This command only creates an empty hardware ACL, it does not configure it. For additional IP hardware ACL configuration commands and configuration parameters, refer to the *Hardware ACL and Access Map Command Set on page 4235* or the *Hardware ACLs in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example creates an IP hardware ACL **Trusted** and enters the IP hardware ACL configuration mode:

```
(config)#ip hw-access-list extended Trusted
        Configuring New IP Hardware Extended ACL "Trusted"
(config-ext-ip-hw-nacl)#
```

Technology Review

Hardware ACLs are used as traffic selectors by the hardware access maps; by themselves they do nothing. Hardware ACLs are composed of an ordered list of entries with an implicit **deny any** at the end of each list. A hardware ACL with no entries includes an implicit **permit any**. An ACL entry contains two parts: an action (**permit** or **deny**) and a frame pattern. A **permit** ACL matches frames (meeting the specified pattern) and allows them to enter the router system. A **deny** ACL advances AOS to the next access list entry.

ACL criteria are compared to the incoming frame in the order in which they were entered or from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Changing hardware ACL or hardware access map configuration or application causes new information to be reinstalled on the hardware. It is possible to run out of hardware resources depending on how many resources are needed to apply the desired change. If there are not enough hardware resources to install the new criteria in the hardware, an error message is displayed. You can view the amount of hardware resources available using the command *show hw-filter-resource on page 672*.

ip igmp join <*ip address*>

Use the **ip igmp join** command to instruct the router stack to join a specific group. The stack may join multiple groups. Use the **no** form of this command to disable this feature.

Syntax Description

<*ip address*>	Specifies the IP address of a multicast group. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

No default values are necessary for this command.

Command History

Release 7.1	Command was introduced.

Functional Notes

This command aids in debugging, allowing the router's IP stack to connect to and respond on a multicast group. The local stack operates as an Internet Control Messaging Protocol (ICMP) host on the attached segment. In multicast stub applications, the global helper address takes care of forwarding IGMP joins/responses on the upstream interface. The router may respond to ICMP echo requests for the joined groups.

Usage Examples

The following example configures the unit to join with the specified multicast group:

(config)**#ip igmp join 172.0.1.50**

ip igmp snooping

Use the **ip igmp snooping** command to globally enable Internet Group Management Protocol (IGMP) snooping. Use the **no** form of this command to disable global IGMP snooping.

Syntax Description

No subcommands.

Default Values

By default, IGMP snooping is disabled.

Command History

Release 12.1	Command was introduced.
Release R10.10.0	Command was removed from the 1234 (2nd Generation), 1234P (2nd Generation), 1238 (2nd Generation), 1238P (2nd Generation), 1534 (2nd Generation), 1534P (2nd Generation), 1535, 1535P, 1544 (2nd Generation), 1544P (2nd Generation), 1638, and 1638P.

Functional Notes

IGMP snooping is a method of preventing switches from flooding all ports with received multicast streams. By monitoring the conversations between a host and a router, the switch can determine which multicast streams will interest a host and load its own forwarding tables to take advantage of that knowledge. When the host sends a leave message to the router, the switch removes the entries after a timeout period.

On the 1534 (1st Generation), 1234 (1st Generation), 1238 (1st Generation), and 1335 platforms, global IGMP snooping must be enabled in order to enable virtual local area network (VLAN) IGMP snooping.

Usage Examples

The following example globally enables IGMP snooping:

(config)**#ip igmp snooping**

ip igmp snooping flood-unknown

Use the **ip igmp flood-unkown** to enable flooding of VLAN ports for unknown multicast frames. Use the **no** form of this command to disable global IGMP snooping.

Syntax Description

No subcommands.

Default Values

By default, flooding of unkown multicast frames is disabled.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example globally enables IGMP snooping:

(config)**#ip igmp snooping**

ip igmp snooping immediate-leave vlan <*vlan id*>

Use the **ip igmp snooping immediate-leave vlan** command to enable the immediate leave setting of Internet Group Management Protocol (IGMP) snooping on the specified virtual local area network (VLAN). With immediate leave enabled, the AOS device immediately removes a port from the IP multicasting group after detecting an IGMP leave message on that port. To enable the immediate leave setting, you must first enable IGMP snooping on the VLAN using the command *ip igmp snooping on page 1407*. Use the **no** form of this command to disable VLAN IGMP snooping.

Syntax Description

<*vlan id*>	Specifies a valid VLAN interface ID. Range is **1** to **4095**.

Default Values

By default, VLAN IGMP immediate leave is disabled.

Command History

Release R 11.5.0	Command was introduced.

Functional Notes

When a host sends a leave group message, a multicast router sends a group-specific query to determine if any other hosts respond on that port. If no response is received and the query times out, the AOS device removes the port from the IP multicasting group. The immediate leave setting, allows the AOS device to remove the port without waiting for the query to time out.

Usage Examples

The following example enables IGMP immediate leave on VLAN 1:

(config)**#ip igmp snooping immediate-leave vlan 1**

ip igmp snooping querier vlan *<vlan id> <source address>*

Use the **ip igmp snooping querier vlan** command to enable the Internet Group Management Protocol (IGMP) snooping querier on the specified VLAN . Use the **no** form of this command to disable this feature.

Syntax Description

<vlan id>	Specifies a valid VLAN interface ID on which the querier will be enabled. Range is **1** to **4094**.
<source address>	Specifies the source address used for IGMP query packets.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Functional Notes

IGMP snooping requires the presence of an IGMP querier in order to function properly. This roll is normally played by a multicast router on the local network. However, in cases where a Layer 3 switch is deployed, the switch itself may be the unicast router and a multicast router may not be present. When no multicast router exists in the VLAN to originate the queries, an IGMP snooping querier must be configured to send membership queries. When enabled, the IGMP querier will send general IGMPv2 queries every 125 seconds.

Usage Examples

The following example enables the IGMP snooping querier on VLAN ID **1** with a source address of **10.10.10.1**:

(config)**#ip igmp snooping querier vlan 1 10.10.10.1**

ip igmp snooping querier period <*seconds*>

Use the **ip igmp snooping querier period** command to set the interval at which the Internet Group Management Protocol (IGMP) snooping querier will send out IGMPv2 snooping queries. Use the **no** form of this command to disable this feature.

Syntax Description

<*seconds*>	Specifies the number of seconds between sent queries. Range is **10** to **1000** seconds.

Default Values

By default, the querier period is **125** seconds.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

IGMP snooping requires the presence of an IGMP querier in order to function. This roll is normally played by a multicast router on the local network. However, in cases where a Layer 3 switch is deployed, the switch itself may be the unicast router and a multicast router may not be present. When no multicast router exists in the VLAN to originate the queries, an IGMP snooping querier must be configured to send membership queries. When enabled, the IGMP querier will send general IGMPv2 queries every 125 seconds.

Usage Examples

The following example specifies a **10** seconds IGMP snooping querier period:

(config)**#ip igmp snooping querier period 10**

ip igmp snooping vlan *<vlan id>*

Use the **ip igmp snooping vlan** command to enable Internet Group Management Protocol (IGMP) snooping on the specified virtual local area network (VLAN). Use the **no** form of this command to disable VLAN IGMP snooping.

Syntax Description

<vlan id>	Specifies a valid VLAN interface ID. Range is **1** to **4095**.

Default Values

By default, VLAN IGMP snooping is disabled on all platforms. However, enabling global IGMP snooping on the 1534 (1st Generation), 1234 (1st Generation), 1238 (1st Generation), and 1335 platformsalso enables VLAN IGMP snooping.

Command History

Release 12.1	Command was introduced.

Functional Notes

IGMP snooping is a method of preventing switches from flooding all ports with received multicast streams. By monitoring the conversations between a host and a router, the switch can determine which multicast streams will interest a host and load its own forwarding tables to take advantage of that knowledge. When the host sends a leave message to the router, the switch removes the entries after a timeout period.

On the 1534 (1st Generation), 1234 (1st Generation), 1238 (1st Generation), and 1335 platforms, global IGMP snooping must be enabled in order to enable virtual local area network (VLAN) IGMP snooping.

Usage Examples

The following example enables IGMP snooping on VLAN 1:

(config)**#ip igmp snooping vlan 1**

ip igmp snooping vlan <*vlan id*> mrouter interface <*interface*>

Use the **ip igmp snooping vlan mrouter interface** command to add a static connection to a multicast router. Use the **no** form of this command to remove a static connection to a multicast router.

Syntax Description

<*vlan id*>	Specifies a valid VLAN interface ID. Range is **1** to **4094**.
<*interface*>	Specifies an interface to be added to the multicast router. Specify an interface in the format <*interface type [slot/port* | *slot/port.subinterface id* | *interface id* | *interface id.subinterface id* | *ap* | *ap/radio* | *ap/radio.vap]*>. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip igmp snooping vlan** <*vlan id*> **mrouter interface ?** for a complete list of applicable interfaces.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.
Release R11.7.0	Command was expanded to include the 10 gigabit switchport interface.

Usage Examples

The following example adds Ethernet interface 0/1 to the list of multicast router interfaces:

(config)**#ip igmp snooping vlan 1 mrouter interface ethernet 0/1**

ip igmp snooping vlan <*vlan id*> static <*mac address*> interface <*interface*>

Use the **ip igmp snooping vlan static interface** command to statically configure a Layer 2 interface as a member of a multicast group. Use the **no** form of this command to remove a Layer 2 interface from a multicast group.

Syntax Description

<*vlan id*>	Specifies the VLAN ID of the multicast group. Range is **1** to **4094**.
<*mac address*>	Specifies the group's 48-bit medium access control (MAC) address. MAC addresses should be expressed in the following format xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).
<*interface*>	Specifies an interface identification for the member interface. Specify an interface in the format <*interface type [slot/port* | *slot/port.subinterface id* | *interface id* | *interface id.subinterface id* | *ap* | *ap/radio* | *ap/radio.vap]*>. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip igmp snooping vlan** <*vlan id*> **static** <*mac address*> **interface ?** for a complete list of applicable interfaces.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Functional Notes

There are two types of multicast addresses: MAC addresses and IP addresses. A multicast IP address is a Class D address (**224.0.0.0** to **239.255.255.255**). These addresses are also referred to as group destination addresses (GDAs). Each GDA has an associated multicast MAC address. A multicast MAC address is formed by using the prefix 01-00-5e followed by the last 23 bits of the GDA. The <*mac address*> specified in this command must be a multicast MAC address. The following table shows examples of multicast MAC addresses.

Multicast Addresses

Multicast IP Address	Multicast MAC Address
226.10.10.10	01-00-5e-0a-0a-0a
228.20.20.20	01-00-5e-14-14-14
230.30.30.30	01-00-5e-1e-1e-1e

This mapping of IP addresses is a many-to-one relationship. For example, 226.10.10.10 maps to the same MAC address as 227.10.10.10. The entire Class D network is not available for multicast. The following table shows the reserved addresses.

Reserved Multicast IP Addresses

224.0.0.1	All Multicast-capable hosts
224.0.0.2	All Multicast-capable routers
224.0.0.5 and 224.0.0.6	Reserved for OSPF
224.0.0.1 to 224.0.0.255	Generally reserved for various protocols

Usage Examples

The following example configures the Ethernet interface 0/1 as a member of the multicast group with multicast MAC address **01:00:5E:01:01:01**:

(config)**#ip igmp snooping vlan 1 static 01:00:5E:01:01:01 interface ethernet 0/1**

ip load-sharing

Use the **ip load-sharing** command to configure whether parallel routes in the route table are used to load-share forwarded packets. If this command is disabled, the route table uses a single “best” route for a given subnet. If this command is enabled, the route table can use multiple “best” routes and alternate between them. Use the **no** form of this command to disable this feature. Variations of this command include:

ip load-sharing per-destination
ip load-sharing per-packet

Syntax Description

per-destination	Specifies that the route used for forwarding a packet be based on a hash of the source and destination IP address in the packet.
per-packet	Specifies that each forwarding route lookup rotates through all the parallel “best” routes. (Parallel routes are defined as routes to the same subnet with the same metrics that only differ by their next-hop address.)

Default Values

By default, ip load-sharing is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example turns on load-sharing per destination:

(config)**#ip load-sharing per-destination**

The following example disables load-sharing:

(config)**#no ip load-sharing**

ip local policy route-map <*name*>

Use the **ip local policy route-map** command to specify a route map for local policy routing on the device. This setting is applied to the local network interface. It can be further specified to a specific virtual routing and forwarding (VRF) by adding the VRF name. Use the **no** form of this command to return to the default route map. Variations of this command include:

ip local policy route-map <*name*>
ip local policy route-map <*name*> **vrf** <*name*>

Syntax Description

<*name*>	Specify the name of the route map.
vrf <*name*>	Optional. Specifies a nondefault VRF on which to define the local policy route map.

Default Values

By default, this command is disabled.

Command History

Release 11.1	Command was introduced.
Release 16.1	Command was expanded to include the **vrf** parameter.

Functional Notes

Before a route map can be specified, it must first be defined using the route-map command. Refer to *route-map on page 1687* for more information.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the above mentioned commands without specifying a VRF will only affect the default unnamed VRF.

There is only one local policy for each VRF instance.

Usage Examples

The following example specifies a route map entitled **myMap** for local policy routing:

(config)**#ip local policy route-map myMap**

ip mcast-stub helper-address *<ip address>*

Use the **ip mcast-stub helper-address** command to specify an IP address toward which Internet Group Management Protocol (IGMP) host reports and leave messages are forwarded. This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub downstream** and **ip mcast-stub upstream** commands. Use the **no** form of this command to return to the default setting.

Syntax Description

<ip address>	Specifies the address to which the IGMP host reports and leave messages are forwarded. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no helper-address is configured.

Command History

Release 7.1	Command was introduced.

Functional Notes

The helper address is configured globally and applies to all multicast-stub downstream interfaces. The address specified may be the next upstream hop or any upstream address on the distribution tree for the multicast source, up to and including the multicast source. The router selects, from the list of multicast-stub upstream interfaces, the interface on the shortest path to the specified address. The router then proxies, on the selected upstream interface (using an IGMP host function), any host joins/leaves received on the downstream interface(s). The router retransmits these reports with addresses set as if the report originated from the selected upstream interface.

For example, if the router receives multiple joins for a group, it will not send any extra joins out the upstream interface. Also, if it receives a leave, it will not send a leave until it is certain that there are no more subscribers on any downstream interface.

Usage Examples

The following example specifies 172.45.6.99 as the helper address:

(config)**#ip mcast-stub helper-address 172.45.6.99**

ip mgcp

Use the **ip mgcp** command to enable the Media Gateway Control Protocol (MGCP) stack. Use the **no** form of this command to disable the MGCP stack.

Syntax Description

No subcommands.

Default Values

By default, the MGCP stack is disabled.

Command History

Release A2	Command was introduced.

Usage Examples

The following example enables the MGCP stack:

(config)**#ip mgcp**

ip mgcp bracketed-ip

Use the **ip mgcp bracketed-ip** command to prevent bracketed IP address format from being used in specifying Media Gateway Control Protocol (MGCP) endpoint names. Use the **no** form of this command to disable the bracket requirement when entering MGCP endpoint IP addresses.

Syntax Description

No subcommands.

Default Values

By default, brackets are used when specifying MGCP endpoints.

Command History

Release A2	Command was introduced.

Functional Notes

Some call agents require that brackets be used when an MGCP gateway uses an IP address as its local domain name, and some call agents do not support the bracketed format. Bracketed IP addresses are displayed as **endpointname@[xx.xx.xx.xx]**, whereas nonbracketed endpoint IP addresses are displayed as **endpointname@xx.xx.xx.xx**. Using this command allows the user to control whether IP addresses will be bracketed or not, rather than entering all IP addresses as bracketed IP addresses.

Usage Examples

The following example disables bracketed IP address control:

(config)**#no ip mgcp bracketed-ip**

ip mgcp call-agent primary *<hostname | ipv4 address>*

Use the **ip mgcp call-agent primary** command to specify the primary Media Gateway Control Protocol (MGCP) call agent host name. Use the **no** form of this command to remove the specified primary call agent.

Syntax Description

<hostname | ipv4 address>	Specifies the call agent host name. Host names can be entered as either a fully qualified domain name (FQDN) or as an IP version 4 (IPv4) address in dotted decimal notation (**XX.XX.XX.XX**).

Default Values

By default, no primary call agents are configured.

Command History

Release A2	Command was introduced.

Functional Notes

The **ip mgcp call-agent primary** command identifies the call agent to the media gateway. Both primary and secondary call agents can be established, but at minimum a primary call agent is required. If a connection with the primary call agent fails, call agents will be tried in the order they are entered in the configuration. For more information regarding call agents and MGCP configuration, refer to the *MGCP in AOS* configuration guide available online at https://supportcommunity.adtran.com.

NOTE *The **no** form of this command will only take effect if there are no secondary call agents configured. If secondary call agents are configured, the primary call agent can be modified by issuing this command with the new host name information.*

NOTE *The primary call agent host name cannot be removed while any secondary call agents are configured. For more information about secondary call agents, refer to the command* *ip mgcp call-agent secondary <hostname | ipv4 address> on page 1422*.

Usage Examples

The following example configures the primary MGCP call agent, **ca1.company.com**:

(config)**#ip mgcp call-agent primary ca1.company.com**

ip mgcp call-agent secondary *<hostname | ipv4 address>*

Use the **ip mgcp call-agent secondary** command to specify the secondary Media Gateway Control Protocol (MGCP) call agent host name. Use the **no** form of this command to remove the specified secondary call agent.

Syntax Description

<hostname | ipv4 address>	Specifies the call agent host name. Host names can be entered as either a fully qualified domain name (FQDN) or as an IP version 4 (IPv4) address in dotted decimal notation (**XX.XX.XX.XX**).

Default Values

By default, no secondary call agents are configured.

Command History

Release A2	Command was introduced.

Functional Notes

Multiple secondary call agent host names can be configured. If a connection with the primary call agent fails, call agents are tried in the order they are entered in the configuration. New secondary call agents are added at the end of the list.

If secondary call agents are configured, primary call agents cannot be removed. For more information about primary call agents, refer to the command *ip mgcp call-agent primary <hostname | ipv4 address> on page 1421*.

Usage Examples

The following example specifies the secondary MGCP call agent as **ca2.company.com**:

(config)**#ip mgcp call-agent secondary ca2.company.com**

ip mgcp local-domain-name

Use the **ip mgcp local-domain-name** command to specify the local Media Gateway Control Protocol (MGCP) domain name. Use the **no** form of this command to remove the associated host name from the AOS product. Variations of this command include:

ip mgcp local-domain-name <*hostname* | *ipv4 address*>
ip mgcp local-domain-name media-gateway

Syntax Description

<*hostname*	*ipv4 address*>	Specifies the gateway host name in either a fully qualified domain name (FQDN) format or as an IP version 4 (IPv4) address in dotted decimal notation (**XX.XX.XX.XX**).
media-gateway	Specifies that the local domain name is based on the media gateway setting on the physical interface used for outbound traffic (for example, the Point-to-Point Protocol (PPP) or the Ethernet interfaces).

Default Values

By default, a local domain name is not configured.

Command History

Release A2	Command was introduced.

Usage Examples

The following example specifies that the local domain name for the media gateway is **mygateway@company.com**:

(config)#**ip mgcp local-domain-name mygateway@company.com**
(config)#

ip mgcp max1 <*value*>

Use the **ip mgcp max1** command to specify the number of Media Gateway Control Protocol (MGCP) message retransmissions between the gateway and the call agent. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the number of message retransmissions that will occur between the gateway and the call agent while the gateway waits for a response from the call agent. Range is **1** to **255**.

Default Values

By default, the **max1** value is set to **5**.

Command History

Release A2	Command was introduced.

Functional Notes

If the gateway does not receive a response from the call agent, the gateway retransmits MGCP messages **max1** times before the gateway either queries the domain naming system (DNS) to detect a possible change in call agent interfaces or directs transmissions to alternate call agent IP addresses.

For more information about MGCP configuration, refer to the *MGCP in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example sets the number of message transmissions between the gateway and the call agent to **20**:

(config)**#ip mgcp max1 20**

ip mgcp max2 <*value*>

Use the **ip mgcp max2** command to specify the number of Media Gateway Control Protocol (MGCP) message retransmissions between the MGCP gateway and the call agent before the gateway disconnects. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the number of message retransmissions that will occur before the gateway disconnects from the call agent. Range is **1** to **255**.

Default Values

By default, MGCP retransmissions before gateway disconnection is set to **7**.

Command History

Release A2	Command was introduced.

Functional Notes

When the gateway has retransmitted MGCP messages **max2** times, it indicates that the gateway has already exceeded the **max1** value (refer to the command *ip mgcp max1 <value> on page 1424*) and it will contact the domain naming system (DNS) to search for alternate call agent interfaces which to connect. If the gateway does not find any available call agent interfaces for connection, the gateway will disconnect.

*The **max2** value must always be greater than the **max1** value. If the **max1** value is specified to be greater than the **max2** value, the **max2** value is automatically defined as **max1** + **1**.*

For more information about MGCP configuration, refer to the *MGCP in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the MGCP gateway will retransmit MGCP messages **30** times before disconnecting from the call agent:

(config)**#ip mgcp max2 30**

ip mgcp persistent-notify

Use the **ip mgcp persistent-notify** command to enable persistent event notification to the Media Gateway Control Protocol (MGCP) call agent. Use the **no** form of this command to disable persistent notification. Variations of this command include:

ip mgcp persistent-notify hd
ip mgcp persistent-notify hu
ip mgcp persistent-notify hf

*Multiple combinations of the **hd**, **hu**, and **hf** parameters can be entered.*

Enabling persistent notification when it is not required can cause unexpected and undesired operation.

Syntax Description

hd	Specifies that notification of endpoint hang down is sent to the call agent.
hu	Specifies that notification of endpoint hang up is sent to the call agent.
hf	Specifies that notification of endpoint hook flash is sent to the call agent.

Default Values

By default, persistent notification is disabled.

Command History

Release A2	Command was introduced.

Functional Notes

When persistent notification is disabled, the media gateway will not send event notifications of endpoint hang down (**hd**), hang up (**hu**), or hook flash (**hf**). When the feature is enabled, the media gateway will send notification of endpoint events even if it has not received a notification request from the call agent. Some call agents require the use of persistent notification. For example, sometimes hd notification is required for initial dial tone once the link has become active. Refer to the configuration materials provided with your call agent for more information.

Usage Examples

The following example enables persistent notification of endpoint hang down:

(config)**#ip mgcp persistent-notify hd**

ip mgcp qos dscp <*value*>

Use the **ip mgcp qos dscp** command to specify the differentiated services code point (DSCP) value in the Media Gateway Control Protocol (MGCP) packets transmitted by the MGCP gateway. This value can be used by quality of service (QoS) mechanisms to give priority for this type of traffic. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the DSCP value. Range is **0** to **63**.

Default Values

By default, the DSCP value for MGCP packets is **46**.

Command History

Release A2	Command was introduced.

Usage Examples

The following example specifies the DSCP value for MGCP gateways as **10**:

(config)**#ip mgcp qos dscp 10**

ip mgcp retransmit-delay

Use the **ip mgcp retransmit-delay** command to specify the constant time between retransmissions of Media Gateway Control Protocol (MGCP) messages. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip mgcp retransmit-delay 100ms
ip mgcp retransmit-delay 250ms
ip mgcp retransmit-delay 500ms
ip mgcp retransmit-delay 1sec
ip mgcp retransmit-delay 2sec
ip mgcp retransmit-delay 4sec

Syntax Description

100ms	Specifies 100 milliseconds between retransmissions.
250ms	Specifies 250 milliseconds between retransmissions.
500ms	Specifies 500 milliseconds between retransmissions.
1sec	Specifies 1 second between retransmissions.
2sec	Specifies 2 seconds between retransmissions.
4sec	Specifies 4 seconds between retransmissions.

Default Values

By default, retransmissions occur with longer and longer delays between retransmissions. These delays are based on RFC 3435, which uses a User Datagram Protocol (UDP) back-off algorithm for MGCP retransmission delay.

Command History

Release A2	Command was introduced.

Usage Examples

The following example specifies that retransmissions will occur at a constant rate of **1sec**:

(config)**#ip mgcp retransmit-delay 1sec**

ip mgcp rfc2833-signaling

Use the **ip mgcp rfc2833-signaling** command to enable the transmission and reception of ABCD signal bits via RFC 2833 packets. Use the **no** form of this command to disable ABCD signaling.

This command should only be used with gateways configured to send ABCD signaling bits out-of-band for TDM passthrough. Configuring this command when it is not needed will likely cause undesired operation.

Syntax Description

No subcommands.

Default Values

By default, ABCD signaling is disabled.

Command History

Release A2	Command was introduced.

Usage Examples

The following example enables ABCD signaling:

(config)**#ip mgcp rfc2833-signaling**

ip mgcp standard

Use the **ip mgcp standard** command to specify the Media Gateway Control Protocol (MGCP) standard the gateway will use. Use the **no** form of this command to return to the default standard. Variations of this command include:

ip mgcp standard rfc3435
ip mgcp standard ncs

Syntax Description

rfc3435	Specifies that the RFC 3435 MGCP standard is used.
ncs	Specifies that the MGCP 0.1/NCS 1.0 standard is used.

Default Values

By default, MGCP gateways use the **rfc3435** standard.

Command History

Release A2	Command was introduced.

Usage Examples

The following example sets the MGCP standard to **ncs**:

(config)**#ip mgcp standard ncs**

ip mgcp udp <*port*>

Use the **ip mgcp udp** command to specify the local listening port for the Media Gateway Control Protocol (MGCP) stack for User Datagram Protocol (UDP) information. Use the **no** form of this command to return to the default port.

Syntax Description

<*port*>	Specifies the port to listen for UDP information. Range is **1** to **65535**.

Default Values

By default, the MGCP gateway listens for UDP on port **2427** as defined by RFC 3435.

Command History

Release A2	Command was introduced.

Usage Examples

The following example specifies that the MGCP gateway will listen for UDP information on port **2727**:

(config)**#ip mgcp udp 2727**

ip multicast-routing

Use the **ip multicast-routing** command to enable the multicast router process. The command does not affect other multicast-related configurations. Use the **no** form of this command to disable this feature. Disabling this command prevents multicast forwarding, but does not remove other multicast commands and processes.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example enables multicast functionality:

(config)**#ip multicast-routing**

ip nat pool *<name>*

Use the **ip nat pool** command to create a new static 1:1 network address translation (NAT) pool and enter its configuration command set. This command can also be used to enter the command set for an existing pool. Use the **no** form of this command to remove a configured NAT pool. Refer to the command *load-protect on page 1575* for more information about mapping addresses for static 1:1 NAT pools. Variations of this command include:

ip nat pool *<name>*
ip nat pool *<name>* **static**

Syntax Description

<name>	Enters the configuration commands set for an existing NAT pool identified by the *<name>* variable.
<name> **static**	Creates NAT pool for 1:1 static NAT and enters its configuration command set. For a given configuration, a local address statically maps to a global address and vice versa.

Default Values

By default, there are no NAT pools configured.

Command History

Release 17.4	Command was introduced to allow static NAT pools only.

Functional Notes

Static 1:1 NAT allows connections initiated from a particular private IP address to always map to a particular public IP address. For every private host that requires a 1:1 NAT mapping, there must be a corresponding NAT address on the public side. In previous versions of AOS, this was accomplished by using an exhaustive list of all address mappings. AOS version 17.4 and later provided support for using NAT pools that lists ranges of local and global IP addresses to create the 1:1 mappings.

Usage Examples

The following example creates a static 1:1 NAT pool named **POOL1** and enters the NAT pool configuration command set:

(config)**#ip nat pool POOL1 static**

The following example enters the configuration command set for an existing NAT pool named **POOL2**:

(config)**#ip nat pool POOL2**

ip policy-class *<ipv4 acp name>*

Use the **ip policy-class** command to create an Internet Protocol version 4 (IPv4) access control policy (ACP) and enter the IPv4 ACP command set. Use the **no** form of this command to delete an IPv4 ACP and all the entries it contains. Refer to the *IPv4 Access Control Policy Command Set on page 4278*.

Configured IPv4 ACPs will only be active if the command ip firewall on page 1367 has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.

Before applying an ACP to an interface, verify your Telnet or secure shell (SSH) connection will not be affected by the policy. If an ACP is applied to the interface you are connecting through and it does not allow Telnet or SSH traffic, your connection will be lost.

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP using an alphanumeric descriptor (maximum of 50 characters). All ACP descriptors are case sensitive.

Default Values

By default, all AOS IPv4 security features are disabled and there are no configured ACP entries.

Command History

Release 2.1	Command was introduced.

Functional Notes

AOS IPv4 ACPs are used to allow, discard, or manipulate (using network address translation (NAT)) data for each physical interface. Each ACP consists of an action (**allow**, **discard**, **nat**) and a selector access control list (ACL). When IPv4 packets are received on an interface, the configured IPv4 ACPs are applied to determine whether the data will be processed or discarded.

*An implicit discard exists at the end of every IPv4 ACP. Specifying a **discard list** is unnecessary in most applications and should be used with caution. A **discard list** can adversely affect certain functions of a unit (virtual private network (VPN), routing protocols, etc.). Specifying an empty ACL or a nonexistent ACL in an ACP will result in an implicit permit.*

IPv4 ACPs and ACLs cannot have the same name as a configured IPv6 ACP or ACL.

Usage Examples

The following example creates an IPv4 ACP named **PRIVATEv4**:

(config)**#ip policy-class PRIVATEv4**
(config-policy-class)#

Technology Review

IPv4 ACPs and ACLs regulate traffic through the routed network. Creating IPv4 ACPs and ACLs to regulate traffic through the routed network is a four-step process:

Step 1:
Enable the IPv4 security features of AOS using the **ip firewall** command. Refer to the command *ip firewall on page 1367* for more information.

Step 2:
Create an IPv4 ACP that uses a configured ACL by issuing the **ip policy-class** command. AOS IPv4 ACPs are used to allow, discard, or manipulate (using NAT) data for each physical interface. Each ACP consists of an action (**allow**, **discard**, **nat**) and a selector (ACL). When packets are received on an interface, the configured ACPs are applied to determine whether the data will be processed or discarded.

Step 3:
Create an IPv4 ACL to permit or deny specified traffic by using either the **ip access-list extended** or **ip access-list standard** command. Standard IPv4 ACLs match based on the source IP address of the packet. Extended IPv4 ACLs match based on the source and destination of the packet. Refer to the command *ip access-list extended <ipv4 acl name> on page 1344* or the command *ip access-list standard <ipv4 acl name> on page 1346* for more information. Sources can be expressed in one of four ways:

1. Using the keyword **any** to match any IP address.

2. Using host <*ip address*> to specify a single host address.

3. Using the <*ip address*> <*wildcard*> format to match all IPv4 addresses in a range. Wildcard masks work in reverse logic from subnet masks. When broken out into binary form, a **0** indicates which bits of the IPv4 address to consider, a **1** indicates which bits are disregarded. For example, specifying **255** in any octet of the wildcard mask equates to a “don’t care” for that octet in the IP address. Additionally, a 30-bit mask would be represented with the wildcard string **0.0.0.3**, a 28-bit mask with **0.0.0.15**, a 24-bit mask with **0.0.0.255**, and so forth.

4. Using the keyword **hostname** to match based on a domain naming system (DNS) name. DNS servers must be configured or host names must be locally defined for this function to work.

Step 4:
Apply the created IPv4 ACP to an interface. To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** <*acpv4 name*>. The following example assigns ACP **UNTRUSTED** to the Ethernet 0/1 interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip access-policy UNTRUSTED**

ip policy-class *<ipv4 acp name>* max-host-sessions *<number>*

Use the **ip policy-class max-host-sessions** command to create or alter settings for an Internet Protocol version 4 (IPv4) access control policy (ACP). For more details on ACP functionality in AOS, refer to the *IPv4 Access Control Policy Command Set on page 4278*. Use the **no** form of this command to return to the default value.

Syntax Description

<ipv4 acl name>	Identifies the configured IPv4 ACP using an alphanumeric descriptor (maximum of 50 characters). All IPv4 ACP descriptors are case sensitive.
<number>	Specifies the maximum number of allowed IPv4 ACP sessions that can be created from each unique source address. This command is used in conjunction with a named IPv4 ACP and only applies the limit to that particular IPv4 ACP. The number must be within the appropriate range limits. The limits depend on the type of AOS device being used. Setting this value to **0** restores the default setting. By default, this feature is turned off (meaning no limits per source address will be enforced).

Default Values

By default, all AOS security features are disabled and there are no configured ACP entries.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example allows no more than **100** policy sessions to be sourced from a single host IP address on the ACP named **PRIVATE**:

(config)**#ip policy-class PRIVATE max-host-sessions 100**

ip policy-class *<ipv4 acp name>* max-sessions *<number>*

Use the **ip policy-class max-sessions** command to specify the number of allowed sessions for an Internet Protocol version 4 (IPv4) access control policy (ACP). For more details on IPv4 ACP functionality in AOS, refer to the *IPv4 Access Control Policy Command Set on page 4278*. Use the **no** form of this command to return to the default value.

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP using an alphanumeric descriptor (maximum of 50 characters). All ACP descriptors are case sensitive.
<number>	Specifies the maximum number of allowed policy sessions for the named IPv4 ACP. This number must be within the appropriate range limits. The limits depend on the type of AOS device being used. Setting this value to **0** restores the default setting. When setting the **max-sessions** for all IPv4 ACPs, this default is determined at boot time based on the amount of memory available. For a named IPv4 ACP, this default is one-third of the total number of allowed ACP sessions.

Default Values

By default, all AOS security features are disabled and there are no configured ACP entries.

Command History

Release 2.1	Command was introduced.

Functional Notes

To set the system-wide maximum limit for ACP sessions (both IPv4 and IPv6), use the command *policy-class max-sessions <number> on page 1654*. To set the maximum limit for IPv6 ACP sessions, use the command *ipv6 policy-class <ipv6 acp name> max-sessions <number> on page 1550*.

Usage Examples

The following example allows no more than **100** IPv4 policy sessions on the ACP named **PRIVATE**:

(config)**#ip policy-class PRIVATE max-sessions 100**

The following example restores the default policy sessions limit on the ACP named **PRIVATE**:

(config)**#no ip policy-class PRIVATE max-sessions**

ip policy-class *<ipv4 acp name>* rpf-check

Use the **ip policy-class rpf-check** command to verify that Internet Protocol version 4 (IPv4) traffic has entered on the appropriate interface using a route lookup. Reverse path forwarding (RPF) is essentially a spoofing check. For more details on IPv4 policy class functionality in AOS, refer to the *IPv4 Access Control Policy Command Set on page 4278*. Use the **no** form of this command to disable this feature.

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 access control policy (ACP) using an alphanumeric descriptor (maximum of 50 characters). All ACP descriptors are case sensitive.
rpf-check	Enables RPF check (spoofing).

Default Values

This command is enabled by default.

Command History

Release 12.1	Command was introduced.

Functional Notes

The **rpf-check** feature should be disabled if your application allows IPv4 traffic to arrive on an interface sourced from networks contradicting the route table. This feature can be disabled on a per ACP basis by issuing this command in conjunction with the ACP name you do not want to be checked.

Usage Examples

The following example turns off the **rpf-check** feature for the IPv4 ACP named **PRIVATE**:

(config)**#no ip policy-class PRIVATE rpf-check**

ip policy-timeout

Use multiple **ip policy-timeout** command to customize timeout intervals for the established Internet Protocol version 4 (IPv4) firewall sessions. The policy session timeout determines when the time to live (TTL) for the session expires and ends the session. This command configures the policy timeout for the following protocols: (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol version 4 (ICMPv4), Authentication Header (AH) Protocol, generic routing encapsulation (GRE), encapsulating security payload (ESP)) or specific services (by listing the particular port number). Use the **no** form of this command to return to the default timeout values. Variations of this command include:

ip policy-timeout [ahp | esp | gre | icmp] <*timeout*>
ip policy-timeout [tcp | udp] all-ports <*timeout*>
ip policy-timeout [tcp | udp] <*port*> <*timeout*>
ip policy-timeout [tcp | udp] range <*beginning port*> <*ending port*> <*timeout*>

Syntax Description

ahp	Specifies the data protocol as AHP.
esp	Specifies the data protocol as ESP.
gre	Specifies the data protocol as GRE.
icmp	Specifies the data protocol as ICMPv4.
<*timeout*>	Specifies the wait interval (in seconds) before an active session is closed. Valid range is **0** to **4294967295** seconds.
tcp	Specifies the data protocol as TCP. If you are using TCP, you can also specify the timeout for a specific port, a range of ports, or all TCP ports.
udp	Specifies the data protocol as UDP. If you are using UDP, you can also specify the timeout for a specific port, a range of ports, or all UDP ports.
all-ports	Specifies all ports of either TCP or UDP are used if a specific match is not found.
<*port*>	Specifies a single TCP or UDP port. Keywords are available for well-known protocols, as those listed below. Valid port range is **0** to **65535**.
range	Customizes timeout intervals for a range of TCP or UDP ports.
<*beginning port*>/<*ending port*>	Specifies the range of ports, to which to apply the timeout value; valid only for specifying TCP and UDP services. Valid ports range between **0** and **65535**. The following is the list of TCP port numbers that may be identified using the text name (in **bold**): **bgp** (Port 179) **chargen** (Port 19) **cmd** (Port 514) **daytime** (Port 13) **discard** (Port 9) **kshell** (Port 544) **login** (Port 513) **lpd** (Port 515) **nntp** (Port 119) **pim-auto-rp** (Port 496)

domain (Port 53)	**pop2** (Port 109)
echo (Port 7)	**pop3** (Port 110)
exec (Port 512)	**smtp** (Port 25)
finger (Port 79)	**ssh** (Port 22)
ftp (Port 21)	**sunrpc** (Port 111)
ftp-data (Port 20)	**tacacs** (Port 49)
gopher (Port 70)	**talk** (Port 517)
hostname (Port 101)	**telnet** (Port 23)
https (Port 443)	**time** (Port 37)
ident (Port 113)	**uucp** (Port 540)
irc (Port 194)	**whois** (Port 43)
klogin (Port 543)	**www** (Port 80)

The following is the list of UDP port numbers that may be identified using the text name (in **bold**):

biff (Port 512)	**pim-auto-rp** (Port 496)
bootpc (Port 68	**rip** (Port 520)
bootps (Port 67)	**ripng** (Port 521)
discard (Port 9)	**snmp** (Port 161)
dnsix (Port 195)	**snmptrap** (Port 162))
domain (Port 53)	**sunrpc** (Port 111)
echo (Port 7)	**syslog** (Port 514)
isakmp (Port 500)	**tacacs** (Port 49)
mobile-ip (Port 434)	**talk** (Port 517)
nameserver (Port 42)	**tftp** (Port 69)
netbios-dgm (Port 138)	**time** (Port 37)
netbios-ns (Port 137)	**who** (Port 513)
netbios-ss (Port 139)	**xdmcp** (Port 177)
ntp (Port 123)	

<timeout> Specifies the wait interval (in seconds) before an active session is closed. Valid range is **0** to **4294967295** seconds.

Default Values

By default, policy session timeouts are set to **600** seconds for established TCP policy sessions, and **60** seconds for all other protocols.

Command History

Release 2.1	Command was introduced.
Release 11.1	Added AHP, GRE, and ESP policies.
Release 18.2	The **syslog** option for TCP ports was removed.
Release R10.1.0	Command was expanded to include the **ripng** option for UDP ports.

Usage Examples

The following example creates customized policy timeouts for the following:

Internet traffic (TCP Port 80) timeout 24 hours (**86400** seconds)
Telnet (TCP Port 23) timeout 20 minutes (**1200** seconds)
FTP (TCP Port 21) timeout 5 minutes (**300** seconds)
All other TCP services timeout 8 minutes (**480** seconds)

(config)**#ip policy-timeout tcp www 86400**
(config)**#ip policy-timeout tcp telnet 1200**
(config)**#ip policy-timeout tcp ftp 300**
(config)**#ip policy-timeout tcp all-ports 480**

The following example creates customized policy timeouts for UDP network basic input/output system (NetBIOS) ports 137 to 139 of **200** seconds and UDP ports **6000** to **7000** of **300** seconds:

(config)**#ip policy-timeout udp range netbios-ns netbios-ss 200**
(config)**#ip policy-timeout udp range 6000 7000 300**

The following example creates a customized policy timeout of **1200** seconds for ESP:

(config)**#ip policy-timeout esp 1200**

The following example creates a customized policy timeout of **1200** seconds for GRE:

(config)**#ip policy-timeout gre 1200**

The following example creates a customized policy timeout of **1200** seconds for AHP:

(config)**#ip policy-timeout ahp 1200**

ip prefix-list <*name*> description *“<text>”*

Use the **ip prefix-list description** command to create and name prefix lists. Use the **no** form of this command to remove a prefix list.

Syntax Description

<name>	Specifies a particular prefix list.
“<text>”	Assigns text (enclosed in quotation marks) used as a description for the prefix list. Maximum length is 80 characters.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.

Functional Notes

This command adds a string of up to 80 characters as a description for a prefix list. It also creates the prefix list if a prefix list of that name does not already exist.

Usage Examples

The following example adds a description to the prefix-list **test**:

(config)**#ip prefix-list test description “An example prefix list”**

ip prefix-list <*name*> seq <*number*>

Use the **ip prefix-list seq** command to specify a prefix to be matched or a range of mask lengths. Use the **no** form of this command to remove a prefix list. Variations of this command include:

ip prefix-list <*name*> **seq** <*number*> **deny** <*network ip /length*>
ip prefix-list <*name*> **seq** <*number*> **deny** <*network ip /length*> **ge** <*value*>
ip prefix-list <*name*> **seq** <*number*> **deny** <*network ip /length*> **le** <*value*>
ip prefix-list <*name*> **seq** <*number*> **permit** <*network ip /length*>
ip prefix-list <*name*> **seq** <*number*> **permit** <*network ip /length*> **ge** <*value*>
ip prefix-list <*name*> **seq** <*number*> **permit** <*network ip /length*> **le** <*value*>

Syntax Description

<*name*>	Specifies a particular prefix list.
<*number*>	Specifies the entry's unique sequence number that determines the processing order. Lower numbered entries are processed first. Range is **1** to **4294967294**.
permit <*network ip /length*>	Permits access to entries matching the specified network IP address and the corresponding network prefix length (for example, **10.10.10.1 /24**).
deny <*network ip /length*>	Denies access to entries matching the specified network IP address and the corresponding network prefix length (for example, **10.10.10.1 /24**).
le <*value*>	Specifies the upper end of the range. Range is **0** to **32**.
ge <*value*>	Specifies the lower end of the range. Range is **0** to **32**.

Default Values

If no ge or le parameters are specified, an exact match is assumed. If only ge is specified, the range is assumed to be from ge-value to 32. If only le is specified, the range is assumed to be from len to le-value.

Command History

Release 8.1	Command was introduced.

Functional Notes

This command specifies a prefix to be matched. If the network address is entered without specifying a range for prefix lengths, the router assumes that the route must be an exact match. For example, if the command **ip prefix-list TEST seq 5 permit 10.1.0.0/16** is entered, the BGP interface will only accept routes to the entire 10.1.0.0 /16 subnet. It will not accept routes to a network, such as 10.1.1.0/ 24, which was subdivided from the /16 network.

Optionally, this command may specify a range of mask lengths. The following rule must be followed: len < ge-value $\leq$ le-value. A filter that exactly matches a prefix length can be created by entering the length for both the **ge** and **le** values. A prefix list with no entries allows all routes. A route that does not match any entries in a prefix list is dropped. As soon as a route is permitted or denied, there is no further processing of the rule in the prefix list. A route that is denied at the beginning entry of a prefix list will not be allowed, even if it matches a permitting entry further down the list.

Usage Examples

The following example creates a prefix list entry in the prefix list TEST that allows all routes to subnets in the 10.1.0.0 /16 network with a prefix length up to and including 24:

(config)**#ip prefix-list TEST seq 5 permit 10.1.0.0/16 le 24**

The following example creates a prefix list entry in the prefix list TEST that allows any route to a /24 subnet in the 10.1.0.0 /16 range, but rejects routes destined for the entire 10.1.0.0 /16 network:

(config)**#ip prefix-list TEST seq 5 permit 10.1.0.0/16 ge 24 le 24**

ip radius source-interface <*interface*>

Use the **ip radius source-interface** command to specify the network attached storage (NAS) IP address attribute passed with the remote authentication dial-in user service (RADIUS) authentication request packet. Specifying the virtual routing and forwarding (VRF) instance using the **vrf** <*name*> keyword applies the configuration to the named VRF instance. Omitting the **vrf** <*name*> keyword applies the configuration to the default unnamed VRF. Use the **no** form of this command to remove a defined source interface. Variations of this command include:

ip radius source-interface <*interface*>
ip radius vrf <*name*> **source-interface** <*interface*>

Syntax Description

<*interface*>	Specifies the source interface. Specify an interface in the format <*interface type [slot/port	slot/port.subinterface id	interface id	interface id.subinterface id	ap	ap/radio	ap/radio.vap]*>. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip radius source-interface ?** for a complete list of interfaces.
vrf <*name*>	Specifies the name of the VRF to which to assign the attribute.

Default Values

By default, no source interface is defined.

Command History

Release 5.1	Command was introduced.
Release 14.1	Command was expanded to include the tunnel interface.
Release 15.1	Command was expanded to include the bridged virtual interface (BVI).
Release 17.1	Command was expanded to include the asynchronous transfer mode (ATM) interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release R10.7.0	Command was expanded to include the **vrf** <*name*> parameter.

Functional Notes

If this value is not defined, the address of the source network interface is used.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example configures the Ethernet 0/1 port to be the source interface:

(config)**#ip radius source-interface ethernet 0/1**

The following example configures the BVI 1 interface to be the source interface:

(config)**#ip radius source-interface bvi 1**

The following example configures the Ethernet 0/1 port to be the source interface:

(config)**#ip radius vrf RED source-interface ethernet 0/1**

The following example configures the BVI 1 interface to be the source interface:

(config)**#ip radius vrf RED source-interface bvi 1**

ip route

Use the **ip route** command to add an Internet Protocol version 4 (IPv4) static route to the IPv4 route table. Use the **no** form of this command to remove a configured IPv4 static route. Variations of this command include:

ip route <*ip address*> <*subnet mask*> <*interface*>
ip route <*ip address*> <*subnet mask*> <*interface*> <*administrative distance*>
ip route <*ip address*> <*subnet mask*> <*interface*> <*administrative distance*> **tag** <*number*>
ip route <*ip address*> <*subnet mask*> <*interface*> <*administrative distance*> **track** <*name*>
ip route <*ip address*> <*subnet mask*> <*interface*> <*administrative distance*> **track** <*name*> **tag** <*number*>
ip route <*ip address*> <*subnet mask*> <*interface*> **tag** <*number*>
ip route <*ip address*> <*subnet mask*> <*ip address*>
ip route <*ip address*> <*subnet mask*> <*ip address*> **tag** <*number*>
ip route <*ip address*> <*subnet mask*> <*ip address*> **track** <*name*>
ip route <*ip address*> <*subnet mask*> <*ip address*> **tag** <*number*> **track** <*name*>
ip route <*ip address*> <*subnet mask*> <*ip address*> <*administrative distance*>
ip route <*ip address*> <*subnet mask*> <*ip address*> <*administrative distance*> **tag** <*number*>
ip route <*ip address*> <*subnet mask*> <*ip address*> <*administrative distance*> **track** <*name*>
ip route <*ip address*> <*subnet mask*> <*ip address*> <*administrative distance*> **track** <*name*> **tag** <*number*>
ip route <*ip address*> <*subnet mask*> **null 0**
ip route <*ip address*> <*subnet mask*> **null 0** <*administrative distance*>
ip route <*ip address*> <*subnet mask*> **null 0** <*administrative distance*> **tag** <*number*>
ip route <*ip address*> <*subnet mask*> **null 0** <*administrative distance*> **track** <*name*>
ip route <*ip address*> <*subnet mask*> **null 0 tag** <*number*>
ip route <*ip address*> <*subnet mask*> **null 0 track** <*name*>

Syntax Description

<*ip address*>	Specifies the IPv4 network address to add to the route table. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*subnet mask*>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
[<*interface*> **|** <*ip address*>**]**	Specifies the far-end IPv4 address or an egress interface in the unit. Use the **ip route** <*ip address*> <*subnet mask*> **?** command to display a complete list of egress interfaces.
null 0	Optional. Specifies that traffic is routed to the null interface. The router drops all packets destined for the null interface. Use the null interface to allow the router to advertise a route, but not forward traffic to the route.
<*administrative distance*>	Optional. Specifies an administrative distance associated with a particular router used to determine the best route when multiple routes to the same destination exist. The lower the administrative distance, the more preferable the route. Range is **1** to **255**.

tag <*number*>	Optional. Specifies a number to use as a tag for this route. Route tags are used to label and filter routes when dynamically redistributing routes into a routing protocol (such as Routing Information Protocol (RIP)/open shortest path first (OSPF)/Border Gateway Protocol (BGP)). Range is **1** to **65535**.
track <*name*>	Optional. Enables tracking on the indicated route. Once the named track enters a fail state, the route specified by the command is disabled and traffic will no longer be routed using that route. For more information on configuring tracks, refer to *track <name> on page 1886*.

Default Values

By default, there are no configured routes in the route table, and the tag of 0 is applied to the route.

Command History

Release 1.1	Command was introduced.
Release 9.1	Tunnel was added as a supported interface.
Release 11.1	Demand was added as a supported interface.
Release 13.1	Command was expanded to include the **track** feature.
Release 15.1	Command was expanded to include route tagging capability.

Usage Examples

The following example adds an IPv4 static route to the **10.220.0.0 /16** network through the next-hop router **192.22.45.254** and an IPv4 default route to **175.44.2.10**:

(config)**#ip route 10.220.0.0 255.255.0.0 192.22.45.254**
(config)**#ip route 0.0.0.0 0.0.0.0 175.44.2.10**

ip route vrf

Use the **ip route vrf** command to create an Internet Protocol version 4 (IPv4) static route in one of the nondefault virtual routing and forwarding (VRF) instances. Use the **no** form of this command to remove the static route. Variations of this command include:

ip route vrf *<name> <ipv4 address> <subnet mask>* **[***<interface>* **|** *<ipv4 address>***]**
ip route vrf *<name> <ipv4 address> <subnet mask>* **[***<interface>* **|** *<ipv4 address>***]** *<distance>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **[***<interface>* **|** *<ipv4 address>***]** *<distance>* **tag** *<number>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **[***<interface>* **|** *<ipv4 address>***]** *<distance>* **tag** *<number>* **track** *<name>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **[***<interface>* **|** *<ipv4 address>***]** *<distance>* **track** *<name>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **[***<interface>* **|** *<ipv4 address>***]** *<distance>* **track** *<name>* **tag** *<number>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **[***<interface>* **|** *<ipv4 address>***]** **tag** *<number>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **[***<interface>* **|** *<ipv4 address>***]** **tag** *<number>* **track** *<name>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **[***<interface>* **|** *<ipv4 address>***]** **track** *<name>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **[***<interface>* **|** *<ipv4 address>***]** **track** *<name>* **tag** *<number>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **null 0**
ip route vrf *<name> <ipv4 address> <subnet mask>* **null 0** *<distance>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **null 0** *<distance>* **tag** *<number>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **null 0** *<distance>* **track** *<name>*
ip route vrf *<name> <ip4v address> <subnet mask>* **null 0 tag** *<number>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **null 0 tag** *<number>* **track** *<name>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **null 0 track** *<name>*
ip route vrf *<name> <ipv4 address> <subnet mask>* **null 0 track** *<name>* **tag** *<number>*

Syntax Description

<name>	Specifies the name of the VRF instance.
<ipv4 address>	Specifies the network address to add to the route table. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**). Valid prefix lengths are 0 to 32.
[*<interface>* **|** *<ipv4 address>***]**	Specifies the far-end IPv4 address or an egress interface in the unit. Use the **ip route** *<ipv4 address> <subnet mask>* **?** command to display a complete list of egress interfaces. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

null 0	Optional. Routes traffic destined for the specified network to the null interface. The router drops all packets destined for the null interface. Use the null interface to allow the router to advertise a route, but not forward traffic to the route.
<distance>	Optional. Specifies an administrative distance associated with a particular router used to determine the best route when multiple routes to the same destination exist. The lower the administrative distance, the more preferable the route. Range is **1** to **255**.
track *<name>*	Optional. Enables tracking on the indicated route. Once the named track enters a fail state, the route specified by the command is disabled and traffic will no longer be routed using that route. For more information on configuring tracks, refer to *track <name> on page 1886*.
tag *<number>*	Optional. Specifies a number to use as a tag for this route. Route tags are used to label and filter routes when dynamically redistributing routes into a routing protocol (such as Routing Information Protocol (RIP)/open shortest path first (OSPF)/Border Gateway Protocol (BGP)). Range is **1** to **65535**.

