authentication host username**. Refer to *client configuration pool <name> on page 5285* for more information. When acting as an Xauth host, this command allows the user to specify the Xauth authentication type if a type other than generic is desired.

Usage Examples

The following example sets the Xauth type to **radius**:

(config)**#crypto ike policy 1**
(config-ike)**#client authentication host xauth-type radius**

client authentication server list <*listname*>

Use the **client authentication server list** command to specify an authentication, authorization, and accounting (AAA) authentication method list to be used in the Internet key exchange (IKE) policy. AAA must be enabled to use this command (refer to the command *aaa on on page 1187*). Use the **no** form of this command to remove the authentication list from the policy. Variations of this command include:

client authentication server list default
client authentication server list <*listname*>

Syntax Description

default	Specifies the default AAA authentication method list is applied in the IKE policy.
<*listname*>	Specifies the named AAA authentication method list is applied in the IKE policy.

Default Values

By default, no AAA authentication method list is applied to the IKE policy and extended authentication is not performed.

Command History

Release 5.1	Command was introduced.

Functional Notes

When this IKE policy is negotiated and the peer has indicated Xauth via the IKE authentication method and/or the Xauth vendor ID, this command allows the unit to perform as an Xauth server (edge device). The specified AAA authentication method list is used to identify the location of the user authentication database.

The AAA authentication method list used by the IKE policy is most often the AAA login authentication method list. For more information about configuring these lists, refer to the command *aaa authentication login on page 1169*.

For more information about configuring AAA in your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the AAA authentication method list **AuthList1** is used in the IKE policy for extended authentication:

(config)**#crypto ike policy 1**
(config-ike)**#client authentication server list AuthList1**

client configuration pool <*name*>

Use the **client configuration pool** command to configure AOS to perform as mode-config server (edge device) when an Internet key exchange (IKE) policy is negotiated. Use the **no** form of this command to return to the default setting. Variations of this command include the following:

client configuration pool <*name*>
client configuration pool <*name*> **initiate**
client configuration pool <*name*> **initiate respond**
client configuration pool <*name*> **respond**
client configuration pool <*name*> **respond initiate**

Syntax Description

<*name*>	Specifies the pool from which to obtain parameters to assign to the client.
initiate	Enables set/ack (push) mode.
respond	Enables request/response mode.

Default Values

By default, if this command is not present in the IKE policy, the Adtran device allocates mode-config IP addresses, domain naming system (DNS) server addresses, and network basic input/output system (NetBIOS) name server addresses, and mode-config is not performed.

Command History

Release 4.1	Command was introduced.

Functional Notes

This command ties an existing client configuration pool to an IKE policy.

By using the **initiate** and **respond** commands, you can configure the IKE policy to initiate and respond, initiate only, or respond only. It is an error if you have both **initiate** and **respond** disabled.

Usage Examples

The following example ties the **ConfigPool1** configuration pool to this IKE policy:

(config)**#crypto ike policy 1**
(config-ike)**#client configuration pool ConfigPool1**

initiate

Use the **initiate** command to allow the Internet key exchange (IKE) policy to initiate negotiation (in main mode or aggressive mode) with peers. Use the **no** form of this command to allow the policy to respond only. Variations of this command include:

initiate aggressive
initiate main

Syntax Description

aggressive	Specifies to initiate using aggressive mode. Aggressive mode can be used when one end of the virtual private network (VPN) tunnel has a dynamically assigned address. The side with the dynamic address must be the initiator of the traffic and tunnel. The side with the static address must be the responder.
main	Specifies to initiate using main mode. Main mode requires that each end of the VPN tunnel has a static wide area network (WAN) IP address. Main mode is more secure than aggressive mode because more of the main mode negotiations are encrypted.

Default Values

By default, the **main** initiation mode is enabled.

Command History

Release 4.1	Command was introduced.

Functional Notes

By using the **initiate** and **respond** commands, you can configure the IKE policy to initiate and respond, initiate only, or respond only. It is an error if you have both **initiate** and **respond** disabled.

Usage Examples

The following example enables the AOS device to initiate IKE negotiation in main mode:

(config)**#crypto ike policy 1**
(config-ike)**#initiate main**

local-id

Use the **local-id** command to set the local ID for the Internet key exchange (IKE) policy. This setting overrides the system local ID setting (set in the Global Configuration mode using the **crypto ike local-id address** command). Use the **no** form of this command to remove a local ID. Variations of this command include:

local-id address <*ip address*>
local-id asn1-dn <*name*>
local-id fqdn <*name*>
local-id user-fqdn <*name*>

Syntax Description

address <*ip address*>	Specifies a remote IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
asn1-dn <*name*>	Specifies an abstract syntax notation distinguished name as the remote ID (enter this value in Lightweight Directory Access Protocol (LDAP) format).
fqdn <*name*>	Specifies a fully qualified domain name (FQDN) (e.g., **adtran.com**) as the remote ID.
user-fqdn <*name*>	Specifies a user FQDN or email address (e.g., **user1@adtran.com**) as the remote ID.