Default Values

No default values are necessary for this command.

Command History

Release R10.7.0	Command was introduced.

Functional Notes

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

The VRF must have already been created (using the command *vrf <name> route-distinguisher on page 1989*) before static routes can be configured.

Usage Examples

The following example adds a static route to the routing and forwarding tables used for the VRF **RED**:

(config)**#ip route vrf RED 10.220.0.0 255.255.0.0 192.22.45.254**
(config)**#ip route vrf RED 0.0.0.0 0.0.0.0 175.44.2.10**

ip route-cache express

Use the **ip route-cache express** command to globally enable Layer 3 switching. Use the **no** form of this command to disable Layer 3 switching.

Syntax Description

No subcommands.

Default Values

Layer 3 switching is disabled by default, except on the NetVanta 1544. Layer 3 switching is enabled by default on the NetVanta 1544.

Functional Notes

Layer 3 switching cannot be disabled on the NetVanta 1544. For more information about Layer 3 switching, refer to the *Layer 3 Switching in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Command History

Release 17.5	Command was introduced.

Usage Examples

The following example globally enables Layer 3 switching:

(config)**#ip route-cache express**

ip route vrf

Use the **ip route vrf** command to create an Internet Protocol version 4 (IPv4) static route in one of the nondefault virtual routing and forwarding (VRF) instances. Use the **no** form of this command to remove the static route. Variations of this command include:

ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **[**<*interface*> **|** <*ipv4 address*>**]**
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **[**<*interface*> **|** <*ipv4 address*>**]** <*distance*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **[**<*interface*> **|** <*ipv4 address*>**]** <*distance*> **tag** <*number*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **[**<*interface*> **|** <*ipv4 address*>**]** <*distance*> **tag** <*number*> **track** <*name*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **[**<*interface*> **|** <*ipv4 address*>**]** <*distance*> **track** <*name*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **[**<*interface*> **|** <*ipv4 address*>**]** <*distance*> **track** <*name*> **tag** <*number*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **[**<*interface*> **|** <*ipv4 address*>**]** **tag** <*number*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **[**<*interface*> **|** <*ipv4 address*>**]** **tag** <*number*> **track** <*name*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **[**<*interface*> **|** <*ipv4 address*>**]** **track** <*name*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **[**<*interface*> **|** <*ipv4 address*>**]** **track** <*name*> **tag** <*number*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **null 0**
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **null 0** <*distance*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **null 0** <*distance*> **tag** <*number*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **null 0** <*distance*> **track** <*name*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **null 0 tag** <*number*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **null 0 tag** <*number*> **track** <*name*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **null 0 track** <*name*>
ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **null 0 track** <*name*> **tag** <*number*>

Syntax Description

<*name*>	Specifies the name of the VRF instance.
<*ipv4 address*>	Specifies the network address to add to the route table. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*subnet mask*>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**). Valid prefix lengths are 0 to 32.
[<*interface*> **|** <*ipv4 address*>**]**	Specifies the far-end IPv4 address or an egress interface in the unit. Use the **ip route** <*ipv4 address*> <*subnet mask*> **?** command to display a complete list of egress interfaces. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

null 0	Optional. Routes traffic destined for the specified network to the null interface. The router drops all packets destined for the null interface. Use the null interface to allow the router to advertise a route, but not forward traffic to the route.
<distance>	Optional. Specifies an administrative distance associated with a particular router used to determine the best route when multiple routes to the same destination exist. The lower the administrative distance, the more preferable the route. Range is **1** to **255**.
track *<name>*	Optional. Enables tracking on the indicated route. Once the named track enters a fail state, the route specified by the command is disabled and traffic will no longer be routed using that route. For more information on configuring tracks, refer to *track <name> on page 1886*.
tag *<number>*	Optional. Specifies a number to use as a tag for this route. Route tags are used to label and filter routes when dynamically redistributing routes into a routing protocol (such as Routing Information Protocol (RIP)/open shortest path first (OSPF)/Border Gateway Protocol (BGP)). Range is **1** to **65535**.

Default Values

No default values are necessary for this command.

Command History

Release 16.1	Command was introduced.
Release 17.5	Command was expanded to include the loopback interface.

Functional Notes

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

The VRF must have already been created (using the command *vrf <name> route-distinguisher on page 1989*) before static routes can be configured.

Usage Examples

The following example adds a static route to the routing and forwarding tables used for the VRF **RED**:

(config)**#ip route vrf RED 10.220.0.0 255.255.0.0 192.22.45.254**
(config)**#ip route vrf RED 0.0.0.0 0.0.0.0 175.44.2.10**

ip routing

Use the **ip routing** command to enable the AOS IP routing functionality. Use the **no** form of this command to disable IP routing.

Syntax Description

No subcommands.

Default Values

By default, IP routing is enabled.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example enables the AOS IP routing functionality:

(config)**#ip routing**

ip rtp dtmf-relay min-duration <*value*>

Use the **ip rtp dtmf-relay min-duration** command to configure dual tone multi-frequency (DTMF) relay duration that the DTMF digits must receive in order to be relayed. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies timeout period (in multiples of 10 milliseconds) allowed for DTMF relay duration. Range is **20** to **250** seconds.

Default Values

By default, the DTMF relay value is **30**.

Command History

Release A2	Command was introduced.

Usage Examples

The following example sets the DTMF relay duration to **50**:

(config)**#ip rtp dtmf-relay min-duration 50**

ip rtp firewall-traversal

Use the **ip rtp firewall-traversal** command to enable dynamic firewall traversal capability for RTP-based traffic, allowing deep packet inspection of Session Description Protocol (SDP) packets to occur so RTP will correctly traverse network address translation (NAT) in the firewall. This will open the proper ports dynamically for the RTP traffic. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip rtp firewall-traversal
ip rtp firewall-traversal <*start udp port*>
ip rtp firewall-traversal <*start udp port*> <*end udp port*>
ip rtp firewall-traversal enforce-symmetric-ip
ip rtp firewall-traversal policy-timeout <*value*>
ip rtp firewall-traversal reuse-nat-ports

Syntax Description

<*end udp port*>	Specifies the ending User Datagram Protocol (UDP) port to reserve for NAT. Range is **2001** to **65535**.
<*start udp port*>	Specifies the starting UDP port to reserve for NAT. Range is **2000** to **65534**.
enforce-symmetric-ip	Optional. Specifies that the same IP address must be used for both transmit and receive for the RTP stream.
policy-timeout <*value*>	Optional. Specifies timeout period in seconds allowed for inactive RTP sessions to remain in the firewall. Range is **1** to **4294967295** seconds.
reuse-nat-ports	Optional. Specifies that NAT ports be reused during calls.

Default Values

By default, the RTP dynamic firewall traversal is disabled and the policy timeout period is **45** seconds.

By default, when the RTP dynamic firewall traversal is enabled for AOS voice products, the UDP starting port is **50000**, and the ending UDP port is **52999**. If no range is specified, the default range is **3000**, unless the starting port is equal to or greater than **62538**, in which case the range will be reduced such that the ending port is **65535**.

Command History

Release 10.1	Command was introduced.
Release 14.1	Command was updated to include the **reuse-nat-ports** option.
Release A2	Command was updated to include the **enforce-symmetric-ip** option.
Release 18.2	Command was updated to include the <*start udp port*> and <*end udp port*> variables.
Release A5.01	Command was updated to include the <*start udp port*> and <*end udp port*> variables for SIP RTP packets on AOS voice products, and the associated voice product defaults.

Functional Notes

Session Initiation Protocol (SIP) uses the SDP to format the SIP message body in order to negotiate a Realtime Transport Protocol (RTP)/Realtime Transport Control Protocol (RTCP) connection between two or more user agents (UAs). The ports used for this will always be selected in a pair, with the even port used for RTP and the odd port for RTCP.

You can also specify which range of NAT UDP ports are reserved for use only for SIP RTP packets using the *<start udp port> <end udp port>* parameters of this command.

The SIP application-level gateway (ALG) (enabled using the **ip firewall alg sip** command) configures the firewall to examine the ALL SIP packets it identifies and maintain knowledge of SIP transmissions on the network. Since SIP packet headers include port information for the call setup, the ALG must intelligently read the packets and remember the information.

For a full SIP implementation, dynamic firewall traversal for RTP traffic must also be enabled using the **ip rtp firewall-traversal** command. This allows the firewall to open the proper ports for the RTP traffic between UAs. For more details on SIP functionality in AOS, refer to the *Functional Notes* and *Technology Review* sections of the command *ip firewall alg on page 1373*.

Usage Examples

The following example enables dynamic firewall traversal, and sets the policy timeout period at **60** seconds:

(config)**#ip rtp firewall-traversal policy-timeout 60**

ip rtp media-anchoring

Use the **ip rtp media-anchoring** command to enable media anchoring for all Realtime Transport Protocol (RTP) calls. Use the **no** form of this command to return to the default setting.

ip rtp media-anchoring
ip rtp media-anchoring qos dscp <*value*>
ip rtp media-anchoring session timeout <*value*>

Syntax Description

qos dscp <*value*>	Specifies the differentiated services code point (DSCP) value for media-anchoring quality of service (QoS) settings. Range is **0** to **63**.
session timeout <*value*>	Specifies the timeout period, in seconds, of an anchoring association after the associated RTP packet flow ends. Range is **32** to **900** seconds.

Default Values

By default, media anchoring is disabled. If media anchoring is enabled, the default **session timeout** value is **45** seconds.

Command History

Release R10.1.0	Command was introduced.
Release R10.5.0	Command was expanded to include the **qos dscp** parameter.

Usage Examples

The following example sets the media anchoring session timeout period at **60** seconds:

(config)**#ip rtp media-anchoring session timeout 60**

Technology Review

Media anchoring, through the use of Session Description Protocol (SDP) manipulation, directs all RTP packets generated in the local network to the media anchoring device (an AOS unit with media anchoring enabled). Outgoing RTP packets (which contain the source IP address and port number of an Internet Protocol (IP) private branch exchange (PBX) or phone and the destination IP address and port of the media anchoring device) are modified to be sourced from the gateway and destined to the public network. The process is reversed for incoming RTP packets.

When a local Voice over Internet Protocol (VoIP) phone makes a call to the public network, the local network will be configured to have all SIP messages routed to the media anchoring device. The media anchoring device will receive a Session Initiation Protocol (SIP) packet with an SDP offer from the IP phone when the phone tries to make the call.

If media anchoring is enabled, the media anchoring device will, based on the SDP offer, determine the egress interface for relaying the SDP to the public network and substitute the IP address of that interface for the connection information IP address contained in the original SDP offer. Additionally, it will substitute a port number in the media anchoring range (User Datagram Protocol (UDP) 10000 and above) in any media descriptions. The offer will then be relayed on the appropriate outbound SIP trunk. This will cause RTP from the public endpoint to be routed to the media anchoring device instead of the VoIP phone.

When the media anchoring device receives the SDP answer from the destination endpoint, the connection information IP address and media description UDP port numbers will be replaced with the IP address of the interface for which the SDP answer was originally destined (i.e., the interface on which the VoIP phone is reachable) and a second port number within the media anchoring UDP port range. This will cause RTP from the VoIP phone to be routed to the media anchoring device instead of the public network.

When the RTP session begins, packets inbound from the public network will have the far-end IP address as the source and the media anchoring device as the destination. The anchoring implementation will replace the source address with the IP address of the egress (to the IP phone) interface on the media anchoring device, and it will replace the destination address with that of the VoIP phone. This information is derived from the UDP port on which the packet was originally received from the network because the anchoring implementation stored this information when the port was allocated.

The same operation will occur on packets inbound from the IP phone. These packets will have the IP phone's IP address and UDP port as the source and the media anchoring device as the destination. The source IP address will be changed to that of the egress (to the public network) interface on the media anchoring device, and the port will be changed to the anchoring port established when the SDP offer was originally manipulated. The destination IP address and UDP port will be changed to that of the public network endpoint.

ip rtp media-anchoring transcoding codec

Use the **ip rtp media-anchoring transcoding codec** command to enable coder/decoder (CODEC) transcoding globally for all Session Initiation Protocol (SIP) endpoints on an AOS session border controller (SBC) device. Use the **no** form of this command to disable the CODEC transcoding feature.

Syntax Description

No subcommands.

Default Values

By default, CODEC transcoding is disabled.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

Before CODEC transcoding can be enabled, media anchoring must be enabled. Refer to the command *ip rtp media-anchoring on page 1458* for more information.

In addition, to configure transcoding you must specify the CODEC settings for each SIP endpoint. Refer to the following sections in this guide for more information: *Voice CODEC List Command Set on page 4893*, *Voice T1 Trunk Command Set on page 5151*, *Voice SIP Trunk Command Set on page 5052*, or *Voice ISDN Trunk Command Set on page 5008*

Usage Examples

The following example enables CODEC transcoding globally on the AOS device:

(config)**#ip rtp media-anchoring transcoding codec**

ip rtp media-anchoring transcoding dtmf

Use the **ip rtp media-anchoring transcoding dtmf** command to enable dualtone multifrequency (DTMF) signal transcoding on a global basis for all Session Initiation Protocol (SIP) endpoints connected to the AOS session border controller (SBC) device. Use the **no** form of this command to disable the DTMF transcoding feature.

Syntax Description

No subcommands.

Default Values

By default, DTMF transcoding is disabled.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

Before DTMF transcoding can be enabled, media anchoring must be enabled. Refer to the command *ip rtp media-anchoring on page 1458* for more information.

In addition, to configure transcoding you must specify the DTMF settings for each SIP endpoint. Refer to the following sections in this guide for more information: *Voice T1 Trunk Command Set on page 5151*, *Voice SIP Trunk Command Set on page 5052*, or *Voice ISDN Trunk Command Set on page 5008*.

Usage Examples

The following example enables DTMF transcoding globally on the AOS device:

(config)**#ip rtp media-anchoring transcoding dtmf**

ip rtp nat-session timeout *<value>*

Use the **ip rtp nat-session timeout** command to configure the network address translation (NAT) session timeout for the Realtime Transport Protocol (RTP) packets. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the timeout period in seconds allowed for an inactive NAT session. Range is **32** to **900** seconds.

Default Values

By default, the timeout period is **32** seconds.

Command History

Release A2.03	Command was introduced.

Usage Examples

The following example sets the NAT session timeout period at **60** seconds:

(config)**#ip rtp nat-session timeout 60**

ip rtp nat-table-timeout <*value*>

Use the **ip rtp nat-table timeout** command to configure the network address translation (NAT) table timeout for the Realtime Transport Protocol (RTP) packets. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the timeout period in seconds allowed for an inactive NAT session. Range is **32** to **900** seconds.

Default Values

By default, the timeout period is **32** seconds.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the NAT session timeout period at **60** seconds:

(config)**#ip rtp nat-session timeout 60**

ip rtp qos dscp *<value>*

Use the **ip rtp qos dscp** command to configure the differentiated services code point (DSCP) value with which to mark IP Realtime Transport Protocol (RTP) packets. This marking can then be used by the quality of service (QoS) mechanisms to give priority for this type of traffic in the unit. Use the **no** form of this command to disable this feature.

Syntax Description

<value>	Specifies the DSCP value. Valid range is **0** to **63**.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example sets the DSCP value to **63**:

(config)**#ip rtp qos dscp 63**

ip rtp quality-monitoring

Use the **ip rtp quality-monitoring** command to globally enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets. Use the **no** form of this command to disable VQM. Variations of this command include:

ip rtp quality-monitoring
ip rtp quality-monitoring scoring-adjustment japan
ip rtp quality-monitoring sip
ip rtp quality-monitoring udp

Syntax Description

scoring-adjustment japan	Optional. Sets the region for scoring adjustment for Japan. In Japan, the mean opinion score (MOS) statistics are calculated differently than in other regions. VQM must be disabled and then enabled again for this setting to take effect.
sip	Optional. Specifies that Session Initiation Protocol (SIP) is the signaling type of the RTP stream to monitor.
udp	Optional. Specifies that User Datagram Protocol (UDP) is the signaling type of the RTP stream to monitor.

Default Values

By default, the VQM is disabled globally.

Functional Notes

Disabling VQM on the global level (for example, to change the scoring adjustment) erases all active calls, new calls, and interface statistics. Call history and endpoint statistics are not affected.

If the **sip** or **udp** parameters are specified, and VQM has not previously been enabled at the global level, VQM will be enabled globally. Enabling UDP packet inspection forces the AOS unit to inspect every UDP packet to determine if it is an RTP packet, placing a significant load on the AOS unit. UDP packet inspection should only be enabled if IP phones are being used and they do not pass through the SIP ALG, SIP proxy, or SIP B2BUA.

For more information about VQM configuration, refer to the configuration guide *Configuring VQM in AOS* available online at https://supportcommunity.adtran.com.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables RTP quality monitoring at the global level and does not specify a scoring region or RTP signaling type:

(config)**#ip rtp quality-monitoring**

ip rtp quality-monitoring filter

Use the **ip rtp quality-monitoring filter** command to filter the number of Realtime Transport Protocol (RTP) voice streams monitored by voice quality monitoring (VQM). Use the **no** form of this command to remove the filter. Variations of this command include:

ip rtp quality-monitoring filter user <*user*>
ip rtp quality-monitoring filter access-class <*name*>

Syntax Description

user <*user*>	Specifies that only calls from certain users are measured. Users are specified by Session Initiation Protocol (SIP) To or From headers, in the format **user@host**. Multiple users can be monitored simultaneously.
access-class <*name*>	Specifies that only RTP streams that match the previously configured access control list (ACL) are measured. The <*name*> parameter is the ACL to be used. Only one ACL can be applied to VQM at a time.

Default Values

By default, VQM is not filtered by user or ACL.

Command History

Release A1	Command was introduced.

Usage Examples

The following example specifies that VQM only monitor RTP streams that match the previously configured ACL, **4thFloorUsers**:

(config)**#ip rtp quality-monitoring filters access-class 4thFloorUsers**

ip rtp quality-monitoring history

Use the **ip rtp quality-monitoring history** commands to configure the call history storage for voice quality monitoring (VQM). You can use this command variations to configure the size of the call history and to specify the thresholds used to decide when calls are stored in the call history. Using the **no** forms of these commands return the call history parameters to the default settings. Variations of this command include:

ip rtp quality-monitoring history cq-mos <*value*>
ip rtp quality-monitoring history jitter <*value*>
ip rtp quality-monitoring history loss <*value*>
ip rtp quality-monitoring history lq-mos <*value*>
ip rtp quality-monitoring history max-streams <*number*>
ip rtp quality-monitoring history out-of-order <*value*>
ip rtp quality-monitoring history pq-mos <*value*>

Syntax Description

cq-mos <*value*>	Specifies a threshold for the conversational quality (CQ) mean opinion score (MOS), and stores statistics below this threshold. The range is **0** to **4.4**.
jitter <*value*>	Specifies a threshold for the jitter. Statistics above this threshold are stored as jitter. The packet-to-packet delay variation is measured in milliseconds (from nAvgPDV). The range is **0** to **30000**.
loss <*value*>	Specifies a threshold for loss (in packets). Statistics above this threshold is stored as lost packets. The range is **0** to **30000**.
lq-mos <*value*>	Specifies a threshold for the listening quality (LQ) MOS, and stores statistics below this threshold. The range is **0** to **4.4**.
max-streams <*number*>	Specifies a number of previously completed call statistics to store. This is a count of Realtime Transport Protocol (RTP) streams; each call can contain two RTP streams. The range is **0** to **2000**.
out-of-order <*value*>	Specifies a threshold for out-of-order packets to be logged. Statistics above this threshold are stored. The range is **0** to **30000**.
pq-mos <*value*>	Specifies a threshold for LQ MOS normalized to the PESQ (PQ) scale, and stores statistics below this threshold. The range is **0** to **4.4**.

Default Values

By default, the maximum number of RTP streams allowed in the history is **100**.

Setting the size of the call history to a large number can result in the AOS unit running out of memory.

By default, MOS thresholds are set to **4.4**, and jitter, loss, and out-of-order packet thresholds are set to **0**.

Command History

Release 17.1	Command was introduced.

Functional Notes

As calls complete, settings configured using this command are examined to determine whether the call should be stored in the call history. The maximum number of streams to store may be configured; newer calls will replace the oldest calls when the call history is full. The MOS, loss, out-of-order packets, and jitter can also be examined when a call completes. By default, all calls are stored in the call history. However, if threshold values are changed from their defaults, only calls with poorer quality than these nondefault thresholds will be stored.

Usage Examples

The following example enables RTP quality monitoring history to store a maximum of **250** RTP streams:

(config)**#ip rtp quality-monitoring history max-streams 250**

ip rtp quality-monitoring jitter-buffer

Use the **ip rtp quality-monitoring jitter-buffer** command to specify the jitter buffer type and configuration for the jitter buffer emulator (JBE) that generates the observable jitter statistics in Realtime Transport Protocol (RTP) quality monitoring. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip rtp quality-monitoring jitter-buffer
ip rtp quality-monitoring jitter-buffer adaptive min <*delay*> **nominal** <*value*>
ip rtp quality-monitoring jitter-buffer adaptive min <*delay*> **nominal** <*value*> **max** <*value*>
ip rtp quality-monitoring jitter-buffer fixed nominal <*value*> **jitter-buffer-size** <*value*>

Syntax Description

adaptive min <*delay*>	Optional. Specifies the minimum acceptable jitter buffer delay to be used by the JBE. The range is **10** to **240** milliseconds.
nominal <*value*>	Optional. Specifies the starting delay applied to packets of the emulated jitter buffer. The range is **10** to **240** milliseconds.
max <*value*>	Optional. Specifies the maximum delay that the adaptive jitter buffer will be allowed to use. The range is **40** to **320** milliseconds.
fixed nominal <*value*>	Optional. Specifies the actual fixed delay that would be applied to the packet in a nonemulated jitter buffer. The range is **4** to **250** milliseconds. There is no default setting.
jitter-buffer-size <*value*>	Optional. Specifies the number of packets that the emulated jitter buffer can hold. The range is **10** to **500** packets. There is no default setting.

Default Values

By default, the jitter buffer is set to **adaptive min 10 nominal 50 max 200**.

Command History

Release 17.1	Command was introduced.
Release A1	Command was introduced in the AOS voice products.
Release A4.01	Command was modified to allow specifying the **nominal** value without specifying the **max** value.

Usage Examples

The following example enables the JBE to hold up to **175** packets in fixed mode:

(config)**#ip rtp quality-monitoring jitter-buffer fixed nominal 50 jitter-buffer-size 175**

ip rtp quality-monitoring jitter-threshold

Use the **ip rtp quality-monitoring jitter-threshold** command to specify the jitter thresholds for the voice quality monitoring (VQM) simulated jitter buffer. These thresholds determine when packets are considered either too early or too late for the jitter buffer window, and are then marked as discarded packets. Changing the jitter threshold will not impact currently active calls, only the calls placed after the configuration change has taken place. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip rtp quality-monitoring jitter-threshold early <*value*>
ip rtp quality-monitoring jitter-threshold late <*value*>

Syntax Description

early <*value*>	Specifies the time by which packets are deemed to have arrived early. The range is **0** to **1000** ms.
late <*value*>	Specifies the time by which packets are deemed to have arrived late. The range is **0** to **1000** ms.

Default Values

By default, jitter thresholds are set to **early 10**, and **late 60**.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example specifies the late jitter threshold at **45** ms:

(config)**#ip rtp quality-monitoring jitter-threshold late 45**

p rtp quality-monitoring reporter <*name*>

Use the **ip rtp quality-monitoring reporter** command to create and name a voice quality monitoring (VQM) reporter. Use the **no** form of this command to delete the reporter. Variations of this command include:

ip rtp quality-monitoring reporter <*name*>
ip rtp quality-monitoring reporter <*name*> **vrf** <*name*>

Syntax Description

<*name*>	Specifies the name of the VQM reporter.
vrf <*name*>	Optional. Specifies a nondefault virtual routing and forwarding (VRF) instance on which to enable the VQM reporter. If no VRF is specified, the VQM reporter is enabled on the default unnamed VRF instance.

Default Values

By default, no VQM reporter exists.

Command History

Release 17.6	Command was introduced.
Release R13.10.0	Command was expanded to include the **vrf** parameter.

Functional Notes

The **ip rtp quality-monitoring reporter** command creates a VQM reporter and also enters the reporter's configuration mode. For more information on configuring VQM reporters, refer to the *VQM Reporter Command Set on page 4945*.

Usage Examples

The following example creates the VQM reporter **Reporter1** and enters the reporter's configuration mode:

```
(config)#ip rtp quality-monitoring reporter Reporter1
    Configuring New Reporter "Reporter1"
(config-rtp-reporter-Reporter1)#
```

ip rtp quality-monitoring round-trip-delay

Use the **ip rtp quality-monitoring round-trip-delay** command to enable packet round-trip calculations for voice quality monitoring (VQM) and to specify the type of round-trip delay testing. Use the **no** form of this command to disable VQM round-trip delay calculations. Variations of this command include:

ip rtp quality-monitoring round-trip-delay icmp-ping
ip rtp quality-monitoring round-trip-delay icmp-timestamp

Syntax Description

icmp-ping	Specifies the use of Internet Control Message Protocol (ICMP) requests for calculating round-trip delay.
icmp-timestamp	Specifies the use of ICMP timestamp requests for calculating round-trip delay.

Default Values

By default, the calculation type is **icmp-ping**.

Functional Notes

Round-trip delay settings appear in the VQM statistics; however, if Realtime Transport Protocol (RTP) extended reports (RTCP XR) are also available, the received RTCP XR reports supersede the round-trip delay settings.

The endpoints and local units must be synchronized (time and date) for the timestamp method to be accurate. In addition, any firewalls between the voice endpoints must be configured to allow ICMP traffic to pass.

For more information about VQM round-trip delay calculations, and VQM configuration, refer to the configuration guide *Configuring VQM in AOS* available online at https://supportcommunity.adtran.com.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example specifies timestamp requests are used to determine round-trip delay:

(config)**#ip rtp quality-monitoring round-trip-delay icmp-timestamp**

ip rtp quality-monitoring sample one-out-of <*number*>

Use the **ip rtp quality-monitoring sample one-out-of** command to limit the number of Realtime Transport Protocol (RTP) streams monitored by voice quality monitoring (VQM). Use the **no** form of this command to disable VQM sampling.

Syntax Description

<*number*>	Specifies the VQM jitter buffer sampling rate, which causes VQM to only monitor 1 out of the specified number of RTP streams. Range is **1** to **100**.

Default Values

By default, the VQM sampling rate is set to **1**, which means that all RTP streams are monitored.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example specifies that VQM monitors 10 percent of all streams (one out of every **10**):

(config)**#ip rtp quality-monitoring sample one-out-of 10**

ip rtp quality-monitoring snmp trap

Use the **ip rtp quality-monitoring snmp trap** command to configure the Simple Network Management Protocol (SNMP) trap parameters of voice quality monitoring (VQM). Using the **no** form of this command disables VQM SNMP trap reports and collections. Variations of this command include:

ip rtp quality-monitoring snmp trap
ip rtp quality-monitoring snmp trap priority-level error
ip rtp quality-monitoring snmp trap priority-level info
ip rtp quality-monitoring snmp trap priority-level notice
ip rtp quality-monitoring snmp trap priority-level warning

Syntax Description

priority-level	**Optional.** Specifies the priority level of the SNMP trap created by VQM.
error	Specifies that an SNMP trap is created when VQM detects an error event.
info	Specifies that an SNMP trap is created when VQM detects an info event.
notice	Specifies that an SNMP trap is created when VQM detects a notice event.
warning	Specifies that an SNMP trap is created when VQM detects a warning.

Default Values

By default, SNMP traps are not enabled for VQM.

Command History

Release 17.6	Command was introduced.

Usage Examples

The following example enables SNMP traps for VQM:

(config)**#ip rtp quality-monitoring snmp trap**

ip rtp quality-monitoring threshold jitter

Use the **ip rtp quality-monitoring threshold jitter** command to specify the threshold values for logging jitter events during voice quality monitoring (VQM). When more jitter is detected in the Realtime Transport Protocol (RTP) than the specified event threshold, an event message is generated. Use the **no** form of this command to disable the event reporting for that message type and threshold. Variations of this command include:

ip rtp quality-monitoring threshold jitter error
ip rtp quality-monitoring threshold jitter error <*value*>
ip rtp quality-monitoring threshold jitter info
ip rtp quality-monitoring threshold jitter info <*value*>
ip rtp quality-monitoring threshold jitter notice
ip rtp quality-monitoring threshold jitter notice <*value*>
ip rtp quality-monitoring threshold jitter warning
ip rtp quality-monitoring threshold jitter warning <*value*>

Syntax Description

error	Specifies the threshold for jitter error messages to be logged.
info	Specifies the threshold for jitter information messages to be logged.
notice	Specifies the threshold for jitter notice messages to be logged.
warning	Specifies the threshold for jitter warning messages to be logged.
<*value*>	Optional. The range is **0** to **30000**.

Default Values

By default, the jitter logging thresholds are **info 0**, **notice 250**, **warning 350**, and **error 450**.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables VQM jitter warning messages to be logged if jitter occurs above **200** ms:

(config)**#ip rtp quality-monitoring threshold jitter warning 200**

ip rtp quality-monitoring threshold loss

Use the **ip rtp quality-monitoring threshold loss** command to specify the threshold values for logging packet loss events during voice quality monitoring (VQM). When more loss is detected in the Realtime Transport Protocol (RTP) than the specified event threshold, an event message is generated. Use the **no** form of this command disables the event reporting for that message type and threshold. Variations of this command include:

ip rtp quality-monitoring threshold loss error
ip rtp quality-monitoring threshold loss error <*value*>
ip rtp quality-monitoring threshold loss info
ip rtp quality-monitoring threshold loss info <*value*>
ip rtp quality-monitoring threshold loss notice
ip rtp quality-monitoring threshold loss notice <*value*>
ip rtp quality-monitoring threshold loss warning
ip rtp quality-monitoring threshold loss warning <*value*>

Syntax Description

error	Specifies the threshold for lost packets error messages to be logged.
info	Specifies the threshold for lost packets information messages to be logged.
notice	Specifies the threshold for lost packets notice messages to be logged.
warning	Specifies the threshold for lost packets warning messages to be logged.
<*value*>	Optional. The range is **0** to **30000**.

Default Values

By default, the lost packets thresholds are **info 0**, **notice 25**, **warning 50**, and **error 100**.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables VQM lost packet **info** messages to be logged if loss occurs above **10** packets:

(config)**#ip rtp quality-monitoring threshold loss info 10**

ip rtp quality-monitoring threshold lq-mos

Use the **ip rtp quality-monitoring threshold lq-mos** command to specify threshold values for logging listening quality (LQ) mean opinion score (MOS) events during voice quality monitoring (VQM). When the call quality detected in the Realtime Transport Protocol (RTP) stream is less than the specified event threshold, an event message is generated. Use the **no** form of this command disables the event reporting for that message type and threshold. Variations of this command include:

ip rtp quality-monitoring threshold lq-mos error
ip rtp quality-monitoring threshold lq-mos error <*value*>
ip rtp quality-monitoring threshold lq-mos info
ip rtp quality-monitoring threshold lq-mos info <*value*>
ip rtp quality-monitoring threshold lq-mos notice
ip rtp quality-monitoring threshold lq-mos notice <*value*>
ip rtp quality-monitoring threshold lq-mos warning
ip rtp quality-monitoring threshold lq-mos warning <*value*>

Syntax Description

error	Specifies the threshold for LQ MOS error messages to be logged.
info	Specifies the threshold for LQ MOS information messages to be logged.
notice	Specifies the threshold for LQ MOS notice messages to be logged.
warning	Specifies the threshold for LQ MOS warning messages to be logged.
<*value*>	Optional. The range is **0** to **4.4**.

Default Values

By default, the LQ MOS thresholds are **info 4.40**, **notice 4.00**, **warning 3.60**, and **error 2.60**.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables VQM LQ MOS **info** messages to be logged if LQ MOS scores fall below **4.25**:

(config)**#ip rtp quality-monitoring threshold lq-mos info 4.25**

ip rtp quality-monitoring threshold out-of-order

Use the **ip rtp quality-monitoring threshold out-of-order** command to specify threshold values for logging out-of-order packet events during voice quality monitoring (VQM). When more out-of-order packets are detected in the Realtime Transport Protocol (RTP) stream than the specified event threshold, an event message is generated. Use the **no** form of this command disables the event reporting for that message type and threshold. Variations of this command include:

ip rtp quality-monitoring threshold out-of-order error
ip rtp quality-monitoring threshold out-of-order error <*value*>
ip rtp quality-monitoring threshold out-of-order info
ip rtp quality-monitoring threshold out-of-order info <*value*>
ip rtp quality-monitoring threshold out-of-order notice
ip rtp quality-monitoring threshold out-of-order notice <*value*>
ip rtp quality-monitoring threshold out-of-order warning
ip rtp quality-monitoring threshold out-of-order warning <*value*>

Syntax Description

error	Specifies the threshold for out-of-order packet error messages to be logged.
info	Specifies the threshold for out-of-order packet information messages to be logged.
notice	Specifies the threshold for out-of-order packet notice messages to be logged.
warning	Specifies the threshold for out-of-order packet warning messages to be logged.
<*value*>	Optional. The range is **0** to **30000**.

Default Values

By default, the out-of-order packet thresholds are **info 0**, **notice 25**, **warning 50**, and **error 100**.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables VQM out-of-order packet **info** messages to be logged if the number of out-of-order packets is greater than **5**:

(config)**#ip rtp quality-monitoring threshold out-of-order info 5**

ip rtp quality-monitoring threshold pq-mos

Use the **ip rtp quality-monitoring threshold pq-mos** command to specify threshold values for logging perceived quality (PQ) mean opinion score (MOS) events during voice quality monitoring (VQM). When the call quality detected in the Realtime Transport Protocol (RTP) stream is less than the specified event threshold, an event message is generated. Use the **no** form of this command disables the event reporting for that message type and threshold. Variations of this command include:

ip rtp quality-monitoring threshold pq-mos error
ip rtp quality-monitoring threshold pq-mos error <*value*>
ip rtp quality-monitoring threshold pq-mos info
ip rtp quality-monitoring threshold pq-mos info <*value*>
ip rtp quality-monitoring threshold pq-mos notice
ip rtp quality-monitoring threshold pq-mos notice <*value*>
ip rtp quality-monitoring threshold pq-mos warning
ip rtp quality-monitoring threshold pq-mos warning <*value*>

Syntax Description

error	Specifies the threshold for listening quality PQ MOS error messages to be logged.
info	Specifies the threshold for listening quality PQ MOS information messages to be logged.
notice	Specifies the threshold for listening quality PQ MOS notice messages to be logged.
warning	Specifies the threshold for listening quality PQ MOS warning messages to be logged.
<*value*>	Optional. The range is **0** to **4.4**.

Default Values

By default, the PQ MOS thresholds are **info 4.40**, **notice 4.00**, **warning 3.60**, and **error 2.60**.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables VQM PQ MOS **info** messages to be logged if the PQ MOS scores fall below **4.25**:

(config)**#ip rtp quality-monitoring threshold pq-mos info 4.25**

ip rtp session timeout <*value*> disconnect

Use the **ip rtp session timeout** <*value*> **disconnect** command to specify the time, in seconds, before calls that have not received Realtime Transport Protocol (RTP) are disconnected. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the timeout period, in seconds, before disconnecting RTP calls once the RTP packet flow ends. Range is **32** to **900** seconds.

Default Values

By default, RTP sessions disconnect after **45** seconds of inactivity.

Command History

Release R13.8.0	Command was introduced.

Usage Examples

The following example specifies that after **60** seconds of no received RTP, RTP calls will be disconnected:

(config)**#ip rtp session timeout 60 disconnect**

ip rtp symmetric-filter

Use the **ip rtp symmetric-filter** command to enable filtering of received nonsymmetric Realtime Transport Protocol (RTP) packets. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, the RTP symmetric filter is enabled on some AOS platforms, and disabled on others. Enter the **show running-config verbose | include rtp symmetric-filter** command from the Enable mode prompt to determine if the RTP symmetric filter is enabled or disabled on the AOS device.

Command History

Release 14.1	Command was introduced.

Usage Examples

The following example enables **ip rtp symmetric-filter**:

(config)**#ip rtp symmetric-filter**

ip rtp udp *<number>*

Use the **ip rtp udp** command to configure a global starting User Datagram Protocol (UDP) port for Realtime Transport Protocol (RTP). Use the **no** form of this command to remove a configured UDP port.

Syntax Description

<number>	Specifies the value of the starting UDP port. Valid range is **1026** to **60000**.

Default Values

The default value for this command is **10000**.

Command History

Release 10.1	Command was introduced.
Release 14.1	Command was updated.

Usage Examples

The following example configures **2000** as the starting value of the UDP port:

(config)**#ip rtp udp 2000**

ip scp server

Use the **ip scp server** command to enable the secure copy server functionality in AOS. Enabling the secure copy server allows AOS to support the transfer of files using a secure connection. A secure connection helps provide protection against outside forces gaining access to configuration files. An external secure copy server is required to facilitate the transfers from the terminal. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, the secure copy server is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example enables the secure copy server function:

(config)**#ip scp server**

ip security monitor

Use the **ip security monitor** command to activate the AOS Security Monitor feature and enter the Security Monitor Configuration mode. For more information on configuring the Security Monitor feature, refer to the *Security Monitor Command Set on page 4503*.

Syntax Description

No Subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 17.5	Command was introduced.

Usage Examples

The following example activates the Security Monitor Configuration feature:

(config-)**#ip security monitor**

ip security monitor stats-filter <*name*>

Use the **ip security monitor stats-filter** command to create a new security monitor filter and enter the filter configuration mode. For more information on configuring the security monitor statistics filter refer to *threat on page 4506*. Use the **no** version of this command to delete the specified filter.

Syntax Description

<*name*>	Specifies the filter to be applied.

Default Values

By default, no security monitor filters exist.

Command History

Release 17.5	Command was introduced.

Usage Examples

The following example applies a filter named **F1**:

(config)**#ip security monitor stats-filter F1**
Creating new filter “F1”.
(config-secmon-filter)#

ip sntp server

Use the **ip sntp server** command to enable the Simple Network Time Protocol (SNTP) server. This allows the unit to accept SNTP requests. Use the **no** form of this command to disable the server.

Syntax Description

No subcommands.

Default Values

By default, the SNTP server is disabled.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example enables the SNTP server:

(config)**#ip sntp server**

ip sntp server send-unsynced

Use the **ip sntp server send-unsynced** command to enable sending the system clock time when requested, even if the device is not synchronized with the Simple Network Time Protocol (SNTP) server. Use the **no** form of this command to disable this setting.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release 14.1	Command was introduced.

Usage Examples

The following example enables the device to send the system clock time regardless of synchronized status with the sntp server:

(config)**#ip sntp server send-unsynced**

ip sntp server source-interface <*interface*>

Use the **ip sntp server source-interface** command to specify a source interface for Simple Network Time Protocol (SNTP) server traffic. The IP address of the specified interface will be used to source all SNTP traffic. Use the **no** form of this command if you do not wish to override the default source IP address.

Syntax Description

<interface>	Specifies the source interface for SNTP server traffic. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip sntp server source-interface ?** for a complete list of valid interfaces.

Default Values

By default, no SNTP server source interface is defined.

Command History

Release 6.1	Command was introduced.
Release 14.1	Command was expanded to include the tunnel interface.
Release 16.1	Command was expanded to include the bridged virtual interface (BVI), Frame Relay, high level data link control (HDLC), and Point-to-Point Protocol (PPP) interfaces.
Release 17.1	Command was expanded to include the asynchronous transfer mode (ATM) interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.

Functional Notes

This command allows you to override the *sender* field in the IP packet. If you have multiple interfaces in your unit, changing the *sender* tells the receiver where to send replies. This functionality can also be used to allow packets to get through firewalls that would normally block the flow.

Usage Examples

The following example configures the unit to use the **loopback 1** interface as the source IP for SNTP traffic:

(config)#**ip sntp server source-interface loopback 1**

ip sntp source-interface *<interface>*

Use the **ip sntp source-interface** command to specify a source interface for Simple Network Time Protocol (SNTP) traffic originated by the unit. The IP address of the specified interface will be used to source all SNTP traffic. Use the **no** form of this command if you do not wish to override the default source IP address.

Syntax Description

<interface>	Specifies the source interface for SNTP traffic. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip sntp source-interface ?** for a complete list of valid interfaces.

Default Values

By default, no SNTP source interface is defined.

Command History

Release 6.1	Command was introduced.
Release 14.1	Command was expanded to include the tunnel interface.
Release 16.1	Command was expanded to include the bridged virtual interface (BVI), Frame Relay, high level data link control (HDLC), and Point-to-Point Protocol (PPP) interfaces.
Release 17.1	Command was expanded to include the asynchronous transfer mode (ATM) interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.

Functional Notes

This command allows you to override the *sender* field in the IP packet. If you have multiple interfaces in your unit, changing the *sender* tells the receiver where to send replies. This functionality can also be used to allow packets to get through firewalls that would normally block the flow.

Usage Examples

The following example configures the unit to use the **loopback 1** interface as the source IP for SNTP traffic:

(config)**#ip sntp source-interface loopback 1**

ip subnet-zero

The **ip subnet-zero** command is the default operation and cannot be disabled. This command signifies the router's ability to route to subnet-zero subnets.

Syntax Description

No subcommands.

Default Values

By default, this command is enabled.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example **subnet-zero** is enabled:

(config)**#ip subnet-zero**

ip tacacs source-interface <*interface*>

Use the **ip tacacs source-interface** command to specify an Internet Protocol version 4 (IPv4) source interface for terminal access controller access-control system plus (TACACS+) traffic originated by the unit. Specifying the virtual routing and forwarding (VRF) instance using the **vrf** <*name*> keyword applies the association to the named VRF instance. Omitting the **vrf** <*name*> keyword applies the association to the default unnamed VRF. The IPv4 address of the specified interface will be used to source all TACACS+ traffic. Use the **no** form of this command if you do not wish to override the default source IP address. Variations of this command include:

ip tacacs source-interface <*interface*>
ip tacacs vrf <*name*> **source-interface** <*interface*>

Syntax Description

<*interface*>	Specifies the source interface for TACACS+ traffic. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip tacacs source-interface ?** for a complete list of valid interfaces.
vrf <*name*>	Specifies the name of the VRF to which to assign the source-interface.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the tunnel interface.
Release 17.1	Command was expanded to include the asynchronous transfer mode (ATM) interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.7.0	Command was expanded to include the **vrf** <*name*> parameter.

Functional Notes

This command allows you to override the *sender* field in the IP packet. If you have multiple interfaces in your unit, changing the *sender* tells the receiver where to send replies. This functionality can also be used to allow packets to get through firewalls that would normally block the flow.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example configures the unit to use the **loopback 1** interface as the source IP for TACACS+ traffic:

(config)**#ip tacacs source-interface loopback 1**

The following example configures the unit to use the **loopback 1** interface on VRF RED as the source IP for TACACS+ traffic:

(config)**#ip tacacs vrf RED source-interface loopback 1**

ip urlfilter allowmode

Use the **ip urlfilter allowmode** command to allow all uniform resource locator (URL) requests in cases when all URL filter servers are down. Use the **no** form of this command to block all URL requests when all URL filter servers are down.

Syntax Description

No subcommands.

Default Values

By default, all URL requests will be blocked when all URL filter servers are down.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example permits all URL requests even when URL filter servers are down:

(config)**#ip urlfilter allowmode**

ip urlfilter exclusive-domain

Use the **ip urlfilter exclusive-domain** command to instruct AOS to always allow or always block a domain without first having to verify with the uniform resource locator (URL) filter server. Use the **no** form of this command to remove an exclusive domain. Variations of this command include:

ip urlfilter exclusive-domain deny *<name>*
ip urlfilter exclusive-domain permit *<name>*

Syntax Description

deny *<name>*	Specifies that the domain name be blocked without verifying with the URL filter server.
permit *<name>*	Specifies that the domain name be allowed without verifying with the URL filter server.

Default Values

By default, no exclusive domains are configured.

Command History

Release 12.1	Command was introduced.

Functional Notes

Domain matching is based on an exact match between the Hypertext Transfer Protocol (HTTP) header and entries in the **ip urlfilter exclusive-domain** command. In order to exactly match requests destined for a domain, entries should list all possible variations of the domain that would appear in the **Host** field of an HTTP header. Refer to the *Usage Examples* section of this command for more detailed information.

Usage Examples

The following example will always allow access to **www.adtran.com** and **adtran.com** without first having to verify the domain with the URL filter server:

(config)**#ip urlfilter exclusive-domain permit www.adtran.com**
(config)**#ip urlfilter exclusive-domain permit adtran.com**

The following example will always block access to **www.localnews.com** without first having to verify the domain with the URL filter server:

(config)**#ip urlfilter exclusive-domain deny www.localnews.com**

ip urlfilter <*name*> http

Use the **ip urlfilter http** command to create a uniform resource locator (URL) filter for Hypertext Transfer Protocol (HTTP) (Transmission Control Protocol (TCP) port 80) traffic. Use the **no** form of this command to delete the specified HTTP URL filter.

The URL filtering software runs on a server independent of the AOS product. For additional information about the URL filtering technology, refer to the vendor's website.

Syntax Description

<*name*>	Specifies the URL filter name.

Default Values

By default, no URL filters are configured.

Command History

Release 12.1	Command was introduced.

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be applied to the appropriate interface by using the **ip urlfilter** <*name*> **[in | out]** command. Refer to this command in the appropriate interface for more information.

Usage Examples

The following example creates the HTTP URL filter called **MyFilter** that can be applied to an interface for content filtering:

(config)**#ip urlfilter MyFilter http**

ip urlfilter max-request <*value*>

Use the **ip urlfilter max-request** command to set the maximum number of outstanding uniform resource locator (URL) lookup requests that can be sent to a URL filter server without a response. Use the **no** form of this command to set the value back to its default setting.

Syntax Description

<*value*>	The maximum number of outstanding URL lookup requests. Valid range is **1** to **500** requests.

Default Values

By default, the number of outstanding requests is **500**.

Command History

Release 12.1	Command was introduced.

Functional Notes

After the maximum number of URL lookup requests is reached, the **no ip urlfilter allowmode** setting will be used to allow or block all following requests until enough URL lookup responses have been received from the URL filter server.

Usage Examples

The following example sets the maximum number of URL lookup requests to **250**:

(config)**#ip urlfilter max-request 250**

ip urlfilter max-response *<value>*

Use the **ip urlfilter max-response** command to set the maximum number of responses allowed to buffer before receiving an allow or block status from the uniform resource locator (URL) filter server. Use the **no** form of this command to set the value back to its default setting.

Syntax Description

<value>	Specifies the maximum number of responses allowed to buffer. Valid range is **1** to **100** responses.

Default Values

By default, the value of buffered responses is **100**.

Command History

Release 12.1	Command was introduced.

Functional Notes

When a URL request comes through the unit and URL filtering is enabled, a lookup request is sent to the URL filter server and the Hypertext Transfer Protocol (HTTP) request is forwarded to the HTTP server at the same time. If the HTTP server responds before the URL filter server, the response must be buffered until the URL filter server responds with **allow** or **block**. Once the maximum number of buffered HTTP responses is reached, all following HTTP responses are dropped until some of the existing buffered responses are released. Buffered responses are released when the URL filter server sends a response, or when the firewall association times out.

Usage Examples

The following example sets the maximum number of buffered responses to **50**:

(config)**#ip urlfilter max-response 50**

ip urlfilter server <*ip address*>

Use the **ip urlfilter server** command to identify a uniform resource locator (URL) filter server by IP address and port number. Use the **no** form of this command to remove the server from use. Variations of this command include:

ip urlfilter server <*ip address*>
ip urlfilter server <*ip address*> **port** <*number*>
ip urlfilter server <*ip address*> **timeout** <*value*>

Syntax Description

<*ip address*>	Specifies the server IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
port <*number*>	Specifies the server Transmission Control Protocol (TCP) port number that will receive requests.
timeout <*value*>	Specifies the number of seconds to wait for a response from the URL filtering server before determining that it is out of service. Range is **1** to **300** seconds.

Default Values

By default, there are no URL filtering servers configured. When configuring a URL filtering server, the port default is 15,868, and the timeout default is 5 seconds.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example identifies a URL filtering server at IP address **10.1.1.1** that listens for URL filtering requests on port 15,868 (default) and waits for a response for **10** seconds before determining that the filtering server is down:

(config)**#ip urlfilter server 10.1.1.1 timeout 10**

ip urlfilter top-website

Use the **ip urlfilter top-website** command to enable reporting of the websites most frequently requested on the system. Use the **no** form of this command to disable top websites reporting.

Enabling this feature may cause a performance degradation in Web browsing.

Syntax Description

No subcommands.

Default Values

By default, top websites reporting is disabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables top websites reporting:

(config)**#ip urlfilter top-website**

ipv6 access-list extended *<ipv6 acl name>*

Use the **ipv6 access-list extended** command to create an empty Internet Protocol version 6 (IPv6) access control list (ACL) and enter the Extended ACL Configuration mode. Use the **no** form of this command to delete an extended ACL and all the entries contained in it.

> NOTE *For a complete list of all extended IPv6 ACL configuration commands, refer to the IPv4 Access Control List Command Set on page 4252.*

Syntax Description

<ipv6 acl name>	Specifies the name of the IPv6 ACL.

Default Values

By default, all AOS security features are disabled, and there are no configured IPv6 ACLs.

Command History

Release 18.1	Command was introduced.

Functional Notes

This command only creates an empty extended IPv6 ACL, it does not configure it. For additional extended ACL configuration commands and configuration parameters, refer to the *IPv4 Access Control List Command Set on page 4252*.

Usage Examples

The following example creates an extended IPv6 ACL **Allowv6** and enters the Extended ACL Configuration mode:

(config)**#ip access-list extended Allowv6**
(config-ext6-nacl)#

Technology Review

IPv6 ACLs are used as packet selectors by different AOS IPv6 features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** ACL is used to match packets (meeting the specified pattern) to enter the router system. A **deny** ACL advances AOS to the next access policy entry. AOS provides two types of ACLs: standard and extended. Standard ACLs match based on the source of the packet. Extended ACLs match based on the source and destination of the packet.

ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

IPv6 ACLs cannot have the same name as IPv4 ACLs. If you are using both IPv4 and IPv6, you must have different ACLs for each IP version.

Virtual routing and forwarding (VRF) on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the above mentioned commands without specifying a VRF will only affect the default unnamed VRF.

ipv6 access-list standard *<ipv6 acl name>*

Use the **ipv6 access-list standard** command to create an empty IPv6 access control list (ACL) and enter the Standard ACL Configuration mode. Use the **no** form of this command to delete an extended ACL and all the entries contained in it.

For a complete list of all standard IPv6 ACL configuration commands, refer to the IPv6 Access Control Policy Command Set on page 4326.

Syntax Description

<ipv6 acl name>	Specifies the name of the IPv6 ACL.

Default Values

By default, all AOS security features are disabled, and there are no configured IPv6 ACLs.

Command History

Release 18.1	Command was introduced.

Functional Notes

This command only creates an empty standard IPv6 ACL, it does not configure it. For additional standard IPv6 ACL configuration commands and configuration parameters, refer to the *IPv4 Access Control Policy Command Set on page 4278*.

Usage Examples

The following example creates a standard IPv6 ACL **Allowv6** and enters the Standard ACL Configuration mode:

(config)**#ipv6 access-list standard Allowv6**
(config-std6-nacl)#

Technology Review

IPv6 ACLs are used as packet selectors by different IPv6 AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** ACL is used to match packets (meeting the specified pattern) to enter the router system. A **deny** ACL advances AOS to the next access policy entry. AOS provides two types of ACLs: standard and extended. Standard ACLs match based on the source of the packet. Extended ACLs match based on the source and destination of the packet.

ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

IPv6 ACLs cannot have the same name as IPv4 ACLs. If you are using both IPv4 and IPv6, you must have different ACLs for each IP version.

Virtual routing and forwarding (VRF) on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the above mentioned commands without specifying a VRF will only affect the default unnamed VRF.

ipv6 crypto

Use the **ipv6 crypto** command to enable Internet Protocol version 6 (IPv6) IP security (IPsec). Use the **no** form of this command to disable IPv6 IPsec. Variations of this command include:

ipv6 crypto
ipv6 crypto vrf <*name*>

Syntax Description

vrf <*name*>	Optional. Specifies a nondefault virtual routing and forwarding (VRF) instance on which to enable IPv6 IPsec. If no VRF is specified, IPv6 IPsec is enabled on the default unnamed VRF instance.

Default Values

By default, IPv6 IPsec is disabled.

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example enables IPv6 IPsec on the default VRF instance:

(config)**#ipv6 crypto**

ipv6 crypto ipsec transform-set *<name> <parameters>*

Use the **ipv6 crypto ipsec transform-set** command to define an Internet Protocol version 6 (IPv6) transform set. Transform sets are used to define the configuration for securing data with IP security (IPsec), and then the sets are applied to crypto maps which use them for specific security algorithms. Use the **no** form of this command to remove the transform set.

The following additional subcommands are available once you have entered the Transform Set Configuration mode:

mode tunnel

Syntax Description

<name>	Specifies the name of the transform set. Names must be unique, and are specified in an alphanumeric string of up to **80** characters.	
<parameters>	Assigns a combination of up to three security algorithms to the set. Available security algorithms are as follows:	
	ah-md5-hmac	Authentication Header. Uses 16 byte key and HMAC-MD5-96 authentication.
	ah-sha-hmac	Authentication Header. Uses 20 byte key and HMAC-SHA1-96 authentication.
	esp-des	Encapsulating Security Payload. Data encryption standard using cipher block chaining and an 8-byte key (DES-56-CBC).
	esp-3des	Encapsulating Security Payload. Data encryption standard using cipher block chaining and a 24-byte key (3DES-168-CBC).
	esp-aes-128-cbc	Encapsulating Security Payload. Advanced encryption standard using cipher block chaining and a 16-byte key.
	esp-aes-192-cbc	Encapsulating Security Payload. Advanced encryption standard using cipher block chaining and a 24-byte key.
	esp-aes-256-cbc	Encapsulating Security Payload. Advanced encryption standard using cipher block chaining and a 32-byte key.
	esp-null	Encapsulating Security Payload with no encryption.
	esp-md5-hmac	Encapsulating Security Payload. Uses 16-byte key and HMAC-MD5-96 authentication.
	esp-sha-hmac	Encapsulating Security Payload. Uses 20-byte key and HMAC-SHA1-96 authentication.
mode tunnel	Specifies the encapsulation mode for the transform set is datagram encapsulation (tunnel) mode.	

Default Values

By default, no IPv6 IPsec transform sets are configured.

Command History

Release R10.7.0	Command was introduced.

Functional Notes

Transform sets are used to define the configuration for securing data with IPsec, and are then applied to crypto maps which reference them for specific security algorithms. Sets are applied using the command *set transform-set <name> on page 5259*. For manual key crypto maps, only one transform set can be specified. If no transform set is used in the crypto map, then the entry is incomplete and will have no effect on the system.

If the transform set is deleted, any references to the transform set by other functions are removed, leaving them incomplete.

Transform set names must be unique among IPv6 transform sets. Entering the name of an existing transform set re-enters the transform set configuration mode for that set.

Usage Examples

The following example creates the transform set **SET1** and its security algorithms:

(config)**#ipv6 crypto ipsec transform-set SET1 esp-3des esp-des**

ipv6 crypto map *<name> <index>*

Use the **ipv6 crypto map** command to create an Internet Protocol version 6 (IPv6) IP security (IPsec) crypto map entry and enter the crypto map entry's configuration mode. Use the **no** form of this command to remove the map and all it's settings. Variations of this command include:

ipv6 crypto map *<name> <index>*
ipv6 crypto map *<name> <index>* **ipsec-manual**

Syntax Description

<name>	Specifies the name of the IPv6 crypto map entry.
<index>	Specifies the crypto map entry sequence number. Valid range is **0** to **65535**.
ipsec-manual	Optional. Specifies that the map supports manually configured IPsec entries.

Default Values

By default, no IPv6 IPsec crypto maps exist.

Command History

Release R10.7.0	Command was introduced.

Functional Notes

If the map is used on an interface, removing the map also removes the map on any interfaces to which it is assigned.

Usage Examples

The following example creates a manually-keyed IPv6 crypto map:

(config)**#ipv6 crypto map MAP1 10 ipsec-manual**

ipv6 crypto map <*name*> rpf-check

Use the **ipv6 crypto map rpf-check** command to enable the reverse path forwarding (RPF) check on the Internet Protocol version 6 (IPv6) IP security (IPsec) crypto map entry. This command enables checking of tunnel traffic to disallow tunnel traffic that is spoofed from another tunnel. The check is applied to any security association (SA) created from any entry in the named crypto map. Use the **no** form of this command to disable the RPF check.

Syntax Description

<*name*>	Specifies the crypto map on which to enable the RPF check.

Default Values

By default, RPF checks are enabled.

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example enables RPF checking for crypto map **MAP1**:

(config)**#ipv6 crypto map MAP1 rpf-check**

ipv6 dhcp address client limit <*number*>

Use the **ipv6 dhcp address client limit** command to specify the maximum number of Internet Protocol version 6 (IPv6) addresses assigned per client by the Dynamic Host Control Protocol version 6 (DHCPv6) server. Use the **no** form of this command to return the maximum number of assigned addresses to the default value.

Syntax Description

<*number*>	Specifies the maximum number of IPv6 addresses that can be assigned to a single DHCPv6 client. Valid range is **0** to **500**. Setting the number to 0 returns the maximum number of allowed IPv6 addresses to the default value.

Default Values

By default, a maximum number of **50** IPv6 addresses can be assigned to a single DHCPv6 client.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example specifies the maximum number of IPv6 addresses that can be assigned to a single DHCPv6 client is **75**:

(config)**#ipv6 dhcp address client limit 75**

ipv6 dhcp address conflict limit <*number*>

Use the **ipv6 dhcp address conflict limit** command to specify the maximum number of conflicting Internet Protocol version 6 (IPv6) addresses that can be stored by the Dynamic Host Control Protocol version 6 (DHCPv6) server. This command limits the number of conflicting addresses stored by the DHCPv6 server to ensure that the AOS unit does not run out of memory. Use the **no** form of this command to reset the count to the default value.

Syntax Description

<*number*>	Specifies the maximum number of conflicting IPv6 addresses that can be stored by the server. Valid range is **1** to **10000** addresses. This maximum number is product-specific and is equivalent to the default value on the product.

Default Values

By default, only a certain number of conflicting IPv6 addresses can be stored. This number varies by AOS product.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example changes the number of conflicting IPv6 addresses stored by the DHCPv6 server to **3500:**

(config)**#ipv6 dhcp address conflict limit 3500**

ipv6 dhcp address limit *<number>*

Use the **ipv6 dhcp address limit** command to specify the maximum number of Internet Protocol version 6 (IPv6) addresses that can be assigned by the Dynamic Host Control Protocol version 6 (DHCPv6) server. This command limits the number of addresses assigned by the DHCPv6 server to ensure that the AOS unit does not run out of memory. Use the **no** form of this command to reset the count to the default value.

Syntax Description

<number>	Specifies the number of IPv6 addresses that can be assigned. Valid range is **1** to **10000**. This maximum number is product-specific, and is equivalent to the default value on the AOS unit.

Default Values

By default, only a certain number of addresses can be assigned by the DHCPv6 server. This number varies by AOS product.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example changes the maximum number of IPv6 addresses that can be assigned by the DHCPv6 server to **2000**:

(config)**#ipv6 dhcp address limit 2000**

ipv6 dhcp database local

Use the **ipv6 dhcp database local** command to enable the Dynamic Host Control Protocol version 6 (DHCPv6) database. The DHCPv6 database stores local DHCPv6 bindings, allowing Internet Protocol version 6 (IPv6) addresses assigned by the DHCPv6 server to be stored in non-volatile random access memory (NVRAM) and preserved across a reboot of the AOS unit. Using this command enables the local database to begin storing DHCPv6 information. Use the **no** form of this command to disable the DHCPv6 database.

Syntax Description

No subcommands.

Default Values

By default, the DHCPv6 database is disabled.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example enables the DHCPv6 database:

(config)**#ipv6 dhcp database local**

ipv6 dhcp excluded-address

Use the **ipv6 dhcp excluded-address** command to specify Internet Protocol version 6 (IPv6) addresses to exclude from any Dynamic Host Control Protocol version 6 (DHCPv6) server pool. These addresses are excluded from the DHCPv6 server pool, and cannot be assigned to DHCP clients by the server of these devices. Use the **no** form of this command to remove the address exclusion and make the address(es) available for use by the DHCPv6 server. Variations of this command include:

ipv6 dhcp excluded-address *<ipv6 address>*
ipv6 dhcp excluded-address *<beginning ipv6 address> <ending ipv6 address>*
ipv6 dhcp excluded-address vrf *<name> <ipv6 address>*
ipv6 dhcp excluded-address vrf *<name> <beginning ipv6 address> <ending ipv6 address>*

Syntax Description

<ipv6 address>	Specifies a single IPv6 address to exclude from any DHCPv6 server pool. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<beginning ipv6 address>	Specifies the lowest IPv6 address in the range of addresses to exclude. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<ending ipv6 address>	Specifies the highest IPv6 address in the range of addresses to exclude. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
vrf *<name>*	Optional. Specifies a nondefault named virtual routing and forwarding (VRF) instance on which to exclude the IPv6 addresses. If a VRF instance is not specified, the addresses are excluded on the default unnamed VRF instance.

Default Values

By default, no IPv6 addresses are excluded.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example excludes the IPv6 addresses on the default VRF instance ranging from **2001:DB8:1::1** to **2001:DB8:1::5** from any DHCPv6 server pool:

(config)**#ipv6 dhcp excluded-address 2001:DB8:1::1 2001:DB8:1::5**

ipv6 dhcp ping packets *<number>*

Use the **ipv6 dhcp ping packets** command to configure the number of ping packets transmitted by the Dynamic Host Control Protocol version 6 (DHCPv6) server when testing an Internet Protocol version 6 (IPv6) address before it is assigned to a client. Use the **no** form of this command to prevent the DHCPv6 server from using ping packets as part of the IPv6 address assignment process.

Syntax Description

<number>	Specifies the number of DHCPv6 ping packets sent on the network before assigning the IPv6 address to a requesting DHCPv6 client. Valid range is **0** to **100** packets.

Default Values

By default, **2** ping packets are sent to test IPv6 addresses before assigning them to a DHCPv6 client.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example specifies that **8** ping packets are used by DHCPv6 to test IPv6 addresses before assigning them to a client:

(config)**#ipv6 dhcp ping packets 8**

ipv6 dhcp ping timeout *<value>*

Use the **ipv6 dhcp ping timeout** command to specify the interval the Dynamic Host Control Protocol version 6 (DHCPv6) server waits for a response to a transmitted DHCPv6 ping packet when testing an Internet Protocol version 6 (IPv6) packet. Use the **no** form of this command to return the timeout period to the default value.

Syntax Description

<value>	Specifies the DHCPv6 ping timeout value in milliseconds. Valid range is **10** to **1000** ms.

Default Values

By default, the DHCPv6 server waits **500** ms for a ping response when testing an IPv6 address.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example specifies the ping timeout value for the DHCPv6 server is **300** ms:

(config)**#ipv6 dhcp ping timeout 300**

ipv6 dhcp pool <*name*>

Use the **ipv6 dhcp pool** command to create a Dynamic Host Control Protocol version 6 (DHCPv6) server address pool and enter the pool's configuration mode. The server pool is used to define the information to be assigned to DHCPv6 clients by the DHCPv6 server. The pool chosen to serve a specific client's request is determined by the current pool selection algorithm, just as in DHCP version 4 (DHCPv4). Use the **no** form of this command to remove the DHCPv6 server pool from the AOS unit's configuration. Refer to the *DHCPv6 Pool Command Set on page 4360* for more information.

Syntax Description

<*name*>	Specifies the name of the DHCPv6 pool using an alphanumeric string (up to 32 characters in length).

Default Values

By default, no DHCPv6 server pools are configured.

Command History

Release 18.3	Command was introduced.

Functional Notes

Use the **ipv6 dhcp pool** command to create multiple DHCPv6 server address pools for various segments of the network. Multiple address pools can be created to service different segments of the network with tailored configurations.

Usage Examples

The following example creates the DHCPv6 server address pool (labeled **Pool1**) and enters the DHCPv6 pool's configuration mode:

```
(config)#ipv6 dhcp pool Pool1
(config-dhcpv6)#
```

ipv6 dhcp prefix limit <*value*>

Use the **ipv6 dhcp prefix limit** command to limit the number of Internet Protocol version 6 (IPv6) prefixes that can be delegated by Dynamic Host Control Protocol (DHCPv6). Prefixes can be limited on a router or client basis. Use the **no** version of this command to remove the limit. Variations of this command include:

ipv6 dhcp prefix client limit <*value*>
ipv6 dhcp prefix limit <*value*>

Syntax Description

client	Optional. Limits the number of IPv6 prefixes that can be delegated to DHCPv6 clients.
<*value*>	Specifies the number of IPv6 prefixes that can be delegated. Valid range is **0** to **164352**. If the value is set to **0**, the limit is removed.

Default Values

By default, the IPv6 prefix limit for DHCPv6 is set to **0** (no limit).

Command History

Release R11.1.0	Command was introduced.

Usage Examples

The following example specifies a limit of **10** IPv6 prefixes for DHCPv6 clients:

(config)**#ipv6 dhcp prefix client limit 10**

ipv6 duplicate-address remove-route

Use the **ipv6 duplicate-address remove-route** command to specify that any duplicate IPv6 addresses detected by Duplicate Address Detection (DAD) are automatically removed from the IPv6 route table. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, any duplicate IPv6 addresses discovered by DAD remain in the IPv6 route table.

Command History

Release 13.6.0	Command was introduced.

Functional Notes

If this feature has been enabled, and then is disabled, a shutdown must be executed on the interfaces for which the duplicate IPv6 addresses should be retained. Without the shutdown, the duplicate address retention will not take effect.

Usage Examples

The following example specifies that duplicate IPv6 addresses detected by DAD are removed from the IPv6 route table:

(config)**#ipv6 duplicate-address remove-route**

ipv6 ffe limit exceptions *<value>*

Use the **ipv6 ffe limit exceptions** command to specify a limit to the number of unhandled Internet Protocol version 6 (IPv6) fast forwarding engine (FFE) exception packets allowed at any given time by the RapidRoute feature. Use the **no** form of this command to return the limit to the default value.

Syntax Description

<value>	Specifies the maximum number of unhandled FFE exception packets allowed at a given time. Valid range is **1** to **1024**.

Default Values

By default, no more than **128** exception packets are allowed.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

Exception packets are any packets that RapidRoute cannot handle, for example, traffic that matches ineligible entries, fragmented packets, packets with header errors, or the first packet in a given traffic flow that is used to build an FFE entry. Once the limit of unhandled FFE exception packets is reached, subsequent exception packets are dropped until the previously unhandled exceptions are resolved.

Usage Examples

The following example specifies the maximum number of IPv6 exception packets allowed by RapidRoute are **200**:

(config)**#ipv6 ffe limit exceptions 200**

ipv6 ffe max-entries <*value*>

Use the **ipv6 ffe max-entries** command to specify a global limit to the number of Internet Protocol version 6 (IPv6) fast forwarding engine (FFE) entries allowed at any given time by the RapidRoute feature. Use the **no** form of this command to return to the default value.

Issuing this command will cause all RapidRoute entries to be cleared from the unit.

Syntax Description

<*value*>	Specifies the total number of RapidRoute entries for all interfaces. Valid range is **1** to **500000**.

Default Values

By default, the **ipv6 ffe max-entries** is set to **16384**.

Command History

Release R10.4.0	Command was introduced.

Usage Examples

The following example sets the total maximum number of IPv6 RapidRoute entries to **500**:

(config)**#ipv6 ffe max-entries 500**

ipv6 ffe timeout

Use the **ipv6 ffe timeout** command to set the time to live (TTL) for Internet Protocol version 6 (IPv6) RapidRoute fast forwarding engine (FFE) entries based on their IPv6 protocol. Use the **no** form of this command to return to the default value. Variations of this command include:

ipv6 ffe timeout ah <*max timeout*>
ipv6 ffe timeout ah <*max timeout*> <*inactive timeout*>
ipv6 ffe timeout esp <*max timeout*>
ipv6 ffe timeout esp <*max timeout*> <*inactive timeout*>
ipv6 ffe timeout gre <*max timeout*>
ipv6 ffe timeout gre <*max timeout*> <*inactive timeout*>
ipv6 ffe timeout icmp <*max timeout*>
ipv6 ffe timeout icmp <*max timeout*> <*inactive timeout*>
ipv6 ffe timeout other <*max timeout*>
ipv6 ffe timeout other <*max timeout*> <*inactive timeout*>
ipv6 ffe timeout tcp <*max timeout*>
ipv6 ffe timeout tcp <*max timeout*> <*inactive timeout*>
ipv6 ffe timeout udp <*max timeout*>
ipv6 ffe timeout udp <*max timeout*> <*inactive timeout*>

Syntax Description

ah	Specifies timeout values in seconds for Authentication Header (AH) Protocol.
esp	Specifies timeout values in seconds for Encapsulating Security Payload (ESP) Protocol.
gre	Specified timeout values in seconds for Generic Route Encapsulation (GRE) Protocol.
icmp	Specifies timeout values in seconds for Internet Control Message Protocol (ICMP).
other	Specifies timeout values in seconds for all protocols not listed.
tcp	Specifies timeout values in seconds for Transmission Control Protocol (TCP).
udp	Specifies timeout values in seconds for User Datagram Protocol (UDP).
<*max timeout*>	Specifies maximum age timeout in seconds. This is the maximum amount of time an entry will be kept in the RapidRoute table regardless of activity. Valid range is **60** to **86400** seconds.
<*inactive timeout*>	Optional. Specifies idle timeout in seconds. This is the amount of time an entry will remain in the RapidRoute table with no additional activity. Valid range is **10** to **86400** seconds.

Default Values

By default, the maximum age timeouts are set to **1800** seconds and the inactive timeouts are set to **15** seconds.

Command History

Release R10.4.0	Command was introduced.

Usage Examples

The following example sets the time to live for IPv6 RapidRoute entries of TCP packets to **1000** seconds.

(config)**#ipv6 ffe timeout tcp 1000**

ipv6 firewall

Use the **ipv6 firewall** command to enable AOS Internet Protocol version 6 (IPv6) security features, including IPv6 access control policies (ACPs) and lists (ACLs) and the stateful inspection firewall. Use the **no** form of this command to disable the IPv6 security functionality. Variations of this command include:

ipv6 firewall
ipv6 firewall vrf <*name*>

*Disabling the AOS IPv6 security features (using the **no ipv6 firewall** command) does not affect security configuration. All configuration parameters will remain intact, but no security data processing will be attempted.*

Syntax Description

vrf <*name*>	Optional. Enables or disables the IPv6 firewall for a specific virtual routing and forwarding (VRF) instance.

Default Values

By default, all AOS IPv6 security features are disabled.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example enables the AOS IPv6 security features:

(config)**#ipv6 firewall**

ipv6 firewall alg ftp

Use the **ipv6 firewall alg ftp** command to enable the Internet Protocol version 6 (IPv6) File Transfer Protocol (FTP) application-level gateway (ALG). Use the **no** form of this command to disable the FTP ALG. Variations of this command include:

ipv6 firewall alg ftp
ipv6 firewall alg ftp tcp
ipv6 firewall alg ftp tcp port <*port*>
ipv6 firewall vrf <*name*> **alg ftp**
ipv6 firewall vrf <*name*> **alg ftp tcp**
ipv6 firewall vrf <*name*> **alg ftp tcp port** <*port*>

Syntax Description

tcp	Optional. Specifies that the port on which the IPv6 FTP ALG is enabled is a Transmission Control Protocol (TCP) port.
port <*port*>	Optional. Specifies a single port on which to enable the IPv6 FTP ALG. Valid range is **0** to **65535**.
vrf <*name*>	Optional. Specifies a nondefault (named) Virtual Routing and Forwarding (VRF) instance on which to enable the IPv6 FTP ALG.

Default Values

By default, the IPv6 FTP ALG is enabled on all VRF instances on TCP port **21**.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

The IPv6 FTP ALG operates by parsing the Layer 5 contents of packets used for FTP, and when necessary, opens pending policy sessions so that FTP data transfers are able to traverse the IPv6 firewall without being dropped by configured access control policies (ACPs). In addition, the IPv6 FTP ALG has the ability to perform FTP-specific attack checking.

During the process of an FTP flow, the IPv6 FTP ALG creates a pending policy session based on a currently active policy session. This pending policy session listens for expected FTP data transfer traffic.

Any IPv6 firewall policy sessions created using a stateless ACP entry bypass all ALG processing, even if the ALG is enabled for the ACP's destination port, allowing global ALG processing for specific ports, but bypassing the global configuration under certain circumstances (such as, on a particular ACP or for particular hosts or networks based on IPv6 ACLs).

The IPv6 FTP ALG cannot be enabled on a protocol and port that is the default protocol and port for any other ALG, even if the other ALG is disabled. The IPv6 FTP ALG also cannot be enabled on a TCP port whose default filtering behavior has been overridden.

Usage Examples

The following example disables the IPv6 FTP ALG on the default port (**21**), and then enables it on TCP ports **10000** and **20000** on the default VRF instance:

(config)**#no ipv6 firewall alg ftp tcp port 21**
(config)**#ipv6 firewall alg ftp tcp port 10000**
(config)**#ipv6 firewall alg ftp tcp port 20000**

ipv6 firewall attack-log threshold <*number*>

Use the **ipv6 firewall attack-log threshold** command to specify the number of possible attack conditions AOS will identify and block before generating a log message when using Internet Protocol version 6 (IPv6). Use the **no** form of this command to return to the default threshold. Variations of this command include:

ipv6 firewall attack-log threshold <*number*>
ipv6 firewall vrf <*name*> **attack-log threshold** <*number*>

The AOS IPv6 firewall must be enabled (using the command ipv6 firewall on page 1523) for the stateful inspection firewall to be activated.

Syntax Description

<*number*>	Specifies the number of possible attack conditions AOS IPv6 will identify before generating a log message. Valid range is **0** to **4294967295**.
vrf <*name*>	Optional. Specifies a virtual routing and forwarding (VRF) instance to monitor. If no VRF is specified, the default unnamed VRF is monitored.

Default Values

By default, the **ipv6 firewall attack-log threshold** is set at **100**.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example specifies a threshold of **25** attacks before generating a log message for the IPv6 firewall:

(config)**#ipv6 firewall attack-log threshold 25**

ipv6 firewall check duplicate-options

Use the **ipv6 firewall check duplicate-options** command to specify that Internet Protocol version 6 (IPv6) packets with duplicate options within a Destination Options or Hop-by-Hop Options extension headers are dropped. Using the **no** form of this command allows IPv6 packets with duplicate options. Variations of this command include:

ipv6 firewall check duplicate-options
ipv6 firewall vrf <*name*> **check duplicate-options**

The AOS IPv6 firewall must be enabled (using the command ipv6 firewall on page 1523) for the stateful inspection firewall to be activated.

Syntax Description

vrf <*name*>	Optional. Specifies a virtual routing and forwarding (VRF) instance on which to drop IPv6 packets with duplicate options headers. If no VRF is specified, the packets on the default unnamed VRF are dropped.

Default Values

By default, this feature is enabled.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example specifies that IPv6 packets with duplicate options headers are dropped on the default VRF:

(config)**#ipv6 firewall check duplicate-options**

ipv6 firewall check ftp-bounce

Use the **ipv6 firewall check ftp-bounce** command enable the File Transfer Protocol (FTP) bounce attack check for the Internet Protocol version 6 (IPv6) firewall. Use the **no** form of this command to disable the FTP bounce attack check. Variations of this command include:

ipv6 firewall check ftp-bounce
ipv6 firewall vrf <*name*> **check ftp-bounce**

Syntax Description

vrf <*name*>	Optional. Specifies a nondefault (named) Virtual Routing and Forwarding (VRF) instance on which the enable the bounce attack check. If no VRF instance is specified, the action is performed on the default unnamed VRF instance.

Default Values

By default, FTP bounce attack check is enabled on the IPv6 firewall.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

In addition to allowing the flow of IPv6 FTP traffic through the IPv6 firewall, the IPv6 FTP application-level gateway (ALG) can be used to protect against FTP bounce attacks. An FTP bounce attack is a network attack where malicious hosts using proxy FTP can target a specific well-known service on one server (Server A) by instructing another FTP server (Server B) to send a file to Server A that contains commands relevant to the service being attacked. For example, this can allow a malicious host to forge mail on Server A without making a direct connection. The lack of a direct file transfer between the attacker and the target server makes the identity of the attacker difficult to determine.

The IPv6 FTP ALG, however, can be used to protect against such an attack. When this feature is enabled, the IPv6 FTP ALG recognizes as an attack any extended port command (EPRT) sent by the FTP client that has a TCP port number less than **1024**, and the ALG closes the connection. The ALG performs this action because TCP port numbers in the range from **0** to **1023** are used by well-known services.

Although the IPv6 FTP ALG can perform bounce attack checks when ports less than 1024 are specified in an EPRT, services running on ports greater than 1023 are still vulnerable to FTP bounce attacks.

Usage Examples

The following example enables the FTP bounce attack check on the nondefault VRF instance **RED1**:

(config)**#ipv6 firewall vrf RED1 check ftp-bounce**

ipv6 firewall check header-order

Use the **ipv6 firewall check header-order** command to enable the dropping of Internet Protocol version 6 (IPv6) packets that have extension headers in an order different than the recommendations proposed in the Systems and Network Analysis Center (SNAC) document *Firewall Design Considerations for IPv6*. Use the **no** form of this command to disable the feature and allow the processing of IPv6 packets with extension headers according to RFC 2460. Variations of this command include:

ipv6 firewall check header-order

ipv6 firewall vrf <*name*> **check header-order**

The AOS IPv6 firewall must be enabled (using the command ipv6 firewall on page 1523) for the stateful inspection firewall to be activated.

Syntax Description

vrf <*name*>	Optional. Specifies a virtual routing and forwarding (VRF) instance to configure. If no VRF is specified, the default unnamed VRF is configured.

Default Values

By default, this feature is enabled.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example specifies that IPv6 packets with out-of-order headers are dropped on the default VRF:

(config)**#ipv6 firewall check header-order**

ipv6 firewall check min-fragment-size <*value*>

Use the **ipv6 firewall check min-fragment-size** command to specify the smallest permitted size for Internet Protocol version 6 (IPv6) fragmented packets. Packets less than the specified size are dropped. Use the **no** form of this command to return to the default value. Variations of this command include:

ipv6 firewall check min-fragment-size <*value*>
ipv6 firewall vrf <*name*> **check min-fragment-size** <*value*>

> *The AOS IPv6 firewall must be enabled (using the command ipv6 firewall on page 1523) for the stateful inspection firewall to be activated.*

Syntax Description

<*value*>	Specifies the packet size in octets. Valid range is **56** to **1280** octets.
vrf <*name*>	Optional. Specifies a virtual routing and forwarding (VRF) instance to configure. If no VRF is specified, the default unnamed VRF is configured.

Default Values

By default, the IPv6 packet fragment size is set to **640** octets.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example changes the smallest permitted size for IPv6 packet fragments on the default VRF to **800** octets:

(config)**#ipv6 firewall check min-fragment-size 800**

ipv6 firewall check multiple-pad1

Use the **ipv6 firewall check multiple-pad1** command to specify that Internet Protocol version 6 (IPv6) packets with more than one Pad1 option back-to-back within the Destination Options or Hop-by-Hop Options extension headers are dropped. Use the **no** form of this command to allow packets with more than one Pad1 option back-to-back. Variations of this command include:

ipv6 firewall check multiple-pad1
ipv6 firewall vrf <*name*> **check multiple-pad1**

The AOS IPv6 firewall must be enabled (using the command ipv6 firewall on page 1523) for the stateful inspection firewall to be activated.

Syntax Description

vrf <*name*>	Optional. Specifies a virtual routing and forwarding (VRF) instance on which to drop IPv6 packets with multiple Pad1 options. If no VRF is specified, the packets on the default unnamed VRF are dropped.

Default Values

By default, this feature is disabled.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example specifies that packets on the default VRF with more than one Pad1 option are dropped:

(config)**#ipv6 firewall check multiple-pad1**

ipv6 firewall check reflexive-traffic

Use the **ipv6 firewall check reflexive-traffic** command to enable the AOS stateful inspection firewall to process Internet Protocol version 6 (IPv6) traffic and check for reflexive traffic. Reflexive traffic refers to packets that are routed out of the same interface on which they arrived. Use the **no** form of this command to disable this check. Variations of this command include:

ipv6 firewall check reflexive-traffic
ipv6 firewall vrf <*name*> **check reflexive-traffic**

The AOS IPv6 firewall must be enabled (using the command ipv6 firewall on page 1523) for the stateful inspection firewall to be activated.

Syntax Description

vrf <*name*>	Optional. Specifies a virtual routing and forwarding (VRF) instance on which to enable reflexive traffic checking. If no VRF is specified, IPv6 traffic is checked on the default unnamed VRF.

Default Values

By default, this reflexive traffic is allowed to bypass the firewall and does not create a policy session.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example enables the AOS IPv6 reflexive traffic check for the default VRF:

(config)**#ipv6 firewall check reflexive-traffic**

ipv6 firewall check tcp-seq-and-ack

Use the **ipv6 firewall check tcp-seq-and-ack** command to direct the Internet Protocol version 6 (IPv6) firewall to inspect each packet of a Transmission Control Protocol (TCP) flow to ensure that the sequence numbers and acknowledgement (ACK) numbers are within the expected window for that firewall session. Use the **no** form of this command to disable the TCP sequence and ACK number check. Variations of this command include:

ipv6 firewall check tcp-seq-and-ack
ipv6 firewall vrf <*name*> **check tcp-seq-and-ack**

Syntax Description

vrf <*name*>	Optional. Specifies a nondefault (named) Virtual Routing and Forwarding (VRF) instance on which to enable or disable the TCP sequence and ACK number check. If no VRF instance is specified, the action is performed on the default unnamed VRF instance.

Default Values

By default, the TCP sequence and ACK number check is enabled.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example enables the TCP sequence and ACK number check on the nondefault VRF instance **RED1**:

(config)**#ipv6 firewall vrf RED1 check tcp-seq-and-ack**

ipv6 firewall check udp-checksum-zero

Use the **ipv6 firewall check udp-checksum-zero** command to specify that Internet Protocol version 6 (IPv6) User Datagram Protocol (UDP) packets with a checksum value of zero are dropped. Use the **no** form of this command to allow UDP packets with a checksum value of zero. Variations of this command include:

ipv6 firewall check udp-checksum-zero

ipv6 firewall vrf <*name*> **check udp-checksum-zero**

The AOS IPv6 firewall must be enabled (using the command ipv6 firewall on page 1523) for the stateful inspection firewall to be activated.

Syntax Descriptions

vrf <*name*>	Optional. Specifies a virtual routing and forwarding (VRF) instance on which to check UDP packets. If no VRF is specified, the default unnamed VRF is inspected.

Default Values

By default, this feature is enabled.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example specifies that UDP packets with a value of zero are dropped on the default VRF:

(config)**#ipv6 firewall check udp-checksum-zero**

ipv6 firewall check unknown-options

Use the **ipv6 firewall check unknown-options** command to specify that Internet Protocol version 6 (IPv6) packets with unknown options in the Destination Options or Hop-by-Hop Options extension headers are dropped. Use the **no** form of this command to allow IPv6 packets with unknown options in the extension header. Variations of this command include:

ipv6 firewall check unknown-options
ipv6 firewall vrf <*name*> **check unknown-options**

The AOS IPv6 firewall must be enabled (using the command ipv6 firewall on page 1523) for the stateful inspection firewall to be activated.

Syntax Description

vrf <*name*>	Optional. Specifies a virtual routing and forwarding (VRF) instance on which to check IPv6 packets. If no VRF is specified, traffic on the default unnamed VRF is dropped.

Default Values

By default, this feature is enabled.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example specifies that IPv6 packets with unknown option extension headers are dropped on the default VRF:

(config)**#ipv6 firewall check unknown-options**

ipv6 firewall fast-allow-failover

Use the **ipv6 firewall fast-allow-failover** command to automatically clear all open Internet Protocol version 6 (IPv6) firewall policy allow sessions when a route table change occurs. This allows the router to immediately send traffic to the failover interface. Use the **no** form of this command to disable this feature.Vairations of this command include:

ipv6 firewall fast-allow-failover
ipv6 firewall vrf <*name*> **fast-allow-failover**

> NOTE *The AOS IPv6 firewall must be enabled (using the command ipv6 firewall on page 1523) for the stateful inspection firewall to be activated.*

Syntax Description

vrf <*name*>	Optional. Enables or disables fast allow failover on the IPv6 firewall for a specific virtual routing and forwarding (VRF) instance.

Default Values

By default, all AOS IPv6 security features are disabled until the IPv6 firewall is enabled. By default, **fast-allow-failover** is disabled.

Command History

Release R10.4.0	Command was introduced.

Functional Note

If the command is not enabled, the router tries to send traffic from existing allowed policy sessions out from the failed IPv6 address until the session times out, resulting in a loss of connectivity. This command should be configured when destination-specific rules are configured. Destination-specific rules are most often used in failover and IPv6 load sharing configurations. Refer to the command *ipv6 policy-class <ipv6 acp name> on page 1549* for more information.

Usage Examples

The following example enables **fast-allow-failover**:

(config)**#ipv6 firewall fast-allow-failover**

ipv6 firewall filtering-behavior

Use the **ipv6 firewall filtering-behavior** command to modify the filtering behavior of the Internet Protocol version 6 (IPv6) firewall. Modifying the filtering behavior settings for a particular port and protocol allow for application-level gateway (ALG)-like behavior in certain applications without requiring parsing of the Layer 5 packet contents used by these applications. By modifying IPv6 firewall filtering behavior, you can enable firewall traversal for applications by adding one or more configuration options if no ALG is available for the application (such as with Trivial File Transfer Protocol (TFTP)). Use the **no** form of this command to return the firewall filtering behavior to the default value. Variations of this command include:

ipv6 firewall filtering-behavior [tcp <*port*> **| udp** <*port*>**] address-dependent**
ipv6 firewall filtering-behavior [tcp <*port*> **| udp** <*port*>**] address-port-dependent**
ipv6 firewall filtering-behavior [tcp <*port*> **| udp** <*port*>**] endpoint-independent**
ipv6 firewall vrf <*name*> **filtering-behavior [tcp** <*port*> **| udp** <*port*>**] address-dependent**
ipv6 firewall vrf <*name*> **filtering-behavior [tcp** <*port*> **| udp** <*port*>**] address-port-dependent**
ipv6 firewall vrf <*name*> **filtering-behavior [tcp** <*port*> **| udp** <*port*>**] endpoint-independent**

Syntax Description

tcp <*port*>	Specifies a Transmission Control Protocol (TCP) port for which the IPv6 firewall filtering behavior is changed. Valid range is **0** to **65535**. The port corresponds to the destination port of the firewall policy session, which is the destination port of the internal traffic.
udp <*port*>	Specifies a User Datagram Protocol (UDP) port for which the IPv6 firewall filtering behavior is changed. Valid range is **0** to **65535**. The port corresponds to the destination port of the firewall policy session, which is the destination port of the internal traffic.
address-dependent	Specifies that address-dependent filtering is used for traffic initiated using the specified destination port.
address-port-dependent	Specifies that address- and port-dependent filtering is used for traffic initiated using the specified destination port. This is the default firewall filtering behavior for most ports.
endpoint-independent	Specifies that endpoint-independent filtering is used for traffic initiated using the specified destination port.
vrf <*name*>	Optional. Specifies a nondefault (named) Virtual Routing and Forwarding (VRF) instance on which to apply the filtering behavior. If no VRF instance is specified, the action is performed on the default unnamed VRF instance.

Default Values

By default, most ports are filtered by traditional firewall filtering (**address-port-dependent**). By default, UDP port **69**, the TFTP port, uses **address-dependent** filtering.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

In AOS firmware release R10.1.0, the ability to configure IPv6 firewall filtering behavior was introduced. The ordinary filtering behavior of the IPv6 firewall is to restrict permitted return traffic to the exact source and destination IP addresses and ports of the initial traffic flow. This is called address- and port-dependent filtering. In some applications, including TFTP, the external traffic generated as part of the application can respond from a different external port than the one specified in the firewall configuration. This traffic might not be allowed to traverse the firewall, depending on the configured access control policy (ACP) rules. If available, an ALG could be used to accommodate such an application. The ALG would parse the application layer payload for traffic from the initiating host, and create an appropriate pending policy session to allow the expected response. With the release of R10.1.0, the IPv6 firewall incorporates two additional configurable filtering behaviors that can take the place of such ALGs for certain applications.

The first additional method of firewall filtering is using **address-dependent** filtering. In this type of filtering, return traffic from an external host to the initiating internal host is allowed from any port, but traffic originating from any other external host will continue to be blocked. The second additional method of firewall filtering is using **endpoint-independent** filtering. In this type of filtering, any external host can respond to traffic from the initiating host from any port.

For more information about the configuration and use of IPv6 firewall filtering behaviors, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that on the default unnamed VRF instance, TCP port **10000** and UDP port **40** are filtered by **endpoint-independent** filtering and that TCP port **20000** and UDP port **30** are filtered by **address-dependent** filtering:

(config)**#ipv6 firewall filtering-behavior tcp 10000 endpoint-independent**
(config)**#ipv6 firewall filtering-behavior tcp 20000 address-dependent**
(config)**#ipv6 firewall filtering-behavior udp 30 address-dependent**
(config)**#ipv6 firewall filtering-behavior udp 40 endpoint-independent**

ipv6 firewall fin-timeout <*timeout*>

Use the **ipv6 firewall fin-timeout** command to configure the firewall policy session timeout for a Transmission Control Protocol (TCP) policy session closed by a bidirectional FINISH (FIN). The policy session timeout determines when the time to live (TTL) for the session expires, and thus ends the session. Using the **no** form of this command returns the timeout to the default value. Variations of this command include:

ipv6 firewall fin-timeout <*timeout*>
ipv6 firewall vrf <*name*> **fin-timeout** <*timeout*>

Syntax Description

<*timeout*>	Specifies the session timeout in seconds. Valid range is **0** to **4294967295** seconds.
vrf <*name*>	Optional. Specifies a nondefault virtual routing and forwarding (VRF) instance on which to perform the timeout. If no VRF is specified, the action occurs on the default unnamed VRF.

Default Values

By default, the FIN timeout is set to **4** seconds.

Command History

Release 18.2	Command was introduced.

Functional Notes

A policy session closed by a TCP FIN is one in which a FIN has been received from both endpoints participating in the session. This command is used when configuring firewall session timeouts for Internet Protocol version 6 (IPv6).

If the timeout is defined to be zero, the policy session will be deleted immediately without entering a post-connection state. This could be necessary for hosts that do not implement the TIME_WAIT TCP state correctly, but instead permit immediately reopening closed sessions.

Usage Examples

The following example changes the IPv6 firewall session timeout for TCP policy sessions closed by a FIN to **10** seconds:

(config)**#ipv6 firewall fin-timeout 10**

ipv6 firewall local-traffic-only

Use the **ipv6 firewall local-traffic-only** command to enable the Internet Protocol version 6 (IPv6) firewall for the processing of local traffic only. Forwarded traffic is not sent to the firewall when this feature is enabled. Use the **no** form of this command to disable the IPv6 firewall. Variations of this command include:

ipv6 firewall local-traffic-only
ipv6 firewall vrf <*name*> **local-traffic-only**

Syntax Description

vrf <*name*>	Optional. Specifies that the local traffic firewall is enabled on the specified virtual routing and forwarding (VRF) instance. If no VRF is specified, the firewall is enabled on the default (unnamed) VRF.

Default Values

By default, the IPv6 firewall is disabled.

Command History

Release R11.4.0	Command was introduced.

Functional Notes

When the firewall is configured to process local traffic only (traffic arriving at the unit's local IP stack), routed traffic is allowed to flow through the AOS unit uninspected, but locally destined traffic is inspected by the firewall. This feature allows the firewall to protect local services running on the AOS unit even when routed traffic bypasses the firewall. When local traffic processing is enabled, several other security features are impacted, such as IPsec, policy classes, IP route cache, and Generic Routing Encapsulation (GRE).

- Local traffic only firewall processing cannot be used with cryptography (**ipv6 crypto**) because for IPsec to function, traffic must proceed through the firewall. If the firewall is configured to process local traffic only, routed traffic that requires IPsec protection will not flow through the firewall and therefore will not receive IPsec protection.
- Policy classes are applied only to traffic destined to the local stack when local traffic processing is enabled. The **self** policy class is applied to local traffic originating from the local stack, allowing all traffic, and cannot be changed.
- IP route cache entries are not created for local destinations or for the Loopback interface when local traffic processing enabled.
- Local GRE traffic encapsulated by a GRE tunnel interface will bypass the firewall when local traffic processing is enabled.
-

For additional IPv6 firewall configuration information, refer to *ipv6 firewall on page 1523*.

Usage Examples

The following example enables the firewall for local traffic processing on the default VRF:

(config)**#ipv6 firewall local-traffic-only**

ipv6 firewall policy-log threshold <*value*>

Use the **ipv6 firewall policy-log threshold** command to specify the number of Internet Protocol version 6 (IPv6) access control policy (ACP) events identified by AOS before generating a log message. Use the **no** form of this command to return to the default value. Variations of this command include:

ipv6 firewall policy-log threshold <*value*>
ipv6 firewall vrf <*name*> **policy-log threshold** <*value*>

The AOS IPv6 firewall must be enabled (using the command ipv6 firewall on page 1523) for the stateful inspection firewall to be activated.

Syntax Description

<*value*>	Specifies the number of IPv6 policy events AOS identifies before creating the log. Valid range is **1** to **4294967295**.
vrf <*name*>	Optional. Specifies a virtual routing and forwarding (VRF) instance for AOS to monitor. If no VRF is specified, the default unnamed VRF is monitored.

Default Values

By default, a log is generated after **100** policy events have been identified.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example specifies that a log is generated when **150** IPv6 ACP events are detected on the default VRF:

(config)**#ipv6 firewall policy-log threshold 150**

ipv6 firewall rst-timeout <*timeout*>

Use the **ipv6 firewall rst-timeout** command to configure the firewall policy session timeout for a Transmission Control Protocol (TCP) policy session closed by a RESET (RST). The policy session timeout determines when the time to live (TTL) for the session expires, and thus ends the session. Using the **no** form of this command returns the timeout to the default value. Variations of this command include:

ipv6 firewall rst-timeout <*timeout*>
ipv6 firewall vrf <*name*> **rst-timeout** <*timeout*>

Syntax Description

<*timeout*>	Specifies the session timeout in seconds. Valid range is **0** to **4294967295** seconds.
vrf <*name*>	Optional. Specifies a nondefault virtual routing and forwarding (VRF) instance on which to perform the timeout. If no VRF is specified, the action occurs on the default unnamed VRF.

Default Values

By default, the RST timeout is set to **20** seconds.

Command History

Release 18.2	Command was introduced.

Functional Notes

A TCP policy session closed by an RST is one in which an RST has been received from both endpoints participating in the session, indicating that enough time has passed to complete the TCP reset process. This command is used when configuring firewall session timeouts for Internet Protocol version 6 (IPv6).

If the timeout is defined to be zero, the policy session will be deleted immediately without entering a post-connection state. This could be necessary for hosts that do not implement the TIME_WAIT TCP state correctly, but instead permit immediately reopening closed sessions.

Usage Examples

The following example changes the IPv6 firewall session timeout for TCP policy sessions closed by a RST sessions to **30** seconds:

(config)**#ipv6 firewall rst-timeout 30**

ipv6 firewall stealth

Use the **ipv6 firewall stealth** command to place the Internet Protocol version 6 (IPv6) firewall in stealth mode. The stealth setting allows the route to be invisible as a route hop to associated devices. Use the **no** form of this command to disable the stealth feature. Variations of this command include:

ipv6 firewall stealth
ipv6 firewall vrf <*name*> **stealth**

The AOS IPv6 firewall must be enabled (using the command ipv6 firewall on page 1523) for the stateful inspection firewall to be activated.

Syntax Description

vrf <*name*>	Optional. Specifies a virtual routing and forwarding (VRF) instance to put in stealth mode. If no VRF is specified, the default unnamed VRF is placed in stealth mode.

Default Values

By default, stealth mode is disabled.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example enables the **stealth** option for the default IPv6 VRF:

(config)**#ipv6 firewall stealth**

ipv6 firewall tcp-unestab-timeout <*timeout*>

Use the **ipv6 firewall tcp-unestab-timeout** command to configure the firewall policy session timeout for a pre-established Transmission Control Protocol (TCP) policy session. The policy session timeout determines when the time to live (TTL) for the session expires, and thus ends the session. Using the **no** form of this command returns the timeout to the default value. Variations of this command include:

ipv6 firewall tcp-unestab-timeout <*timeout*>
ipv6 firewall vrf <*name*> **tcp-unestab-timeout** <*timeout*>

Syntax Description

<*timeout*>	Specifies the session timeout in seconds. Valid range is **0** to **4294967295** seconds.
vrf <*name*>	Optional. Specifies a nondefault virtual routing and forwarding (VRF) instance on which to perform the timeout. If no VRF is specified, the action occurs on the default unnamed VRF.

Default Values

By default, the timeout is set to **20** seconds for pre-established TCP firewall sessions.

Command History

Release 18.2	Command was introduced.

Functional Notes

A pre-established TCP policy session is a firewall session that has been opened by a TCP SYN, on which the full three-way TCP handshake has not yet been observed. This command is used when configuring firewall session timeouts for Internet Protocol version 6 (IPv6), and specifies the time period allowed for TCP to complete the three-way handshake at the beginning of the connection.

Usage Examples

The following example changes the IPv6 firewall session timeout for pre-established TCP sessions to **30** seconds:

(config)**#ipv6 firewall tcp-unestab-timeout 30**

ipv6 load-sharing

Use the **ipv6 load-sharing** command to allow parallel routes in the Internet Protocol version 6 (IPv6) route table to be used to balance IPv6 traffic to a specific destination across up to six equal paths. When this command is enabled, the IPv6 route table can use multiple *best* routes and alternate between them. When this command is disabled, the IPv6 route table uses a single *best* route. Use the **no** form of this command to disable IPv6 load sharing. Variations of this command include:

ipv6 load-sharing per-destination
ipv6 load-sharing per-packet

Syntax Description

per-destination	Specifies that the route used to forward a packet is based on a hash of the source and destination IPv6 packet.
per-packet	Specifies that each forwarding route lookup rotates through all the parallel *best* routes.

Default Values

By default, IPv6 load sharing is disabled.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example enables IPv6 load sharing based on the source and destination of the IPv6 packets:

(config)**#ipv6 load-sharing per-destination**

ipv6 named-prefix *<prefix name> <ipv6 prefix/prefix-length>*

Use the **ipv6 named-prefix** command to manually assign a value to a named Internet Protocol version 6 (IPv6) prefix. A named prefix is useful when the upper part of the prefix could change over time (such as when using provider-dependent addresses in Dynamic Host Control Protocol for IPv6 (DHCPv6)). By creating a named prefix, the variable holding the value of the prefix is defined once, and then applied in various ways without having to manually enter the prefix value at each use. Use the **no** form of this command to remove one prefix from within a named prefix when the prefix and prefix length are specified, or to remove all prefixes from within a named prefix if entered with only the prefix name. Variations of this command include:

ipv6 named-prefix *<prefix name> <ipv6 prefix/prefix-length>*
ipv6 named-prefix *<prefix name> <ipv6 prefix/prefix-length>* **expiration-date** *<date> <time>*

Syntax Description

<prefix name>	Specifies the name of the variable that holds the service provider assigned value for the prefix.
<ipv6 prefix/prefix-length>	Specifies the numerical value and length of the prefix. The prefix value is specified in colon hexadecimal format (**X:X::X/<Z>**), for example: **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**. The IPv6 prefix cannot be a link-local address.
expiration-date *<date> <time>*	Optional. Specifies the time at which the prefix will expire. Enter future expiration date value in the MM/DD/YY format, and the time parameter in the HH:MM or HH:MM:SS format.

Default Values

By default, no named prefixes exist.

Command History

Release R10.9.0	Command was introduced.

Functional Notes

Changes made to the named prefix are automatically applied at each interface using the named prefix form of the IPv6 address command.