Default Values

By default, the local ID is not defined.

Command History

Release 4.1	Command was introduced.

Functional Notes

The local ID for a particular IKE policy can be set in two ways. The first (default) method is done in the Global Configuration mode:

(config)**#crypto ike local-id address**

This command, which by default is executed on startup, makes the local ID of an IKE policy equal to the IPv4 address of the interface on which an IKE negotiation is occurring. This is particularly useful for products that could have multiple public interfaces.

The second method is to use the IKE policy command:

(config)**#crypto ike policy 1**
(config-ike)**#local-id [address | asn1-dn | fqdn | user-fqdn]** <*ip address or name*>

This policy-specific command allows you to manually set the local ID for an IKE policy on a per-policy basis. You can use both methods simultaneously in the product. Several IKE policies can be created, some of which use the default system setting of the IPv4 address of the public interface. Others can be set to override this system setting and manually configure a local ID specific to those policies. When a new IKE policy is created, they default to **no local-id**. This allows the system local ID setting to be applied to the policy.

Usage Examples

The following example sets the local ID of this IKE policy to the IPv4 address **63.97.45.57**:

(config)**#crypto ike policy 1**
(config-ike)**#local-id address 63.97.45.57**

nat-traversal

Use the **nat-traversal** command to allow, force, or disable network address translation (NAT) traversal versions 1 and 2 on a specific Internet key exchange (IKE) policy. Use the **no** form of this command to disable this feature. Variations of this command include:

nat-traversal v1 allow
nat-traversal v1 disable
nat-traversal v1 force
nat-traversal v2 allow
nat-traversal v2 disable
nat-traversal v2 force

Syntax Description

v1	Specifies NAT traversal version 1.
v2	Specifies NAT traversal version 2.
allow	Sets the IKE policy to allow the specified NAT traversal version.
disable	Sets the IKE policy to disable the specified NAT traversal version.
force	Sets the IKE policy to force the specified NAT traversal version.

Default Values

The default values for this command are **nat-traversal v1 allow** and **nat-traversal v2 allow**.

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example disables version **2** on IKE policy **1**:

(config)**#crypto ike policy 1**
(config-ike)**#nat-traversal v2 disable**

peer

Use the **peer** command to enter the IP address of the peer device. Repeat this command for multiple peers. Use the **any** keyword if you want to set up a policy that will initiate or respond to any peer. Use the **no** form of this command to remove a peer device. Variations of this command include:

peer <*ip address*>
peer any

Syntax Description

<*ip address*>	Specifies a peer IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
any	Allows any peer to connect to this Internet key exchange (IKE) policy.

Default Values

No default values are necessary for this command.

Command History

Release 4.1	Command was introduced.

Functional Notes

An IKE policy is incomplete unless one of the peer commands is specified. Only one IKE policy can be configured with **peer any**.

Usage Examples

The following example sets multiple peers on an IKE policy for an initiate-and-respond policy using preshared secret, DES, message digest 5(MD5), and Diffie-Hellman Group 1:

(config)**#crypto ike policy 1**
(config-ike)**#peer 63.97.45.57**
(config-ike)**#peer 63.105.15.129**
(config-ike)**#peer 192.168.1.3**
(config-ike)**#respond anymode**
(config-ike)**#initiate main**

The following example sets up a policy allowing any peer to initiate using preshared secret, DES, MD5, and Diffie-Hellman Group 1.

(config)**#crypto ike policy 1**
(config-ike)**#peer any**
(config-ike)**#respond anymode**
(config-ike)**#initiate main**

Technology Review

IKE policies must have a peer address associated with them to allow certain peers to negotiate with the Adtran product. This is a problem when you have roaming users (those who obtain their IP address using Dynamic Host Configuration Protocol (DHCP) or some other dynamic means). To allow for roaming users, the IKE policy can be set up with **peer any** to allow any peer to negotiate with the Adtran product. There can only be one **peer any** policy in the running configuration.

respond

Use the **respond** command to allow the Internet key exchange (IKE) policy to respond to negotiations by a peer. Use the **no** form of this command to allow the policy to only initiate negotiations. Variations of this command include:

respond aggressive
respond anymode
respond main

Syntax Description

aggressive	Specifies to respond only to aggressive mode.
anymode	Specifies to respond to any mode.
main	Specifies to respond only to main mode.

Default Values

By default, respond to any mode is enabled.

Command History

Release 4.1	Command was introduced.

Functional Notes

By using the **initiate** and **respond** commands, you can configure the IKE policy to initiate and respond, initiate only, or respond only. It is an error if you have both **initiate** and **respond** disabled.

Usage Examples

The following example configures the router to initiate and respond to IKE negotiations:

(config)**#crypto ike policy 1**
(config-ike)**#respond anymode**