Usage Examples

The following example assigns a value to the previously created prefix **PREFIX1**:

(config)**#ipv6 named-prefix PREFIX1 2001:DB8:3F::/64**

ipv6 neighbor *<ipv6 address> <interface> <mac address>*

Use the **ipv6 neighbor** command to manually enter a static entry into the Internet Protocol version 6 (IPv6) Neighbor Discovery (ND) cache. Use the **no** form of this command to remove the static entry from the neighbor cache. Variations of this command include:

ipv6 neighbor *<ipv6 address> <interface> <mac address>*
ipv6 neighbor *<ipv6 address>* **mef-ethernet** *<slot/port> <mac address>*
ipv6 neighbor *<ipv6 address>* **system-control-evc**
ipv6 neighbor *<ipv6 address>* **system-control-evc** *<mac address>*
ipv6 neighbor *<ipv6 address>* **system-management-evc**
ipv6 neighbor *<ipv6 address>* **system-management-evc** *<mac address>*

Syntax Description

<ipv6 address>	Specifies the IPv6 address of the neighbor entry. IPv6 addresses should be specified in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
<interface>	Specifies the interface of the link on which the neighbor entry is connected. Interfaces are specified using the *<interface> <slot/port* | *interface id>* format. For example, to specify a Point-to-Point Protocol (PPP) interface, enter **ppp 1**.
<mac address>	Specifies the medium access control (MAC) address of the neighbor. MAC addresses should be expressed in the following format: XX:XX:XX:XX:XX:XX (for example, **00:A0:C8:00:00:01**).
mef-ethernet *<slot/port>*	Specifies the Metro Ethernet Forum (MEF) Ethernet interface.
system-control-evc	Specifies the system control Ethernet virtual connection (EVC). This EVC exists by default and cannot be deleted.
system-management-evc	Specifies the system management EVC. This EVC exists by default and cannot be deleted.

Default Values

By default, no static neighbor entries exist in the neighbor cache.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was changed to include the **system-control-evc** and **system-management-evc** parameters.
Release R10.11.0	Command was expanded to include the MEF Ethernet interface.

Functional Notes

In IPv6, neighbors are usually managed dynamically using the ND protocol. However, you can manually enter a static entry into the neighbor cache using the **ipv6 neighbor** command. When you enter a static entry into the neighbor cache, you should be aware of the following:

- A static entry entirely overrides an existing or new dynamic entry learned through ND.
- Neighbor unreachability detection (NUD) is not performed on static neighbors, so the neighbor's state is limited to either an incomplete modified state (interface is down) or a reachable modified state (interface is up).
- Using the **no** form of the **ipv6 neighbor** command removes static entries and not dynamic entries from the neighbor cache.
- Using the command *clear ipv6 neighbors on page 172* clears the dynamic entries from the neighbor cache, but not the static entries.
- Disabling IPv6 on an interface does not remove the static neighbor cache entries, although it will change the entry state to incomplete.

Usage Examples

The following example adds a static neighbor with an IPv6 address of **2001:DB8:3F::/48** on the Ethernet 0/1 interface, and has a MAC address of **00:A0:C8:00:00:01** to the neighbor cache:

(config)**#ipv6 neighbor 2001:DB8:3F::/48 ethernet 0/1 00:A0:C8:00:00:01**

ipv6 policy-class *<ipv6 acp name>*

Use the **ipv6 policy-class** command to create an Internet Protocol version 6 (IPv6) access control policy (ACP) and enter the ACP configuration mode. Use the **no** form of this command to delete an IPv6 ACP and all the entries it contains. Each ACP can contain up to 20 entries. For more information, refer to the *IPv6 Access Control Policy Command Set on page 4326*.

Configured IPv6 ACPs will only be active if the command ipv6 firewall on page 1523 has been entered at the Global Configuration mode prompt to enable the AOS IPv6 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.

Before applying an ACP to an interface, verify your Telnet or secure shell (SSH) connection will not be affected by the policy. If an ACP is applied to the interface you are connecting through and it does not allow Telnet or SSH traffic, your connection will be lost.

Syntax Description

<ipv6 acp name>	Identifies the configured IPv6 ACP using an alphanumeric descriptor (maximum of 50 characters). All ACP descriptors are case sensitive.

Default Values

By default, there are no configured IPv6 ACPs.

Command History

Release 18.1	Command was introduced.

Functional Notes

AOS IPv6 ACPs are used to allow or discard data for each physical interface. Each IPv6 ACP consists of an action (**allow**, **discard**) and a selector IPv6 access control list (ACL). When IPv6 packets are received on an interface, the configured IPv6 ACPs are applied to determine whether the data will be processed or discarded.

IPv6 ACPs only work with IPv6 ACLs, and IPv4 ACPs only work with IPv4 ACLs. You cannot have an IPv6 ACP or ACL with the same name as an IPv4 ACP or ACL.

Usage Examples

The following example creates an IPv6 ACP named **PRIVATEv6**:

```
(config)#ip policy-class PRIVATEv6
(config-policy6-class)#
```

ipv6 policy-class *<ipv6 acp name>* max-sessions *<number>*

Use the **ipv6 policy-class max-sessions** command to specify the maximum number of allowed Internet Protocol version 6 (IPv6) policy sessions on a specific IPv6 access control policy (ACP). For more details on IPv6 ACP functionality in AOS, refer to the *IPv6 Access Control Policy Command Set on page 4326*. Use the **no** form of this command to return to the default value.

Syntax Description

<ipv6 acp name>	Identifies the configured IPv6 ACP to which the maximum session limit is applied. Use an alphanumeric descriptor (maximum of 50 characters). All ACP descriptors are case sensitive.
<number>	Specifies the maximum number of allowed IPv6 ACP sessions. Valid range is **1** up to a value based on the amount of RAM in the AOS unit (refer to *Default Values* below).

Default Values

By default, the maximum IPv6 ACP sessions allowed are based on the amount of RAM in the AOS unit. The following table outlines the default values based on RAM:

RAM Amount	Default Max Sessions
64 MB	10000
128 MB	30000
256 MB	80000
512 MB	200000
768 MB	300000
1 GB	450000

Command History

Release 18.1	Command was introduced.

Functional Notes

To set the system-wide maximum limit for ACP sessions (both IPv4 and IPv6), use the command *policy-class max-sessions <number> on page 1654*.

Usage Examples

The following example allows no more than **100** policy sessions on the IPv6 ACP named **PRIVATEv6**:

(config)**#ipv6 policy-class PRIVATEv6 max-sessions 100**

ipv6 policy-class *<ipv6 acp name>* rpf-check

Use the **ipv6 policy-class rpf-check** command to verify that Internet Protocol version 6 (IPv6) traffic has entered on the appropriate interface using a route lookup. Reverse path forwarding (RPF) is essentially a spoofing check. For more details on IPv6 policy class functionality in AOS, refer to the *IPv6 Access Control Policy Command Set on page 4326*. Use the **no** form of this command to disable this feature.

Syntax Description

<ipv6 acp name>	Identifies the configured IPv6 access control policy (ACP) using an alphanumeric descriptor (maximum of 50 characters). All ACP descriptors are case sensitive.
rpf-check	Enables RPF check (spoofing).

Default Values

This command is enabled by default.

Command History

Release 18.1	Command was introduced.

Functional Notes

When enabled, after an IPv6 packet is received, the IPv6 firewall performs a route lookup on the packet's source IPv6 address to determine what interface would be used to forward the packet back to that address. The firewall then checks the IPv6 ACP assigned to that interface. If the IPv6 ACP does not match the IPv6 ACP of the interface on which the packet was received, the packet is dropped.

The **rpf-check** feature should be disabled if your application allows traffic to arrive on an interface sourced from networks contradicting the route table. This feature can be disabled on a per ACP basis by issuing this command in conjunction with the ACP name you do not want to be checked.

Usage Examples

The following example turns off the **rpf-check** feature for the IPv6 ACP named **PRIVATEv6**:

(config)**#no ip policy-class PRIVATEv6 rpf-check**

ipv6 policy-timeout

Use multiple **ipv6 policy-timeout** commands to customize policy timeout intervals for established Internet Protocol version 6 (IPv6) firewall sessions. The policy session timeout determines when the time to live (TTL) for the session expires and ends the session. This command configures the policy timeout for the following protocols: (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol version 6 (ICMPv6), Authentication Header (AH) Protocol, generic routing encapsulation (GRE), encapsulating security payload (ESP)) or specific services (by listing the particular port number). Use the **no** form of this command to return to the default timeout values. Variations of this command include:

ipv6 policy-timeout [vrf <*name*>**] match** <*ipv6 acl name*> **[policy** <*ipv6 acp name*>**]** <*timeout*>
ipv6 policy-timeout [vrf <*name*>**] [all-protocols | ahp | esp | gre | icmpv6 | tcp | udp |** <*protocol number*>**] [policy** <*ipv6 acp name*>**]** <*timeout*>
ipv6 policy-timeout [vrf <*name*>**] [tcp | udp] all-ports [policy** <*ipv6 acp name*>**]** <*timeout*>
ipv6 policy-timeout [vrf <*name*>**] [tcp | udp]** <*port*> **[policy** <*ipv6 acp name*>**]** <*timeout*>
ipv6 policy-timeout [vrf <*name*>**] [tcp | udp] range** <*beginning port*> <*ending port*> **[policy** <*ipv6 acp name*>**]** <*timeout*>

Syntax Description

<*timeout*>	Specifies the wait interval (in seconds) before an active session is closed. Valid range is **1** to **4294967295** seconds.
match <*ipv6 acl name*>	Specifies that if traffic creating the policy session matches the specified IPv6 access control list (ACL), the policy timeout value set using this command is used for the policy session. Because an ACL can be used to specify protocol and port information, you do not need to specify ports or protocols when using this version of the command. If the named ACL does not exist when this command is issued, an implicit ACL is created.
policy <*ipv6 acp name*>	Optional. Specifies that if the policy session uses the specified IPv6 access control policy (ACP) as its ingress policy class, the policy timeout value set using this command is used for the policy session (provided the ACL or protocol/port information matches if specified). If the named ACP does not exist when this command is issued, an implicit ACP is created.
ahp	Specifies the data protocol as AHP.
esp	Specifies the data protocol as ESP.
gre	Specifies the data protocol as GRE.
icmpv6	Specifies the data protocol as ICMPv6.
all-protocols	Specifies the timeout for all protocols. This policy session timeout is used when a specific protocol match is not found.

<protocol number>	Specifies the IPv6 next header value (protocol number) to match for using the specified timeout. Valid protocol number range is **0** to **255**. The following are accepted protocol numbers and their associated protocols: **51** (AHP), **50** (ESP), **47** (GRE), **58** (ICMPv6), **6** (TCP), and **17** (UDP). Protocol numbers reserved for extension headers cannot be used. For example, you cannot use **0** (hop-by-hop options), **43** (routing), **44** (fragment), **59** (no next header), **60** (destination options), or **135** (mobility).
tcp	Specifies the data protocol as TCP. If you are using TCP, you can also specify the timeout for a specific port, a range of ports, or all TCP ports.
udp	Specifies the data protocol as UDP. If you are using UDP, you can also specify the timeout for a specific port, a range of ports, or all UDP ports.
all-ports	Specifies all ports of either TCP or UDP are used if a specific match is not found.
<port>	Specifies a single TCP or UDP port. Keywords are available for well-known protocols, as those listed below. Valid port range is **0** to **65535**.
range	Customizes timeout intervals for a range of TCP or UDP ports.
<beginning port>/<ending port>	Specifies the range of ports, to which to apply the timeout value; valid only for specifying TCP and UDP services. Valid ports range between **0** and **65535**.
	The following is the list of TCP port numbers that may be identified using the text name (in **bold**):

bgp (Port 179)	**kshell** (Port 544)
chargen (Port 19)	**login** (Port 513)
cmd (Port 514)	**lpd** (Port 515)
daytime (Port 13)	**nntp** (Port 119)
discard (Port 9)	**pim-auto-rp** (Port 496)
domain (Port 53)	**pop2** (Port 109)
echo (Port 7)	**pop3** (Port 110)
exec (Port 512)	**smtp** (Port 25)
finger (Port 79)	**ssh** (Port 22)
ftp (Port 21)	**sunrpc** (Port 111)
ftp-data (Port 20)	**tacacs** (Port 49)
gopher (Port 70)	**talk** (Port 517)
hostname (Port 101)	**telnet** (Port 23)
https (Port 443)	**time** (Port 37)
ident (Port 113)	**uucp** (Port 540)
irc (Port 194)	**whois** (Port 43)
klogin (Port 543)	**www** (Port 80)

The following is the list of UDP port numbers that may be identified using the text name (in **bold**):

biff (Port 512)	**pim-auto-rp** (Port 496)
bootpc (Port 68	**rip** (Port 520)
bootps (Port 67)	**ripng** (Port 521)
discard (Port 9)	**snmp** (Port 161)
dnsix (Port 195)	**snmptrap** (Port 162))
domain (Port 53)	**sunrpc** (Port 111)
echo (Port 7)	**syslog** (Port 514)
isakmp (Port 500)	**tacacs** (Port 49)
mobile-ip (Port 434)	**talk** (Port 517)
nameserver (Port 42)	**tftp** (Port 69)
netbios-dgm (Port 138)	**time** (Port 37)
netbios-ns (Port 137)	**who** (Port 513)
netbios-ss (Port 139)	**xdmcp** (Port 177)
ntp (Port 123)	

vrf <*name*> Optional. Specifies a nondefault virtual routing and forwarding (VRF) instance on which to perform the policy timeout. If no VRF is specified, the action is performed on the default unnamed VRF.

Default Values

By default, policy session timeouts are set to **600** seconds for established TCP policy sessions, and **60** seconds for all other protocols.

Command History

Release 18.2	Command was introduced.
Release R10.1.0	Command was expanded to include the **ripng** option for UDP ports.

Functional Notes

This **ipv6 policy-timeout** command is used to configure the session timeout value for established policy sessions. Use the commands *ipv6 firewall rst-timeout <timeout> on page 1542*, *ipv6 firewall rst-timeout <timeout> on page 1542*, and *ipv6 firewall tcp-unestab-timeout <timeout> on page 1544* to configure timeout values for TCP FINISH (FIN), TCP RESET (RST), and pre-established TCP policy sessions.

Established TCP policy sessions are firewall sessions in which a three-way handshake has been observed, but no RST has been received by either endpoint, nor has a FIN been received from both endpoints. Established policy sessions can also be a stateless TCP policy session prior to the receipt of an RST from either endpoint or a FIN from both endpoints, or a policy session for all non-TCP protocols. Established policy session timeouts are configured to customize timeout intervals for protocols (by specifying the protocol or a specific access control list (ACL)), specific services (by specifying the port used or a specific ACL), and specific ingress policy classes. Multiple commands can be used to specify different timeouts for different protocols, services, and ingress policy classes.

Usage Examples

The following examples configure multiple policy session timeouts based on different protocols (and the associated ACLs):

(config)**#ipv6 policy-timeout match A1 policy P1 1000**
(config)**#ipv6 policy-timeout match A2 policy P1 2000**
(config)**#ipv6 policy-timeout tcp ssh policy P1 3000**
(config)**#ipv6 policy-timeout tcp range 100 200 policy P1 4000**
(config)**#ipv6 policy-timeout tcp range 150 250 policy P1 5000**
(config)**#ipv6 policy-timeout tcp all-ports policy P1 6000**
(config)**#ipv6 policy-timeout match A3 7000**
(config)**#ipv6 policy-timeout tcp ssh 8000**

(config)**#ipv6 access-list extended A1**
(config-ex6-nacl)**#permit gre host 2001:DB8:1234:1::1 any**
(config-ex6-nacl)**#permit tcp any any eq www**

(config)**#ipv6 access-list extended A2**
(config-ex6-nacl)**#permit tcp host 2001:DB8:1234:1::1 any**

(config)**#ipv6 access-list extended A3**
(config-ex6-nacl)**#permit esp any any**

ipv6 prefix-list <*name*> seq <*number*>

Use the **ipv6 prefix-list seq** command to specify an Internet Protocol version 6 (IPv6) prefix to be matched when filtering IPv6 routes. Use the **no** form of this command to remove a prefix list. Variations of this command include:

ipv6 prefix-list <*name*> **seq** <*number*> **deny** <*ipv6 address/prefix-length*>
ipv6 prefix-list <*name*> **seq** <*number*> **deny** <*ipv6 address/prefix-length*> **ge** <*value*>
ipv6 prefix-list <*name*> **seq** <*number*> **deny** <*ipv6 address/prefix-length*> **le** <*value*>
ipv6 prefix-list <*name*> **seq** <*number*> **permit** <*ipv6 address/prefix-length*>
ipv6 prefix-list <*name*> **seq** <*number*> **permit** <*ipv6 address/prefix-length*> **ge** <*value*>
ipv6 prefix-list <*name*> **seq** <*number*> **permit** <*ipv6 address/prefix-length*> **le** <*value*>

Syntax Description

<*name*>	Specifies a particular prefix list. Prefix list names can be up to **80** characters in length.
<*number*>	Specifies the entry's unique sequence number that determines the processing order. Lower numbered entries are processed first. Range is **1** to **4294967294**.
permit <*ipv6 address/prefix-length*>	Permits access to entries matching the specified network IPv6 address and the corresponding network prefix length. IPv6 addresses and prefixes are expressed in colon hexadecimal format (for example, **2001:DB8:0:3F3B::/64**).
deny <*ipv6 address/prefix-length*>	Denies access to entries matching the specified network IPv6 address and the corresponding network prefix length. IPv6 addresses and prefixes are expressed in colon hexadecimal format (for example, **2001:DB8:0:3F3B::/64**).
le <*value*>	Specifies the upper end of the range and indicates that the length must be less than or equal to the specified value in order to match. Range is **0** to **32**.
ge <*value*>	Specifies the lower end of the range and indicates that the length must be greater than or equal to the specified value in order to match. Range is **0** to **32**.

Default Values

If no **ge** or **le** parameters are specified, an exact match is assumed. If only **ge** is specified, the AOS device assumes 32 as the upper limit. If only **le** is specified, the AOS device assumes the network address's length as the lower limit.

Command History

Release 10.1.0	Command was introduced.

Functional Notes

This command specifies a prefix to be matched when filtering routes. Prefix lists can be useful in configurations of Border Gateway Protocol (BGP) to define the routes that an AOS device can advertise to or receive from a BGP address family (AF) neighbor. Common uses for prefix lists include: preventing a network from becoming a transit for external traffic when multihoming, receiving only routes from remote virtual private network (VPN) sites, prohibiting the advertisement of a network, and load balancing outbound traffic. When using this command, if the network address is entered without specifying a range for prefix lengths, the router assumes that the route must be an exact match.

Optionally, this command may specify a range of prefix lengths. The following rule must be followed: len < ge-value ≤ le-value. A filter that exactly matches a prefix length can be created by entering the length for both the **ge** and **le** values. A prefix list with no entries allows all routes. A route that does not match any entries in a prefix list is dropped. As soon as a route is permitted or denied, there is no further processing of the rule in the prefix list. A route that is denied with the initial entry of a prefix list will not be allowed, even if it matches a permitting entry further down the list.

Usage Examples

The following example creates a prefix list entry in the IPv6 prefix list TEST that allows all routes to prefixes in the **2001:DB8:0:3F3B::/64** network:

(config)**#ipv6 prefix-list TEST seq 5 permit 2001:DB8:0:3F3B::/64 le 24**

ipv6 route

Use the **ipv6 route** command to add an Internet Protocol version 6 (IPv6) static route to the IPv6 route table. Use the **no** form of this command to remove a configured IPv6 static route. To specify a route using a named prefix, refer to *ipv6 route named-prefix on page 1561*. Variations of this command include:

ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address>* **[mef-ethernet** *<slot/port>* **| system-control-evc | system-management-evc]**
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address>* **[mef-ethernet** *<slot/port>* **| system-control-evc | system-management-evc] tag** *<value>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address>* **[mef-ethernet** *<slot/port>* **| system-control-evc | system-management-evc] track** *<name>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address>* **[mef-ethernet** *<slot/port>* **| system-control-evc | system-management-evc] tag** *<value>* **track** *<name>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address> <administrative distance>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address> <administrative distance>* **tag** *<value>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address> <administrative distance>* **track** *<name>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address> <administrative distance>* **tag** *<value>* **track** *<name>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address> <interface>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address> <interface>* **tag** *<value>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address> <interface>* **track** *<name>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address> <interface>* **tag** *<value>* **track** *<name>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address> <interface> <administrative distance>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address> <interface> <administrative distance>* **tag** *<value>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address> <interface> <administrative distance>* **track** *<name>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address> <interface> <administrative distance>* **tag** *<value>* **track** *<name>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address>* **null 0**
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address>* **null 0 tag** *<value>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address>* **null 0 track** *<name>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address>* **null 0 tag** *<value>* **track** *<name>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address>* **null 0** *<administrative distance>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address>* **null 0** *<administrative distance>* **tag** *<value>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address>* **null 0** *<administrative distance>* **track** *<name>*
ipv6 route [vrf *<name>***]** *<ipv6 prefix/prefix length> <ipv6 address>* **null 0** *<administrative distance>* **tag** *<value>* **track** *<name>*

Syntax Description

<ipv6 prefix/prefix length>	Specifies the network defined by this static route entry. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**. The IPv6 prefix cannot be a link-local address.
<ipv6 address>	Optional. Specifies the next-hop IPv6 address defined by the static route. This is not a link-local IPv6 address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
<interface>	Optional. Specifies an egress interface on the router which connects to the next-hop IPv6 device on the path toward the specified network. Interfaces are entered in the *<interface> <slot/port | interface id>* format. You must use the *<interface>* parameter in conjunction with the next-hop IPv6 address if you are specifying a link-local IPv6 address (**FE80::**) as the next hop.
null 0	Optional. Specifies that traffic is routed to the null interface. The router drops all packets destined for the null interface. Use the null interface to allow the router to advertise a route, but not forward traffic to the route.
<administrative distance>	Optional. Specifies an administrative distance associated with the static route, and is used to determine the best route when multiple routes to the same destination exist. The route with the lowest administrative distance is the preferred route. Administrative distance range is **1** to **255**.
tag *<value>*	Optional. Specifies a number to use as a tag for this route. Valid range is **1** to **65535**.
track *<name>*	Optional. Enables tracking on the indicated route. Once the named track enters a fail state, the route specified by the command is disabled and traffic will no longer be routed using that route. For more information on configuring tracks, refer to *track <name> on page 1886*.
mef-ethernet *<slot/port>*	Specifies the Metro Ethernet Forum (MEF) Ethernet interface.
system-control-evc	Optional. Specifies the system control Ethernet virtual connection (EVC). This EVC is preconfigured on the unit.
system-mangement-evc	Optional. Specifies the system management EVC. This EVC is preconfigured on the unit.
vrf *<name>*	Optional. Specifies to create the static route on a specific virtual routing and forwarding (VRF).

Default Values

By default, no static routes are added to the IPv6 route table. If a static route is created, the administrative distance is **1** by default.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.
Release R10.5.0	Command was expanded to include the loopback interface.

Release R10.10.0	Command was expanded to include the **system-control-evc** and **system-management-evc** parameters.
Release R10.11.0	Command was expanded to include the **track** parameter and MEF Ethernet interface.

Functional Notes

Each static route is only added to the IPv6 route table when the IPv6 interface is configured and in an UP state. There are three types of static routes that can be used: directly attached, recursive, and fully specified.

A directly attached static route is a route in which the next hop for the route is entered as an interface. Packets destined for the specified network are assumed to be directly reachable on the specified interface. If you are using a directly attached static route, and the interface you are using uses Layer 2 addresses (for example, as an Ethernet interface does), then address resolution is performed when a packet is delivered to the network. For Point-to-Point Protocol (PPP) interfaces, the packet is simply forwarded through the interface in the same way that a packet is forwarded when an IPv6 on-link prefix is defined at the interface.

A recursive static route is a route in which the next hop for the route is entered as the IPv6 address of the next-hop router. When a recursive static route is used, AOS attempts to determine the interface used to reach the next-hop address. Recursive routes are added to the route table only when the router has determined which interface to use for egress traffic.

A fully specified static route is a route in which the next hop is entered as an IPv6 address and an interface for the next-hop router is specified. This type of static route restricts the use of the route to the specified interface. A fully specified static route MUST be used when the next hop is specified by its link-local address, which alone has no context of location.

Usage Examples

The following example creates a static route in the IPv6 routing table that has a local-link next-hop address, egresses from the **ethernet 0/1** interface, includes a tag of **3**, and has an administrative distance of **2**:

(config)**#ipv6 route 2001:DB8:3F::/48 fe80::202:b3ff:fe1e:8345 ethernet 0/1 tag 3 2**

ipv6 route named-prefix

Use the **ipv6 route named-prefix** command to add an Internet Protocol version 6 (IPv6) static route to the IPv6 route table using a named prefix. Use the **no** form of this command to remove a configured IPv6 static route. To specify a route without using a named prefix, refer to *ipv6 route on page 1558*. Variations of this command include:

ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address>* **[mef-ethernet** *<slot/port>* | **system-control-evc | system-management-evc]**
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address>* **[mef-ethernet** *<slot/port>* | **system-control-evc | system-management-evc] tag** *<value>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address>* **[mef-ethernet** *<slot/port>* | **system-control-evc | system-management-evc] track** *<name>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address>* **[mef-ethernet** *<slot/port>* | **system-control-evc | system-management-evc] tag** *<value>* **track** *<name>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address> <administrative distance>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address> <administrative distance>* **tag** *<value>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address> <administrative distance>* **track** *<name>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address> <administrative distance>* **tag** *<value>* **track** *<name>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address> <interface>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address> <interface>* **tag** *<value>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address> <interface>* **track** *<name>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address> <interface>* **tag** *<value>* **track** *<name>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address> <interface> <administrative distance>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address> <interface> <administrative distance>* **tag** *<value>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address> <interface> <administrative distance>* **track** *<name>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address> <interface> <administrative distance>* **tag** *<value>* **track** *<name>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address>* **null 0**
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address>* **null 0 tag** *<value>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address>* **null 0 track** *<name>*
ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address>* **null 0**

tag *<value>* **track** *<name>*

ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address>* **null 0** *<administrative distance>*

ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address>* **null 0** *<administrative distance>* **tag** *<value>*

ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address>* **null 0** *<administrative distance>* **track** *<name>*

ipv6 route [vrf *<name>***] named-prefix** *<prefix-name> <ipv6 prefix/prefix length> <ipv6 address>* **null 0** *<administrative distance>* **tag** *<value>* **track** *<name>*

Syntax Description

<prefix name>	Specifies a route is created using a named prefix. The *<prefix name>* parameter specifies the prefix variable name.
<ipv6 prefix/prefix length>	Specifies the network defined by this static route entry. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**. The IPv6 prefix cannot be a link-local address.
<ipv6 address>	Specifies the next-hop IPv6 address defined by the static route. This is not a link-local IPv6 address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
<interface>	Optional. Specifies an egress interface on the router which connects to the next-hop IPv6 device on the path toward the specified network. Interfaces are entered in the *<interface> <slot/port* | *interface id>* format. You must use the *<interface>* parameter in conjunction with the next-hop IPv6 address if you are specifying a link-local IPv6 address (**FE80::**) as the next hop.
null 0	Optional. Specifies that traffic is routed to the null interface. The router drops all packets destined for the null interface. Use the null interface to allow the router to advertise a route, but not forward traffic to the route.
<administrative distance>	Optional. Specifies an administrative distance associated with the static route, and is used to determine the best route when multiple routes to the same destination exist. The route with the lowest administrative distance is the preferred route. Administrative distance range is **1** to **255**.
tag *<value>*	Optional. Specifies a number to use as a tag for this route. Valid range is **1** to **65535**.
track *<name>*	Optional. Enables tracking on the indicated route. Once the named track enters a fail state, the route specified by the command is disabled and traffic will no longer be routed using that route. For more information on configuring tracks, refer to *track <name> on page 1886*.
mef-ethernet *<slot/port>*	Specifies the Metro Ethernet Forum (MEF) Ethernet interface.
system-control-evc	Optional. Specifies the system control Ethernet virtual connection (EVC). This EVC is preconfigured on the unit.
system-management-evc	Optional. Specifies the system management EVC. This EVC is preconfigured on the unit.

vrf <*name*>	Optional. Specifies to create the static route on a specific virtual routing and forwarding (VRF).

Default Values

By default, no static routes are added to the IPv6 route table. If a static route is created, the administrative distance is **1** by default.

Command History

Release R10.9.0	Command was introduced.
Release R10.10.0	Command was expanded to include the **system-control-evc** and **system-management-evc** parameters.
Release R10.11.0	Command was expanded to include the **track** parameter and MEF Ethernet interface.

Functional Notes

Each static route is only added to the IPv6 route table when the IPv6 interface is configured and in an UP state. There are three types of static routes that can be used: directly attached, recursive, and fully specified.

A directly attached static route is a route in which the next hop for the route is entered as an interface. Packets destined for the specified network are assumed to be directly reachable on the specified interface. If you are using a directly attached static route, and the interface you are using uses Layer 2 addresses (for example, as an Ethernet interface does), then address resolution is performed when a packet is delivered to the network. For Point-to-Point Protocol (PPP) interfaces, the packet is simply forwarded through the interface in the same way that a packet is forwarded when an IPv6 on-link prefix is defined at the interface.

A recursive static route is a route in which the next hop for the route is entered as the IPv6 address of the next-hop router. When a recursive static route is used, AOS attempts to determine the interface used to reach the next-hop address. Recursive routes are added to the route table only when the router has determined which interface to use for egress traffic.

A fully specified static route is a route in which the next hop is entered as an IPv6 address and an interface for the next-hop router is specified. This type of static route restricts the use of the route to the specified interface. A fully specified static route MUST be used when the next hop is specified by its link-local address, which alone has no context of location.

Usage Examples

The following example creates a static route named **PREFIX1** in the IPv6 routing table that has a local-link next-hop address, egresses from the **ethernet 0/1** interface, includes a tag of **3**, and has an administrative distance of **2**:

(config)**#ipv6 route named-prefix PREFIX1 2001:DB8:3F::/48 fe80::202:b3ff:fe1e:8345 ethernet 0/1 tag 3 2**

ipv6 unicast-routing

Use the **ipv6 unicast-routing** command to enable Internet Protocol version 6 (IPv6) unicast routing and specify the router as an IPv6 neighbor. Use the **no** form of this command to disable the IPv6 routing subsystem, remove any routing protocol entries from the IPv6 routing table, cease IPv6 routing functions, and disable IPv6 unicast routing.

Syntax Description

No subcommands.

Default Values

By default, IPv6 unicast routing is disabled.

Command History

Release 18.1	Command was introduced.

Functional Notes

This **ipv6 unicast-routing** command functions similarly to the **ip routing** command for IPv4 services. In order to enable IPv6 unicast routing, you must first configure interfaces to use IPv6 before IPv6 communication takes place. When IPv6 unicast routing is enabled globally, the router flag is set to **1** in neighbor advertisement (NA) messages.

Using the **no** form of this command disables the IPv6 routing subsystem, removes any routing protocol entries from the IPv6 route table, causes IPv6 routing functions to cease, and disables IPv6 unicast routing. In addition, NA

messages are sent at each interface indicating the neighbor is no longer a router (router flag is set to **0**), and that the router is no longer the default router for any advertised prefixes. When IPv6 unicast routing is disabled, the existing IPv6 configuration is retained, but no IPv6 packets are routed and no routing resources are consumed.

If IPv6 unicast routing is not enabled, but an interface has IPv6 enabled, that interface may communicate as an IPv6 host to other devices. If IPv6 packets are received that are not addressed to that interface, the packets are dropped.

Usage Examples

The following example enables IPv6 unicast routing and specifies the router as an IPv6 neighbor:

(config)**#ipv6 unicast-routing**

isdn-group <*number*>

Use the **isdn-group** command to enter the ISDN Group Configuration mode command set. Use the **no** form of this command to disable this feature. Refer to the section *Voice ISDN Group Command Set on page 4656* for more information on the commands available for each group.

Syntax Description

<number>	Specifies the integrated services digital network (ISDN) group. Range is **1** to **255**.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Functional Notes

An ISDN group allows the user to specify the maximum and minimum number of B-channels that can be used for a specific type of call. It is a logical group of B-channels from one or more ISDN interfaces. The interfaces can be of different types (e.g., primary rate interface (PRI) and basic rate interface (BRI)). An ISDN interface can be a member of multiple ISDN groups that makes it possible to share its B-channels between different types of calls.

Usage Examples

The following example uses the **isdn-group** command to enter the ISDN Group Configuration mode for ISDN group 1:

```
(config)#isdn-group 1
(config-isdn-group 1)#
```

isdn-number-template

Use the **isdn-number-template** command to create an entry in the integrated services digital network (ISDN) number-type template that is used when encoding the called party and calling party information elements (IEs) for inbound and outbound ISDN calls. Use the **no** form of this command to delete the configured entry. Variations of this command include the following:

isdn-number-template <*template id*> **prefix** <*number*> **abbreviated** <*pattern*>
isdn-number-template <*template id*> **prefix** <*number*> **international** <*pattern*>
isdn-number-template <*template id*> **prefix** <*number*> **national** <*pattern*>
isdn-number-template <*template id*> **prefix** <*number*> **network-specific** <*pattern*>
isdn-number-template <*template id*> **prefix** <*number*> **plan** <*indicator*> **type** <*number*> <*pattern*>
isdn-number-template <*template id*> **prefix** <*number*> **subscriber** <*pattern*>
isdn-number-template <*template id*> **prefix** <*number*> **unknown** <*pattern*>

Syntax Description

<*template id*>	Specifies a numeric identifier for the template entry. Valid range is **1** to **255**.
prefix <*number*>	Specifies the expected prefix for the call type. Prefixes can be left blank (using double quotation marks " "), or consist of unlimited length strings of zeros and ones. For example, for international calls made from within the United States, a prefix of 011 is expected.
abbreviated	Specifies using **abbreviated** (bits 110) in the type of number (TON) octet. Abbreviated is used mainly in private ISDN network applications and the implementation is network dependent.
international	Specifies using **international** (bits 001) in the TON octet. International is used for calls destined outside the national calling area. International calls have the international direct dialing (IDD) prefix removed. For example, consider an international call of 011-N$, where the IDD prefix is 011 and the N$ represents the digits necessary for routing the call at the destination. When the called party IE is created for this call, the prefix is stripped and the N$ digits are placed in the number digits field.
national	Specifies using **national** (bits 010) in the TON octet. National is used for calls destined for inside the national calling area (i.e., does not cross into an international local access and transport area (LATA)). National calls have the direct dialing prefix removed. For example, consider a national call with a direct dialing prefix of 1 and NXX-NXX-XXXX to represent the ten-digit number necessary for routing the call. When the called party IE is created for this call, the prefix (1) is stripped and the NXX-NXX-XXXX digits are placed in the number digits field.

network-specific	Specifies using **network-specific** (bits 011) in the TON octet. Network-Specific is used for calls that require special access to a private network, which requires the use of a prefix that should be stripped once access to the network has been gained. Network-specific calls have the dialing prefix removed. For example, a call to a private network with the 700 consists of 700-N$, where 700 is the dialing prefix and N$ represents the digits necessary for routing the call at the destination. When the Called Party IE is created for this call, the prefix is stripped and the N$ is placed in the Number Digits field.
plan <*indicator*>	Specifies the numbering plan indicator (NPI) to use in combination with the TON and associate it with a number pattern. Valid range is **0** to **15**.
subscriber	Specifies using **subscriber** (bits 100) in the TON octet. Subscriber is used for local calls (not long distance). Subscriber calls, by default, have the area code removed. For example, a subscriber call to 916-555-1212 would have the prefix 916 stripped and 555-1212 in the number digits field. For areas with mandatory ten-digit dialing, a blank prefix should be entered to ensure that all ten digits are passed to the number digits field.
type <*number*>	Specifies the TON to use in combination with the NPI and associate it with a number pattern. Valid range is **0** to **7**.
unknown	Specifies using **unknown** (bits 000) in the TON octet. Unknown is used when the number type is not known. Unknown numbers are assumed to have no prefix, and the entire dialed number is presented in the number digits field.
<*pattern*>	Specifies a pattern for this template. Refer to *Functional Notes* for more information.

Default Values

By default, the following number template for domestic emergency calls (911) is the only template preconfigured in AOS:

isdn-number-template 0 prefix “ ” subscriber 911

Command History

Release 11.1	Command was introduced.
Release A4.05	Command was expanded to include the **plan** <*indicator*> **type** <*number*> <*pattern*> parameter.

Functional Notes

The command **isdn-number-template** <*template id*> **prefix** <*number*> **plan** <*indicator*> **type** <*number*> <*pattern*> is used to associate any combination of NPIs and TONs with a number pattern. Not all combination values are allowed, and AOS does not check the entry validity. Refer to the International Telecommunication Union (ITU) recommendation Q.931 for the most current information.

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example creates a number template (labeled **1**) and prefix (labeled **1**) for national calls:

(config)**#isdn-number-template 1 prefix 1 national Nxx-Nxx-xxxx**

led status-led startup-state

Use the **led status-led startup-state** command to control the state of the status LED upon system startup of an applicable AOS device. This command can be used to turn off the LED, as well as control both the LED color and blink rate. Use the **no** form of this command to return to the default setting. Variations of this command include:

led status-led startup-state [green | red]
led status-led startup-state [green | red] blink [fast | slow]
led status-led startup-state red-green
led status-led startup-state off

Syntax Description

green	Modifies the status LED display to green.
red	Modifies the status LED display to red.
red-green	Modifies the status LED to alternate between red and green
blink	Specifies the status LED blink rate. If the blink rate is not specified, the display color will be solid (i.e., non-blinking).
fast	Specifies a blink rate of five times per second.
slow	Specifies a blink rate of once per second.
off	Turns off the status LED.

Default Values

By default, the status LED is solid green.

Command History

Release R11.7.0	Command was introduced.

Functional Notes

This command only controls the state of the LED upon startup; it does not alter the current state of the status LED.

Usage Examples

The following example changes the startup state of the status LED display to slow, blinking red:

(config)**#led status-led startup-state red blink slow**

license server

Use the **license server** command to configure a license server, from which license keys are automatically retrieved by the AOS unit. This command must be issued before using the command *license activate <activation key> on page 500* to activate AOS feature licenses. Use the **no** form of this command to remove the license server configuration and return to the default server. Variations of this command include:

license server url *<url>*
license server vrf *<name>* **url** *<url>*

Syntax Description

url *<url>*	Specifies the uniform resource locator (URL) address of the license server. Specify the URL using either Hypertext Transfer Protocol (HTTP) or HTTP Secure (HTTPS), for example, **https://example.com**.
vrf *<name>*	Optional. Specifies a non-default virtual routing and forwarding (VRF) instance on which to configure the license server.

Default Values

If no license server is configured, a license key request is automatically sent to **https://portal.adtran.com/web/ptapi/generate**.

Command History

Release R13.4.0	Command was introduced.

Functional Notes

The server configured with the command is used in conjunction with the command *license activate <activation key> on page 500*. The activation keys used with the **license activate** command are provided to you when you purchase licenses for additional AOS features. When the **license activate** command is issued, the entered activation keys are automatically sent to the licensing server configured with the **license server** command, and then the features are automatically licensed on the AOS unit.

This two-step licensing procedure replaces the four-step licensing process introduced in AOS firmware release R11.8.0. For more information about the AOS feature licensing process, refer to the quick start guide, *Licensing AOS Features*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures a license server with the URL **https://example.com**, on the default VRF, for use with AOS feature license activation keys:

(config)**#license server url https://example.com**

line

Use the **line** command to enter the line configuration for the specified console, Telnet, or secure shell (SSH) session. Refer to the sections *Line (Console) Interface Command Set on page 2021*, *Line (Telnet) Interface Command Set on page 2054*, and *Line (SSH) Interface Command Set on page 2038* for information on the subcommands. Variations of this command include:

line console *<line number>*
line ssh *<line number>*
line ssh *<line number> <ending number>*
line telnet *<line number>*
line telnet *<line number> <ending number>*

Syntax Description

console	Enters the configuration mode for the DB-9 (female) **CONSOLE** port located on the rear panel of the unit. Refer to the section *Line (Console) Interface Command Set on page 2021* for information on the subcommands found in that command set.
telnet	Enters the configuration mode for Telnet session(s), allowing you to configure for remote access. Refer to the section *Line (Telnet) Interface Command Set on page 2054* for information on the subcommands found in that command set.
ssh	Enters the configuration mode for SSH. Refer to the section *Line (SSH) Interface Command Set on page 2038* for information on the subcommands found in that command set.
<line number>	Specifies the starting session to configure for remote access. Valid range for console is **0**. Valid range for Telnet and SSH is **0** to **4**. If configuring a single Telnet or SSH session, enter a single line number.
<ending number>	Optional. Specifies the last Telnet or SSH session to configure for remote access. Valid range is **0** to **4**. For example, to configure all available Telnet sessions, enter **line telnet 0 4**.

Default Values

By default, there are no configured Telnet or SSH sessions. By default, the AOS line console parameters are configured as follows:

Data Rate: 9600
Data bits: 8
Stop bits: 1
Parity Bits: 0
No flow control

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the SSH.

Usage Examples

The following example begins the configuration for the **CONSOLE** port located on the rear of the unit:

```
(config)#line console 0
(config-con0)#
```

The following example begins the configuration for all available Telnet sessions:

```
(config)#line telnet 0 4
(config-telnet0-4)#
```

The following example begins the configuration for all available SSH sessions:

```
(config)#line ssh 0 4
(config-ssh0-4)#
```

lldp

Use the **lldp** command to configure global settings that control the way Link Layer Discovery Protocol (LLDP) functions. Use the **no** form of this command to return to the default setting. Variations of this command include:

lldp med-fast-start-interval <*value*>
lldp minimum-transmit-interval <*value*>
lldp reinitialization-delay <*value*>
lldp system-capabilities exclude telephone
lldp transmit-interval <*value*>
lldp ttl-multiplier <*value*>

Syntax Description

med-fast-start-interval	Specifies the fast start transmit interval (in seconds) that LLDP-Media Endpoint Discovery (LLDP-MED) time length values (TLVs) are sent once every second, allowing rapid automatic configuration of LLDP-MED capable endpoints at startup. Range is **1** to **10** seconds. Default value is 4 seconds.
minimum-transmit-interval	Defines the minimum amount of time between transmission of LLDP frames in seconds. Range is **1** to **8192** seconds.
reinitialization-delay	Defines the minimum amount of time to delay after LLDP is enabled on a port before allowing transmission of additional LLDP frames on that port in seconds. Range is **1** to **10** seconds.
system-capabilities	Configures local system capabilities.
exclude telephone	Excludes telephone flag in the system capabilities TLV. Enabling this command prevents the AOS unit from advertising the telephone system capabilities in both the system capabilities and enabled capabilities portions of the LLDP packet.
transmit-interval	Defines the delay between LLDP frame transmission attempts during normal operation in seconds. Range is **5** to **32768** seconds.
ttl-multiplier	Defines the time to live (TTL) multiplier to be applied to the transmit interval to compute the time to live for data sent in an LLDP frame. Range is **2** to **10**.
<*value*>	Specifies the interval, delay, or multiplier.

Default Values

By default, **med-fast-start-interval** is **4** seconds; **minimum-transmit-interval** is **2** seconds; **reinitialization-delay** is **2** seconds; **transmit-interval** is **30** seconds; and **ttl-multiplier** is **4**.

Command History

Release 8.1	Command was introduced.
Release 17.2	Command was expanded to include the **med-fast-start-interval** parameter.
Release A5.01	Command was expanded to include the **system-capabilities** and **exclude telephone** parameters.

Functional Notes

Once a device receives data from a neighboring device in an LLDP frame, it will retain that data for a limited amount of time. This amount of time is called time to live, and it is part of the data in the LLDP frame. The time to live transmitted in the LLDP frame is equal to the transmit interval multiplied by the TTL multiplier.

Usage Examples

The following example sets the LLDP minimum transmit interval to **10** seconds:

(config)**#lldp minimum-transmit-interval 10**

The following example sets the LLDP reinitialization delay to **5** seconds:

(config)**#lldp reinitialization-delay 5**

The following example sets the LLDP transmit interval to **15** seconds:

(config)**#lldp transmit-interval 15**

The following example sets the LLDP transmit interval to **15** seconds and the TTL multiplier to **2** for all LLDP frames transmitted from the unit. The resulting TTL is 30 seconds:

(config)**#lldp transmit-interval 15**
(config)**#lldp ttl-multiplier 2**

load-protect

Use the **load-protect** command to enable and configure load-protect CPU throttling. Variations of this command include:

load-protect background rate-limit
load-protect background rate-limit <*increase percentage*> <*decrease percentage*>
load-protect background interval <*value*> **rate-limit**
load-protect background interval <*value*> **rate-limit** <*increase percentage*> <*decrease percentage*>
load-protect cli rate-limit
load-protect cli rate-limit <*increase percentage*> <*decrease percentage*>
load-protect cli interval <*value*> **rate-limit**
load-protect cli interval <*value*> **rate-limit** <*increase percentage*> <*decrease percentage*>

Syntax Description

background	Specifies the scope of the command is all encompassing.
cli	Specifies the scope of the command is limited to the command line interface.
interval <*value*>	Optional. Sets the maximum latency, in milliseconds, allowed to occur before declaring the CLI or background in congestion.
rate-limit	Specifies that load protect be enabled utilizing a simple step function, unless a percentage of increase and decrease are defined.
<*increase percentage*>	Optional. Sets the percentage increase to be added to the current percentage of packets that the CPU handles.
<*decrease percentage*>	Optional. Sets the percentage decrease to be removed from the current percentage of packets that the CPU handles.

Default Values

If no **interval** <*value*> is entered, the command defaults to a simple step function to throttle high CPU utilization.

Command History

Release R11.10.0	Command was introduced.

Usage Examples

The following example enables load protect for the CLI with a maximum latency of 200 ms:

(config)**#load-protect cli interval 200 rate limit**

load-protect protocol

Use the **load-protect protocol** command to enable and configure a specified protocol's queue and values for the load protect feature's protocol rate limiter. Variations of this command include:

load-protect protocol arp cbs <*number*>
load-protect protocol arp cir <*number*>
load-protect protocol arp queue <*number*>
load-protect protocol default cir <*number*>
load-protect protocol default cir <*number*> **cbs** <*number*>
load-protect protocol dhcp cbs <*number*>
load-protect protocol dhcp cir <*number*>
load-protect protocol dhcp queue <*number*>
load-protect protocol icmp cbs <*number*>
load-protect protocol icmp cir <*number*>
load-protect protocol icmp queue <*number*>
load-protect protocol icmp-unreachable cbs <*number*>
load-protect protocol icmp-unreachable cir <*number*>
load-protect protocol icmp-unreachable queue <*number*>
load-protect protocol ipv6-hop-by-hop cbs <*number*>
load-protect protocol ipv6-hop-by-hop cir <*number*>
load-protect protocol ipv6-hop-by-hop queue <*number*>
load-protect protocol ipv6-nd cbs <*number*>
load-protect protocol ipv6-nd cir <*number*>
load-protect protocol ipv6-nd queue <*number*>
load-protect protocol ntp cbs <*number*>
load-protect protocol ntp cir <*number*>
load-protect protocol ntp queue <*number*>
load-protect protocol radius cbs <*number*>
load-protect protocol radius cir <*number*>
load-protect protocol radius queue <*number*>
load-protect protocol snmp cbs <*number*>
load-protect protocol snmp cir <*number*>
load-protect protocol snmp queue <*number*>
load-protect protocol ssh cbs <*number*>
load-protect protocol ssh cir <*number*>
load-protect protocol ssh queue <*number*>
load-protect protocol vrrp cbs <*number*>
load-protect protocol vrrp cir <*number*>
load-protect protocol vrrp queue <*number*>
load-protect protocol vrrpv3 cbs <*number*>
load-protect protocol vrrpv3 cir <*number*>
load-protect protocol vrrpv3 queue <*number*>

Syntax Description

arp	Specifies internet protocol version 4 (IPv4) Address Resolution Protocol (ARP) packets.
default	Specifies the feature behavior for packets not specified by another protocol.
dhcp	Specifies Dynamic Host Configuration Protocol version 4 (DHCPv4) and DHCPv6 packets.
icmp	Specifies all IPv4 and IPv6 Internet Control Message Protocol (ICMP) packets, except for unreachables.
icmp-unreachable	Specifies IPv4 and IPv6 ICMP unreachable packets.
ipv6-hop-by-hop	Specifies any IPv6 packet with a hop-by-hop option correctly set on the packet.
ipv6-nd	Specifies IPv6 neighbor discovery packets.
ntp	Specifies Network Time Protocol (NTP), Simple Network Time Protocol (SNTP) packets.
radius	Specifies Remote Authentication Dial-in User Service (RADIUS) packets.
snmp	Specifies Simple Network Management Protocol (SNMP) packets.
ssh	Specifies Secure Shell (SSH), Session Control Protocol (SCP) packets.
vrrp	Specifies Virtual Router Redundancy Protocol version 2 (VRRPv2) packets.
vrrpv3	Specifies VRRPv3 packets.
cbs <*number*>	Specifies the committed burst size (CBS) for the given protocol in number of packets.
cir <*number*>	Specifies the packet per second committed information rate (CIR) that is rate limited to the CPU for the given protocol.
queue <*number*>	Specifies the destination queue for the given protocol.

Default Values

By default the load protect feature is not enabled.

Command History

Release R11.10.0	Command was introduced.

Usage Examples

The following example enables queue number **1** for all DHCPv4 and DHCPv6 packets whose CBS and CIR values may then be configured:

(config)**#load-protect protocol dhcp queue 1**

load-protect queue <*number*> weight packet <*weight*>

Use the **load-protect queue weight packet** command to set the weighted round robin (WRR) weight in packets per second for the specified queue.

Syntax Description

<*number*>	Specifies the desired queue.
<*weight*>	Specifies the WRR weight in packets per second.

Default Values

No default values are necessary for this command.

Command History

Release R11.10.0	Command was introduced.

Usage Examples

The following example sets the number of packets per second to **50** for queue number **1**:

(config)**#load-protect queue 1 weight packet 50**

local *<start ip address> <end ip address>* **global** *<start ip address> <end ip address>*

Use the **local global** command to define local and global network range of addresses for static 1:1 network address translation (NAT) mapping. This command is entered from within the NAT pool's configuration command set by using the **ip nat pool** command. Refer to *ip nat pool <name> on page 1433* for more information.

Syntax Description

<start ip address>	Specifies the first IP address in the range.
<end ip address>	Specifies the last IP address in the range. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

No default values are necessary for this command.

Command History

Release 17.4	Command was introduced.

Functional Notes

Static pools define a local network range of addresses whose size must be equal to the global range. Source NAT will translate from the local range to the global range. Destination NAT will translate from the global range to the local range. The addresses do not have to start at the same offset. If this command is entered and the two ranges are not of the same size, an error message is displayed. The command will fail and the pool will remain in its original state. If the pool was configured with an existing address range prior to issuing the failed command, that range will remain unchanged. If no address range was present, the pool will remain incomplete.

In some situations, an address needs to be excluded that falls within a range. For example, suppose you are excluding 10.1.1.10 because it is the address used for many-to-one source NAT for other nonstatic NAT hosts. This can be accomplished by creating multiple pools. This configuration requires multiple policy class entries, but each can use the same access control list (ACL).

Usage Examples

The following example creates a static NAT pool named **POOL1** and defines the local range from **10.1.1.1** to **10.1.1.12** and the global range as **192.168.1.1** to **192.168.1.12**:

(config)**#ip nat pool POOL1 static**
(config-natpool)**#local 10.1.1.1 10.1.1.12 global 192.168.1.1 192.168.1.12**

The following example creates two static NAT pools named **POOL1** and **POOL2**. This example defines the local range from **10.1.1.1** to **10.1.1.254** and the global range as **192.168.1.1** to **192.168.1.254** while excluding the address **10.1.1.10**:

(config)**#ip nat pool POOL1 static**
(config-natpool)**#local 10.1.1.1 10.1.1.9 global 192.168.1.1 192.168.1.9**
(config)**#ip nat pool POOL2 static**
(config-natpool)**#local 10.1.1.11 10.1.1.254 global 192.168.1.11 192.168.1.254**

logging console

Use the **logging console** command to enable AOS to log events to all consoles. Use the **no** form of this command to disable console event logging.

Syntax Description

No subcommands.

Default Values

By default, logging console is disabled.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example enables AOS to log events to all consoles:

(config)**#logging console**

logging email address-list <*email address*> ; <*email address*>

Use the **logging email address-list** command to specify one or more email addresses that will receive event notification. The criteria for event matching is configured using the command *logging email priority-level on page 1589*. Use the **no** form of this command to remove a listed address.

Syntax Description

<email address>	Specifies the complete email address to use when sending logged messages. (This field allows up to 256 characters.) Enter as many email addresses as desired, placing a semi-colon (;) between addresses.

Default Values

By default, there are no configured logging email addresses.

Command History

Release 1.1	Command was introduced.

Functional Notes

In order for the unit to send logging emails, the following features must be configured on the unit using the associated commands:

- The primary and secondary Domain Name System (DNS) server IP address must be configured using the command *name-server on page 1622*.
- Domain name lookup for DNS entries must be enabled using the command *domain-lookup on page 1261*.
- Event history logging must be enabled using the command *event-history on on page 1299*.
- Email logging must be enabled using the command *logging email on on page 1588*.
- The IPv4 address or host name of the SMTP mail server used for sending logging emails must be configured using the command *logging email receiver-ip <ipv4 address | hostname> on page 1591*.
- The sender (From address) of the logging email must be configured using the command *logging email sender on page 1594*.
- The source interface for communicating with the SMTP server must be specified using the command *logging email source-interface <interface> on page 1596*.

Usage Examples

The following example specifies three email addresses to use when sending logged messages:

(config)#**logging email address-list**
admin@adtranemail.com;ntwk@adtranemail.com;support@adtranemail.com

logging email error-report address-list *<email address>* ; *<email address>*

Use the **logging email error-report address-list** command to specify one or more email addresses to receive exception reports and Hypertext Transfer Protocol (HTTP) error reports for use in troubleshooting. Use the **no** form of this command to remove a listed address.

Syntax Description

<email address>	Specifies the email address(es) to use when sending exception and HTTP error reports. This field allows up to 256 characters. Enter as many email addresses as desired, placing a semi-colon (;) between each address.

Default Values

By default, there are no configured logging email addresses.

Command History

Release R11.1	Command was introduced
Release R10.8.0	Command changed from **logging email exception-report address-list** to **logging email error-report address-list**.

Functional Notes

When AOS experiences an exception, it will generate a file with detailed information that Adtran's Technical Support can use to diagnose the problem. This command allows the unit to email the exception report to a list of addresses upon rebooting after the exception. In order for the unit to send logging emails, the following features must be configured on the unit using the associated commands:

- The primary and secondary Domain Name System (DNS) server IP address must be configured using the command *name-server on page 1622*.
- Domain name lookup for DNS entries must be enabled using the command *domain-lookup on page 1261*.
- Event history logging must be enabled using the command *event-history on on page 1299*.
- Email logging must be enabled using the command *logging email on on page 1588*.
- The IPv4 address or host name of the SMTP mail server used for sending logging emails must be configured using the command *logging email receiver-ip <ipv4 address | hostname> on page 1591*.
- The sender (From address) of the logging email must be configured using the command *logging email sender on page 1594*.
- The source interface for communicating with the SMTP server must be specified using the command *logging email source-interface <interface> on page 1596*.

Usage Examples

The following example will enable exception report forwarding to **john.doe@company.com** using the **1.1.1.1** SMTP email server:

(config)#**logging email error-report address-list john.doe@company.com**

logging email ip urlfilter top-websites

Use the **logging email ip urlfilter top-websites** command to specify the parameters for receiving top websites reports via email. Use the **no** form of this command to disable top websites reporting email notification. Variations of this command include:

logging email ip urlfilter top-websites address-list *<email addresses>*
logging email ip urlfilter top-websites send-time *<HH:MM:SS>*

Syntax Description

address-list	Specifies the configuration of a list of email addresses to receive top websites reports.
send-time	Specifies the configuration of when email reports for top websites will be sent.
<email addresses>	Specifies the complete email address to use when sending top websites reports. (This field allows up to 256 characters.) Enter as many email addresses as desired, placing a semi-colon (;) between addresses.
<HH:MM:SS>	Specifies the hours, minutes, and seconds in a 24-hour format for sending top websites reports by email.

Default Values

By default, there are no configured logging email addresses or times for top websites reporting.

Once an address list is specified and top websites email reports are enabled, the default send-time for the reports is 12:00 a.m.

Command History

Release 16.1	Command was introduced.

Functional Notes

In order for the unit to send logging emails, the following features must be configured on the unit using the associated commands:

- The primary and secondary Domain Name System (DNS) server IP address must be configured using the command *name-server on page 1622*.
- Domain name lookup for DNS entries must be enabled using the command *domain-lookup on page 1261*.
- Event history logging must be enabled using the command *event-history on on page 1299*.
- Email logging must be enabled using the command *logging email on on page 1588*.
- The IPv4 address or host name of the SMTP mail server used for sending logging emails must be configured using the command *logging email receiver-ip <ipv4 address | hostname> on page 1591*.
- The sender (From address) of the logging email must be configured using the command *logging email sender on page 1594*.

- The source interface for communicating with the SMTP server must be specified using the command *logging email source-interface <interface> on page 1596*.

Usage Examples

The following example configures top websites reports to be emailed to **sys.admin@adtran.com** at 5:30 a.m.:

(config)**#logging email ip urlfilter top-websites address-list sys.admin@adtran.com**
(config)**#logging email ip urlfilter top-websites send-time 05:30:00**

logging email max-queue-depth

Use the **logging email max-queue-depth** to specify the maximum number of queued email messages awaiting delivery via Simple Mail Transfer Protocol (SMTP). Messages generated when the queue is full will be discarded without notification (except for the exception report email, which is always permitted in the queue). Variations of this command include:

logging email max-queue-depth
logging email max-queue-depth <*value*>

Syntax Description

<value>	Optional. Specifies the maximum number of email messages allowed in the queue.

Default Values

By default, 100 messages are allowed in the queue.

Command History

Release A5.01	Command was introduced.

Functional Notes

If messages are being generated faster than the SMTP client (or connected server) can process the messages, the queue will become filled and subsequent messages will be discarded without notification. In this case, the events causing the large number of messages to be generated should be investigated and addressed, the severity threshold for email logging should be adjusted using the command *logging email priority-level on page 1589*, or the queue size should be adjusted using this command, depending on available memory resources.

In order for the unit to send logging emails, the following features must be configured on the unit using the associated commands:

- The primary and secondary Domain Name System (DNS) server IP address must be configured using the command *name-server on page 1622*.
- Domain name lookup for DNS entries must be enabled using the command *domain-lookup on page 1261*.
- Event history logging must be enabled using the command *event-history on on page 1299*.
- Email logging must be enabled using the command *logging email on on page 1588*.
- The IPv4 address or host name of the SMTP mail server used for sending logging emails must be configured using the command *logging email receiver-ip <ipv4 address | hostname> on page 1591*.
- The sender (From address) of the logging email must be configured using the command *logging email sender on page 1594*.
- The source interface for communicating with the SMTP server must be specified using the command *logging email source-interface <interface> on page 1596*.

Usage Examples

The following example specifies that 200 email messages are allowed in the queue:

(config)**#logging email max-queue-depth 200**

logging email on

Use the **logging email on** command to enable the AOS email event notification feature. Use the command *logging email address-list <email address> ; <email address> on page 1582* to specify email address(es) that will receive notification when an event is received. Refer to *logging email priority-level on page 1589* for defining matching the criteria. Use the **no** form of this command to disable the email notification feature.

Syntax Description

No subcommands.

Default Values

By default, email event notification is disabled.

Command History

Release 1.1	Command was introduced.

Functional Notes

The domain name is appended to the sender name when sending event notifications. Refer to the command *domain-name <domain name> on page 1263* for related information.

In order for the unit to send logging emails, the following features must be configured on the unit using the associated commands:

- The primary and secondary Domain Name System (DNS) server IP address must be configured using the command *name-server on page 1622*.
- Domain name lookup for DNS entries must be enabled using the command *domain-lookup on page 1261*.
- Event history logging must be enabled using the command *event-history on on page 1299*.
- Email logging must be enabled using the command *logging email on*.
- The IPv4 address or host name of the SMTP mail server used for sending logging emails must be configured using the command *logging email receiver-ip <ipv4 address | hostname> on page 1591*.
- The sender (From address) of the logging email must be configured using the command *logging email sender on page 1594*.
- The source interface for communicating with the SMTP server must be specified using the command *logging email source-interface <interface> on page 1596*.

Usage Examples

The following example enables the AOS email event notification feature:

(config)**#logging email on**

logging email priority-level

Use the **logging email priority-level** command to set the threshold for events sent to the addresses specified using the command *logging email address-list <email address> ; <email address> on page 1582*. All events with the specified priority or higher will be sent to all addresses in the list. The command *logging email on on page 1588* must be enabled. Use the **no** form of this command to return to the default priority. Variations of this command include:

logging email priority-level error
logging email priority-level fatal
logging email priority-level info
logging email priority-level notice
logging email priority-level warning

Syntax Description

Sets the minimum priority threshold for sending messages to email addresses specified using the **logging email address-list** command. The following priorities are available (ranking from lowest to highest):

error	Logs events with **error** and **fatal** priorities.
fatal	Logs only events with a **fatal** priority.
info	Logs all events.
notice	Logs events with **notice**, **warning**, **error**, and **fatal** priorities.
warning	Logs events with **warning**, **error**, and **fatal** priorities.

Default Values

By default, the **logging email priority-level** is set to **warning**.

Command History

Release 1.1	Command was introduced.

Functional Notes

In order for the unit to send logging emails, the following features must be configured on the unit using the associated commands:

- The primary and secondary Domain Name System (DNS) server IP address must be configured using the command *name-server on page 1622*.
- Domain name lookup for DNS entries must be enabled using the command *domain-lookup on page 1261*.
- Event history logging must be enabled using the command *event-history on on page 1299*.
- Email logging must be enabled using the command *logging email on on page 1588*.
- The IPv4 address or host name of the SMTP mail server used for sending logging emails must be configured using the command *logging email receiver-ip <ipv4 address | hostname> on page 1591*.
- The sender (From address) of the logging email must be configured using the command *logging email sender on page 1594*.

- The source interface for communicating with the SMTP server must be specified using the command *logging email source-interface <interface> on page 1596*.

Usage Examples

The following example sends all messages with **warning** level or greater to the email addresses listed using the **logging email address-list** command:

(config)**#logging email priority-level warning**

logging email receiver-ip *<ipv4 address | hostname>*

Use the **logging email receiver-ip** command to specify the IP address or host name of the email server to use when sending email event notification. Use the **no** form of this command to remove a configured address. Variations of this command include:

logging email receiver-ip *<ipv4 address | hostname>*
logging email receiver-ip *<ipv4 address | hostname>* **allow-tls1.0**
logging email receiver-ip *<ipv4 address | hostname>* **allow-tls1.0 allow-tls1.1**
logging email receiver-ip *<ipv4 address | hostname>* **allow-tls1.0 allow-tls1.1 allow-sslv3**
logging email receiver-ip *<ipv4 address | hostname>* **allow-tls1.0 allow-sslv3**
logging email receiver-ip *<ipv4 address | hostname>* **allow-tls1.1**
logging email receiver-ip *<ipv4 address | hostname>* **allow-tls1.1 allow-sslv3**
logging email receiver-ip *<ipv4 address | hostname>* **allow-sslv3**
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>*
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-tls1.0**
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-tls1.0 allow-tls1.1**
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-tls1.0 allow-tls1.1 allow-sslv3**
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-tls1.0 allow-sslv3**
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-tls1.1**
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-tls1.1 allow-sslv3**
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-sslv3**
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **auth-username** *<username>* **auth-password** *<password>*
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-tls1.0 auth-username** *<username>* **auth-password** *<password>*
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-tls1.0 allow-tls1.1 auth-username** *<username>* **auth-password** *<password>*
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-tls1.0 allow-tls1.1 allow-sslv3 auth-username** *<username>* **auth-password** *<password>*
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-tls1.0 allow-sslv3 auth-username** *<username>* **auth-password** *<password>*
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-tls1.1 auth-username** *<username>* **auth-password** *<password>*
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-tls1.1 allow-sslv3 auth-username** *<username>* **auth-password** *<password>*
logging email receiver-ip *<ipv4 address | hostname>* **port** *<number>* **allow-sslv3 auth-username** *<username>* **auth-password** *<password>*
logging email receiver-ip *<ipv4 address | hostname>* **auth-username** *<username>* **auth-password** *<password>*
logging email receiver-ip *<ipv4 address | hostname>* **allow-tls1.0 auth-username** *<username>* **auth-password** *<password>*
logging email receiver-ip *<ipv4 address | hostname>* **allow-tls1.0 allow-tls1.1 auth-username** *<username>* **auth-password** *<password>*
logging email receiver-ip *<ipv4 address | hostname>* **allow-tls1.0 allow-tls1.1 allow-sslv3 auth-username** *<username>* **auth-password** *<password>*

logging email receiver-ip <*ipv4 address* | *hostname*> **allow-tls1.0 allow-sslv3 auth-username** <*username*> **auth-password** <*password*>
logging email receiver-ip <*ipv4 address* | *hostname*> **allow-tls1.1 auth-username** <*username*> **auth-password** <*password*>
logging email receiver-ip <*ipv4 address* | *hostname*> **allow-tls1.1 allow-sslv3 auth-username** <*username*> **auth-password** <*password*>
logging email receiver-ip <*ipv4 address* | *hostname*> **allow-sslv3 auth-username** <*username*> **auth-password** <*password*>

Syntax Description

<*ipv4 address* **|** *hostname*>	Specifies the IPv4 address or host name of the email server to use when sending logged messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
allow-tls1.0	Optional. Allows the email server to use Transport Layer Security protocol version 1.0. If **allow-tls1.0** is enabled, Secure Socket Layer version 3 (SSLv3) can also optionally be enabled.
allow-tls1.1	Optional. Allows the email server to use TLS protocol version 1.1. If **allow-tls1.1** is enabled, SSLv3 can also optionally be enabled.
allow-sslv3	Optional. Allows the server to use SSLv3. If SSLv3 is enabled, TLS version 1.0 is automatically enabled.
auth-username <*username*>	Optional. Specifies the user name to use if your email server requires authentication.
auth-password <*password*>	Optional. Specifies the password to use if your email server requires authentication.
port <*number*>	Optional. Specifies the port number of the remote email server. Range is **1** to **65535**.

Default Values

By default, there are no configured email server addresses.

Command History

Release 1.1	Command was introduced.
Release 15.1	Command was expanded to include the **auth-username** and **auth-password** options.
Release 16.1	Command was expanded to include the port number specification option.
Release R12.3.0	Command was expanded to include the **allow-tls1.0** and **allow-sslv3** parameters.
Release R13.9.0	Command was expanded to include the **allow-tls1.1** parameter.

Functional Notes

In order for the unit to send logging emails, the following features must be configured on the unit using the associated commands:

- The primary and secondary Domain Name System (DNS) server IP address must be configured using the command *name-server on page 1622*.
- Domain name lookup for DNS entries must be enabled using the command *domain-lookup on page 1261*.
- Event history logging must be enabled using the command *event-history on on page 1299*.
- Email logging must be enabled using the command *logging email on on page 1588*.
- The IPv4 address or host name of the SMTP mail server used for sending logging emails must be configured using the command *logging email receiver-ip <ipv4 address | hostname> on page 1591*.
- The sender (From address) of the logging email must be configured using the command *logging email sender on page 1594*.
- The source interface for communicating with the SMTP server must be specified using the command *logging email source-interface <interface> on page 1596*.

Usage Examples

The following example specifies an email server (with IP address **172.5.67.99**) to use when sending logged messages:

(config)**#logging email receiver-ip 172.5.67.99**

logging email sender

Use the **logging email sender** command to specify the sender in an outgoing logging email message. This name will appear in the **From** field of the receiver's inbox. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.

Functional Notes

In order for the unit to send logging emails, the following features must be configured on the unit using the associated commands:

- The primary and secondary Domain Name System (DNS) server IP address must be configured using the command *name-server on page 1622*.
- Domain name lookup for DNS entries must be enabled using the command *domain-lookup on page 1261*.
- Event history logging must be enabled using the command *event-history on on page 1299*.
- Email logging must be enabled using the command *logging email on on page 1588*.
- The IPv4 address or host name of the SMTP mail server used for sending logging emails must be configured using the command *logging email receiver-ip <ipv4 address | hostname> on page 1591*.
- The sender (From address) of the logging email must be configured using the command *logging email sender*.
- The source interface for communicating with the SMTP server must be specified using the command *logging email source-interface <interface> on page 1596*.

Usage Examples

The following example sets a sender for outgoing messages:

(config)#**logging email sender myUnit@myNetwork.com**

logging email smdr address-list *<email address>* ; *<email address>*

Use the **logging email smdr address-list** command to specify one or more email addresses that will receive notification when the station messaging detail record (SMDR) log had reached 80 percent of its total capacity. Use the **no** form of this command to remove a listed address.

Syntax Description

<email address>	Specifies the complete email address to use when sending logged SMDR messages. (This field allows up to 256 characters.) Enter as many email addresses as desired, placing a semi-colon (;) between addresses.

Default Values

By default, there are no configured logging email addresses.

Command History

Release A5.01	Command was introduced.

Functional Notes

In order for the unit to send logging emails, the following features must be configured on the unit using the associated commands:

- The primary and secondary Domain Name System (DNS) server IP address must be configured using the command *name-server on page 1622*.
- Domain name lookup for DNS entries must be enabled using the command *domain-lookup on page 1261*.
- Event history logging must be enabled using the command *event-history on on page 1299*.
- Email logging must be enabled using the command *logging email on on page 1588*.
- The IPv4 address or host name of the SMTP mail server used for sending logging emails must be configured using the command *logging email receiver-ip <ipv4 address | hostname> on page 1591*.
- The sender (From address) of the logging email must be configured using the command *logging email sender on page 1594*.
- The source interface for communicating with the SMTP server must be specified using the command *logging email source-interface <interface> on page 1596*.

Usage Examples

The following example specifies three email addresses to use when sending logged SMDR messages:

(config)#**logging email smdr address-list**
admin@adtranemail.com;ntwk@adtranemail.com;support@adtranemail.com

logging email source-interface *<interface>*

Use the **logging email source-interface** command to use the specified interface as the source for email messages transmitted by the unit. Use the **no** form of this command if you do not wish to override the normal source IP address.

Syntax Description

<interface>	Specifies the interface to be used as the source for email messages. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **logging email source-interface ?** for a complete list of valid interfaces.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.
Release 14.1	Command was expanded to include the tunnel interface.
Release 17.1	Command was expanded to include the asynchronous transfer mode (ATM) interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.

Functional Notes

This command allows you to override the *sender* field in the IP packet. If you have multiple interfaces in your unit, changing the *sender* tells the receiver where to send replies. This functionality can also be used to allow packets to get through firewalls that would normally block the flow.

In order for the unit to send logging emails, the following features must be configured on the unit using the associated commands:

- The primary and secondary Domain Name System (DNS) server IP address must be configured using the command *name-server on page 1622*.
- Domain name lookup for DNS entries must be enabled using the command *domain-lookup on page 1261*.
- Event history logging must be enabled using the command *event-history on on page 1299*.
- Email logging must be enabled using the command *logging email on on page 1588*.
- The IPv4 address or host name of the SMTP mail server used for sending logging emails must be configured using the command *logging email receiver-ip <ipv4 address | hostname> on page 1591*.

- The sender (From address) of the logging email must be configured using the command *logging email sender on page 1594*.
- The source interface for communicating with the SMTP server must be specified using the command *logging email source-interface <interface>*.

Usage Examples

The following example configures the unit to use the **loopback 1** interface as the source IP for email messages:

(config)**#logging email source-interface loopback 1**

logging facility *<type>*

Use the **logging facility** command to specify a syslog facility type for the syslog server. Error messages meeting specified criteria are sent to the syslog server. For this service to be active, the command *logging forwarding on on page 1600* must be enabled. Use the **no** form of this command to return to the default setting.

Syntax Description

<type>	Specifies the syslog facility type. The following is a list of valid facility types:	
	auth	Authorization system
	cron	Cron facility
	daemon	System daemon
	kern	Kernel
	local0 - local7	Reserved for locally defined messages
	lpr	Line printer system
	mail	Mail system
	news	USENET news
	sys9 - sys14	System use
	syslog	System log
	user	User process
	uucp	UNIX-to-UNIX copy system

Default Values

The default value is **local7**.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example configures the syslog facility to the cron facility type:

(config)**#logging facility cron**

logging forwarding auxiliary-receiver-ip *<ipv4 address>*

Use the **logging forwarding auxiliary-receiver-ip** command to specify the IPv4 address of a secondary syslog server to use when logging events that match the criteria configured using the command *logging forwarding priority-level on page 1602*. This command can be applied to the default virtual private network (VPN) routing and forwarding (VRF) instance or a specific VRF instance. Use the **no** form of this command to remove an auxiliary receiver server address. Variations of this command include:

logging forwarding auxiliary-receiver-ip *<ip address>*
logging forwarding vrf *<name>* **auxiliary-receiver-ip** *<ip address>*

Syntax Description

<ipv4 address>	Specifies the IPv4 address of a secondary syslog server to use when logging messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
vrf *<name>*	Optional. Specifies a nondefault VRF instance on which the secondary syslog server is located. If no VRF instance is specified, the default unnamed VRF instance is assumed.

Default Values

By default, no secondary syslog servers are configured.

Command History

Release 17.7	Command was introduced.
Release A4.05	Command was introduced in AOS voice products.
Release R11.4.0	Command was expanded to include the **vrf** parameter.

Functional Notes

Configuring a secondary syslog server allows the redundant transmission of messages to two different servers. This server configuration is optional, and does not function as a failover address; therefore, the primary server should always be configured using the command *logging forwarding receiver-ip <ipv4 address> on page 1603*. Syslog transmits to this auxiliary address independently of normal server addresses.

Usage Examples

The following example specifies that messages are logged to both a primary syslog server (**172.5.67.99**) and an auxiliary syslog server (**172.5.69.100**):

(config)**#logging forwarding receiver-ip 172.5.67.99**
(config)**#logging forwarding auxiliary-receiver-ip 172.5.69.100**

logging forwarding on

Use the **logging forwarding on** command to enable the AOS syslog event feature. Use the command *logging forwarding priority-level on page 1602* to specify the event matching criteria used by AOS to determine whether a message should be forwarded to the syslog server. Use the **no** form of this command to disable the syslog event feature.

Syntax Description

No subcommands.

Default Values

By default, syslog event notification is disabled.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example enables the AOS syslog event feature:

(config)**#logging forwarding on**

logging forwarding debug <*line*>

Use the **logging forwarding debug** command to send debug messages for various protocols and features to the AOS syslog server. Use the **no** form of this command to disable debug messages in the syslog server.

Turning on a large amount of debug information can adversely affect the performance of your unit.

Syntax Description

<line>	Specifies the protocol or feature for which debug messages are forwarded to the syslog server.

Default Values

By default, debug messages are not sent to the syslog server.

Command History

Release R12.3.0	Command was introduced.

Functional Notes

To receive debug messages through syslog, you must first set the syslog priority to debug, using the command *logging forwarding priority-level on page 1602*.

Usage Examples

The following example specifies that Link Layer Discovery Protocol (LLDP) debug messages are sent to the AOS syslog server:

(config)**#logging forwarding debug lldp**

logging forwarding priority-level

Use the **logging forwarding priority-level** command to set the threshold for events sent to the configured syslog server specified using the command *logging forwarding receiver-ip <ipv4 address> on page 1603*. All events with the specified priority or higher will be sent to all configured syslog servers. Use the **no** form of this command to return to the default priority. Variations of this command include:

logging forwarding priority-level debug
logging forwarding priority-level error
logging forwarding priority-level fatal
logging forwarding priority-level info
logging forwarding priority-level notice
logging forwarding priority-level smdr
logging forwarding priority-level warning

Syntax Description

Sets the minimum priority threshold for sending messages to the syslog server specified using the **logging forwarding receiver-ip** command. The following priorities are available (ranking from lowest to highest):

debug	Logs subsystem debugging events.
error	Logs events with **error** and **fatal** priorities.
fatal	Logs only events with a **fatal** priority.
info	Logs all events.
notice	Logs events with **notice**, **warning**, **error**, and **fatal** priorities.
smdr	Logs events with **smdr** priorities.
warning	Logs events with **warning**, **error**, and **fatal** priorities.

Default Values

By default, the **logging forwarding priority-level** is set to **warning**.

Command History

Release 1.1	Command was introduced.
Release 12.1	Command was expanded to include the **smdr** parameter.
Release R10.1.0	Command was expanded to include the **debug** keyword.

Usage Examples

The following example sends all messages with **warning** level or greater to the syslog server listed using the **logging forwarding receiver-ip** command:

(config)**#logging forwarding priority-level warning**

logging forwarding receiver-ip *<ipv4 address>*

Use the **logging forwarding receiver-ip** command to specify the IPv4 address of the syslog server to use when logging events that match the criteria configured using the command *logging forwarding priority-level on page 1602*. Enter this command multiple times to develop a list of syslog servers to use. This command can be applied to the default virtual private network (VPN) routing and forwarding (VRF) instance or a specific VRF instance. Use the **no** form of this command to remove the entry. Variations of this command include:

logging forwarding receiver-ip *<ipv4 address>*
logging forwarding vrf *<name>* **receiver-ip** *<ipv4 address>*

Syntax Description

<ipv4 address>	Specifies the IPv4 address of the syslog server to use when logging messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
vrf *<name>*	Optional. Specifies a nondefault VRF instance on which the syslog server is located. If no VRF instance is specified, the default unnamed VRF instance is assumed.

Default Values

By default, there are no configured syslog server addresses.

Command History

Release 1.1	Command was introduced.
Release R11.4.0	Command was expanded to include the **vrf** parameter.

Usage Examples

The following example specifies a syslog server (with address **172.5.67.99**) to use when logging messages:

(config)#**logging forwarding receiver-ip 172.5.67.99**

logging forwarding source-interface <*interface*>

Use the **logging forwarding source-interface** command to configure the specified interface's for the syslog server to use when logging events. This command can be applied to the default virtual private network (VPN) routing and forwarding (VRF) instance or a specific VRF instance. Use the **no** form of this command to remove the source-interface. Variations of this command include:

logging forwarding source-interface <*interface*>
logging forwarding vrf <*name*> **source-interface** <*interface*>

Syntax Description

<*interface*>	Specifies the interface to be used as the source for event log traffic. Specify an interface in the format <*interface type [slot/port	slot/port.subinterface id	interface id	interface id.subinterface id	ap	ap/radio	ap/radio.vap]*>. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; and for an ATM subinterface, use **atm 1.1**. Type **logging forwarding source-interface?** for a complete list of valid interfaces.
vrf <*name*>	Optional. Specifies a nondefault VRF instance on which the syslog server is located. If no VRF instance is specified, the default unnamed VRF instance is assumed.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.
Release 14.1	Command was expanded to include the tunnel interface.
Release 17.1	Command was expanded to include the asynchronous transfer mode (ATM) interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R11.4.0	Command was expanded to include the **vrf** parameter.

Functional Notes

This command allows you to override the *sender* field in the IP packet. If you have multiple interfaces in your unit, changing the *sender* tells the receiver where to send replies. This functionality can also be used to allow packets through firewalls that would normally be blocked.

Usage Examples

Configures the unit to use the **loopback 1** interface as the source interface for event log traffic:

(config)**#logging forwarding source-interface loopback 1**

mac access-list standard <*name*>

Use the **mac access-list standard** command to create an empty medium access control (MAC) access control list (ACL) and enter the Standard MAC Access List command set. Use the **no** form of this command to delete a MAC ACL and all the entries contained in it. The **mac access-list standard** command is currently for use only with wireless access points (APs). The following lists the complete syntax for the **mac access-list standard** command:

(config)**#mac access-list standard** <*name*>
(config-std-mac-acl)#<*action*> <*source*>

Syntax Description

<*name*>	Identifies the configured MAC ACL using an alphanumeric descriptor. All MAC ACL descriptors are case sensitive.
<*action*>	**permit** Permits entry to the access point for specified wireless station MACs.
<*source*>	Specifies the source used for packet matching. Sources are expressed by using **host** <*mac address*> to specify a single host address. MAC addresses should be expressed in the following format: xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).

Default Values

By default, all AOS security features are disabled and there are no configured MAC ACLs.

Command History

Release 15.1	Command was introduced.

Functional Notes

MAC ACLs are used as packet selectors by the wireless features; by themselves, the MAC ACLs do nothing. A MAC ACL entry contains two parts: an action (**permit**) and a MAC address. A **permit** ACL is used to match packets (meeting the specified pattern) to enter the AP. AOS provides only standard MAC ACLs. Standard ACLs match based on the source of the packet.

Usage Examples

The following example creates a MAC ACL named **Trusted** to permit all packets entry to the AP with MAC address **00:A0:C8:00:00:01**.

(config)**#mac access-list standard Trusted**
(config-std-mac-acl)**#permit 00:A0:C8:00:00:01**

For more information about configuring MAC ACLs, refer to the *MAC ACL* quick configuration guide available online at https://supportcommunity.adtran.com.

mac address-table aging-time <*value*>

Use the **mac address-table aging-time** command to set the length of time dynamic medium access control (MAC) addresses remain in the switch or bridge forwarding table. Use the **no** form of this command to reset this length to the default setting.

Syntax Description

<*value*>	Sets an aging time in seconds. Range is **10** to **1000000** seconds. Set to 0 to disable the timeout.

Default Values

By default, the aging time is **300** seconds.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example sets the aging time to **10** minutes:

(config)**#mac address-table aging-time 600**

mac address-table static *<mac address>*

Use the **mac address-table static** command to insert a static medium access control (MAC) address entry into the MAC address table. Use the **no** form of this command to remove an entry from the table. Variations of this command include:

mac address-table static *<mac address>* **bridge** *<bridge id>* **interface** *<interface>*
mac address-table static *<mac address>* **vlan** *<vlan id>* **interface** *<interface>*

Syntax Description

<mac address>	Specifies a valid 48-bit MAC address. MAC addresses should be expressed in the following format xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).
bridge *<bridge id>*	Specifies a bridge interface ID. Valid range is 1 to 255.
vlan *<vlan id>*	Specifies a virtual local area network (VLAN) interface ID. Valid range is **1** to **4094**.
interface *<interface>*	Specifies an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **mac address-table static bridge interface ?** or **mac address-table static** *<mac address>* **vlan** *<vlan id>* **interface ?** for a complete list of valid interfaces.

Default Values

By default, there are no static entries configured.

Command History

Release 5.1	Command was introduced
Release 10.1	Command was expanded to include the bridge interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release R11.7.0	Command was expanded to include the 10 gigabit switchport interface.

Usage Examples

The following example adds a static MAC address to Point-to-Point Protocol (PPP) 1 on bridge 4:

(config)**#mac address-table static 00:A0:C8:00:00:01 bridge 4 interface ppp 1**

The following example adds a static MAC address to Ethernet 0/1 on VLAN 4:

(config)**#mac address-table static 00:A0:C8:00:00:01 00:12:79:00:00:01 vlan 4 interface ethernet 0/1**

mac hw-access-list extended <*name*>

Use the **mac hw-access-list extended** command to create and name a medium access control (MAC) hardware access control list (ACL). This command also enters the ACL's configuration mode. Using the **no** form of this command deletes the MAC hardware ACL.

> NOTE *For a complete list of all MAC hardware ACL configuration commands, refer to the* *Hardware ACL and Access Map Command Set on page 4235*.

Syntax Description

<*name*>	Specifies the name of the MAC hardware ACL.

Default Values

By default, all AOS security features are disabled, and there are no configured hardware ACLs.

Command History

Release 17.6	Command was introduced.

Functional Notes

This command only creates an empty hardware ACL, it does not configure it. For additional MAC hardware ACL configuration commands and configuration parameters, refer to the *Hardware ACL and Access Map Command Set on page 4235* or the *Hardware ACLs in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example creates a MAC hardware ACL **Trusted** and enters the MAC hardware ACL configuration mode:

```
(config)#mac hw-access-list extended Trusted
        Configuring New MAC Hardware Extended ACL "Trusted"
(config-ext-mac-hw-nacl)#
```

Technology Review

Hardware ACLs are used as frame selectors by the hardware access maps; by themselves they do nothing. Hardware ACLs are composed of an ordered list of entries with an implicit **deny any** at the end of each list. A hardware ACL with no entries includes an implicit **permit any**. An ACL entry contains two parts: an action (**permit** or **deny**) and a frame pattern. A **permit** ACL matches frames (meeting the specified pattern) and allows them to enter the router system. A **deny** ACL advances AOS to the next access list entry.

ACL criteria are compared to the incoming frame in the order in which they were entered or from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Changing hardware ACL or hardware access map configuration or application causes new information to be reinstalled on the hardware. It is possible to run out of hardware resources depending on how many resources are needed to apply the desired change. If there are not enough hardware resources to install the new criteria in the hardware, an error message is displayed. You can view the amount of hardware resources available using the command *show hw-filter-resource on page 672*.

mail-client *<agent name>*

Use the **mail-client** command to create a general-purpose mail agent and enter the Mail Agent Configuration mode. Use the **no** form of this command to delete the mail agent. Refer to the *Mail Agent Command Set on page 4423* for more information.

Syntax Description

<agent name>	Specifies the name of the created mail agent.

Default Values

By default, no mail agents exist.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example creates a mail agent called **myagent** and enters the Mail Agent Configuration mode:

```
(config)#mail-client myagent
(config-mail-client-myagent)#
```

mef evc <*name*>

Use the **mef evc** command to create an Ethernet virtual connection (EVC) and enter the EVC configuration mode. Using the **no** form of this command removes the EVC from the AOS unit's configuration.

Syntax Description

<*name*>	Specifies the name for the EVC.

Default Values

By default, no EVCs are configured.

Command History

Release A4.01	Command was introduced.

Functional Notes

The EVC connects two endpoints (for example, an Ethernet in the first mile (EFM) group and the Metro Ethernet Forum (MEF) Ethernet interface) and passes Ethernet service frames though the endpoints. The EVCs prevent data transfer between subscriber sites that are not part of the same EVC, thus providing data privacy and security similar to a Frame Relay or an asynchronous transfer mode (ATM) permanent virtual circuit (PVC). EVCs are configured to be part of a bonding group (EFM group).

More information about the configuration of EVCs can be found in the *MEF EVC Command Set on page 3674* or in the *Configuring EFM NIM2s and the MEF Ethernet Interface in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example creates an EVC named **DATA** and enters the EVC configuration mode:

```
(config)#mef evc DATA
(config-evc-DATA)#
```

mef evc-map *<name>*

Use the **mef evc-map** command to create a Metro Ethernet Forum (MEF) Ethernet virtual connection (EVC) map and enter the EVC Map Configuration mode. The EVC map is used to match traffic to a specific EVC using matching criteria similar to that of quality of service (QoS) matching. Using the **no** form of this command removes the EVC map from the AOS unit's configuration.

Syntax Description

<name>	Specifies the name of the EVC map.

Default Values

By default, no EVC maps are configured.

Command History

Release A4.01	Command was introduced.

Functional Notes

Once an EVC map is created, it must be configured and applied to both an EVC and a user network interface (UNI). For more information about the configuration of EVC maps, refer to *MEF EVC Map Command Set on page 3678* or the *Configuring EFM NIM2s and the MEF Ethernet Interface in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example creates the EVC map **Map1** and enters the EVC Map Configuration mode:

```
(config)#mef evc-map Map1
(config-evc-map-Map1)#
```

mef policer *<name>*

Use the **mef policer** command to create a Metro Ethernet Forum (MEF) policer policy and enter the MEF Policer Policy Configuration mode. The EVC policer policy limits the amount of traffic outbound from the AOS unit to the Metro Ethernet network (MEN). Using the **no** form of this command removes the MEF policer policy from the AOS unit's configuration.

Syntax Description

<name>	Specifies the name of the MEF policer policy.

Default Values

By default, no MEF policer policies are configured.

Command History

Release A4.01	Command was introduced.

Functional Notes

The EVC policer policy can limit traffic on Ethernet virtual connections (EVCs), user network interfaces (UNIs), or EVC maps based on traffic committed burst size (CBS), committed information rate (CIR), excess burst size (EBS), and excess information rate (EIR). These thresholds are used to determine when the EVC bandwidth usage is too great, and the traffic is either queued or dropped based on the configured thresholds. For more information about the configuration and use of EVC policer policies, refer to *MEF Policer Policy Command Set on page 3684* or the *Configuring EFM NIM2s and the MEF Ethernet Interface in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example creates the MEF policer policy **Policy1** and enters the MEF Policer Policy Configuration mode:

```
(config)#mef policer Policy1
(config-policer-Policy1)#
```

mef qos

Use the **mef qos** command to configure the Metro Ethernet Forum (MEF) Ethernet quality of service (QoS) parameters. These parameters specify the hardware queues used by the Ethernet virtual connection (EVC) when traffic matching an EVC map is discovered, as well as the Metro Ethernet network (MEN) priority given to untagged traffic. Using the **no** form of this command returns the MEF QoS settings to the default values. Variations of this command include:

mef qos cos-map <*number*> <*value*>
mef qos untagged <*value*>

Syntax Description

cos-map <*number*> <*value*>	Specifies default mapping of queues to class of service (CoS) markings for EVC traffic. The <*number*> parameter is the queue to which a CoS value is mapped. Valid range is **1** to **8**. The <*value*> parameter is the CoS value assigned to the queue. Valid value range is **0** to **7**.
untagged <*value*>	Specifies the MEN priority for untagged traffic on the EVC. Valid range is **0** to **7**.

Default Values

By default, a MEN priority of **0** is assigned to untagged traffic.

The default MEF QoS queue assignments are outlined below.

Queue and Assigned CoS Values	One CoS Value Is Assigned to Each Queue by Default
(config)**#mef qos cos-map 1 1**	CoS value 1 is assigned to queue 1 by default.
(config)**#mef qos cos-map 2 0**	CoS value 0 is assigned to queue 2 by default.
(config)**#mef qos cos-map 3 2**	CoS value 2 is assigned to queue 3 by default.
(config)**#mef qos cos-map 4 3**	CoS value 3 is assigned to queue 4 by default.
(config)**#mef qos cos-map 5 4**	CoS value 4 is assigned to queue 5 by default.
(config)**#mef qos cos-map 6 5**	CoS value 5 is assigned to queue 6 by default.
(config)**#mef qos cos-map 7 6**	CoS value 6 is assigned to queue 7 by default.
(config)**#mef qos cos-map 8 7**	CoS value 7 is assigned to queue 8 by default.

Command History

Release A4.01	Command was introduced.

Functional Notes

The MEF QoS CoS map values are used by the EVC map when the MEN queue setting is specified as **inherit**. For more information about the relationships between and configuration of MEF components, refer to the *Configuring EFM NIM2s and the MEF Ethernet Interface in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that traffic with CoS values **3** and **4** are mapped to queue **1**:

(config)**#mef qos cos-map 1 3 4**

The following example specifies the MEN priority for untagged traffic is **5**:

(config)**#mef qos untagged 5**

modem countrycode <*value*>

Use the **modem countrycode** command to specify the modem configuration for the applicable country.

Syntax Description

<*value*>	Specifies the modem configuration for the applicable country. Refer to *Functional Notes* for countrycode values.

Default Values

By default, **modem countrycode** is set to **USA/Canada**.

Command History

Release 10.1	Command was introduced.

Functional Notes

The following country codes are available for modem configuration:

Algeria	- Algeria Modem configuration
Argentina	- Argentina Modem configuration
Australia	- Australia Modem configuration
Austria	- Austria Modem configuration
Bahrain	- Bahrain Modem configuration
Belgium	- Belgium Modem configuration
Bolivia	- Bolivia Modem configuration
Brazil	- Brazil Modem configuration
Chile	- Chile Modem configuration
China	- China Modem configuration
Colombia	- Colombia Modem configuration
Costa_Rica	- Costa_Rica Modem configuration
Cyprus	- Cyprus Modem configuration
Czechoslovakia	- Czechoslovakia Modem configuration
Denmark	- Denmark Modem configuration
Ecuador	- Ecuador Modem configuration
Egypt	- Egypt Modem configuration
Finland	- Finland Modem configuration
France	- France Modem configuration
Germany	- Germany Modem configuration
Greece	- Greece Modem configuration
Guatemala	- Guatemala Modem configuration
Hong_Kong	- Hong_Kong Modem configuration
Hungary	- Hungary Modem configuration
India	- India Modem configuration
Indonesia	- Indonesia Modem configuration
Ireland	- Ireland Modem configuration
Israel	- Israel Modem configuration

Italy	- Italy Modem configuration
Japan	- Japan Modem configuration
Jordan	- Jordan Modem configuration
Korea	- Korea Modem configuration
Kuwait	- Kuwait Modem configuration
Lebanon	- Lebanon Modem configuration
Malaysia	- Malaysia Modem configuration
Mexico	- Mexico Modem configuration
Morocco	- Morocco Modem configuration
Netherlands	- Netherlands Modem configuration
New_Zealand	- New_Zealand Modem configuration
Norway	- Norway Modem configuration
Oman	- Oman Modem configuration
Panama	- Panama Modem configuration
Peru	- Peru Modem configuration
Philippines	- Philippines Modem configuration
Poland	- Poland Modem configuration
Portugal	- Portugal Modem configuration
Puerto_Rico	- Puerto_Rico Modem configuration
Qatar	- Qatar Modem configuration
Russia	- Russia Modem configuration
Saudi_Arabia	- Saudi_Arabia Modem configuration
Singapore	- Singapore Modem configuration
Slovakia	- Slovakia Modem configuration
Slovenia	- Slovenia Modem configuration
South_Africa	- South_Africa Modem configuration
Spain	- Spain Modem configuration
Sweden	- Sweden Modem configuration
Switzerland	- Switzerland Modem configuration
Syria	- Syria Modem configuration
Taiwan	- Taiwan Modem configuration
Thailand	- Thailand Modem configuration
Trinidad	- Trinidad Modem configuration
Tunisia	- Tunisia Modem configuration
Turkey	- Turkey Modem configuration
UAE	- UAE Modem configuration
UK	- UK Modem configuration
USA/Canada	- USA/Canada Modem configuration
Uruguay	- Uruguay Modem configuration
Venezuela	- Venezuela Modem configuration
Yemen	- Yemen Modem configuration

Usage Examples

The following example specifies to use the **USA/Canada** modem configuration.

(config)**#modem countrycode USA/Canada**

monitor session <*number*>

Use the **monitor session** command to configure a port mirroring session. Use the **no** form of this command to remove a port mirroring session or to remove a source or destination interface. Variations of this command include:

monitor session <*number*> **destination interface** <*interface*> **no-isolate**
monitor session <*number*> **destination interface** <*interface*> **no-tag**
monitor session <*number*> **destination interface** <*interface*> **no-isolate no-tag**
monitor session <*number*> **destination interface** <*interface*> **no-tag no-isolate**
monitor session <*number*> **source interface** <*interface*>
monitor session <*number*> **source interface** <*interface*> **both**
monitor session <*number*> **source interface** <*interface*> **rx**
monitor session <*number*> **source interface** <*interface*> **tx**

Syntax Description

<*number*>	Selects the monitor session number (only one is allowed).
destination	Selects the destination interface.
source	Selects the source interface(s). A range of interfaces is allowed.
interface <*interface*>	Specifies an interface in the format <*interface type [slot/port	slot/port.subinterface id	interface id	interface id.subinterface id	ap	ap/radio	ap/radio.vap]*>. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **monitor session** <*number*> **[destination	source] interface ?** for a complete list of valid interfaces.
both	Optional. Monitors both transmitted and received traffic.
rx	Optional. Monitors received traffic only.
tx	Optional. Monitors transmitted traffic only.
no-tag	Removes the virtual local area network (VLAN) tag that is normally appended to mirrored traffic.
no-isolate	Allows native traffic to continue to pass on the port set as the mirroring session destination.

Default Values

By default, traffic is monitored in both directions. Also by default, the destination port is isolated from passing native traffic.

Command History

Release 5.1	Command was introduced.
Release 13.1	Command was expanded to include the **no-isolate** parameter.
Release R11.7.0	Command was expanded to include the 10 gigabit switchport interface.

Usage Examples

The following example sets Ethernet 0/1 as the destination interface and adds Ethernet 0/2, Ethernet 0/3, and Ethernet 0/5 as source ports:

(config)**#monitor session 1 destination interface eth 0/1**
(config)**#monitor session 1 source interface eth 0/2-3, eth 0/5**

The following example sets gigabit switchport 0/1 as the destination interface and removes the VLAN tag:

(config)**#monitor session 1 destination interface gigabit-switchport 0/1 no-tag**

The following example sets switchport 0/1 as the source interface and monitors both transmitted and received traffic:

(config)**#monitor session 1 source interface switchport 0/1 both**

The following example sets gigabit switchport 0/1, and switchport 0/2 through switchport 0/12 as source interfaces and monitors only received traffic:

(config)**#monitor session 1 source interface gigabit 0/1, eth 0/2-12 rx**

name-server

Use the **name-server** command to designate an address for one or more name servers to use for name-to-address domain naming server (DNS) resolution. This command can be applied to the default virtual private network (VPN) routing and forwarding (VRF) instance or a specific VRF instance. Use the **no** form of this command to remove an address. Variations of this command include:

name-server <*ipv4 address*>
name-server <*ipv6 address*>
name-server vrf <*name*> <*ipv4 address*>
name-server vrf <*name*> <*ipv6 address*>

Syntax Description

<*ipv4 address*>	Specifies an Internet Protocol version 4 (IPv4) name server address. IPv4 addresses should be specified in dotted decimal notation (for example, **10.10.10.1**).
<*ipv6 address*>	Specifies an Internet Protocol version 6 (IPv6) name server address. IPv6 address should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
vrf <*name*>	Optional. Specifies a nondefault VRF instance on which to add a name server address. If no VRF instance is specified, the name server is added on the default unnamed VRF instance.

Default Values

By default, no name servers are specified.

Command History

Release 3.1	Command was introduced.
Release 16.1	Command was expanded to include the **vrf** parameter.
Release 18.3	Command was expanded to include IPv6 support for Adtran internetworking products.
Release R10.1.0	Command was expanded to include IPv6 support for Adtran voice products.

Functional Notes

The addition of the server address occurs at the end of the IPv4 or IPv6 addresses in the server list. There is no limit to the number of name server addresses that can be entered. Addresses added using this command are combined with those learned dynamically, and if an IPv6 DNS name server is added, its address is combined with those configured using IPv4 DNS.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the above mentioned commands without specifying a VRF will only affect the default unnamed VRF.

Usage Examples

The following example specifies IPv4 host **172.34.1.111** as the primary name server and IPv4 host **172.34.1.2** as the secondary server:

(config)**#name-server 172.34.1.111 172.34.1.2**

network-forensics ip dhcp

Use the **network-forensics ip dhcp** command to enable passive monitoring of Dynamic Host Configuration Protocol (DHCP) message exchanges between the server and the client. Using the **no** form of this command disables network forensics.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release 17.8	Command was introduced.

Functional Notes

Network forensics is an AOS feature that collects client information through DHCP messages sent between clients connected to the network and the network server.

Once network forensics is enabled, the AOS unit begins collecting DHCP information. The collected data can be viewed either by using the command *show name-server on page 878* or *debug network-forensics ip dhcp on page 422* to view the information in realtime. For more information about network forensics, refer to the *Network Forensics in AOS* troubleshooting guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables the network forensics feature:

(config)**#network-forensics ip dhcp**

network-sync

Use the **network-sync** command to enable network synchronization (Network Sync) configuration and enter the Network Sync Configuration mode. Use the **no** form of this command to remove Network Sync configuration from the unit.

Syntax Description

No subcommands.

Default Values

By default, Network Sync is disabled.

Command History

Release R10.11.0	Command was introduced.

Usage Examples

The following example enables Network Sync and enters the Network Sync Configuration mode:

```
(config)#network-sync
(config-ntwk-sync)#
```

no activchassis

Use the **no activchassis** command to disable ActivChassis and return the AOS device to a standalone device.

Syntax Description

No subcommands.

Default Values

No default values necessary for this command.

Command History

Release AC1.0	Command was introduced.

Functional Notes

Devices that are currently ActivChassis members can be restarted in standalone mode. To restart a device in standalone mode, you must first disconnect the device from all other ActivChassis-enabled devices and reboot the unit. The device attempts (and fails) to detect an ActivChassis, and successfully boots as a standalone device. Once the device is disconnected from ActivChassis, and has been rebooted as a standalone device, enter this command from the device's local console. You must confirm that you want the device configuration and mode to be altered. By confirming the action, the local manifest is updated with indications that ActivChassis mode should be disabled at device boot. The startup configuration file is backed up and then deleted, causing the configuration to return to default at the next boot. The device is then rebooted and is in standalone mode.

This command is available from both the ActivChassis master and linecard devices' CLI. For more information about the difference between linecard and master devices, how to access the CLI for each, and additional configuration information, refer to the configuration guide *Configuring ActivChassis in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example disables ActivChassis and returns the device to standalone mode (after it has been disconnected from the ActivChassis):

(config)**#no activchassis**

ntp ip access-class <*ipv4 acl*> in

Use the **ntp ip access-class** command to apply an Internet Protocol version 4 (IPv4) access control list (ACL) to incoming connections on the IPv4 Network Time Protocol (NTP) server. Use the **no** form of this command to remove the ACL from the NTP server. Variations of this command include:

ntp ip access-class <*ipv4 acl*> **in**
ntp ip access-class <*ipv4 acl*> **in any-vrf**
ntp ip access-class <*ipv4 acl*> **in vrf** <*name*>

Syntax Description

<*ipv4 acl*>	Specifies the IPv4 ACL to apply to the IPv4 NTP server.
in	Specifies that the ACL is applied to incoming connections.
any-vrf	Optional. Specifies that incoming connections from any virtual routing and forwarding (VRF) instance are allowed.
vrf <*name*>	Optional. Specifies that incoming connections from the specified nondefault VRF instance are allowed. If no VRF is specified, incoming connections only from the default unnamed VRF instance are allowed.

Default Values

By default, no ACLs are applied to the NTP server.

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example applies the IPv4 ACL **MYIPV4ACL** to incoming connections on the default VRF instance to the IPv4 NTP server:

(config)**#ntp ip access-class MYIPV4ACL in**

ntp ipv6 access-class <*ipv6 acl*> in

Use the **ntp ipv6 access-class** command to apply an Internet Protocol version 6 (IPv6) access control list (ACL) to incoming connections on the IPv6 Network Time Protocol (NTP) server. Use the **no** form of this command to remove the ACL from the NTP server. Variations of this command include:

ntp ipv6 access-class <*ipv6 acl*> **in**
ntp ipv6 access-class <*ipv6 acl*> **in any-vrf**
ntp ipv6 access-class <*ipv6 acl*> **in vrf** <*name*>

Syntax Description

<*ipv6 acl*>	Specifies the IPv6 ACL to apply to the IPv6 NTP server.
in	Specifies that the ACL is applied to incoming connections.
any-vrf	Optional. Specifies that incoming connections from any virtual routing and forwarding (VRF) instance are allowed.
vrf <*name*>	Optional. Specifies that incoming connections from the specified nondefault VRF instance are allowed. If no VRF is specified, incoming connections only from the default unnamed VRF instance are allowed.

Default Values

By default, no ACLs are applied to the NTP server.

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example applies the IPv6 ACL **MYIPV6ACL** to incoming connections on the default VRF instance to the IPv6 NTP server:

(config)**#ntp ipv6 access-class MYIPV6ACL in**

ntp master

Use the **ntp master** command to globally set the system as an authoritative Network Time Protocol (NTP) server. Variations of this command include:

ntp master
ntp master <*value*>

Syntax Description

<*value*>	Optional. Specify the stratum number. The valid range is **1** to **15**. We recommend not setting the stratum higher than **2**.

Default Values

By default, the NTP server is not enabled.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example enables the master NTP server:

(config)**#ntp master**

ntp max-associations <*value*>

Use the **ntp max-associations** command to set the maximum number of simultaneous Network Time Protocol (NTP) associations allowed with other NTP clients or peers. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specify the maximum number of associations. The valid range is **1** to **4294967295**.

Default Values

By default, the maximum associations is **100**.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example specifies the maximum associations of **250**:

(config)**#ntp max-associations 250**

ntp peer <*hostname* | *ipv4 address*>

Use the **ntp peer** command to specify an Internet Protocol version 4 (IPv4) peer association with another Network Time Protocol (NTP) system and configure its parameters. Any combination of peer associations can be simultaneously configured. Specifying the virtual routing and forwarding (VRF) instance using the **vrf** <*name*> keyword applies the association to the named VRF instance. Omitting the **vrf** <*name*> keyword applies the association to the default unnamed VRF. Use the **no** form of this command to return to the default setting. Variations of this command include:

ntp peer <*hostname* | *ipv4 address*>
ntp peer <*hostname* | *ipv4 address*> **maxpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **minpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **normal-sync**
ntp peer <*hostname* | *ipv4 address*> **prefer**
ntp peer <*hostname* | *ipv4 address*> **source** <*interface*>
ntp peer <*hostname* | *ipv4 address*> **version**

ntp peer <*hostname* | *ipv4 address*> **efm-group** <*group id*> **maxpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **efm-group** <*group id*> **minpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **efm-group** <*group id*> **normal-sync**
ntp peer <*hostname* | *ipv4 address*> **efm-group** <*group id*> **prefer**
ntp peer <*hostname* | *ipv4 address*> **efm-group** <*group id*> **source** <*interface*>
ntp peer <*hostname* | *ipv4 address*> **efm-group** <*group id*> **source** <*interface*> **maxpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **efm-group** <*group id*> **version**
ntp peer <*hostname* | *ipv4 address*> **efm-group** <*group id*> **version maxpoll** <*value*>

ntp peer <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*>
ntp peer <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **maxpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **minpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **normal-sync**
ntp peer <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **prefer**
ntp peer <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **source** <*interface*>
ntp peer <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **source** <*interface*> **maxpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **version**
ntp peer <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **version maxpoll** <*value*>

ntp peer <*hostname* | *ipv4 address*> **system-control-evc**
ntp peer <*hostname* | *ipv4 address*> **system-control-evc maxpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **system-control-evc minpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **system-control-evc normal-sync**
ntp peer <*hostname* | *ipv4 address*> **system-control-evc prefer**
ntp peer <*hostname* | *ipv4 address*> **system-control-evc source** <*interface*>
ntp peer <*hostname* | *ipv4 address*> **system-control-evc source** <*interface*> **maxpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **system-control-evc version**
ntp peer <*hostname* | *ipv4 address*> **system-control-evc version maxpoll** <*value*>

ntp peer <*hostname* | *ipv4 address*> **system-management-evc**

ntp peer <*hostname* | *ipv4 address*> **system-management-evc maxpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **system-management-evc minpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **system-management-evc normal-sync**
ntp peer <*hostname* | *ipv4 address*> **system-management-evc prefer**
ntp peer <*hostname* | *ipv4 address*> **system-management-evc source** <*interface*>
ntp peer <*hostname* | *ipv4 address*> **system-management-evc source** <*interface*> **maxpoll** <*value*>
ntp peer <*hostname* | *ipv4 address*> **system-management-evc version**
ntp peer <*hostname* | *ipv4 address*> **system-management-evc version maxpoll** <*value*>

ntp peer vrf <*name*> <*hostname* | *ipv4 address*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **maxpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **minpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **normal-sync**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **prefer**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **source** <*interface*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **version**

ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*> **maxpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*> **minpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*> **normal-sync**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*> **prefer**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*> **source** <*interface*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*> **source** <*interface*> **maxpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*> **version**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*> **version maxpoll** <*value*>

ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **maxpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **minpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **normal-sync**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **prefer**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **source** <*interface*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **source** <*interface*> **maxpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **version**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **version maxpoll** <*value*>

ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-control-evc**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-control-evc maxpoll** <*value*>

ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-control-evc source** <*interface*>

maxpoll <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-control-evc version**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-control-evc version maxpoll** <*value*>

ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc maxpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc minpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc normal-sync**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc prefer**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc source** <*interface*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc source** <*interface*> **maxpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc version**
ntp peer vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc version maxpoll** <*value*>

Syntax Description

<*hostname* | *ipv4 address*>	Specify the host name or IPv4 address of the NTP server. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
efm-group <*group id*>	Specifies an Ethernet in the first mile (EFM) group ID. Range is **1** to **1024**.
maxpoll <*value*>	Optional. Specifies the maximum polling interval for NTP packets, in seconds as a power of two. The allowable range is **4** to **17**. For example, setting the **maxpoll** to 10 would indicate a maximum polling interval of **1024** seconds. Refer to the fuctional notes of this command for more information.
mef-ethernet <*slot/port*>	Specifies the Metro Ethernet Forum (MEF) Ethernet interface.
minpoll <*value*>	Optional. Specifies the minimum polling interval for NTP packets, in seconds as a power of two. The allowable range is **4** to **17**. For example, setting the **minpoll** to 6 would indicate a minimum polling interval of **64** seconds. Refer to the *Functional Notes* for more information.
normal-sync	Optional. Disables the rapid synchronization feature.
prefer	Optional. Specifies the preference of using the specified server above all other configured NTP servers.
source <*interface*>	Optional. Specifies the source interface (physical or virtual) to use for the peer. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id]>*. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; and for an ATM subinterface, use **atm 1.1**. Type **ntp peer** <*name*> **source ?** for a list of valid interfaces.
system-control-evc	Specifies the system control Ethernet virtual connection (EVC). This EVC exists by default and cannot be deleted.
system-management-evc	Specifies the system management EVC. This EVC exists by default and cannot be deleted.
version	Specifies the version number for outgoing NTP packets. Valid range is **2** to **4**.

vrf <*name*>	Specifies the name of the VRF to which to assign the association. If no VRF is specified, the association is applied to the default unnamed VRF.

Default Values

By default, the **ntp peer** is not set. Once enabled, the default version is **4**, the default **minpoll** interval is **6** (64 seconds) and the default **maxpoll** interval is **10** (1024 seconds).

Command History

Release 17.2	Command was introduced.
Release 17.6	Command was expanded to include **maxpoll** and **minpoll** parameters.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.1.0	Command was expanded to include the bridged virtual interface (BVI).
Release R10.5.0	Command was expanded to include the loopback interface.
Release R10.7.0	Command was expanded to include the **vrf** <*name*> parameter.
Release R10.10.0	Command was expanded to include the **system-control-evc** and **system-management-evc** parameters.
Release R10.11.0	Command was expanded to include the MEF Ethernet interface.
Release R11.2.0	Command was expanded to include Ethernet in the first mile (EFM) group parameter.
Release R13.7.0	Command was expanded to include the virtual local area network (VLAN) interface.

Functional Notes

The IPv4 **ntp peer** command can be executed with any combination of the following parameters:

maxpoll <*value*>
minpoll <*value*>
normal-sync
prefer
source <*interface*>
version

For example, the **normal-sync** and **source** <*interface*> parameters can be used in conjunction with one another. In this case, the command would look like this:

#ntp peer 10.10.10.1 normal-sync source ppp 1

These parameters can be combined in any order to obtain the desired configuration.

In order to determine the appropriate value to enter for **maxpoll** or **minpoll**, use the following formula: 2^n where n = <*value*>. For example, to set the minimum polling interval to 64 seconds, you would enter **6** as the **minpoll** value. This corresponds to 2^6 in the formula, or 2x2x2x2x2x2, which equals 64 seconds.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example defines **10.10.10.1** as the IPv4 NTP peer:

(config)**#ntp peer 10.10.10.1**

The following example creates an IPv4 peer association with **10.10.10.1** and sets the maximum polling interval of 64 seconds:

(config)**#ntp peer** 10.10.10.1 **maxpoll 6**

ntp peer <*hostname* | *ipv6 address*>

Use the **ntp peer** command to enable Network Time Protocol (NTP), and specify an Internet Protocol version 6 (IPv6) peer association with another NTP system and configure the association's parameters. Any combination of peer associations can be simultaneously configured. Specifying the virtual routing and forwarding (VRF) instance using the **vrf** <*name*> keyword applies the association to the named VRF instance. Omitting the **vrf** <*name*> keyword applies the association to the default unnamed VRF. Use the **no** form of this command to return to the default setting. Variations of this command include:

ntp peer <*hostname* | *ipv6 address*>
ntp peer <*hostname* | *ipv6 address*> **maxpoll** <*value*>
ntp peer <*hostname* | *ipv6 address*> **minpoll** <*value*>
ntp peer <*hostname* | *ipv6 address*> **normal-sync**
ntp peer <*hostname* | *ipv6 address*> **prefer**
ntp peer <*hostname* | *ipv6 address*> **source** <*interface*>
ntp peer <*hostname* | *ipv6 address*> **version**

ntp peer <*hostname* | *ipv6 address*> <*interface*>
ntp peer <*hostname* | *ipv6 address*> <*interface*> **maxpoll** <*value*>
ntp peer <*hostname* | *ipv6 address*> <*interface*> **minpoll** <*value*>
ntp peer <*hostname* | *ipv6 address*> <*interface*> **normal-sync**
ntp peer <*hostname* | *ipv6 address*> <*interface*> **prefer**
ntp peer <*hostname* | *ipv6 address*> <*interface*> **source** <*interface*>
ntp peer <*hostname* | *ipv6 address*> <*interface*> **version**

ntp peer <*hostname* | *ipv6 address*> **system-control-evc**
ntp peer <*hostname* | *ipv6 address*> **system-control-evc maxpoll** <*value*>
ntp peer <*hostname* | *ipv6 address*> **system-control-evc minpoll** <*value*>
ntp peer <*hostname* | *ipv6 address*> **system-control-evc normal-sync**
ntp peer <*hostname* | *ipv6 address*> **system-control-evc prefer**
ntp peer <*hostname* | *ipv6 address*> **system-control-evc source** <*interface*>
ntp peer <*hostname* | *ipv6 address*> **system-control-evc source** <*interface*> **maxpoll** <*value*>
ntp peer <*hostname* | *ipv6 address*> **system-control-evc version**
ntp peer <*hostname* | *ipv6 address*> **system-control-evc version maxpoll** <*value*>

ntp peer <*hostname* | *ipv6 address*> **system-management-evc**
ntp peer <*hostname* | *ipv6 address*> **system-management-evc maxpoll** <*value*>
ntp peer <*hostname* | *ipv6 address*> **system-management-evc minpoll** <*value*>
ntp peer <*hostname* | *ipv6 address*> **system-management-evc normal-sync**
ntp peer <*hostname* | *ipv6 address*> **system-management-evc prefer**
ntp peer <*hostname* | *ipv6 address*> **system-management-evc source** <*interface*>
ntp peer <*hostname* | *ipv6 address*> **system-management-evc source** <*interface*> **maxpoll** <*value*>
ntp peer <*hostname* | *ipv6 address*> **system-management-evc version**
ntp peer <*hostname* | *ipv6 address*> **system-management-evc version maxpoll** <*value*>

ntp peer vrf <*name*> <*hostname* | *ipv6 address*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **maxpoll** <*value*>

ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **minpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **normal-sync**
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **prefer**
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **source** <*interface*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **version**

ntp peer vrf <*name*> <*hostname* | *ipv6 address*> <*interface*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> <*interface*> **maxpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> <*interface*> **minpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> <*interface*> **normal-sync**
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> <*interface*> **prefer**
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> <*interface*> **source** <*interface*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> <*interface*> **version**

ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc**
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc maxpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc minpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc normal-sync**
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc prefer**
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc source** <*interface*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc source** <*interface*> **maxpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc version**
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc version maxpoll** <*value*>

ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc**
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc maxpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc minpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc normal-sync**
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc prefer**
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc source** <*interface*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc source** <*interface*> **maxpoll** <*value*>
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc version**
ntp peer vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc version maxpoll** <*value*>

Syntax Description

<*hostname* | *ipv6 address*>	Specify the host name or IPv6 address of the NTP server. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.

<interface>	Specifies which interface NTP should use to send NTP requests. This option is only available when a link-local IPv6 address is used for the NTP peer, and it must be specified. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id]>*. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; and for an ATM subinterface, use **atm 1.1**. Type **ntp peer** *<name>* **source ?** for a list of valid interfaces.
maxpoll *<value>*	Optional. Specifies the maximum polling interval for NTP packets, in seconds as a power of two. The allowable range is **4** to **17**. For example, setting the **maxpoll** to 10 would indicate a maximum polling interval of **1024** seconds. Refer to the the *Functional Notes* for more information.
minpoll *<value>*	Optional. Specifies the minimum polling interval for NTP packets, in seconds as a power of two. The allowable range is **4** to **17**. For example, setting the **minpoll** to 6 would indicate a minimum polling interval of **64** seconds. Refer to the the *Functional Notes* for more information.
normal-sync	Optional. Disables the rapid synchronization feature.
prefer	Optional. Specifies the preference of using the specified peer above all other configured NTP servers.
source *<interface>*	Optional. Specifies the source interface (physical or virtual) to use for the peer. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id]>*. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; and for an ATM subinterface, use **atm 1.1**. Type **ntp peer** *<name>* **source ?** for a list of valid interfaces.
system-control-evc	Specifies the system control Ethernet virtual connection (EVC). This EVC exists by default and cannot be deleted.
system-management-evc	Specifies the system management EVC. This EVC exists by default and cannot be deleted.
version	Specifies the version number for outgoing NTP packets. Valid range is **2** to **4**.
vrf *<name>*	Specifies the name of the VRF to which to assign the association. If no VRF is specified, the association is applied to the default unnamed VRF.

Default Values

By default, the IPv6 **ntp peer** is not set. Once enabled, the default version is **4**, the default **minpoll** interval is **6** (64 seconds) and the default **maxpoll** interval is **10** (1024 seconds).

Command History

Release R10.3.0	Command was introduced.
Release R10.7.0	Command was expanded to include the **vrf** *<name>* parameter.
Release R10.10.0	Command was expanded to include the **system-control-evc** and **system-management-evc** parameters.

Release R13.7.0	Command was expanded to include the Gigabit Ethernet and virtual loacl area network (VLAN) interfaces.

Functional Notes

The IPv6 **ntp peer** command can be executed with any combination of the following parameters:

maxpoll <*value*>
minpoll <*value*>
normal-sync
prefer
source <*interface*>
version

For example, the **normal-sync** and **source** <*interface*> parameters can be used in conjunction with one another. In this case, the command would look like this:

#ntp peer fe80::2 vlan 1 normal-sync source ppp 1

These parameters can be combined in any order to obtain the desired configuration.

In order to determine the appropriate value to enter for **maxpoll** or **minpoll**, use the following formula: 2^n where n = <*value*>. For example, to set the minimum polling interval to 64 seconds, you would enter **6** as the **minpoll** value. This corresponds to 2^6 in the formula, or 2x2x2x2x2x2, which equals 64 seconds.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example defines **fe80::2 vlan 1** as the IPv6 NTP peer:

(config)**#ntp peer fe80::2 vlan 1**

The following example creates an IPv6 peer association with **2001:DB8:1::1** and sets the maximum polling interval of 64 seconds:

(config)**#ntp peer 2001:DB8:1::1 maxpoll 6**

ntp server <*hostname* | *ipv4 address*>

Use the **ntp server** command to specify an Internet Protocol version 4 (IPv4) server association with another Network Time Protocol (NTP) system and configure its parameters. Any combination of server associations can be simultaneously configured. Specifying the virtual routing and forwarding (VRF) instance using the **vrf** <*name*> keyword applies the association to the named VRF instance. Omitting the **vrf** <*name*> keyword applies the association to the default unnamed VRF. Use the **no** form of this command to return to the default setting. Variations of this command include:

ntp server <*hostname* | *ipv4 address*>
ntp server <*hostname* | *ipv4 address*> **maxpoll** <*value*>
ntp server <*hostname* | *ipv4 address*> **minpoll** <*value*>
ntp server <*hostname* | *ipv4 address*> **prefer**
ntp server <*hostname* | *ipv4 address*> **source** <*interface*>
ntp server <*hostname* | *ipv4 address*> **version** <*number*>

ntp server <*hostname* | *ipv4 address*> **efm-group** <*group id*>
ntp server <*hostname* | *ipv4 address*> **efm-group** <*group id*> **maxpoll** <*value*>
ntp server <*hostname* | *ipv4 address*> **efm-group** <*group id*> **minpoll** <*value*>
ntp server <*hostname* | *ipv4 address*> **efm-group** <*group id*> **prefer**
ntp server <*hostname* | *ipv4 address*> **efm-group** <*group id*> **source** <*interface*>
ntp server <*hostname* | *ipv4 address*> **efm-group** <*group id*> **source** <*interface*> **maxpoll** <*value*>
ntp server <*hostname* | *ipv4 address*> **efm-group** <*group id*> **version**
ntp server <*hostname* | *ipv4 address*> **efm-group** <*group id*> **version maxpoll** <*value*>

ntp server <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*>
ntp server <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **maxpoll** <*value*>
ntp server <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **minpoll** <*value*>
ntp server <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **normal-sync**
ntp server <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **prefer**
ntp server <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **source** <*interface*>
ntp server <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **source** <*interface*> **maxpoll** <*value*>
ntp server <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **version**
ntp server <*hostname* | *ipv4 address*> **mef-ethernet** <*slot/port*> **version maxpoll** <*value*>

ntp server <*hostname* | *ipv4 address*> **system-control-evc**
ntp server <*hostname* | *ipv4 address*> **system-control-evc maxpoll** <*value*>
ntp server <*hostname* | *ipv4 address*> **system-control-evc minpoll** <*value*>
ntp server <*hostname* | *ipv4 address*> **system-control-evc normal-sync**
ntp server <*hostname* | *ipv4 address*> **system-control-evc prefer**
ntp server <*hostname* | *ipv4 address*> **system-control-evc source** <*interface*>
ntp server <*hostname* | *ipv4 address*> **system-control-evc source** <*interface*> **maxpoll** <*value*>
ntp server <*hostname* | *ipv4 address*> **system-control-evc version**
ntp server <*hostname* | *ipv4 address*> **system-control-evc version maxpoll** <*value*>

ntp server <*hostname* | *ipv4 address*> **system-management-evc**
ntp server <*hostname* | *ipv4 address*> **system-management-evc maxpoll** <*value*>

ntp server <*hostname* | *ipv4 address*> **system-management-evc minpoll** <*value*>
ntp server <*hostname* | *ipv4 address*> **system-management-evc prefer**
ntp server <*hostname* | *ipv4 address*> **system-management-evc source** <*interface*>
ntp server <*hostname* | *ipv4 address*> **system-management-evc source** <*interface*> **maxpoll** <*value*>
ntp server <*hostname* | *ipv4 address*> **system-management-evc version**
ntp server <*hostname* | *ipv4 address*> **system-management-evc version maxpoll** <*value*>

ntp server vrf <*name*> <*hostname* | *ipv4 address*>
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **maxpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **minpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **prefer**
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **source** <*interface*>
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **version** <*number*>

ntp server vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*>
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*> **maxpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*> **minpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*> **prefer**
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*> **source** <*interface*>
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **efm-group** <*group id*> **source** <*interface*> **maxpoll** <*value*>

ntp server vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc**

ntp server vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc maxpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc minpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc prefer**
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc source** <*interface*>
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc source** <*interface*> **maxpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc version**
ntp server vrf <*name*> <*hostname* | *ipv4 address*> **system-management-evc version maxpoll** <*value*>

Syntax Description

<*hostname* | *ipv4 address*>	Specify the host name or IPv4 address of the NTP server. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
efm-group <*group id*>	Specifies an Ethernet in the first mile (EFM) group ID. Range is **1** to **1024**.
maxpoll <*value*>	Optional. Specifies the maximum polling interval for NTP packets, in seconds as a power of two. The allowable range is **4** to **17**. For example, setting the maxpoll to 10 would indicate a maximum polling interval of **1024** seconds. Refer to the the *Functional Notes* for more information.
mef-ethernet <*slot/port*>	Specifies the Metro Ethernet Forum (MEF) Ethernet interface.
minpoll <*value*>	Optional. Specifies the minimum polling interval for NTP packets, in seconds as a power of two. The allowable range is **4** to **17**. For example, setting the minpoll to 6 would indicate a minimum polling interval of **64** seconds. Refer to the the *Functional Notes* for more information.
prefer	Optional. Specifies the preference of using the specified server above all other configured NTP servers.
source <*interface*>	Optional. Specifies the source interface (physical or virtual) to use for the server. Specify an interface in the format <*interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id]*>. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; and for an ATM subinterface, use **atm 1.1**. Enter **ntp server** <*name*> **source ?** for a list of valid interfaces.
system-control-evc	Specifies the system control Ethernet virtual connection (EVC). This EVC exists by default and cannot be deleted.
system-management-evc	Specifies the system management EVC. This EVC exists by default and cannot be deleted.
version <*number*>	Specifies the version number for outgoing NTP packets. Valid range is **2** to **4**.
vrf <*name*>	Specifies the name of the VRF to which to assign the association. If no VRF is specified, the association is applied to the default unnamed VRF.

Default Values

By default, the IPv6 **ntp server** is not set. Once enabled, the default version is **4**, the default **minpoll** interval is **6** (64 seconds) and the default **maxpoll** interval is **10** (1024 seconds).

Command History

Release 17.2	Command was introduced.
Release 17.6	Command was expanded to include **maxpoll** and **minpoll** parameters.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.1.0	Command was expanded to include the bridged virtual interface (BVI).
Release R10.5.0	Command was expanded to include the loopback interface.
Release R10.7.0	Command was expanded to include the **vrf** <*name*> parameter.
Release R10.10.0	Command was expanded to include the **system-control-evc** and **system-management-evc** parameters.
Release R10.11.0	Command was expanded to include the MEF Ethernet interface.
Release R11.2.0	Command was expanded to include Ethernet in the first mile (EFM) group parameter.

Functional Notes

The IPv4 **ntp server** command can be executed with any combination of the following parameters:

maxpoll <*value*>
minpoll <*value*>
prefer
source <*interface*>
version

For example, the **prefer** and **source** <*interface*> parameters can be used in conjunction with one another. In this case, the command would look like this:

#ntp server 10.10.10.1 prefer source ppp 1

These parameters can be combined in any order to obtain the desired configuration.

In order to determine the appropriate value to enter for **maxpoll** or **minpoll**, use the following formula: 2^n where n = <*value*>. For example, to set the minimum polling interval to 64 seconds, you would enter **6** as the **minpoll** value. This corresponds to 2^6 in the formula, or 2x2x2x2x2x2, which equals 64 seconds.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example defines **10.10.10.1** as the preferred IPv4 NTP server:

(config)**#ntp server 10.10.10.1 prefer**

The following example associates the IPv4 NTP server **10.10.10.1** and sets the minimum polling interval of 256 seconds:

(config)**#ntp server 10.10.10.1 maxpoll 8**

ntp server <*hostname* | *ipv6 address*>

Use the **ntp server** command to specify an Internet Protocol version 6 (IPv6) server association with another Network Time Protocol (NTP) system and configure the association's parameters. Any combination of server associations can be simultaneously configured. Specifying the virtual routing and forwarding (VRF) instance using the **vrf** <*name*> keyword applies the association to the named VRF instance. Omitting the **vrf** <*name*> keyword applies the association to the default unnamed VRF. Use the **no** form of this command to return to the default setting. Variations of this command include:

ntp server <*hostname* | *ipv6 address*>
ntp server <*hostname* | *ipv6 address*> **maxpoll** <*value*>
ntp server <*hostname* | *ipv6 address*> **minpoll** <*value*>
ntp server <*hostname* | *ipv6 address*> **prefer**
ntp server <*hostname* | *ipv6 address*> **source** <*interface*>
ntp server <*hostname* | *ipv6 address*> **version** <*number*>

ntp server <*hostname* | *ipv6 address*> **system-control-evc**
ntp server <*hostname* | *ipv6 address*> **system-control-evc maxpoll** <*value*>
ntp server <*hostname* | *ipv6 address*> **system-control-evc minpoll** <*value*>
ntp server <*hostname* | *ipv6 address*> **system-control-evc normal-sync**
ntp server <*hostname* | *ipv6 address*> **system-control-evc prefer**
ntp server <*hostname* | *ipv6 address*> **system-control-evc source** <*interface*>
ntp server <*hostname* | *ipv6 address*> **system-control-evc source** <*interface*> **maxpoll** <*value*>
ntp server <*hostname* | *ipv6 address*> **system-control-evc version**
ntp server <*hostname* | *ipv6 address*> **system-control-evc version maxpoll** <*value*>

ntp server <*hostname* | *ipv6 address*> **system-management-evc**
ntp server <*hostname* | *ipv6 address*> **system-management-evc maxpoll** <*value*>
ntp server <*hostname* | *ipv6 address*> **system-management-evc minpoll** <*value*>
ntp server <*hostname* | *ipv6 address*> **system-management-evc prefer**
ntp server <*hostname* | *ipv6 address*> **system-management-evc source** <*interface*>
ntp server <*hostname* | *ipv6 address*> **system-management-evc source** <*interface*> **maxpoll** <*value*>
ntp server <*hostname* | *ipv6 address*> **system-management-evc version**
ntp server <*hostname* | *ipv6 address*> **system-management-evc version maxpoll** <*value*>

ntp server <*hostname* | *ipv6 address*> <*interface*>
ntp server <*hostname* | *ipv6 address*> <*interface*> **maxpoll** <*value*>
ntp server <*hostname* | *ipv6 address*> <*interface*> **minpoll** <*value*>
ntp server <*hostname* | *ipv6 address*> <*interface*> **prefer**
ntp server <*hostname* | *ipv6 address*> <*interface*> **source** <*interface*>
ntp server <*hostname* | *ipv6 address*> <*interface*> **version** <*number*>

ntp server vrf <*name*> <*hostname* | *ipv6 address*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **maxpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **minpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **prefer**
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **source** <*interface*>

ntp server vrf <*name*> <*hostname* | *ipv6 address*> **version** <*number*>

ntp server vrf <*name*> <*hostname* | *ipv6 address*> <*interface*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> <*interface*> **maxpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> <*interface*> **minpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> <*interface*> **prefer**
ntp server vrf <*name*> <*hostname* | *ipv6 address*> <*interface*> **source** <*interface*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> <*interface*> **version** <*number*>

ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc**
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc maxpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc minpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc prefer**
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc source** <*interface*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc source** <*interface*> **maxpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc version**
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-control-evc version maxpoll** <*value*>

ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc**
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc maxpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc minpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc prefer**
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc source** <*interface*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc source** <*interface*> **maxpoll** <*value*>
ntp server vrf <*name*> <*hostname* | *ipv6 address*> **system-management-evc version**

Syntax Description

<*hostname* | *ipv6 address*>	Specify the host name or IPv6 address of the NTP server. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<*interface*>	Specifies which interface NTP should use to send NTP requests. This option is only available when a link-local IPv6 address is used for the NTP peer, and it must be specified. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id]>*. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; and for an ATM subinterface, use **atm 1.1**. Type **ntp peer** <*name*> **source ?** for a list of valid interfaces.
maxpoll <*value*>	Optional. Specifies the maximum polling interval for NTP packets, in seconds as a power of two. The allowable range is **4** to **17**. For example, setting the maxpoll to 10 would indicate a maximum polling interval of **1024** seconds. Refer to the the *Functional Notes* for more information.

minpoll <*value*>	Optional. Specifies the minimum polling interval for NTP packets, in seconds as a power of two. The allowable range is **4** to **17**. For example, setting the minpoll to 6 would indicate a minimum polling interval of **64** seconds. Refer to the the *Functional Notes* for more information.
prefer	Optional. Specifies the preference of using the specified server above all other configured NTP servers.
source <*interface*>	Optional. Specifies the source interface (physical or virtual) to use for the server. Specify an interface in the format <*interface type [slot/port* | *slot/port.subinterface id* | *interface id* | *interface id.subinterface id]*>. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; and for an ATM subinterface, use **atm 1.1**. Enter **ntp server** <*name*> **source ?** for a list of valid interfaces.
system-control-evc	Specifies the system control Ethernet virtual connection (EVC). This EVC exists by default and cannot be deleted.
system-management-evc	Specifies the system management EVC. This EVC exists by default and cannot be deleted.
version <*number*>	Specifies the version number for outgoing NTP packets. Valid range is **2** to **4**.
vrf <*name*>	Specifies the name of the VRF to which to assign the association. If no VRF is specified, the association is applied to the default unnamed VRF.

Default Values

By default, the **ntp server** is not set. Once enabled, the default version is **4**, the default **minpoll** interval is **6** (64 seconds) and the default **maxpoll** interval is **10** (1024 seconds).

Command History

Release R10.3.0	Command was introduced.
Release R10.7.0	Command was expanded to include the **vrf** <*name*> parameter.
Release R10.10.0	Command was expanded to include the **system-control-evc** and **system-management-evc** parameters.

Functional Notes

The IPv6 **ntp server** command can be executed with any combination of the following parameters:

maxpoll <*value*>
minpoll <*value*>
prefer
source <*interface*>
version

For example, the **prefer** and **source** <*interface*> parameters can be used in conjunction with one another. In this case, the command would look like this:

#ntp server 10.10.10.1 prefer source ppp 1

These parameters can be combined in any order to obtain the desired configuration.

In order to determine the appropriate value to enter for **maxpoll** or **minpoll**, use the following formula: 2^n where n = <*value*>. For example, to set the minimum polling interval to 64 seconds, you would enter **6** as the **minpoll** value. This corresponds to 2^6 in the formula, or 2x2x2x2x2x2, which equals 64 seconds.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example defines **fe80::2 vlan 1** as the preferred IPv6 NTP server:

(config)**#ntp server fe80::2 vlan 1 prefer**

The following example associates the IPv6 NTP server **2001:DB8:1::1** and sets the minimum polling interval of 256 seconds:

(config)**#ntp server 2001:DB8:1::1 maxpoll 8**

ntp source *<interface>*

Use the **ntp source** command to specify the source interface for the Network Time Protocol (NTP) packets. Specifying the virtual routing and forwarding (VRF) instance using the **vrf** <*name*> keyword applies the association to the named VRF instance. Omitting the **vrf** <*name*> keyword applies the association to the default unnamed VRF. Use the **no** form of this command to return to the default setting. Variations of this command include:

ntp source <*interface*>
ntp vrf <*name*> **source** <*interface*>

Syntax Description

<interface>	Specifies the source interface (physical or virtual) to use for the server. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; and for an ATM subinterface, use **atm 1.1**. Enter **ntp source ?** for a list of valid interfaces.
vrf <*name*>	Specifies the name of the VRF to which to assign the association. If no VRF is specified, the association is applied to the default unnamed VRF.

Default Values

By default, the NTP source interface is not set.

Command History

Release 17.2	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.7.0	Command was expanded to include the **vrf** <*name*> parameter.

Functional Notes

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example defines NTP source interface as **ppp 1**:

(config)**#ntp source ppp 1**

ntp update-rtc

Use the **ntp update-rtc** command to specify periodically updating the clock in real time. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, the Network Time Protocol (NTP) is disabled.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example sets the clock to periodically update the timing:

(config)**#ntp update-rtc**

over-temperature protection

Use the **over-temperature protection** command to enter the Over-Temperature Protection Configuration mode, from which to configure the over temperature protection feature. Additional commands are available for configuring this feature and are explained in *Over-Temperature Protection Command Set on page 4446*.

Syntax Description

No subcommands.

Default Values

By default, the over-temperature protection mode is disabled.

Command History

Release R11.6.0	Command was introduced.

Functional Notes

For more information regarding over-temperature protection configuration, refer to the *Over-Temperature Protection Command Set on page 4446*.

Usage Examples

The following example enters the Over-Temperature Protection Configuration mode:

```
(config)#over-temperature protection
(config-over-temp-protection)#
```

packet-capture <*name*>

Use the **packet-capture** command to create a packet-capture on the AOS device and enter the packet-capture's configuration mode. Packet-captures are used with network monitoring on interfaces to effectively capture data packets as they traverse the network. Use the **no** form of this command to remove the packet-capture. Variations of this command include:

packet-capture <*name*> **standard**
packet-capture <*name*> **sip**

Syntax Description

<*name*>	Specifies the name of the packet-capture. Names can be between **1** and **32** characters in length.
standard	Specifies that all ingress and egress Internet Protocol version 4 (IPv4) packets are captured.
sip	Specifies that all ingress and egress User Datagram Protocol (UDP) packets that are related to Session Initiation Protocol (SIP) messages are captured.

Default Values

By default, no packet-captures are configured.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

The AOS packet capture feature is used with network monitoring to effectively capture data packets as they traverse the network. As data packets pass through an interface on which the packet capturing feature is enabled, a packet-capture monitors the traffic and captures the header and payload of specified packets as they pass through. The captured packets are then exported and stored in either flash memory or CompactFlash storage, and can then be reviewed to determine the cause of network problems, identify security threats, and to maintain efficient data transmission over the network. For more information about the configuration and use of packet capturing, refer to *Packet Capture Command Set on page 4450* or the configuration guide *Configuring Packet Capture in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example creates the standard packet-capture **7CAPTURE** and enters the packet-capture configuration mode:

(config)#**packet-capture 7CAPTURE standard**
(config-packet-capture-7CAPTURE)#

policer <*name*>

Use the **policer** command to create a Layer 2/Layer 3 Ethernet virtual connection (EVC) policer policy and enter the Layer2/Layer 3 EVC Policer Policy Configuration mode. The EVC policer policy limits the amount of traffic outbound from the AOS unit to the Metro Ethernet network (MEN). Using the **no** form of this command removes the EVC policer policy from the AOS unit's configuration. Variations of this command include:

policer <*name*>
policer <*name*> <*slot*>

Syntax Description

<*name*>	Specifies the name of the EVC policer policy.
<*slot*>	Optional. Identifies the slot on which to apply the EVC policer policy.

Default Values

By default, no EVC policer policies are configured.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

The EVC policer policy can limit traffic on EVCs, user network interfaces (UNIs), or EVC maps based on traffic committed burst size (CBS), committed information rate (CIR), excess burst size (EBS), and excess information rate (EIR). These thresholds are used to determine when the EVC bandwidth usage is too great, and the traffic is either queued or dropped based on the configured thresholds. For more information about the configuration and use of EVC policer policies, refer to *MEF Policer Policy Command Set on page 3684*.

Usage Examples

The following example creates the EVC policer policy **Policy1** and enters the Layer 2/Layer 3 EVC Policer Policy Configuration mode:

```
(config)#policer Policer1
(config-policer Policer1)#
```

policy-class max-sessions *<number>*

Use the **policy-class max-sessions** command to specify the maximum number of allowed policy sessions in the AOS product for both Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6) combined. This command sets the maximum session limit for ALL access control policies (ACPs) on the AOS unit. To set the maximum number of policy sessions only for IPv4, use the command *ip policy-class <ipv4 acp name> max-sessions <number> on page 1437*. To set the maximum number of policy sessions only for IPv6, use the command *ipv6 policy-class <ipv6 acp name> max-sessions <number> on page 1550*. Use the **no** form of this command to return to the default value.

Syntax Description

<number>	Specifies the number of allowed ACP sessions. Valid range is **1** to a value based on the amount of RAM in the AOS unit (refer to *Default Values* below).

Default Values

By default, the maximum IPv4 and IPv6 ACP sessions allowed are based on the amount of RAM in the AOS unit. The following table outlines the default values based on RAM:

RAM Amount	Default Max Sessions
64 MB	10000
128 MB	30000
256 MB	80000
512 MB	200000
768 MB	300000
1 GB	450000

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example sets the maximum number of ACP sessions allowed in the AOS unit (for both IPv4 and IPv6 ACP sessions) to **250000**:

(config)**#policy-class max-sessions 250000**

portal-list *<name> <portal1 portal2 portal3>*

Use the **portal-list** command to create a portal list to associate with a local user name. Use the command *username <username> password <password> on page 1887* to assign this portal list to an previously configured user name. Use the **no** form of this command to remove the portal list.

> NOTE *Entering this command with the same name, but a different portal list will overwrite the original portal list.*

Syntax Description

<name>	Specifies the name of the portal list (maximum of 80 characters).
<portal>	Specifies the portals assigned to this portal list. The list can contain any combination of the portals listed below:
console	Allows the list holder to access the unit via the console.
ftp	Allows the list holder to access the unit via File Transfer Protocol (FTP).
http-admin	Allows the list holder to view the configuration and statistics via Hypertext Transfer Protocol (HTTP).
ssh	Allows the list holder to access the unit via secure shell (SSH).
telnet	Allows the list holder to access the unit via Telnet.

Default Values

By default, no portal lists are defined.

Command History

Release 17.1	Command was introduced.

Functional Notes

The same portal list can be assigned to multiple user names. Once the list is assigned to the user name, that user name can only authenticate the portals in the list. If a list is not assigned to a user name, that user name can be used with any portal that is set for local login.

Usage Examples

The following example assigns the **console**, **telnet**, and **ssh** portals the portal list **engineers**:

(config)**#portal-list engineers console telnet ssh**

port-auth default

Use the **port-auth default** command to set all global port-authentication settings to their default states.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example sets all global port-authentication settings to their default states:

(config)**#port-auth default**

port-auth max-req <*number*>

Use the **port-auth max-req** command to specify the maximum number of identity requests the authenticator will transmit before restarting the authentication process. Use the **no** form of this command to return to the default setting.

Syntax Description

<*number*>	Specifies the maximum number of authentication requests.

Default Values

By default, the maximum number of authentication requests is set at 2.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example sets the maximum number of authentication requests at **4**:

(config)**#port-auth max-req 4**

port-auth re-authentication

Use the **port-auth re-authentication** command to enable re-authentication. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, re-authentication is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example enables re-authentication:

(config)**#port-auth re-authentication**

port-auth supplicant

Use the **port-auth supplicant** command to enable the port-authentication supplicant mode feature and to enter the Port-Authentication Supplicant Configuration mode. Use the **no** form of this command to remove the supplicant mode parameters. Variations of this command include:

port-auth supplicant
port-auth supplicant username <*username*> **password** <*password*>

Syntax Description

supplicant	Specifies that port authentication is in supplicant mode.
username <*username*>	Specifies the user name used for supplicant authentication.
password <*password*>	Specifies the password used for supplicant authentication.

Default Values

By default, port authentication and port authentication supplicant mode is disabled.

Command History

Release 10.1	Command was introduced.

Functional Notes

The supplicant user name and password can be stored in the port and set in the session if it exists. This allows for the user name and password to be set before the supplicant functionality is enabled.

Usage Examples

The following example sets the user name of **admin** and the password of **password** for supplicant mode authentication on the **eth 0/1** interface:

(config)**#interface eth 0/1**
(config-eth-0/1)**#port-auth supplicant username admin password password**

port-auth timeout

Use the **port-auth timeout** command to configure various port authentication timers. Use the **no** form of this command to return to the default setting. Variations of this command include:

port-auth timeout quiet-period <*value*>
port-auth timeout re-authperiod <*value*>
port-auth timeout tx-period <*value*>

Syntax Description

quiet-period <*value*>	Specifies the amount of time the system will wait before attempting another authentication once a failure has occurred. Range is **1** to **65535** seconds.
re-authperiod <*value*>	Specifies the amount of time between scheduled re-authentication attempts. Range is **1** to **4294967295** seconds.
tx-period <*value*>	Specifies the amount of time the authenticator will wait between identity requests. Range is **1** to **65535** seconds.

Default Values

By default, **quiet-period** is set to 60 seconds, **re-authperiod** is set to 3600 seconds (1 hour), and **tx-period** is set to 30 seconds.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example sets the quiet-period to **10** seconds:

(config)**#port-auth timeout quiet-period 10**

port-channel load-balance

Use the **port-channel load-balance** command to configure port aggregation load distribution. Use the **no** form of this command to reset distribution to its default setting. Variations of this command include:

port-channel load-balance dst-mac
port-channel load-balance src-mac

Syntax Description

dst-mac	Specifies the destination medium access control (MAC) address.
src-mac	Specifies the source MAC address.

Default Values

By default, load balance is set to **src-mac**.

Command History

Release 5.1	Command was introduced.

Functional Notes

During port aggregation, the port channel interface must determine on which physical port to transmit packets. With the source-address configuration, the source MAC address of the received packets is used to determine this allocation. Packets coming from a specific host always use the same physical port. Likewise, when the destination address configuration is used, packets are forwarded based on the MAC address of the destination. Packets destined for a specific host always use the same physical port.

Usage Examples

The following example sets the load distribution to use the destination MAC address:

(config)**#port-channel load-balance dst-mac**

power-supply shutdown automatic

Use the **power-supply shutdown automatic** command to enable the power supplies to automatically shut down when the unit temperature exceeds the maximum operating temperature. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is enabled.

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example enables the power supplies to shut down automatically if the temperature gets too high:

(config)**#power-supply shutdown automatic**

privilege <*mode*> level <*level*>

Use the **privilege level** command to assigned a privilege level to specific commands. The exact command mode name is required to identify the correct commands or command string. The command mode can be learned using the command *show command-mode on page 584*. Variations of this command include:

privilege <*mode*> **all level** <*level*>
privilege <*mode*> **all level** <*level*> <*command string*>
privilege <*mode*> **level** <*level*> <*command string*>

The following command strings cannot have their privilege levels changed: ***exit****,* ***enable****,* ***logout****, and* ***do****.*

Syntax Description

<*mode*>	Specifies the exact command mode name to which the command or command string belongs. Refer to the *Functional Notes* below for more information.
all	Specifies the privilege level be applied to all commands in the specified command mode. When used in conjunction with the <*command string*> variable, the privilege level is applied to only the parameters beyond the specified command string. Refer to the examples in the *Functional Notes* and *Usage Examples* below for more details.
level <*level*>	Specifies the privilege level to be applied to the commands. Valid range is **1** through **7**.
<*command string*>	Optional. Specifies the command string to which the privilege level is to be applied. This can include the full command string or partial command string. Refer to the examples in the *Functional Notes* and *Usage Examples* below for more details.

Default Values

By default, privilege levels are set to **1** for commands in the **exec** command mode and **7** for all other command modes.

Command History

Release R10.11.0	Command was introduced.
Release R11.3.0	Command was altered. The <*command string*> variable is no longer required, but is optional. This allows the **all** keyword to be used to specify changing the privilege level for all commands in a command mode.
Release R11.5.0	Command was expanded to include the Secure Realtime Transfer Protocol (SRTP) and Transport Layer Security (TLS) profile command modes as well as the standard Media Access Control (MAC) hardware access control list (ACL) command set.
Release R11.7.0	Command was expanded to include the 10 gigabit switchport interface.

Release R11.9.0	Command was expanded to include the **crypto-ipsec-profile**, **tunnel-gre** and **tunnel-mgre** command sets.
Release R11.10.0	Command was expanded to include the battery command set.
Release R11.11.0	Command was expanded to include the tunnel interface.

Functional Notes

The command mode name must be entered exactly in order to execute this command. Because the available command modes differ between AOS products, the most reliable method for learning the available command mode names is to use the CLI help. Enter the **privilege ?** command to display a list of all available command modes on the AOS device. Refer to the *Configuring Privilege Levels in AOS* configuration guide for more information.

The **all** keyword is useful for changing the privilege level on all commands within a command mode. For example, to assign all commands in the **interface-gigabit-ethernet** command mode to privilege level 3, enter the following command:

(config)**#privilege interface-gigabit-ethernet all level 3**

When used in conjunction with the <*command string*> variable, the **all** keyword changes the privilege level for a group of commands with several parameters, such as **show** or **debug** commands. For example, to assign all **show** commands a privilege level **5**, enter the following command:

(config)**#privilege exec all level 5 show**

The command string can include more specific parameters to reduce the number of commands affected. For example, entering **privilege exec all level 5 show ip route**, assigns the following list of commands a privilege level **5**:

show ip route
show ip route <*ipv4 address*>
show ip route <*ipv4 address*> <*subnet mask*>
show ip route <*ipv4 address*> **longer-prefixes**
show ip route <*ipv4 address*> <*subnet mask*> **longer-prefixes**
show ip route bgp
show ip route bgp verbose
show ip route connected
show ip route ospf
show ip route ospf verbose
show ip route rip
show ip route rip verbose
show ip route static
show ip route static verbose
show ip route summary
show ip route summary realtime
show ip route table
show ip route vrf <*name*>
show ip route vrf <*name*> <*ipv4 address*>
show ip route vrf <*name*> <*ipv4 address*> <*subnet mask*>

show ip route vrf <*name*> <*ipv4 address*> **longer-prefixes**
show ip route vrf <*name*> <*ipv4 address*> <*subnet mask*> **longer-prefixes**
show ip route vrf <*name*> **bgp**
show ip route vrf <*name*> **connected**
show ip route vrf <*name*> **ospf**
show ip route vrf <*name*> **rip**
show ip route vrf <*name*> **static**
show ip route vrf <*name*> **summary**
show ip route vrf <*name*> **table**

Any future AOS firmware updates in which new commands are introduced, will require the new commands to be altered as necessary related to this privilege level configuration.

Usage Examples

The following example assigns the privilege level **3** to all commands within the Ethernet Interface Configuration mode:

(config)**#privilege interface-ethernet all level 3**

The following example assigns the privilege level **3** to the **shutdown** command from within the Ethernet Interface Configuration mode:

(config)**#privilege interface-ethernet level 3 shutdown**

The following example assigns the privilege level **3** to all **show ip route** command parameters by using the **all** keyword:

(config)**#privilege exec all level 3 show ip route**

probe

Use the **probe** command to create a probe as part of network monitoring. This command is also used to enter into the Network Monitoring Probe command set once a probe is created. A probe can be one of five types: **http-request**, **icmp-echo**, **icmp-timestamp**, **tcp-connect**, or **twamp**. Each probe type has a set of commands used for configuration. These additional commands are covered in *Network Monitor Probe Command Set on page 4062*. Use the **no** form of this command to delete the probe. Variations of this command include:

probe <*name*> **http-request**
probe <*name*> **icmp-echo**
probe <*name*> **icmp-timestamp**
probe <*name*> **tcp-connect**
probe <*name*> **twamp**

*Issue the **no shutdown** command to activate the probe once it is configured. Issuing the **shutdown** command at the probe configuration prompt will disable a probe, causing it to cease generating traffic. While a probe is shut down, it will return a fail value to a track.*

The probe is not operational until tolerance is defined. Refer to Network Monitor Probe Command Set on page 4062 for more information.

Syntax Description

<name>	Specifies the name of the probe being created, or indicates the probe affected by the commands that follow.
http-request	Specifies the probe type being created as an Hypertext Transfer Protocol (HTTP) request.
icmp-echo	Specifies the probe type being created as an Internet Control Message Protocol (ICMP) echo.
icmp-timestamp	Specifies the probe type being created as an ICMP timestamp.
tcp-connect	Specifies the probe type being created as a Transmission Control Protocol (TCP) connect.
twamp	Specifies the probe type being created as a Two-Way Active Measurement Protocol (TWAMP).

Default Values

By default, there are no probes configured.

Command History

Release 13.1	Command was introduced.
Release 17.2	Command was expanded to include the ICMP timestamp and TWAMP probe types.

Usage Examples

The following example creates an ICMP echo probe called **probe1**:

>**enable**
#configure terminal
(config)**#probe probe1 icmp-echo**
(config-probe-probe1)#

Technology Review

Probes are standalone objects that help determine the status of a route based on the success or failure of probe traffic across the path. The probes can be configured to trigger at particular intervals. There are three types of probes supported by AOS: **icmp-echo**, **tcp-connect**, and **http-request**. Commands common to all the probe types are identified in the following section, as well as isolated commands that only apply to the specific probe types.

Additional configuration commands are available for associating tracks with each probe. These are explained in the *Network Monitor Track Command Set on page 4098*.

probe responder

Use the **probe responder** command to enable a probe responder to respond to specific probe packets. Additional commands for each responder type are covered in *Network Monitor Probe Responder Command Set on page 4089*. Use the **no** form of this command to stop the probe responder from responding to the specific probe packets. Variations of this command include:

probe responder icmp-timestamp
probe responder twamp
probe responder udp-echo

*Issue the **no shutdown** command to activate the probe responder once it is configured. By default, probe responders are shut down when created. Issuing the **shutdown** command disables the probe responder and it will not respond to packets.*

Syntax Description

icmp-timestamp	Specifies the probe responder type as Internet Control Message Protocol (ICMP) timestamp.
twamp	Specifies the probe responder type as Two-Way Active Measurement Protocol (TWAMP).
udp-echo	Specifies the probe responder type as a User Datagram Protocol (UDP) echo.

Default Values

By default, there are no probe responders enabled.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example enables the UDP echo probe responder:

>**enable**
#configure terminal
(config)**#probe responder udp-echo**
(config-probe-probe1)#

procare

Use the **procare** command to sync a device with an activated, qualifying ProCare plan with Adtran's ProCare server and enable the configuration backup service. For more information about verifying and activating your ProCare plan, refer to the *Functional Notes* below. The backup service retains the last saved configuration of the AOS device on the Adtran ProCare hosted infrastructure.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release R11.4.0	Command was introduced.

Functional Notes

Only devices covered by an activated, qualifying ProCare plan will be able to communicate with the ProCare hosted infrastructure. For more information about ProCare plans, visit www.adtran.com/procare. Configuration backup service is not offered with ProCare Basic plans. To confirm or request activation, email ProCareBackups@adtran.com and include your name, phone number, unit serial number, and the public IP address for the device. To purchase a ProCare plan, please contact your preferred partner. For a list of partners, click on the Where to Buy link at www.adtran.com.

To connect to Adtran ProCare, your device must have an Internet connection with a public IP address that is not 0.0.0.0.

Usage Examples

The following example enables the configuration backup service:

<config>**#procare**

procloud

Use the **procloud** command to connect an AOS device to Adtran ProCloud service. For more information about verifying and activating ProCloud, refer to the *Functional Notes* below.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release R11.4.0	Command was introduced.

Functional Notes

Adtran's ProCloud service offers hosted, managed cloud network services. Only devices with qualifying ProCloud coverage can use this service. To validate your coverage, call 1-800-874-2237, email serviceplan@adtran.com, or visit the Service Plan Portal at www.adtran.com/serviceplan. To purchase a ProCloud plan, please contact your preferred partner. For a list of partners, click on the Where to Buy link at www.adtran.com.

To connect to Adtran ProCloud LAN, your device must have an Internet connection with a public IP address that is not 0.0.0.0.

Usage Examples

The following example connects the device to the Adtran ProCloud service:

<config>**#procloud**

qos cos-map *<cos queue id> <cos value>*

Use the **qos cos-map** command to associate class of service (CoS) values with each queue. Use the **no** form of this command to return to the default setting.

Syntax Description

<cos queue id>	Specifies the queue number that you are assigning CoS value(s).
<cos value>	Associates listed CoS values with a particular priority queue. Multiple CoS values can be applied to a specified queue. Valid range is **0** to **7**.

Default Values

On NetVanta switch products, there are four queues and the default CoS value mapped to each queue are as outlined below:

Queue 1 is mapped to CoS 0 and 1

Queue 2 is mapped to CoS 2 and 3

Queue 3 is mapped to CoS 4 and 5

Queue 4 is mapped to CoS 6 and 7

On carrier Ethernet products, there are eight queues and the default CoS values mapped to each queue are as outlined below:

Queue 0 is mapped to CoS 1

Queue 1 is mapped to CoS 0

Queue 2 is mapped to CoS 2

Queue 3 is mapped to CoS 3

Queue 4 is mapped to CoS 4

Queue 5 is mapped to CoS 5

Queue 6 is mapped to CoS 6

Queue 7 is mapped to CoS 7

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example maps CoS values 4 and 5 to queue 1:

(config)#**qos cos-map 1 4 5**

qos dscp-cos

Use the **qos dscp-cos** command to set the differentiated services code point (DSCP) to class of service (CoS) map and enable the mapping process. Use the **no** form of this command to disable mapping. Variations of this command include:

qos dscp-cos <*dscp value*> **to** <*cos value*>
qos dscp-cos default

Syntax Description

<*dscp value*>	Specifies DSCP values (separating multiple values with a space). Valid range is **0** to **63**.
<*cos value*>	Specifies CoS values (separating multiple values with a space). Valid range is **0** to **7**.
default	Sets the map to the following default values: DSCP 0 | 8 | 16 | 24 | 32 | 40 | 48 | 56 CoS 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Functional Notes

When one of the specified DSCP values is detected in an incoming packet, the CoS priority is altered based on the corresponding map value. By configuring the list, the mapping functionality is enabled.

Usage Examples

The following example enables the mapping of DSCP values 24 and 48 to CoS values 1 and 2:

(config)**#qos dscp-cos 24 48 to 1 2**

The following example disables DSCP-to-CoS mapping:

(config)**#no qos dscp-cos**

qos map <*name*> <*number*>

Use the **qos map** command to create a quality of service (QoS) map and activate the QoS Map Command Set (which allows you to edit a QoS map). For details on specific commands, refer to the *Quality of Service Map Command Set on page 4464*. Use the **no** form of this command to delete a map entry. Variations of this command include:

qos map <*name*> <*number*>
qos map <*name*> <*number*> **match-all**
qos map <*name*> <*number*> **match-any**

Syntax Description

<*name*>	Specifies the QoS map name.
<*number*>	Assigns a sequence number to differentiate this QoS map and provide a match order. Valid range is **0** to **65535**.
match-all	Optional. Indicates the traffic must match all conditions before the set action is issued.
match-any	Optional. Indicates the traffic can match any of the conditions to be processed, which is the default behavior.

Default Values

By default, there are no QoS maps defined. Once created, the default behavior is to match any of the conditions set for the QoS map.

Command History

Release 6.1	Command was introduced.
Release 17.2	Command was expanded to include the **match-all** and **match-any** parameters.

Functional Notes

AOS uses QoS maps to classify packets into groups for matching. A QoS map contains multiple class entries, each of which has packet match cases, and a set of actions for the particular group (actions are defined by **bandwidth**, **priority**, **set**, and **shape** commands). Multiple map entries for the same QoS map are differentiated by a sequence number. The sequence number is used to assign the order in which the conditions are matched.

Once created, a QoS map must be applied to an interface (using the **qos-policy out** command) in order to actively process traffic. Refer to *qos-policy on page 2306* for more information on assigning the map to an interface. Any traffic for the interface that is not sent to the priority queue is sent using the default queuing method for the interface (such as weighted fair queuing (WFQ)).

Usage Examples

The following example demonstrates basic settings for a QoS map and assigns a map to the Frame Relay interface:

>**enable**
#config terminal
(config)**#qos map VOICEMAP 10**
(config-qos-map)**#match precedence 5**
(config-qos-map)**#priority 512**
(config-qos-map)**#exit**
(config)**#interface fr 1**
(config-fr 1)**#qos-policy out VOICEMAP**

qos policer mode non-bias

Use the **qos policer mode non-bias** command to specify the policer algorithm used in Metro Ethernet Forum (MEF) policer quality of service (QoS) configurations. Use the **no** form of this command to specify the policer uses the MEF10 reference algorithm.

Syntax Description

No subcommands.

Default Values

By default, the MEF policer is configured to use the **non-bias** setting.

Command History

Release R11.5.2	Command was introduced.

Functional Notes

This command configures the AOS device to use a policer algorithm that largely eliminates the MEF10 policer algorithm's bias for small frames. When a policer drops a packet in a flow, it drops all subsequent packets in the flow until the policer credit builds up to at least the hardware maximum transmission unit (MTU). Prior to AOS release R11.6.0, the hardware MTU was set to 2000 bytes. After AOS release R11.6.0, the hardware MTU is set to 9200 bytes to allow for jumbo frames. When the **no** form of this command is used, the policer uses the MEF10 reference algorithm, which has a bias for small frames over large frames.

Usage Examples

The following example specifies that the MEF policer uses the MEF10 reference algorithm:

(config)**#no qos policer mode non-bias**

qos queue-type strict-priority

Use the **qos queue-type strict-priority** command to enable queuing based strictly on the priority of each queue. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, the queue type is weighted round robin (WRR).

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example enables strict-priority queuing:

(config)**#qos queue-type strict-priority**

qos queue-type wrr

Use the **qos queue-type wrr** command to set weights for up to four queues. Use the **no** form of this command to set all queues to be weighted round robin (WRR). Variations of this command include:

qos queue-type wrr <*weight1*> <*weight2*> <*weight3*> **expedite**
qos queue-type wrr <*weight1*> <*weight2*> <*weight3*> <*weight4*>

Syntax Description

<*weight1-4*>	Sets the weight of each queue (up to four). All queue weights must be greater than zero, except for the weight for the last queue (queue 4). The range for queues 1 to 3 is 1 to 255. The range for queue 4 is **0** to **255**.
expedite	The queue 4 entry can be replaced by the **expedite** command. If set to **expedite**, then it becomes a high-priority queue. All outbound traffic is transmitted on an expedite queue prior to any other traffic in other queues.

Default Values

By default, all four weights are set to **25**.

Command History

Release 5.1	Command was introduced.

Functional Notes

The actual weight is a calculated value based on the sum of all entered weights. It is the ratio of the individual weight over the sum of all weights.

For example:

If the user enters 10, 20, 30, and 40 as the weight values, the first queue will have a ratio of 1/10. This is derived from the formula 10/(10+20+30+40). Therefore, this queue will transmit 1 packet out of every 10 opportunities.

Usage Examples

The following example configures weights for all four queues:

(config)**#qos queue-type wrr 10 20 30 40**

queue interface

Use the **queue interface** command to configure a queue on an interface. Use the **no** form of this command to remove the queue configuration on the interface. Variations of this command include:

queue interface efm-group <*slot/group*> <*queue*>
queue interface gigabit-ethernet <*slot/port*> <*queue*>

Syntax Description

efm-group <*slot/group*>	Specifies the queue is configured on an Ethernet in the first mile (EFM) group interface. Group range is **1** to **1024**.
gigabit-ethernet <*slot/port*>	Specifies the Gigabit Ethernet interface on which to configure the queue.
<*queue*>	Specifies the queue to configure. Carrier Ethernet products have eight queues, with a valid range of **0** to **7**.

Default Values

By default, no queues on configured on the EFM group or Gigabit Ethernet interfaces.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

Once you have entered the **queue interface** command, you can configure the queue from the Ethernet virtual connection (EVC) Queue Configuration mode. Refer to *Carrier Ethernet Queue Command Set on page 3728* for queue configuration commands.

Usage Examples

The following example enters the queue's configuration mode on an EFM group interface:

```
(config)#queue interface efm-group 1/1 5
(config-queue 5)#
```

queue time-constant wred <*value*>

Use the **queue time-constant wred** command to configure the weighted random early detection (WRED) time constant used to calculate the average queue depth for all queues.

Syntax Description

<*value*>	Specifies the time constant used to calculate the average queue depth for all queues. Accepted values are **2**, **4**, **8**, **16**, **32**, **62**, **125**, **250**, and **500** milliseconds (ms).

Default Values

No default values are necessary for this command.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

The WRED time constant allows the user to adjust the time component used to calculate the average queue depth. For example, if the WRED time constant is set to **8** ms, the queue depth will be the average number of packets over an 8 ms period of time. If the WRED time constant is set too low, bursty traffic may inadvertently be marked for discard. Conversely, if the WRED time constant is set too high, traffic may remain in the queue substantially longer than usual which can impact Transmission Control Protocol (TCP) throughput. Adtran recommends setting the WRED time constant to the approximate round trip delay for TCP packets.

Usage Examples

The following example sets the WRED queue time constant to **62** ms.

(config)**#queue time-constant wred 62**

radius-server

Use the **radius-server** command to configure several remote authentication dial-in user service (RADIUS) parameters for all RADIUS servers on the network. Most of these global settings can be overridden on a per-server basis (using the command *radius-server host on page 1682*). Use the **no** form of this command to return to the default setting. Variations of this command include the following:

radius-server challenge-noecho
radius-server deadtime <*value*>
radius-server enable-username <*name*>
radius-server key <*key*>
radius-server retry <*number*>
radius-server timeout <*value*>

Syntax Description

challenge-noecho	Specifies that when users enter text in response to challenge questions the entered text does not appear on the screen.
deadtime <*value*>	Specifies the time to wait (in minutes) before attempting to reconnect to a RADIUS server that has timed out. Range is **0** to **1440** minutes. Changing this parameter changes the time to wait for all configured RADIUS servers.
enable-username <*name*>	Specifies a user name to be used for authentication to enter the Enable mode. This user name is the name sent for AAA Enable mode access requests. Changing this parameter changes the user name for all configured RADIUS servers.
key <*key*>	Specifies the encryption key shared by all RADIUS servers. This is a global setting; however, it can be overridden on a per-server basis.
retry <*number*>	Specifies the number of connection attempts to a RADIUS server. Attempt range is **0** to **10**. This is a global setting; however, it can be overridden on a per-server basis.
timeout <*value*>	Specifies the amount of time (in seconds) that RADIUS servers have to respond to a request. Time range is **1** to **1000** seconds. This is a global setting; however, it can be overridden on a per-server basis.

Default Values

challenge-noecho	Echo is disabled and users do not see on-screen what they enter.
deadtime	**0** minutes
enable-username	**$enab15$**
key	No default
retry	**0** attempts
timeout	**5** seconds

Command History

Release 5.1	Command was introduced.
Release 7.1	Added the **enable-username** selection.

Functional Notes

It is recommended that you use a user name that is a unique name for your network and one that only the network administrators know. If the default user name is used, it is possible for unauthorized users to gain access to the network.

By default, there is a **0** minute wait time before attempting to reconnect to a timed out server. Leaving the wait time at **0** minutes means that the server will never be declared dead. The time period value is **0** to **1440** minutes, although you should enter a value of at least **1** minute or greater.

Usage Examples

The following example shows a typical configuration of these parameters:

(config)**#radius-server deadtime 10**
(config)**#radius-server enable-username fantastico**
(config)**#radius-server key mysecretkey**
(config)**#radius-server retry 4**
(config)**#radius-server timeout 2**

radius-server host

Use the **radius-server host** command to specify the parameters for a remote authentication dial-in user service (RADIUS) server. Specifying the virtual routing and forwarding (VRF) instance using the **vrf** <*name*> keyword applies the configuration to the named VRF instance. Omitting the **vrf** <*name*> keyword applies the settings to the default unnamed VRF. Use the **no** form of this command to return to the default setting. Variations of this command include:

radius-server host <*hostname* | *ip address*>
radius-server host <*hostname* | *ip address*> **acct-port** <*port*>
radius-server host <*hostname* | *ip address*> **auth-port** <*port*>
radius-server host <*hostname* | *ip address*> **key** <*key*>
radius-server host <*hostname* | *ip address*> **retransmit** <*number*>
radius-server host <*hostname* | *ip address*> **timeout** <*value*>
radius-server vrf <*name*> **host** <*hostname* | *ip address*>
radius-server vrf <*name*> **host** <*hostname* | *ip address*> **acct-port** <*port*>
radius-server vrf <*name*> **host** <*hostname* | *ip address*> **auth-port** <*port*>
radius-server vrf <*name*> **host** <*hostname* | *ip address*> **key** <*key*>
radius-server vrf <*name*> **host** <*hostname* | *ip address*> **retransmit** <*number*>
radius-server vrf <*name*> **host** <*hostname* | *ip address*> **timeout** <*value*>

Each parameter after <hostname | ip address> specifies the characteristics of the individual RADIUS server. Parameters can be entered in a single command line, in any order, but each may only be used once.

Syntax Description

<*hostname* | *ip address*>	Specifies the server to configure. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). If a host name is used, a domain naming system (DNS) server should be learned by the AOS device using Dynamic Host Configuration Protocol (DHCP), Point-to-Point Protocol (PPP), or specified in the Global Configuration mode with the command *name-server on page 1622*.
acct-port <*port*>	Specifies the User Datagram Protocol (UDP) port used by the AAA accounting server. Port range is **0** to **65535**. This command is reserved for future use as currently AOS does not allow RADIUS servers for use with AAA accounting.
auth-port <*port*>	Specifies the UDP port used by the AAA authentication server. The port range is **0** to **65535**.
key <*key*>	Specifies the encryption key used by the RADIUS server. This command overrides the global RADIUS key setting (set with the command *radius-server on page 1680*). This command must be entered last in the command line because everything after the **key** parameter is read as the new key.
retransmit <*number*>	Specifies the number of connection attempts made to the server. Attempt range is **1** to **100**.

timeout <*value*>	Specifies the time to wait (in seconds) for this server to reply to requests. Range is **1** to **1000** seconds.
vrf <*name*>	Specifies the name of the VRF to which to assign the association. If no VRF is specified, the association is applied to the default unnamed VRF.

Default Values

By default, **acct-port** is set to **1813** and **auth-port** is set to **1812**. By default, the key, retransmit and timeout values are the values set by the command *radius-server on page 1680*.

Command History

Release 5.1	Command was introduced.
Release R10.7.0	Command was expanded to include the **vrf** <*name*> parameter.

Functional Notes

At a minimum, the address (IP or host name) of the server must be given. The other parameters can be entered in any order (except the **key** parameter) and, if the parameters are not specified, they will take default values or fall back on the global RADIUS server's default settings (set using the command *radius-server on page 1680*).

If global password protection is enabled on the AOS device, encryption will be applied to the authentication key (**key** <*key*>). If global password protection is off, the authentication key will display as clear text. Refer to *service password-encryption on page 1699* for more information

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example specifies that the RADIUS server at IP address **10.10.10.2** uses the global key setting (left unspecified), a timeout value of **10** seconds, the default authorization port (left unspecified), and a retransmit number of **5**:

(config)**#radius-server host 10.10.10.2 retransmit 5 timeout 10**

The following example specifies that the RADIUS server at IP address **10.10.10.2** on VRF **RED**, uses the global key setting (left unspecified), a timeout value of **10** seconds, the default authorization port (left unspecified), and a retransmit number of **5**:

(config)**#radius-server vrf RED host 10.10.10.2 retransmit 5 timeout 10**

resource-utilization

Use the **resource-utilization** command to set a threshold limit for CPU or heap utilization notifications. When the utilization threshold is surpassed, a resource trap is sent. Use the **no** form of this command to remove the threshold setting. Variations of this command include:

resource-utilization cpu threshold <*percentage*> **time-interval** <*value*>
resource-utilization heap threshold <*percentage*>

Syntax Description

cpu	Sets the threshold for CPU utilization notification.
heap	Sets the threshold for heap utilization notification.
threshold <*percentage*>	Specifies the threshold limit as a percentage of resource utilization. Valid range is **1** to **100** percent.
time-interval <*value*>	Specifies the time interval for the actual utilization to exceed the threshold before a notification is sent. Valid range is **1** to **86400** seconds.

Default Values

By default, there are no thresholds configured.

Command History

Release A2.04	Command was introduced.

Functional Notes

Simple Network Management Protocol (SNMP) resource traps must be enabled before exceeded threshold notifications are sent. Refer to *snmp-server enable traps on page 1792*.

Usage Examples

The following example configures the CPU resource notification to be sent when the CPU usage maintains at least 75 percent utilization for 40 seconds:

(config)**#resource-utilization cpu threshold 75 time-interval 40**

restricted boot

Use the **restricted boot** command to restrict issuing specific bootcode commands. Refer to the *Functional Notes* below. Use the **no** form of this command to disable the feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release R11.4.0	Command was introduced.
Release R12.1.0	Command was made unavailable for virtual AOS (vAOS) instances.

Functional Notes

Once enabled, the restricted boot feature will prohibit a user from performing any of the following functions in bootcode:

- Bypass password option
- Bypass startup-config option
- Erase or overwrite individual files
- Copy files from flash

*The **erase file-system** and **erase *** commands are both allowed for unit recovery even when **restricted boot** is enabled.*

This command is not available in vAOS instances.

Usage Examples

The following example enables the restricted boot feature:
(config)**#restricted boot**

rtcp

Use the **rtcp** command to enable sending Realtime Transport Control Protocol (RTCP) sender reports to improve interoperation with other network equipment. The RTCP Sender Report is sent at periodic intervals when when RTP is being received. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, RTCP sender reports are disabled.

Command History

Release R11.7.0	Command was introduced.

Functional Notes

RTCP sender reports are sent for the following call scenarios:

- Session Initiation Protocol (SIP) to foreign exchange station (FXS)
- SIP to foreign exchange office (FXO)
- SIP to T1 (primary rate interface (PRI) and robbed-bit signaling (RBS))

For SIP to SIP calls, RTCP sender reports are passed through the unit unmodified.

For all supported products, the RTCP port number is the next odd port number following the even Realtime Transport Protocol (RTP) port number.

If, during a call, RTP is not being sent (i.e., RTP is receive-only), then a sender report is sent instead of a receiver report as described in RFC 3550.

Usage Examples

The following example enables the sending of RTCP sender reports:

```
(config)#rtcp
```

route-map

Use the **route-map** command to create a route map and enter the Route Map Configuration command set. A route map is a type of filter that matches various attributes and then performs actions on the way the route is redistributed. Use the **no** form of this command to delete a route map. Variations of this command include:

route-map <*name*> <*number*>
route-map <*name*> **deny** <*number*>
route-map <*name*> **permit** <*number*>

Syntax Description

<*name*>	Specifies a name for the route map.
deny	Specifies not to redistribute routes matching the route map attributes.
permit	Redistributes routes matching the route map attributes.
<*number*>	Specifies a sequence number of this route entry. Range is **1** to **4294967295**.

Default Values

By default, no route maps are defined.

Command History

Release 9.3	Command was introduced.

Functional Notes

Route maps can be used to filter inbound and outbound routes and to apply attributes to the routes being filtered. A route map applied to outbound data determines how the router advertises routes to a neighbor. The **outbound** route map can be configured to perform such tasks as:

- Define the routes that the router can advertise according to specified attributes or prefixes.
- Prepend private AS numbers to specific routes to help balance inbound traffic.
- Set an MED on specific routes to help balance inbound traffic.
- Request that the neighbor advertise the route to certain communities only.
- When a route map is applied to inbound data, it determines which of the service provider advertised routes the local router accepts.

The **inbound** route map can be configured to perform such tasks as:

- Filter external routes according to specified attributes or prefixes
- Apply attributes to filtered routes, including:
  - Local preference
  - Community
  - MED value
  - Prepended AS path
- Delete communities defined for the routes

The route map itself is created first. Matching criteria and attributes are defined within the route map configuration menu. Once a route map has been established, it can be assigned to a BGP neighbor.

Match and set commands used for filtering and defining attributes are found in the *Route Map Command Set on page 4168*.

Usage Examples

The following example creates the route map, specifies that routes matching its criteria will be denied, and assigns a sequence number of 100:

(config)**#route-map MyMap deny 100**
(config-route-map)#

You can then define the attributes of the route map from the Route Map Configuration command set. Enter a **?** at the **(config-route-map)#** prompt to explore the available options.

router bgp *<value>*

Use the **router bgp** command to enable BGP and enter the BGP Configuration mode. Refer to the *BGP Command Set on page 3981* for more information. Use the **no** form of this command to disable Border Gateway Border (BGP) routing.

Syntax Description

<value>	Specifies the AS number of the local system of which this BGP router is a member. Range is **1** to **4294967295**.

Default Values

By default, BGP is disabled.

Command History

Release 10.1	Command was introduced.
Release 18.1	Command was altered to support 4-byte AS numbers (previously AOS only supported 2-byte numbers).

Functional Notes

The AS number of the local system of which this BGP router is a member must always be entered with this command, even when re-entering BGP Configuration mode after BGP has already been activated on the router.

Usage Examples

The following example uses the **router bgp** command to enable BGP and enter the BGP Configuration mode:

```
(config)#router bgp 100
(config-bgp)#
```

router ospf *<process id>*

Use the **router ospf** command to activate Open Shortest Path First version 2 (OSPFv2) in the router and to enter the OSPF Configuration mode. This command creates a new OSPFv2 process, or allows you to edit a previously configured OSPFv2 process. Refer to the *Router OSPFv2 Command Set on page 4120* for more information. Use the **no** form of this command to remove the OSPFv3 process and all of its settings at both the global and interface level. Variations of this command include:

router ospf
router ospf *<process id>*
router ospf *<process id>* **vrf** *<name>*

Syntax Description

<process id>	Specifies a process ID for the OSPFv2 process. These IDs must be unique among all other OSPFv2 processes on the device. Valid ID range is **1** to **65535**.
vrf *<name>*	Optional. Specifies a nondefault virtual routing and forwarding (VRF) instance on which to create the OSPFv2 process. If no VRF is specified, the process is created on the default (unnamed) VRF.

Default Values

By default, OSPF is disabled.

Command History

Release 3.1	Command was introduced.
Release R11.3.0	Command was expanded to include the *<process id>* and **vrf** *<name>* parameters.

Functional Notes

AOS can be configured to use OSPF with the firewall enabled (using the **ip firewall** command). To do this, configure the OSPF networks as usual, specifying which networks the system will listen for and broadcast OSPF packets to. Refer to *ip firewall on page 1367* for more information.

To apply stateful inspection to packets coming into the system, create a policy class that describes the type of action desired and then associate that policy class to the particular interface (refer to *ip policy-class <ipv4 acp name> on page 1434*). The firewall is intelligent and will only allow OSPF packets that were received on an OSPF configured interface. No modification to the policy class is required to allow OSPF packets into the system.

Usage Examples

The following example uses the **router ospf** command to enter the OSPF Configuration mode:

(config)#**router ospf 1**

router ospfv3 <*process id*>

Use the **router ospfv3** command to enable Open Shortest Path First version 3 (OSPFv3), create an OSPFv3 process, and enter the router's OSPFv3 Configuration mode. This command creates a new OSPFv3 process, or allows you to edit a previously configured OSPFv3 process. Use the **no** form of this command to remove the OSPFv3 process and all of its settings at both the global and interface level. Variations of this command include:

router ospfv3 <*process id*>
router ospfv3 <*process id*> **vrf** <*name*>

Syntax Description

<*process id*>	Specifies a process ID for the OSPFv3 process. These IDs must be unique among all other OSPFv3 processes on the device. Valid ID range is **1** to **65535**.
vrf <*name*>	Optional. Specifies a nondefault virtual routing and forwarding (VRF) instance on which to create the OSPFv3 process. If no VRF is specified, the process is created on the default (unnamed) VRF.

Default Values

By default, no OSPFv3 processes or process IDs exist.

Command History

Release R10.5.0	Command was introduced.
Release R10.8.0	Command was expanded to include the **vrf** parameter.

Functional Notes

For more information about commands available in the OSPFv3 Configuration mode, refer to *Router OSPFv3 Command Set on page 4141*.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring OSPFv3 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables OSPFv3, creates the OSPFv3 process **5**, and enters the OSPFv3 Configuration mode:

```
(config)#router ospfv3 5
(config-ospfv3)#
```

router pim-sparse

Use the **router pim-sparse** command to globally enable protocol-independent multicast (PIM) on the unit and to enter the PIM Sparse Configuration mode. Use the **no** form of this command to disable PIM Sparse routing. Refer to the *Router PIM Sparse Command Set on page 4201* for more information on the subcommands for PIM Sparse Configuration mode.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Functional Notes

Additional commands for PIM are found in the related interface configuration modes. Refer to the **ip pim-sparse** commands in sections such as *Ethernet Interface Command Set on page 2156*, *Frame Relay Subinterface Command Set on page 2748*, *HDLC Interface Command Set on page 2888*, *Loopback Interface Command Set on page 2968*, *PPP Interface Command Set on page 3060*, *Tunnel Interface Command Set on page 3211*, and *VLAN Interface Command Set on page 3370* for more information.

Usage Examples

The following example uses the **router pim-sparse** command to enter the PIM Sparse Configuration mode:

```
(config)#router pim-sparse
(config-pim-sparse)#
```

router rip

Use the **router rip** command to enter the RIP Configuration mode. Use the **no** form of this command to disable Routing Information Protocol (RIP) routing. Refer to the *Router RIP Command Set on page 4205* for more information.

Syntax Description

No subcommands.

Default Values

By default, RIP is disabled.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example uses the **router rip** command to enter the RIP Configuration mode:

```
(config)#router rip
(config-rip)#
```

Technology Review

The RIP protocol is based on the Bellham-Ford (distance-vector) algorithm. This algorithm provides that a network will converge to the correct set of shortest routes in a finite amount of time, provided that:

Gateways continuously update their estimates of routes.

Updates are not overly delayed and are made on a regular basis.

The radius of the network is not excessive.

No further topology changes take place.

RIP is described in RFC 1058 (Version 1) and updated in RFCs 1721, 1722, and 1723 for Version 2. Version 2 includes components that ease compatibility in networks operating with RIP V1.

All advertisements occur on regular intervals (every 30 seconds). Normally, a route that is not updated for 180 seconds is considered dead. If no other update occurs in the next 60 seconds for a new and better route, the route is flushed after 240 seconds. Consider a connected route (one on a local interface). If the interface fails, an update is immediately triggered for that route only (advertised with a metric of 16).

Now consider a route that was learned and does not receive an update for 180 seconds. The route is marked for deletion, and even if it was learned on an interface, a poisoned (metric equals 16) route should be sent by itself immediately and during the next two update cycles with the remaining normal split horizon update routes. Following actual deletion, the poison reverse update ceases. If an update for a learned route is not received for 180 seconds, the route is marked for deletion. At that point, a 120-second garbage collection (GC) timer is started. During the GC timer period, expiration updates are sent with the metric for the timed-out route set to 16.

If an attached interface goes down, the associated route is immediately (within the same random five-second interval) triggered. The next regular update excludes the failed interface. This is the so-called first hand knowledge rule. If a gateway has first hand knowledge of a route failure (connected interfaces) or reestablishment, the same action is taken. A triggered update occurs, advertising the route as failed (metric equals 16) or up (normal metric) followed by the normal scheduled update.

The assumption here is that if a gateway missed the triggered update, it will eventually learn from another gateway in the standard convergence process. This conserves bandwidth.

RIP-Related Definitions:

Route	A description of the path and its cost to a network.
Gateway	A device that implements all or part of RIP (a router).
Hop	A metric that provides the integer distance (number of intervening gateways) to a destination network gateway.
Advertisement	A broadcast or multicast packet to port 520 that indicates the route for a given destination network.
Update	An advertisement sent on a regular 30-second interval, including all routes exclusive of those learned on an interface.

schedule <*name*>

Use the **schedule** command to create a general-purpose schedule. Use the **no** form of this command to delete a schedule. Variations of this command include:

schedule <*name*>

Additional subcommands are available once you have entered the Schedule Configuration mode:

absolute start <*schedule*> **end** <*schedule*>
periodic <*day*> **[**<*time*> **to** <*time*>**]**
periodic <*day*> <*time*> **to** <*day*> <*time*>
periodic <*day*> **[**<*time*> **for** <*duration*>**]**
periodic <*day*> <*time*> **for** <*duration*>
periodic <*time*> **for** <*duration*> <*day*>
periodic daily <*time*> **to** <*time*>
periodic daily <*time*> **for** <*duration*>
periodic weekday <*time*> **to** <*time*>
periodic weekday <*time*> **for** <*duration*>
periodic weekend <*time*> **to** <*time*>
periodic weekend <*time*> **for** <*duration*>
relative start-after <*delay*>

Syntax Description

<*name*>	Specifies the name of the schedule.
absolute start end	Indicates the schedule's **start** and **end** time and date values.
<*schedule*>	Specifies the start and end schedules. Schedules are expressed in the format <*time*> <*day*> <*month*> <*year*> (for example, **08:15 2 February 2007**).
<*time*>	Time is expressed in the 24-hour format hours:minutes (HH:MM) (for example, **08:15**).
<*day*>	The day of the month is expressed with a number. Range is 1 to 31.
<*month*>	The name of the month can be spelled out or abbreviated.
<*year*>	The year is expressed in the format YYYY (for example, **2007**).
periodic	Specifies the weekly behavior of the schedule by configuring start/end days, times, and duration.
to	Specifies the schedule's start/end day and time.
for <*duration*>	Specifies the schedule's duration. Duration is expressed in the 24-hour format hours:minutes (HH:MM).
daily	Optional. Specifies recurring period to be every day of the week.
weekday	Optional. Specifies recurring period to be Monday through Friday.
weekend	Optional. Specifies recurring period to be Saturday and Sunday.
<*time*>	Time is expressed in the 24-hour format hours:minutes (HH:MM) (for example, **08:15**).

<*day*>	The day of the week can be spelled out or abbreviated.
relative start-after <*delay*>	Specifies the time delay before the schedule becomes active. Valid range is **1** to **65535** seconds.

Default Values

By default, no schedules exist.

Functional Notes

Periodic schedules can be expressed in the format <*day*> <*time*> to <*day*> <*time*> (for example, **periodic monday 08:15 to wednesday 17:15**), or up to 7 days can be entered (for example, **periodic tuesday wednesday thursday 08:15 to 17:15**).

Command History

Release 14.1	Command was introduced.
Release 15.1	Command was expanded.
Release 16.1	Command was expanded to include the **for** parameter.

Usage Examples

The following example creates a schedule **Closed** and enters the Schedule Configuration mode:

(config)**#schedule Closed**
(config-schedule-Closed)#

The following example sets the start time in the schedule named **Closed** to 8:15 a.m. on February 2, 2007, and sets the end time to 10:15 a.m. on April 2, 2007:

(config-schedule-Closed)**#absolute start 08:15 2 february 2007 end 10:15 2 april 2007**

The following example sets the recurring start and end day and time in the schedule named **Closed** to Saturday from 8:15 a.m. to 5:15 p.m.:

(config-schedule-Closed)**#periodic saturday 08:15 to 17:15**

The following example sets the execution delay for the schedule named **Closed** to **30** seconds:

(config-schedule-Closed)**#relative start-after 30**

The following example sets the duration for the schedule named **Closed** to **30** minutes at 1:00 p.m. every day of the week:

(config-schedule-Closed)**#periodic daily 13:00 for 00:30**

sdp grammar hold

Use the **sdp grammar hold** command to specify how to format hold messages in Session Description Protocol (SDP) announcements. Use the **no** form of this command to return to the default value. Variations of this command include the following:

sdp grammar hold rfc2543
sdp grammar hold rfc3264

Syntax Description

rfc2543	Specifies the use of RFC 2543 for formatting hold messages.
rfc3264	Specifies the use of RFC 3264 for formatting hold messages.

Default Values

By default, RFC 2543 is used for formatting hold messages.

Command History

Release 12.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example specifies to use RFC 3264 to format hold messages:

(config)**#sdp grammar hold rfc3264**

sdp grammar ptime

Use the **sdp grammar ptime** command to specify which packet times to send in Session Description Protocol (SDP) announcements. Use the **no** form of this command to return to the default value. Variations of this command include the following:

sdp grammar ptime explicit
sdp grammar ptime implicit

Syntax Description

explicit	Specifies sending all packet times.
implicit	Specifies sending only packet times of **10** and **30** ms.

Default Values

By default, implicit packet times are sent.

Command History

Release A4.01	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example specifies sending **explicit** packet times:

(config)**#sdp grammar ptime explicit**

service password-encryption

Use the **service password-encryption** command to turn on global password protection. Use the **no** form of this command to return to the default setting.

If you need to go back to a previous revision of the code (e.g., AOS Revision 10), this command must be disabled first. Once the service is disabled, all necessary passwords must be re-entered so that they are in the clear text form. If this is not done properly, you will not be able to log back in to the unit after you revert to a previous revision that does not support password encryption.

Syntax Description

No subcommands.

Default Values

By default, global password protection is disabled.

Command History

Release 11.1	Command was introduced.

Functional Notes

When enabled, all currently configured passwords are encrypted. Also, any new passwords are encrypted after they are entered. Password encryption is applied to all passwords, including passwords for user name, Enable mode, Telnet/console, Point-to-Point Protocol (PPP), Border Gateway Protocol (BGP), and authentication keys. When passwords are encrypted, unauthorized persons cannot view them in configuration files since the encrypted form of the password is displayed in the running-config. While this provides some level of security, the encryption method used with password encryption is not a strong form of encryption so you should take additional network security measures.

You cannot recover a lost encrypted password. You must erase the startup-config and set a new password.

Usage Examples

The following example enables password encryption for all passwords on the unit:

(config)**#service password-encryption**

sfp trap threshold alarm time-interval <*value*>

Use the **sfp trap threshold alarm time-interval** command to set the polling interval for monitoring the sfp alarm thresholds. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the minimum polling interval in seconds. Valid range is from **1** to **86400** seconds.

Default Values

By default, the alarm polling interval is **300** seconds.

Command History

Release 13.3.0	Command was introduced.

Usage Examples

The following example configures the sfp trap threshold alarm polling interval to 600 seconds:

(config)**#sfp trap threshold alarm time-interval 600**

shaper <*name*>

Use the **shaper** command to create an Ethernet virtual connection (EVC) rate shaper and enter the shaper configuration mode. Use the **no** form of this command to remove the shaper. Variations of this command include:

shaper <*name*>
shaper <*name*> <*slot*>

Syntax Description

<*name*>	Specifies the name of the rate shaper.
<*slot*>	Optional. Specifies the slot to which the rate shaper is applied.

Default Values

By default, no EVC shapers are configured.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example creates an EVC rate shaper named **Shaper1** on slot **0**:

(config)**#shaper Shaper1 0**

Technology Review

Rate shaping is a mechanism designed to smooth out bursts of traffic. Unlike a policer, which discards large bursts of traffic, a shaper is able to delay bursts. The port shaper uses a token bucket, much like a policer, however when large bursts are received, the packets are queued rather than being discarded immediately. When a packet arrives at the shaper, if there are sufficient tokens available, the packet is transmitted without delay. If there are insufficient tokens in the bucket, the packet is delayed until there are enough tokens in the bucket to allow transmission. The benefit of a shaper is that it will not drop frames with a small burst of traffic, but it does add latency. The benefit of a policer is that it does not add latency while protecting the network, but does drop any traffic that exceeds the burst capacity. Selecting one over the other is dependent on the latency and/or loss tolerance of the data. Rate shapers are much friendlier to Transmission Control Protocol (TCP) traffic flows than policers. A small delay in latency leads to better TCP Goodput than large losses of traffic that can force TCP to revert to Slow Start. Traffic may still be discarded due to the queue congestion management strategy employed.

sip

Use the **sip** command to enable the AOS Session Initiation Protocol (SIP) stack and to specify the protocol and port used by the SIP stack. When the SIP stack is enabled, memory is allocated for SIP functionality. Use the **no** form of this command to disable the SIP stack and free the memory allocated to the stack. Variations of this command include:

sip
sip tcp
sip tcp <*port*>
sip udp
sip udp <*port*>
sip vrf <*name*>

Syntax Description

tcp	Optional. Specifies that the SIP stack operates using Transmission Control Protocol (TCP).
udp	Optional. Specifies that the SIP stack operates using User Datagram Protocol (UDP).
<*port*>	Optional. Specifies the TCP or UDP port used by the SIP stack. Range is **1** to **65535**.
vrf <*name*>	Optional. Enables the SIP stack on the specified nondefault virtual routing and forwarding (VRF) instance.

Default Values

By default, the SIP stack is enabled on AOS voice products and disabled on AOS data products. The SIP stack operates using UDP on port **5060** if no protocol or port are specified. If a protocol is specified, but no port is specified, the SIP stack uses port **5060**.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was expanded to include the **tcp**, **udp**, and <*port*> parameters.
Release R10.5.0	Command was expanded to include the **vrf** parameter.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

By default, the AOS SIP application layer gateway (ALG) is enabled. This ALG allows the firewall to examine all SIP packets it identifies and to maintain information of SIP transmissions on the network based on the SIP header. The SIP ALG requires the use of the SIP stack and the SIP proxy server in order to properly route SIP calls and maintain the SIP information. For more details on the operation of SIP and the SIP ALG, refer to the command *ip firewall alg on page 1373*.

For proper SIP operation, the firewall must also be configured to allow for dynamic holes for the Realtime Transfer Protocol (RTP) and the Realtime Transfer Control Protocol (RTCP) traffic associated with SIP calls between user agents. This functionality must be manually enabled. For more details on enabling this functionality, refer to the command *ip rtp firewall-traversal on page 1456*.

The SIP stack is used for many AOS features, including Transparent Proxy and Voice Quality Monitoring (VQM) Reporting. Refer to the configuration guides available online at https://supportcommunity.adtran.com for more information about SIP operation with specific features.

Usage Examples

The following example enables the SIP stack and specifies that the stack operates using TCP:

(config)**#sip tcp**

sip access-class <*name*> in

Use the **sip access-class in** command to limit the traffic allowed to reach the Session Initiation Protocol (SIP) stack by applying access control lists (ACLs) to incoming connections. Use the **no** form of this command to disable this feature. Variations of this command include:

sip access-class ip <*name*> **in**
sip access-class ipv6 <*name*> **in**

Syntax Description

ip	Specifies an Internet Protocol version 4 (IPv4) ACL.
ipv6	Specifies an Internet Protocol version 6 (IPv6) ACL.
<*name*>	Specifies the name of a previously configured ACL to apply to incoming traffic.

Default Values

By default, no ACL is configured or applied, and all traffic reaches the SIP stack.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to relocate the **ip** keyword and add the **ipv6** keyword.

Functional Notes

The **sip access-class in** command can be entered multiple times to apply multiple ACLs to incoming traffic to the SIP stack.

For more information regarding ACL configuration, refer to the *IPv4 Access Control List Command Set on page 4252* and *IPv6 Access Control List Command Set on page 4296*.

Usage Examples

The following example specifies an IPv4 SIP ACL name of **HSV**:

(config)**#sip access-class ip HSV in**

sip authenticate

Use the **sip authenticate** command to enable the Session Initiation Protocol (SIP) server authentication. Use the **no** form of this command to disable the feature.

Syntax Description

No subcommands.

Default Values

By default, the SIP server authentication is disabled.

Command History

Release 9.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example enables the SIP server authentication:

(config)**#sip authenticate**

sip database local

Use the **sip database local** command to store the location database of Session Initiation Protocol (SIP) user agents (UAs) across a power loss using memory on the local router. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 11.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example specifies storing the location database on the local router:

(config)**#sip database local**

sip default-call-routing

Use the **sip default-call-routing** command to specify the method used to route a call in the internal transaction distribution unit (TDU) when the destination of a call is ambiguous. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip default-call-routing proxy
sip default-call-routing reject
sip default-call-routing switchboard

Syntax Description

proxy	Specifies that the call is routed to a proxy server.
reject	Specifies that the call is rejected.
switchboard	Specifies that the call is routed to an internal switchboard.

Default Values

By default, the call routing method is **proxy**.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

The **sip default-call-routing** command is applicable to AOS voice products only. This command is not available on AOS data products.

Usage Examples

The following example specifies that calls are routed to an internal switchboard:

(config)**#sip default-call-routing switchboard**

sip grammar

Use the **sip grammar** command to populate privacy lists, indicating how caller ID is handled. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip grammar default-privacy critical
sip grammar default-privacy header
sip grammar default-privacy none
sip grammar default-privacy session
sip grammar default-privacy user
sip grammar restricted-privacy critical
sip grammar restricted-privacy header
sip grammar restricted-privacy none
sip grammar restricted-privacy session
sip grammar restricted-privacy user

Syntax Description

default-privacy	Specifies entries into the default-privacy list for unrestricted caller ID calls.
restricted-privacy	Specifies entries into the restricted-privacy list for restricted caller ID calls.
critical	Adds critical to the Privacy header format. At least one other entry must be added to the list when using this setting.
header	Adds header to the Privacy header format.
none	Adds none to the Privacy header format. No other entries can be added to the list when using this setting.
session	Adds session to the Privacy header format.
user	Adds user to the Privacy header format.

Default Values

By default, both privacy lists are empty.

Command History

Release 13.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example sets all calls to have session privacy:

(config)**#sip grammar default-privacy session**

sip grammar alert-info url *<url>*

Use the **sip grammar alert-info url** command to specify the Alert-Info header host in outbound Session Initiation Protocol (SIP) messages. Use the **no** form of this command to return to the default setting.

Syntax Description

<url>	Specifies an Hypertext Transfer Protocol (HTTP) uniform resource locator (URL) to be used in the Alert-Info header for IP phone tone.

Default Values

By default, the local loopback address is the host in the Alert-Info header (127.0.0.1).

Command History

Release 13.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example sets the Alert-Info header to use a specific URL as shown in the sample header below:

(config)**#sip grammar alert-info url www.notused.com**

Sample header:

Alert-Info:<http://www.notused.com>;info=alert-internal

sip grammar contact host local

Use the **sip grammar contact host local** command to configure the Contact header on Session Initiation Protocol (SIP) messages. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip grammar contact host local
sip grammar contact host local fqdn

Syntax Description

host local	Specifies that the local IP is used in the SIP Contact header.
fqdn	Optional. Specifies that a fully qualified domain name (FQDN) is used in the SIP Contact header.

Default Values

By default, SIP Contact headers use a local IP.

Command History

Release R13.11.0	Command was introduced.

Usage Examples

The following example specifies that AOS device should use a FQDN in the Contact header of SIP messages:

(config)**#sip grammar contact host local fqdn**

sip grammar contact host port persistent

Use the **sip grammar contact host port persistent** command to configure the AOS device to use the Transmission Control Protocol (TCP) port from which AOS initiated a Transport Layer Security (TLS) connection in the Contact uniform resource identifier (URI) sent by AOS. Use the **no** form of this command to disable this feature.

Syntax Description

host	Specifies the Contact header Host field setting.
port	Specifies the Contact header host port.
persistent	Specifies that the persistent connection port should be used for the Contact header host port.

Default Values

No default values are necessary for this command.

Command History

Release R11.5.0	Command was introduced

Functional Notes

This configuration is useful when using client-only authentication. With this type of authentication, a persistent connection is established to the SIP server. Many SIP servers and enterprise session border controllers (eSBCs) need to see the TCP port from which AOS initiated the TLS connection in the Contact URI sent by AOS.

Usage Examples

The following example specifies that AOS device should use the TCP port from which AOS initiated the TLS connection in the Contact URI sent by AOS:

(config)**#sip grammar contact host port persistent**

sip grammar from

Use the **sip grammar from** command to configure the From header on Session Initiation Protocol (SIP) messages. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip grammar from host domain
sip grammar from host local
sip grammar from host local fqdn
sip grammar from host override registered-users domain
sip grammar from host override registered-users local
sip grammar from host override registered-users sip-server
sip grammar from host sip-server
sip grammar from user domestic
sip grammar from user domestic <*Txx*>
sip grammar from user international
sip grammar from user international <*Txx*>

Syntax Description

host	Specifies the Host field formatting.
domain	Specifies the Domain for formatting the header.
local	Specifies the Local IP for formatting the header.
fqdn	Optional. Specifies a fully qualified domain name (FQDN) is used for formatting the header.
override registered-users	Overrides the current **sip grammar from host** setting for SIP messages originating from registered users.
sip-server	Specifies the SIP server for formatting the header.
user	Specifies the User field formatting.
domestic	Sends the number as specified by the calling party.
international	Sends the number with E.164 formatting.
<*Txx*>	Optional. Indicates a two-digit trunk identifier (i.e., T01).

Default Values

By default, the host for formatting messages is **sip-server**. Also, the default for the user format is **domestic**.

Command History

Release 11.1	Command was introduced.
Release 13.1	Command was expanded to include the domestic and international formats for the From User header.
Release A5.01	Command was expanded to include the **override registered-users** parameter.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Release R13.11.0	Command was expanded to include the **fqdn** parameter.

Functional Notes

Omitting the trunk option when issuing the **sip grammar from user** command specifies the User header globally.

Usage Examples

The following example sets the From header format to use a local IP:

(config)**#sip grammar from host local**

The following example sets the From header format to use calling party format on trunk **T02**:

(config)**#sip grammar from user domestic T02**

Technology Review

This technology review provides information about the E.164 recommendation for International numbering plans and telephone number formats.

A fully specified telephone number can have a maximum of 15 digits, including country code, area code, and the subscriber's number. These numbers usually consist of a + prefix. E.164 numbers exclude dialing prefixes. The most familiar prefixes are international direct dialing (IDD) and national direct dialing (NDD). In countries other than the USA, the IDD and NDD are represented by different numbers.

Additionally, E.123 describes the use of + to indicate a fully specified international number. The + is used in SIP headers to provide consistency across national and international phone calls.

AOS products provide support for E.164 by being able to specify a country code and an IDD prefix. National format telephone numbers are converted to international format by prefixing them with + and the country code. On outbound international calls, + is substituted for the IDD. On incoming international calls, the + is removed. If the country code matches the configured value, it too is removed.

*Setting the From header to **international** will cause phone numbers to be formatted as indicated by E.164. The country code must be configured, and the number must be of type **national** for this feature to work successfully.*

sip grammar p-asserted-identity host

Use the **sip grammar p-asserted-identity host** command to enable and format the private extensions to Session Initiation Protocol (SIP) for asserted identity within trusted networks. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip grammar p-asserted-identity host domain
sip grammar p-asserted-identity host local
sip grammar p-asserted-identity host local fqdn
sip grammar p-asserted-identity host sip-server

Syntax Description

domain	Specifies the domain host for formatting the header.
local	Specifies the local IP as host for formatting the header.
fqdn	Optional. Specifies a fully qualified domain name (FQDN) is used for formatting the header.
sip-server	Specifies the SIP server as host for formatting the header.

Default Values

By default, the host for formatting messages is **sip-server**.

Command History

Release 13.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.
Release R13.11.0	Command was expanded to include the **fqdn** parameter.

Usage Examples

The following example sets the P-Asserted-Identity to use a local IP:

(config)**#sip grammar p-asserted-identity host local**

sip grammar p-early-media supported

Use the **sip grammar p-early-media supported** command to enable sending a P-Early-Media header with a value of "supported" in Session Initiation Protocol (SIP) INVITE, PRACK, and UPDATE requests. Use the **no** form of this command to disable the early media detection feature.

Syntax Description

No subcommands.

Default Values

By default, sending of the P-Early-Media header is disabled.

Command History

Release 13.6.0	Command was introduced.

Functional Notes

Support for sending the P-Early-Media header can be configured globally, using the **sip grammar p-early-media supported** command described here, or it can be configured on a per-trunk basis, using the command *grammar p-early-media supported on page 5076*. The trunk setting will always take precedence over the globally configured setting.

Usage Examples

To enable sending the P-Early-Media header, enter the command as follows:

(config)**#sip grammar p-early-media supported**

sip grammar proxy-require privacy

Use the **sip grammar proxy-require privacy** command to add a proxy-require header to Session Initiation Protocol (SIP) message packets containing a privacy header. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release 13.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example allows a proxy-require header to be added to packets containing a privacy header:

(config)**#sip grammar proxy-require privacy**

sip grammar refer-to

Use the **sip grammar refer-to** command to configure the Session Initiation Protocol (SIP) Refer-To header on intratrunk attended transfers. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip grammar refer-to intratrunk-attended-transfer source contact
sip grammar refer-to intratrunk-attended-transfer source to-from

Syntax Description

intratrunk-attended-transfer source	Configures the source for Refer-To header of an intratrunk attended transfer.
contact	Specifies the Contact header as the source for the Refer-To header.
to-from	Specifies either the To or From header as the source for Refer-To header.

Default Values

By default, the To or From header is the source for the Refer-To header on intratrunk attended transfers.

Command History

Release A5.01	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example specifies the Contact header as the source for the Refer-To header of an intratrunk attended transfer:

(config)**#sip grammar refer-to intratrunk-attended-transfer source contact**

sip grammar request-uri

Use the **sip grammar request-uri** command to format the Request uniform resource identifier (URI) for Session Initiation Protocol (SIP) messages. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip grammar request-uri host domain
sip grammar request-uri host sip-server
sip grammar request-uri host-resolve
sip grammar request-uri transmit-network-selection <*parameter name*>

Syntax Description

host domain	Specifies the domain for formatting the header.
host sip-server	Specifies the SIP server IP for formatting the header.
host-resolve	Enables the local unit to resolve the domain before resolving the request URI.
transmit-network-selection <*parameter name*>	Specifies that Transmit Network Selection is included in the request URI.

Default Values

By default, the host for formatting messages is the SIP server. Also by default, **host-resolve** is disabled.

Command History

Release 11.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.
Release R13.8.0	Command was expanded to include the **transmit-network-selection** parameter.

Usage Examples

The following example enables SIP messages to resolve the request URI from the host domain:

(config)**#sip grammar request-uri host domain**

The following example enables SIP messages to resolve the request URI from the local unit:

(config)**#sip grammar request-uri host-resolve**

sip grammar require 100rel

Use the **sip grammar require 100rel** command to add **100rel** to the Require header of a Session Initiation Protocol (SIP) provisional response. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, **sip grammar require 100rel** is disabled.

Command History

Release 15.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

This command enables or disables the sending of reliable provisional responses to clients that *support* 100rel. Reliable provisional responses will always be sent to clients that *require* 100rel even with **sip grammar require 100rel** disabled.

Usage Examples

The following example enables **sip grammar require 100rel**:

(config)**#sip grammar require 100rel**

Technology Review

There are two Require headers that may use the 100rel tag, one in the initial request, and one in the provisional response.

The user agent client (UAC) is used to initiate SIP requests. When the UAC creates a new request, it can require reliable provisional responses for that request by adding the option tag 100rel to the Require header of that request.

The user agent server (UAS) contacts the user when SIP requests are received, and returns responses on behalf of the user, using provisional responses for request progress information. Provisional responses (100 to 199) are transmitted on a best-effort basis. By using reliable provisional responses, responses are sent by the UAS until they are acknowledged as received. This is especially beneficial when sending provisional responses over an unreliable transport, such as User Datagram Protocol (UDP).

The UAS must send any non-100 provisional responses reliably if the initial request contained a Require header field with the option tag 100rel. If the UAS is unwilling to do so, it must reject the initial request with a Bad Extension message and include an Unsupported header field containing the option tag 100rel. If the client *supports* 100rel, the UAS has the *option* of sending provisional responses with or without the Require 100rel tag as instructed by the **sip grammar require 100rel** command.

sip grammar supported 100rel

Use the **sip grammar supported 100rel** command to include 100rel in the supported header of the Session Initiation Protocol (SIP) message. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, **sip grammar supported 100rel** is disabled.

Command History

Release 14.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example enables **sip grammar supported 100rel**:

(config)**#sip grammar supported 100rel**

sip grammar to host

Use the **sip grammar to host** command to format the host format of the To header of a Session Initiation Protocol (SIP) message. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip grammar to host domain
sip grammar to host sip-server

Syntax Description

domain	Specifies the domain for formatting the header.
sip-server	Specifies the SIP server for formatting the header.

Default Values

By default, the host for formatting messages is the SIP server.

Command History

Release 11.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example sets the To header format to use a domain host:

(config)**#sip grammar to host domain**

sip grammar user-agent

Use the **sip grammar user-agent** command to configure the user agent (UA) header format in Session Initiation Protocol (SIP) messages. The UA header can be given the default value for the product, a user-defined value, or no value at all, in which case the UA header is not sent in SIP messages. In addition, other specific values can be included in the UA header. Use the **no** form of this command to return to the default of the product. Variations of this command include the following:

sip grammar user-agent <*word*>
sip grammar user-agent default
sip grammar user-agent include custom-text <*word*>
sip grammar user-agent include firmware-version
sip grammar user-agent include hostname
sip grammar user-agent include serial-number
sip grammar user-agent none

Syntax Description

<*word*>	Specifies a word as a user-defined value to replace the default UA value. Maximum 128 letters.
default	Returns the UA header field to the default value.
include	Specifies that additional information is included in the UA header.
custom-text <*word*>	Specifies that a user-defined value is included in the UA header. Maximum 128 letters.
firmware-version	Specifies that the firmware version is included in the UA header.
hostname	Specifies that the host name is included in the UA header.
serial-number	Specifies that the serial number is included in the UA header.
none	Disables the UA header field resulting in no UA header sent in SIP messages.

Default Values

By default, the UA value is set to the default value of the product.

Command History

Release 15.1	Command was introduced.
Release R10.3.0	Command was expanded to include the **include** parameters.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example removes the UA header field from SIP messages:

(config)**#sip grammar user-agent none**

sip hmr

Use the **sip hmr** command to apply a Session Initiation Protocol (SIP) header manipulation rule (HMR) policy to all SIP traffic on the AOS device. Use the **no** form of this command to remove the HMR policy. Variations of this command include:

sip hmr <*name*> **in**
sip hmr <*name*> **out**

Syntax Description

<*name*>	Specifies the name of the HMR policy to apply to the SIP traffic.
in	Specifies that the HMR policy is applied to ingress SIP traffic.
out	Specifies that the HMR policy is applied to egress SIP traffic.

Default Values

By default, no SIP HMR policies are applied to SIP traffic.

Command History

Release R10.1.0	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

For more information about SIP HMR and its uses and configuration, refer to the configuration guide *Manipulating SIP Headers and Messages in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example adds the HMR policy **MYPOLICY1** to the AOS unit for all inbound SIP traffic:

(config)**#sip hmr MYPOLICY1 in**

sip inbound-trunk-matching

Use the **sip inbound-trunk-matching** command to enable and configure inbound trunk matching. Use the **no** form of this command to return to the default settings. Variations of this command include:

sip inbound-trunk-matching default-trunk <*Txx*>
sip inbound-trunk-matching prefer trunk-routing
sip inbound-trunk-matching require-registration

Syntax Description

default-trunk <*Txx*>	Specifies a trunk to use when matching fails. The trunk is specified in the format Txx (e.g., **T01**).
prefer trunk-routing	Specifies that trunk matches are preferred over users.
require-registration	Indicates that the request uniform resource identifier (URI) user is required to be registered on a trunk.

Default Values

By default, there is no default trunk set and the **require-registration** option is disabled.

Command History

Release A2.03	Command was introduced.
Release A4.01	Command was expanded to include the **prefer trunk-routing** parameter.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example configures AOS to require registration for inbound trunk matching:

(config)**#sip inbound-trunk-matching require-registration**

sip location

Use the **sip location** command to manually add a Session Initiation Protocol (SIP) user agent (UA) to the location database. Use the **no** form of this command to disable this feature. Variations of this command include:

sip location *<username> <ip address>*
sip location *<username> <ip address> <port>*
sip location *<username> <ip address> <port>* **tcp**
sip location *<username> <ip address> <port>* **tcp** *<number>*
sip location *<username> <ip address> <port>* **udp**
sip location *<username> <ip address> <port>* **udp** *<number>*

Syntax Description

<username>	Specifies the user name for the UA being added to the location database.
<ip address>	Specifies the IP address for the UA being added to the location database. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). IPv6 addresses should be expressed in colon hexadecimal notation (for example, **2001:DB8:1::1**).
<port>	Optional. Specifies the port of the UA to add to the database. If no port is specified, default port is **5060**.
tcp	Optional. Specifies the use of Transmission Control Protocol (TCP) for session communication.
udp	Optional. Specifies the use of User Datagram Protocol (UDP) for session communication.
<number>	Optional. Specifies the time in seconds that a user is stored in the database. Range from **0** to **36000**. If no time is specified, default time is zero seconds.

Default Values

By default, this command is disabled.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was expanded to include a choice of transport protocols and expiration time.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example specifies an IPv4 SIP location of **192.33.5.99** for a user named **2001**:

(config)**#sip location 2001 192.33.5.99**

sip prefer double-reinvite

Use the **sip prefer double-reinvite** command to specify globally that Session Initiation Protocol (SIP) double reInvite messages are included in calls in the system. Calls that typically require a double reInvite are forwarded calls from call overage and any attended transfer, and when these calls connect, a double reInvite message is initiated when the feature is enabled. Using the **no** form of this command indicates that double reInvites are not globally preferred. Use the commands *prefer double-reinvite on page 5113* and *prefer reinvite-without-sdp on page 5114* to specify the trunk settings for this feature.

This command should only be issued by advanced users or at the direction of Adtran technical support.

Syntax Description

No subcommands.

Default Values

By default, all calls in the system prefer a double reInvite.

Command History

Release A5.01	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

The **sip prefer double-reinvite** command is used in the Global Configuration mode to determine whether a double reInvite is preferred in calls in the system. By default, the system is configured so that double reInvites are preferred, and all trunk accounts prefer a double reInvite. Double reInvites are used, for example, when a SIP trunk in local transfer mode is providing ring-back during a blind transfer. In this scenario, a double reInvite must occur in order to establish a talk path after the transfer target answers.

You can specify whether a specific trunk prefers a double reInvite by using the command *prefer double-reinvite on page 5113*.

You can also specify whether Session Description Protocol (SDP) is used in the double reInvite message. To send a double reInvite without SDP, refer to the command *prefer reinvite-without-sdp on page 5114*. When a double reInvite is initiated, the first reInvite without SDP is not sent to the account that does not require it. When both accounts do not require a reInvite with SDP, the target account sends the initial reInvite message.

Usage Examples

The following example specifies that SIP double reInvites are not preferred in the system:

(config)**#no sip prefer double-reinvite**

sip privacy

Use the **sip privacy** command to specify outbound calls to include privacy headers (when configured) and inbound calls to be filtered on privacy settings. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, Session Initiation Protocol (SIP) privacy is disabled.

Command History

Release 13.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example enables SIP privacy:

(config)**#sip privacy**

sip proxy

Use the **sip proxy** command to enable Stateful and Outbound modes of Session Initiation Protocol (SIP) proxy operation at the global level. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

Although the **sip proxy** command enables Stateful and Outbound modes of SIP proxy operation, it is also necessary to use this command in conjunction with the **sip proxy transparent** command for transparent proxy mode. For more information about transparent proxy, refer to the command *sip proxy transparent on page 1764*.

For more information about SIP proxy, refer to the *Configuring SIP Proxy in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example allows the SIP proxy server to operate in the Stateful and Outbound modes:

(config)**#sip proxy**

sip proxy allowed-servers <*hostname* | *ip address*>

Use the **sip proxy allowed-servers** command to specify a server to which devices behind the proxy are allowed to send Session Initiation Protocol (SIP) traffic. Use the **no** form of this command to return to the default setting.

Syntax Description

<*hostname* | *ip address*>	Specifies the fully qualified domain name (FQDN) or IP address of the SIP proxy server. IPv4 addresses should be expressed in dotted decimal notation (for example, **208.61.209.1**). IPv6 addresses should be expressed in colon hexadecimal notation (for example, **2001:DB8:1::1**).

Default Values

By default, SIP traffic to any server is allowed in Transparent and Outbound proxy modes. This means that if no server is specified, traffic to any server is permitted, but if this command is entered, only traffic to the configured servers is allowed.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

The **sip proxy allowed-servers** command can be entered multiple times to allow traffic to multiple servers.

Usage Examples

The following example adds the server with an IPv4 address of **10.200.1.9** as an allowed SIP proxy server:

(config)**#sip proxy allowed-servers 10.200.1.9**

sip proxy dial-string source

Use the **sip proxy dial-string source** command to specify the dial-string source for the Session Initiation Protocol (SIP) proxy server. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip proxy dial-string source request-uri
sip proxy dial-string source to

Syntax Description

request-uri	Specifies the Request-URI user field as the dial-string source.
to	Specifies the To header as the dial-string source.

Default Values

By default, the dial-string source is set to **request-uri**.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example sets the To header as the dial-string source:

(config)**#sip proxy dial-string source to**

sip proxy domain *<string>*

Use the **sip proxy domain** command to specify a domain string for Session Initiation Protocol (SIP) proxy messaging. Use the **no** form of this command to return to the default setting.

Syntax Description

<string>	Specifies the domain string for SIP messaging.

Default Values

By default, **sip proxy domain** is not configured.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example specifies **Sample** as the SIP proxy domain string:

(config)**#sip proxy domain Sample**

sip proxy emergency-call-routing

Use the **sip proxy emergency-call-routing** command to first specify the Session Initiation Protocol (SIP) proxy method used to route a call during failover and to then specify the calls that are considered emergency calls for SIP proxy emergency routing. Use the **no** form of this command to disable emergency call routing and to remove the call routing templates. Variations of this command include:

sip proxy emergency-call-routing local
sip proxy emergency-call-routing proxy
sip proxy emergency call-routing accept *<template>*
sip proxy emergency-call-routing reject *<template>*

Syntax Description

local	Specifies that all emergency calls are routed directly through the switchboard.
proxy	Specifies that all emergency calls are routed through the proxy before sending them to the switchboard.
accept *<template>*	Specifies that calls matching the template are accepted as emergency calls. Refer to the Functional Notes section of this command for more information.
reject *<template>*	Specifies that calls matching the template are rejected as emergency calls. Refer to the Functional Notes section of this command for more information.

Default Values

By default, the SIP proxy is set to send all emergency calls directly through the switchboard (the **local** parameter). By default, no emergency number templates or patterns are configured in the system; therefore, no calls are classified as emergency calls.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

Before specifying which calls are defined as emergency calls, you should configure the method used for routing emergency calls (using the **sip proxy emergency-call-routing local** or **sip proxy emergency-call-routing proxy** commands). For the default emergency call routing method (**local**) to function on AOS data products, a local SIP gateway must be configured using the command *sip proxy local-gateway <hostname | ip address> on page 1751*. On AOS voice products, the local SIP gateway is enabled by default.

After the emergency call routing method has been specified, emergency calls must be defined for emergency call routing to perform any action. Emergency call definitions are configured using the **sip proxy emergency-call routing accept** *<template>* and **sip proxy emergency-call-routing reject** *<template>* commands.

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example enables SIP proxy emergency call routing on an AOS voice product and specifies the routing method as **proxy**:

(config)**#sip proxy emergency-call-routing proxy**

The following example specifies a local SIP gateway and enables SIP proxy emergency call routing on an AOS data product:

(config)**#sip proxy local-gateway 10.19.209.55**
(config)**#sip proxy emergency-call-routing local**

The following example specifies that 911 calls are accepted as emergency calls on an AOS voice product:

(config)**#sip proxy emergency-call-routing proxy**
(config)**#sip proxy emergency-call-routing accept 911**

The following example specifies that 911 calls are accepted as emergency calls on an AOS data product:

(config)**#sip proxy local-gateway 10.19.209.55**
(config)**#sip proxy emergency-call-routing local**
(config)**#sip proxy emergency-call-routing accept 911**

sip proxy failover accept-registrations

Use the **sip proxy failover accept-registrations** command to configure the Session Initiation Protocol (SIP) proxy server to accept new registrations when the system is in survivability (failover) mode. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release A2.03	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example enables the server to accept registration during failover conditions:

(config)**#sip proxy failover accept-registrations**

sip proxy failover codec-group <*name*>

Use the **sip proxy failover codec-group** command to specify the Session Initiation Protocol (SIP) proxy server's coder-decoder (CODEC) when the system is in failover mode. Use the **no** form of this command to return to the default setting.

Syntax Description

<*name*>	Specifies the name of a previously created CODEC list to be used during failover.

Default Values

By default, no CODEC list is configured or applied.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

The **sip proxy failover codec-group** command is available on AOS voice products only. This command is not available on AOS data products. For more information regarding CODEC list configuration, refer to the *Voice CODEC List Command Set on page 4893*.

For more information regarding SIP proxy configuration, refer to the *Configuring SIP Proxy in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables the CODEC list named **List1** during failover:

(config)**#sip proxy failover codec-group List1**

sip proxy failover dial-string source

Use the **sip proxy failover dial-string source** command to specify the dial-string source for the Session Initiation Protocol (SIP) proxy server when the system is in survivability (failover) mode. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip proxy failover dial-string source request-uri
sip proxy failover dial-string source to

Syntax Description

request-uri	Specifies the Request-URI user field as the dial-string source.
to	Specifies the To header as the dial-string source.

Default Values

By default, the dial-string source is **request-uri**.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example specifies using the To header for the dial-string source:

(config)**#sip proxy failover dial-string source to**

sip proxy failover direct-inbound

Use the **sip proxy failover direct-inbound** command to allow direct inbound routing of calls to proxy users during failover mode without first routing the call out a Session Initiation Protocol (SIP) trunk. This feature is used when a network configuration does not use a SIP trunk. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, direct inbound call routing is disabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables direct inbound routing of calls during failover:

(config)**#sip proxy failover direct-inbound**

sip proxy failover group match-value <*pattern*> new-value <*pattern*>

Use the **sip proxy failover group match-value new-value** command to enable forking of calls to users registered with unique extensions in survivability (failover) mode. Use the **no** form of this command to return to remove the entry.

The following configurations can lead to unexpected behavior:

- *Matching a valid extension with multiple groups.*
- *Creating a failover group with an existing extension.*

Syntax Description

<pattern>	Specifies a number pattern using either traditional number matching or regular expression matching methods. Refer to the *Functional Notes* below for more information.

Default Values

By default, there are no failover group patterns defined.

Command History

Release R11.6.0	Command was introduced.

Functional Notes

For more information about configuring SIP proxy failover, refer to the *Configuring SIP Proxy in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Both the **match-value** <*pattern*> and the **new-value** <*pattern*> parameters can be defined using traditional number matching and regular expression matching methods. Traditional number matching uses numbers and wildcard variables to enter a pattern.

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

In regular expressions number matching, the match strings are encapsulated by paired */* (slash) symbols. This indicates that the pattern is to be treated as a regular expression. Using regular expressions allows greater flexibility in matching multiple number templates with fewer expressions.

NOTE *AOS is compatible with Perl compatible regular expressions (PCREs). More information on understanding and using regular expressions is available at* http://www.pcre.org.

NOTE *The use of quotation marks in a command syntax, when entering a string is not necessary unless the string requires using a space or* **?***. Using either of these characters outside of quotation marks is interpreted by the CLI as commands and not recognized as part of the string. The use of quotation marks in the following examples are provided to cover all possible user-entered strings. These examples can be entered without the quotation marks and function in the same manner.*

Usage Examples

The following example uses the regular expression number matching method to match a dial string beginning with **5551111.sca** and create a failover group that can be dialed as **5551111**:

(config)**#sip proxy failover group match-value "/^5551111\.sca/" new-value "/5551111/"**

sip proxy failover match-alias <*pattern*> substitute <*pattern*>

Use the **sip proxy failover match-alias substitute** command to configure an alias to match a dial string and substitute the specified pattern. This feature is used to route a survivability call when the Session Initiation Protocol (SIP) proxy is in failover mode. If an INVITE message is directed toward a matching alias, the substitution pattern is evaluated and compared to current proxy users. The first user to match the substitution pattern is selected to receive the SIP message. Use the **no** form of this command to return to the default setting.

Syntax Description

<*pattern*>	Specifies a number pattern using either traditional number matching or regular expression matching methods. Refer to the *Functional Notes* below for more information.

Default Values

By default, there are not match-alias substitutions defined.

Command History

Release A4.05	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

SIP proxy failover occurs using an automatically created trunk contained in AOS's basic configuration. This trunk is a hidden SIP trunk with the same default settings as a regular SIP trunk. For more information about configuring SIP proxy failover, refer to the *Configuring SIP Proxy in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Both the **match-alias** <*pattern*> and the **substitute** <*pattern*> parameters can be defined using traditional number matching and regular expression matching methods. Traditional number matching uses numbers and wildcard variables to enter a pattern.

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

In regular expressions number matching, the match strings are encapsulated by paired **/** (slash) symbols. This indicates that the pattern is to be treated as a regular expression. Using regular expressions allows greater flexibility in matching multiple number templates with fewer expressions.

NOTE

AOS is compatible with Perl compatible regular expressions (PCREs). More information on understanding and using regular expressions is available at http://www.pcre.org.

NOTE

The use of quotation marks in a command syntax, when entering a string is not necessary unless the string requires using a space or **?***. Using either of these characters outside of quotation marks is interpreted by the CLI as commands and not recognized as part of the string. The use of quotation marks in the following examples are provided to cover all possible user-entered strings. These examples can be entered without the quotation marks and function in the same manner.*

Usage Examples

The following example uses the traditional number matching method to match a 7-digit number beginning with **555** and replace it with **5551111**:

(config)**#sip proxy failover match-alias “555XXXX” substitute “5551111”**

The following example uses the regular expression number matching method to match a 7-digit number beginning with **555** and replace it with **5551111**:

(config)**#sip proxy failover match-alias “/555\d{4}/” substitute “/5551111/”**

sip proxy failover match-digits *<value>*

Use the **sip proxy failover match-digits** command to specify the number of least-significant digits of the dial string to match in order to route a surviving call to proxy users during when in failover mode. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the number of digits within a template to match during failover. The valid range is **1** to **255**.

Default Values

By default, the number of **match-digits** is not specified.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

The **sip proxy failover match-digits** command can be entered multiple times.

Session Initiation Protocol (SIP) proxy failover occurs using an automatically created trunk contained in AOS's basic configuration. This trunk is a hidden SIP trunk with the same default settings as a regular SIP trunk. For more information about configuring SIP proxy failover, refer to the *Configuring SIP Proxy in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example sets the **sip proxy failover match-digits** to **7**:

(config)**#sip proxy failover match-digits 7**

sip proxy failover register-expires <*value*>

Use the **sip proxy failover register-expires** command to specify the length of time Session Initiation Protocol (SIP) phone registrations remain in the SIP Proxy database while in failover mode. Once the **register-expires** time has elapsed, the SIP phones must re-register or they will be removed from the SIP Proxy database. This setting only applies when the SIP Proxy is in failover mode. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the amount of time (in seconds) that the registration is valid. Time range is **30** to **86400** seconds.

Default Values

By default, the registration value is 300 seconds.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example specifies the failover registration is valid for 120 seconds:

(config)**#sip proxy failover register-expires 120**

sip proxy failover sip-keep-alive

Use the **sip proxy failover sip-keep-alive** command to configure the Session Initiation Protocol (SIP) proxy server keep-alive method when the system is in survivability (failover) mode. Keep-alive messages must be sent between the SIP device and the registrar to keep the connected channel open for communication. Use the **no** form of this command to return to the default setting. Variations of this command include the following:

sip proxy failover sip-keep-alive info
sip proxy failover sip-keep-alive info <*value*>
sip proxy failover sip-keep-alive options
sip proxy failover sip-keep-alive options <*value*>

Syntax Description

<*value*>	Specifies the amount of time in seconds between keep-alive messages sent during a call. The range is **30** to **3600** seconds.
info	Specifies using the INFO keep-alive method on this trunk.
options	Specifies using the OPTIONS keep-alive method on this trunk.

Default Values

By default, this command is not configured.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example enables the INFO method to be used as the SIP keep-alive method with the timeout between messages set to 3 minutes:

(config)**#sip proxy failover sip-keep-alive info 180**

sip proxy failover trust-domain

Use the **sip proxy failover trust-domain** command to enable the AOS unit to use P-Asserted Identity Session Initiation Protocol (SIP) privacy when communicating with the softswitch when in failover mode. Use the **no** form of this command to disable this feature. Variations of this command include:

sip proxy failover trust-domain
sip proxy failover trust-domain p-asserted-identity-required

Syntax Description

p-asserted-identity-required	Specifies that P-Asserted-Identity is required for this domain.

Default Values

By default, this command is disabled.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

The **sip proxy failover trust-domain** command allows the AOS unit to look at any P-Asserted-Identity header the phones might send while the AOS device is in failover mode. The **p-asserted-identity-required** parameter is only used with nonstandard softswitches and should not be used in normal configurations.

Usage Examples

The following example specifies that P-Asserted-Identity is enabled:

(config)**#sip proxy failover trust-domain**

sip proxy force-port-translation

Use the **sip proxy force-port-translation** command to enable **force-port-translation** for Session Initiation Protocol (SIP) proxy operation. Enabling this feature allows a SIP user to register from multiple phones to the SIP Proxy. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip proxy force-port-translation
sip proxy force-port-translation exclude-via

This command has a very limited application and only applies to very specific network configurations. If you are not familiar with its usage, contact Adtran Technical Support for assistance.

Syntax Description

exclude-via	Indicates excluding the Via header from port translation.

Default Values

By default, this feature is disabled.

Command History

Release 17.9	Command was introduced for AOS data products.
Release A2.07	Command was included for AOS voice products.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

Enabling **force-port-translation** allows the SIP Proxy to create a unique registration in the user database for the same user from multiple phones. This feature retains the key generated by the proxy and inserted into the user portion of the Contact header. It also uses the source port that is generated by the firewall when doing NAT. The source port is inserted at the end of the host portion of any address translated in the SIP header. Enabling the **exclude-via** parameter on this command, excludes the Via header from the source port translation.

Usage Examples

The following example enables **force-port-translation**:

(config)**#sip proxy force-port-translation**

sip proxy grammar

Use the **sip proxy grammar** command to specify the Session Initiation Protocol (SIP) proxy grammar options. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip proxy grammar contact outbound-server-reference host domain
sip proxy grammar contact outbound-server-reference host sip-server
sip proxy grammar expires param-conversion
sip proxy grammar non-invite domain-undo
sip proxy grammar from host domain
sip proxy grammar from host sip-server
sip proxy grammar request-uri host domain
sip proxy grammar request-uri host sip-server
sip proxy grammar to host domain
sip proxy grammar to host sip-server

Syntax Description

expires param-conversion	Enables conversion of Expires parameters to Expires headers.
non-invite domain-undo	Enables translation of domain address to proxy address for inbound stateful requests.
from	Configures grammar for the From header.
request-uri	Configures grammar for the Request URI header.
to	Configures grammar for the To header.
host	Configures the host portion of the specified header.
domain	Specifies using the configured domain string in the specified header.
sip-server	Specifies using the resolved SIP server address in the specified header.
contact	Configures grammar for the Contact header.
outbound-server-reference	Configures the Contact header grammar for outbound server references**.**

Default Values

By default, **sip proxy grammar** for all option headers is **sip-server**.

Command History

Release 16.1	Command was introduced.
Release 17.3	Command was expanded to include the Expires header option.
Release A2	Command was expanded to include the Non-Invite header option.
Release A5.01	Command was expanded to include the Contact header option and **outbound-server-reference** parameter.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example configures the To header using the configured SIP proxy domain string:

(config)**#sip proxy grammar to host domain**

sip proxy hmr

Use the **sip proxy hmr** command to apply a Session Initiation Protocol (SIP) header manipulation rule (HMR) policy to SIP traffic to or from devices (such as phones) behind a SIP proxy or to SIP proxy traffic travelling to or from proxy servers. Use the **no** form of this command to remove the HMR policy. Variations of this command include:

sip proxy hmr server <*name*> **in**
sip proxy hmr server <*name*> **out**
sip proxy hmr user <*name*> **in**
sip proxy hmr user <*name*> **out**

Syntax Description

<*name*>	Specifies the name of the HMR policy to apply to the SIP traffic.
server	Specifies that the HMR policy is applied to SIP traffic to or from SIP proxy servers.
user	Specifies that the HMR policy is applied to SIP traffic to or from devices behind the SIP proxy (such as phones).
in	Specifies the HMR policy is applied to ingress traffic.
out	Specifies the HMR policy is applied to egress traffic.

Default Values

By default, no SIP HMR policies are applied to SIP traffic.

Command History

Release R10.1.0	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

For more information about SIP HMR and its uses and configuration, refer to the configuration guide *Manipulating SIP Headers and Messages in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example adds the HMR policy **MYPOLICY1** for all inbound SIP proxy user traffic:

(config)**#sip hmr proxy user MYPOLICY1 in**

The following example adds the HMR policy **MYPOLICY1** for all inbound SIP proxy server traffic:

(config)**#sip hmr proxy server MYPOLICY1 in**

sip proxy local-gateway <*hostname* | *ip address*>

Use the **sip proxy local-gateway** command to configure the local Session Initiation Protocol (SIP) gateway. Use the **no** form of this command to disable this feature. Variations of this command include:

sip proxy local-gateway <*hostname* | *ip address*>
sip proxy local-gateway <*hostname* | *ip address*> **tcp**
sip proxy local-gateway <*hostname* | *ip address*> **tcp** <*port*>
sip proxy local-gateway <*hostname* | *ip address*> **udp**
sip proxy local-gateway <*hostname* | *ip address*> **udp** <*port*>

Syntax Description

<*hostname* | *ip address*>	Specifies the host name or IP address of the local SIP proxy gateway. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). IPv6 addresses should be expressed in colon hexadecimal notation (for example, **2001:DB8:1::1**).
tcp	Optional. Configures the gateway to use Transmission Control Protocol (TCP).
udp	Optional. Configures the gateway to use User Datagram Protocol (UDP).
<*port*>	Optional. Specifies the TCP or UDP port used by the gateway. Range is **1** to **65535**.

Default Values

By default, the **sip proxy local-gateway** is not configured. When configured, the default protocol is **udp** on port **5060**. If a particular protocol is configured and no port is specified, the default port is set to **5060**.

Command History

Release 17.3	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

The **sip proxy local-gateway** command enables the necessary local SIP gateway in AOS data products. This gateway is necessary for routing emergency calls when using SIP proxy. On AOS voice products, the local gateway is enabled by default.

Usage Examples

The following example sets the local gateway:

(config)**#sip proxy local-gateway serviceprovider@network.com**

sip proxy register rate-adaption

Use the **sip proxy register rate-adaption** command to configure REGISTER rate-adaption for Session Initiation Protocol (SIP) proxy users. This command allows you to reduce the rate that SIP proxy users' REGISTER requests are forwarded by the unit to the SIP server. Use the **no** form of this command to return to disable this feature. Variations of this command include:

sip proxy register rate-adaption
sip proxy register rate-adaption server-expires <*value*>
sip proxy register rate-adaption threshold absolute <*value*>
sip proxy register rate-adaption threshold percentage <*percentage*>
sip proxy register rate-adaption user-expires <*value*>

Syntax Description

server-expires <*value*>	Specifies the expiration period requested from the SIP server in the REGISTER request. Valid range is **30** to **86400** seconds.
threshold absolute <*value*>	Specifies a fixed amount of time that is used to determine when the unit will forward a REGISTER request from the SIP proxy user to the SIP server. The value of this parameter must be less than the value set by the **server-expires** <*value*> parameter. Valid range is **5** to **604800** seconds
threshold percentage <*percentage*>	Specifies a percentage of the REGISTER expiration period that is used to determine when the unit will forward a REGISTER request from the SIP proxy user to the SIP server. Valid range is **10** to **90** percent.
user-expires <*value*>	Specifies the expiration period (in seconds) given to the SIP proxy user in the REGISTER response. Valid range is **30** to **86400** seconds.

Default Values

The default **server-expires** value is **3600**. The default **user-expires** value is **60**. The default threshold is **threshold percentage 50**.

Command History

Release A5.02	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

This command allows the unit to reduce the load of REGISTER requests sent by SIP proxy users to the SIP server. When this command is enabled, the unit modifies the Expires header to be a large value in outbound REGISTER requests to the SIP server (defined by the **server-expires** <*value*> parameter). In the corresponding responses from the SIP server, the unit modifies the Expires header to be a small value when forwarding the REGISTER response to the phone (defined by the **user-expires** <*value*> parameter). The ratio between these two times determines how many REGISTER requests (after the first) the unit forwards to the SIP server and how many REGISTER requests the unit will handle locally. SIP proxy user REGISTER requests are forwarded by the unit if the time remaining in the REGISTER expiration period is less than or equal to the REGISTER expiration period received from the SIP server minus the threshold (defined by the **threshold absolute** <*value*> and **threshold percentage** <*percentage*> parameters) minus the modified REGISTER expiration period forwarded to the SIP proxy user. All other REGISTER requests from SIP proxy users are handled locally by the unit. For example, if the REGISTER expiration period from the SIP server is 3600 seconds, the threshold is set to **threshold absolute 180**, and the REGISTER expiration period in the modified REGISTER response forwarded to the user is 60 seconds, then the first REGISTER request from the SIP proxy user that occurs after 3360 seconds (3600 - 180 - 60) will be forwarded to the SIP server. Similarly, if the REGISTER expiration period from the SIP server is 3600 seconds, the threshold is set to **threshold percent 10**, and the modified Expires period in the REGISTER response given to the user is 60 seconds, then the first REGISTER request from the SIP proxy user that occurs after 3180 seconds (3600 - .10(3600) - 60) will be forwarded to the SIP server.

Usage Examples

The following example specifies a rate-adaption threshold of **10** percent of the Expires period from the SIP server:

(config)**#sip proxy register rate-adaption threshold percentage 10**

sip proxy routing contact-comparison strict

Use the **sip proxy routing contact-comparison strict** command to configure the Session Initiation Protocol (SIP) proxy server to make strict comparisons between Contact headers. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release A2.03	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example modifies the Contact comparison settings to make strict comparisons of Contact headers during routing:

(config)**#sip proxy routing contact-comparison strict**

sip proxy routing server-selection in-dialog

Use the **sip proxy routing server-selection in-dialog** command to configure the Session Initiation Protocol (SIP) server selection method used by the SIP proxy for new outbound SIP requests within an existing dialog. Use the **no** form of this command to return to the default setting.Variations of this command include the following:

sip proxy routing server-selection in-dialog configured
sip proxy routing server-selection in-dialog learned

Syntax Description

configured	Specifies that the SIP proxy uses configured SIP servers (in order) as the destination for new outbound SIP requests in an existing dialog.
learned	Specifies that the SIP proxy uses the SIP server learned from a given dialog as the destination for new outbound SIP requests in that dialog.

Default Values

By default, the SIP proxy server selection is set to **learned**.

Command History

Release R12.2.0	Command was introduced.

Usage Examples

The following example configures the SIP proxy to use previously configured SIP servers as the destination for new outbound SIP requests in an existing dialog:

(config)**#sip proxy routing server-selection in-dialog configured**

sip proxy sip-server monitor

Use the **sip proxy sip-server monitor** command to enable the Session Initiation Protocol (SIP) proxy server monitor feature and enter the SIP Proxy SIP-Server Monitor command set. Use the **no** form of this command to disable the feature and return to the default settings. For more information on commands available for configuring this feature, refer to *SIP Proxy Monitor Command Set on page 4866*.

Syntax Description

No subcommands.

Default Values

By default, **sip proxy sip-server monitor** is disabled.

Command History

Release R10.9.0	Command was introduced.

Functional Notes

The SIP proxy SIP server monitor feature adds rollover support to the SIP proxy in stateful mode. If the currently selected SIP server becomes unresponsive, the proxy uses a secondary proxy server for all future calls. The proxy monitor polls the failed SIP servers to detect when they are operational again. Calls are routed to more preferred servers as service is restored.

Usage Examples

The following example enables the **sip proxy sip-server monitor** and enters the SIP Proxy SIP-Server Monitor configuration mode:

```
(config)#sip proxy sip-server monitor
    Configuring New Proxy Monitor.
(config-proxy-monitor)#
```

sip proxy sip-server monitor stateful

Use the **sip proxy sip-server monitor stateful** command to enable the Session Initiation Protocol (SIP) proxy server monitor feature for transparent SIP proxy. Use the **no** form of this command to disable the feature and return to the default settings. Variations of this command include:

sip proxy sip-server monitor stateful-transparent
sip proxy sip-server monitor stateful-only

Syntax Description

stateful-transparent	Specifies that SIP monitor is enabled for stateful and transparent SIP proxy.
stateful-only	Specifies that SIP monitor is enabled for stateful SIP proxy only.

Default Values

By default, **sip proxy sip-server monitor** is set to **stateful-only**.

Command History

Release R11.9.0	Command was introduced.

Functional Notes

This command sets the SIP monitor state for the transparent SIP proxy; it does NOT create a SIP proxy monitor for non-transparent proxy, or enter the monitor's configuration. The SIP monitor for non-transparent proxy configuration is available only using the command *sip proxy sip-server monitor on page 1756*.

When the transparent proxy monitor is enabled, it compares the destination SIP server in the SIP packet to the configured list of SIP servers. If the destination matches a server in the list, the proxy determines if any of the configured servers are UP. If at least one server is up, the transparent proxy does not go into failover mode, and the phone is expected to try another SIP server. If none of the monitored servers are UP, the proxy transitions the call to failover mode.

Usage Examples

The following example enables the SIP transparent proxy monitor:

(config)**#sip proxy sip-server monitor stateful-transparent**

sip proxy sip-server primary

Use the **sip proxy sip-server primary** command to configure the primary Session Initiation Protocol (SIP) server softswitch. Use the **no** form of this command to disable the softswitch. The softswitch cannot be disabled unless all configured secondary softswitches are removed (refer to the command *sip proxy sip-server secondary on page 1761*). Variations of this command include:

sip proxy sip-server primary *<hostname | ip address>*
sip proxy sip-server primary *<hostname | ip address>* **tcp**
sip proxy sip-server primary *<hostname | ip address>* **tcp** *<port>*
sip proxy sip-server primary *<hostname | ip address>* **tls** *<profile name>*
sip proxy sip-server primary *<hostname | ip address>* **tls** *<profile name> <TLS port>*
sip proxy sip-server primary *<hostname | ip address>* **tls** *<profile name> <TLS port>*
srv *<service-name-prefix>*
sip proxy sip-server primary *<hostname | ip address>* **tls** *<profile name> <TLS port>*
srv *<service-name-prefix> <transport-name-prefix>*
sip proxy sip-server primary *<hostname | ip address>* **tls** *<profile name>* **srv** *<service-name-prefix>*
sip proxy sip-server primary *<hostname | ip address>* **tls** *<profile name>* **srv** *<service-name-prefix>*
<transport-name-prefix>
sip proxy sip-server primary *<hostname | ip address>* **udp**
sip proxy sip-server primary *<hostname | ip address>* **udp** *<port>*

Syntax Description

<hostname | ip address>	Specifies the fully qualified domain name (FQDN) or IP address of the outbound SIP proxy server. IPv4 addresses should be expressed in dotted decimal notation (for example, **208.61.209.1**). IPv6 addresses should be expressed in colon hexadecimal notation (for example, **2001:DB8:1::1**).
tcp	Optional. Configures the softswitch to use Transmission Control Protocol (TCP).
<port>	Optional. Specifies the TCP port used by the softswitch. Range is **1** to **65535**.
tls *<profile name>*	Optional. Specifies the SIP traffic uses Transport Layer Security (TLS). If TLS is specified, a TLS profile must be specified. The TLS profile must have been created prior to issuing this command (refer to the command *tls-profile <profile name> on page 1885*).
<TLS port>	Optional. Specifies the TLS destination port. Range is **1** to **65535**.
srv *<service name prefix>*	Optional. Specifies the service name prefix for the DNS SRV request. Underscores are added automatically.
<transport-name-prefix>	Optional. Specifies the transport prefix for the DNS SRV request. Underscores are added automatically.
udp	Optional. Configures the softswitch to use User Datagram Protocol (UDP).
<port>	Optional. Specifies the UDP port used by the softswitch. Range is **1** to **65535**.

Default Values

By default, no softswitches are configured. If a softswitch is configured, the default protocol is UDP on port **5060**. If a particular protocol is configured and no port is specified, the default port is set to **5060**.

If TLS is used, port **5061** is used by default. By default, SIP TLS requests use **sips** as the service name prefix and **tcp** as the transport name prefix.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.
Release R13.1.0	Command was expanded to include the **tls** <*profile name*>, <*TLS port*>, and **srv** parameters.

Functional Notes

The guidelines for configuring the softswitch(es) depend on the mode of operation selected. Softswitch configuration is always needed for Stateful mode. It is only needed for Outbound mode and Transparent mode when the SIP Request does not contain any fields that can be resolved to the softswitch's location.

If a host name is used to specify the outbound SIP proxy server, a domain naming system (DNS) server must be configured on the AOS unit using the command *name-server on page 1622* or learned via a dynamic IP interface.

To configure the primary softswitch with a TLS profile, the TLS profile must have been created prior to issuing this command (refer to the command *tls-profile <profile name> on page 1885*). If a specified TLS profile is ever deleted, this softswitch is automatically removed from the AOS device's configuration. If the TLS profile specified by the primary softswitch is removed from the AOS device configuration, both the primary and all secondary softswitches are automatically removed from the AOS device configuration.

Usage Examples

The following example sets the primary softswitch:

(config)**#sip proxy sip-server primary 208.61.209.1**

sip proxy sip-server rollover

Use the **sip proxy sip-server rollover** command to configure the rollover behavior of the Session Initiation Protocol (SIP) proxy. This setting specifies the conditions necessary to trigger the proxy to roll over to the next SIP server. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip proxy sip-server rollover service-unavailable-or-timeout
sip proxy sip-server rollover timeout-only

Syntax Description

service-unavailable-or-timeout	Specifies the rollover to the next SIP server to occur after receiving a 503 Service Unavailable message or no response.
timeout-only	Specifies the rollover to the next SIP server to occur only after no response is received.

Default Values

By default, the **sip-server rollover** is set to **timeout-only**.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example sets the SIP server rollover to **service-unavailable-or-timeout**:

(config)**#sip proxy sip-server rollover service-unavailable-or-timeout**

sip proxy sip-server secondary

Use the **sip proxy sip-server secondary** command to configure the secondary Session Initiation Protocol (SIP) softswitch. This command can be entered multiple times to specify numerous secondary softswitches. Use the **no** form of this command to disable this feature. Variations of this command include:

sip proxy sip-server secondary *<hostname | ip address>*
sip proxy sip-server secondary *<hostname | ip address>* **tcp**
sip proxy sip-server secondary *<hostname | ip address>* **tcp** *<port>*
sip proxy sip-server secondary *<hostname | ip address>* **tls** *<profile name>*
sip proxy sip-server secondary *<hostname | ip address>* **tls** *<profile name> <TLS port>*
sip proxy sip-server secondary *<hostname | ip address>* **tls** *<profile name> <TLS port>* **srv** *<service-name-prefix>*
sip proxy sip-server secondary *<hostname | ip address>* **tls** *<profile name> <TLS port>* **srv** *<service-name-prefix> <transport-name-prefix>*
sip proxy sip-server secondary *<hostname | ip address>* **tls** *<profile name>* **srv** *<service-name-prefix>*
sip proxy sip-server secondary *<hostname | ip address>* **tls** *<profile name>* **srv** *<service-name-prefix> <transport-name-prefix>*
sip proxy sip-server secondary *<hostname | ip address>* **udp**
sip proxy sip-server secondary *<hostname | ip address>* **udp** *<port>*

Syntax Description

<hostname | ip address>	Specifies the fully qualified domain name (FQDN) or IP address of the outbound SIP proxy server. IPv4 addresses should be expressed in dotted decimal notation (for example, **208.61.209.2**). IPv6 addresses should be expressed in colon hexadecimal notation (for example, **2001:DB8:1::1**).
tcp	Optional. Configures the softswitch to use Transmission Control Protocol (TCP).
<port>	Optional. Specifies the TCP port used by the softswitch. Range is **1** to **65535**.
tls *<profile name>*	Optional. Specifies the SIP traffic uses Transport Layer Security (TLS). If TLS is specified, a TLS profile must be specified. The TLS profile must have been created prior to issuing this command (refer to the command *tls-profile <profile name> on page 1885*).
<TLS port>	Optional. Specifies the TLS destination port. Range is **1** to **65535**.
srv *<service name prefix>*	Optional. Specifies the service name prefix for the DNS SRV request. Underscores are added automatically.
<transport-name-prefix>	Optional. Specifies the transport prefix for the DNS SRV request. Underscores are added automatically.
udp	Optional. Configures the softswitch to use User Datagram Protocol (UDP).
<port>	Optional. Specifies the UDP port used by the softswitch. Range is **1** to **65535**.

Default Values

By default, no softswitches are configured. If a softswitch is configured, the default protocol is UDP on port **5060**. If a particular protocol is configured and no port is specified, the default port is set to **5060**.

If TLS is used, port **5061** is used by default. By default, SIP TLS requests use **sips** as the service name prefix and **tcp** as the transport name prefix.

Command History

Release 16.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.
Release R13.1.0	Command was expanded to include the **tls** <*profile name*>, <*TLS port*>, and **srv** parameters.

Functional Notes

The guidelines for configuring the softswitch(es) depend on the mode of operation selected. Softswitch configuration is always needed for Stateful mode. It is only needed for Outbound mode and Transparent mode when the SIP Request does not contain any fields that can be resolved to the softswitch's location.

When disabling softswitches, all secondary softswitches must be removed before the primary softswitch can be removed.

If a host name is used to specify the outbound SIP proxy server, a domain naming system (DNS) server must be configured on the AOS unit using the command *name-server on page 1622* or learned via a dynamic IP interface.

To configure the secondary softswitch with a TLS profile, the TLS profile must have been created prior to issuing this command (refer to the command *tls-profile <profile name> on page 1885*). If a specified TLS profile is ever deleted, this softswitch is automatically removed from the AOS device's configuration. If the TLS profile specified by the secondary softswitch is removed from the AOS device configuration, the secondary softswitch is automatically removed from the AOS device configuration.

Usage Examples

The following example sets the secondary softswitch:

(config)**#sip proxy sip-server secondary 208.61.209.2**

sip proxy srtp server *<profile name>*

Use the **sip proxy srtp server** command to configure Secure Realtime Transport Protocol (SRTP) on the on the server side of the Session Initiation Protocol (SIP) proxy. Use the **no** form of this command to disable the SRTP feature. Variations of this command include:

sip proxy srtp server *<profile name>*
sip proxy srtp server *<profile name>* **allow-non-rtp-media**
sip proxy srtp server *<profile name>* **allow-non-rtp-media tls-optional**
sip proxy srtp server *<profile name >* **tls-optional**

Syntax Description

<profile name>	Specifies the SRTP profile name.
allow-non-rtp-media	Optional. Configures the SRTP to allow non-Realtime Transport Protocol (RTP) media, such as T.38 over UDPTL, that cannot be protected by SRTP. When this option is specified, RTP media is secured by SRTP, but any non-RTP media is forwarded unsecured.
tls-optional	Optional. Removes the requirement that SRTP key negotiation is protected by Transport Layer Security (TLS). Adtran does not recommend this configuration.

Default Values

By default, no SRTP profile is configured. If an SRTP profile is configured, it rejects any non-RTP media by default. In addition, if an SRTP profile is configured TLS is required by default.

Functional Notes

SRTP must be configured with a profile name; however, the optional **allow-non-rtp-media** and **tls-optional** parameters can be entered in the CLI in any order, or before the profile name is specified.

Command History

Release R13.3.0	Command was introduced.

Usage Examples

The following example configures an SRTP profile **PROFILE1** on the SIP proxy server that allows non-RTP media:

(config)**#sip proxy srtp server PROFILE1 allow-non-rtp-media**

sip proxy transparent

Use the **sip proxy transparent** command to enable Session Initiation Protocol (SIP) proxy operation in the transparent mode. Use the **no** form of this command to disable this feature. Variations of this command include:

sip proxy transparent
sip proxy transparent nat-simulate
sip proxy transparent ip-spoofing

Syntax Description

nat-simulate	Optional. Specifies the network address translation (NAT) simulation.
ip-spoofing	Optional. Specifies that the source IP address on SIP packets heading towards the phone is replaced with the softswitch IP address.

Default Values

By default, this feature is disabled.

Command History

Release 16.1	Command was introduced.
Release A1	Command was expanded to include the NAT simulation.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.
Release R11.9.0	Command was expanded to include the **ip-spoofing** parameter.

Functional Notes

For an AOS product to use SIP proxy in transparent mode, SIP proxy must be enabled. To enable SIP proxy, enter the **sip proxy** command before entering the **sip proxy transparent** command.

For an AOS data product to use SIP proxy in transparent mode, the firewall SIP application layer gateway (ALG) must be disabled. For more information on disabling the firewall SIP ALG, refer to the command *ip firewall alg on page 1373*.

For more information on the operation and configuration of SIP proxy in transparent mode, refer to the *Configuring SIP Proxy in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables SIP proxy to operate in transparent mode on an AOS voice product:

(config)**#sip proxy**
(config)**#sip proxy transparent**

The following example enables SIP proxy to operate in transparent mode on an AOS data product:

(config)**#no ip firewall alg sip**
(config)**#sip proxy**

(config)**#sip proxy transparent**

sip proxy user-template *<name>*

Use the **sip proxy user-template** command to create a Session Initiation Protocol (SIP) proxy user template and enter the proxy user template configuration mode. Use the **no** form of this command to remove the template. Refer to the *Proxy User Template Command Set on page 4856* for more information.

Syntax Description

<name>	Specifies the name of the proxy user template being created.

Default Values

By default, this feature is disabled.

Command History

Release A4.01	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

Additional information is available in the following sections of this guide:

For more information about SIP proxy, refer to the command *sip proxy on page 1728*. For more information about transparent proxy, refer to the command *sip proxy transparent on page 1764*.

For more information about SIP proxy, refer to the configuration guide *Configuring SIP Proxy in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example creates a proxy user template named **Set1** and enters the proxy user template configuration mode:

```
(config)#sip proxy user-template Set1
(config-template-Set1)#
```

sip qos dscp *<value>*

Use the **sip qos dscp** command to configure the differentiated services code point (DSCP) value to mark Session Initiation Protocol (SIP) packets with. This marking can then be used by the quality of service (QoS) mechanisms to give priority for this type of traffic in the unit. Use the **no** form of this command to disable this feature.

Syntax Description

<value>	Specifies the DSCP value. Valid range is **0** to **63**.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example sets the DSCP value to **63**:

(config)**#sip qos dscp 63**

sip registrar

Use the **sip registrar** command to configure the Session Initiation Protocol (SIP) registrar server used for registering user agents (UAs) into the location database. For more details on SIP operation, refer to the *Technology Review* section of the command *ip firewall alg on page 1373*. Use the **no** form of the **sip registrar** command to disable the registrar server. Variations of this command include:

sip registrar
sip registrar authenticate
sip registrar default-expires <*value*>
sip registrar max-expires <*value*>
sip registrar min-expires <*value*>
sip registrar realm <*string*>

Syntax Description

authenticate	Specifies that authentication is required for each UA during registration.
default-expires <*value*>	Specifies the default expiration period for the UA listing in the location database. UAs requesting registration without specifying an expiration period are given this default expiration period. Range is **0** to **2592000** seconds.
max-expires <*value*>	Specifies the maximum expiration period for the UA listing in the location database. All UAs registering with the SIP proxy server request an expiration period for the listing in the database. UAs requesting an expiration period between the **max-expires** and **min-expires** values are honored. Range is **0** to **2592000** seconds.
min-expires <*value*>	Specifies the minimum expiration period for the UA listing in the location database. All UAs registering with the SIP proxy server request an expiration period for the listing in the database. UAs requesting an expiration period between the **max-expires** and **min-expires** values are honored. Range is **0** to **2592000** seconds.
realm <*string*>	Specifies a realm (using an ASCII character string) for the UA listing in the location database.

Default Values

By default, the registrar server is disabled.

Command History

Release 11.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example sets the default expiration to **5** seconds:

(config)**#sip registrar default-expires 5**

The following example sets the realm string:

(config)**#sip registrar realm voice.adtran.com**

sip secure remote-user

Use the **sip secure remote-user** command to enter the remote user security command set and configure the blacklist options. Use the **no** form of this command to return to the default settings.

Additional subcommands are available once you have entered the SIP Secure Remote User Configuration mode:

blacklist
blacklist attack-threshold <*number*>
blacklist time <*seconds*>

Syntax Description

blacklist	Enables the blacklist to record unauthorized attempts to access the system by an unknown voice user.
attack-threshold <*number*>	Optional. Specifies the number of unauthorized attempts allowed before placing the IPv4 address on the blacklist. Valid range is **1** to **1000**.
time <*seconds*>	Optional. Specifies the number of seconds entries remain on the blacklist before they are automatically removed. Entries do not persist across reboots. Valid range is **0** to **2147483646**. If the time is set to **0**, the entries will be permanent.

Default Values

By default, the **blacklist attack-threshold** is **5** attempts. The **blacklist time** is **3600** seconds.

Functional Notes

When the blacklist is enabled, the system monitors the configured secure ports (refer to *sip udp <port> secure remote-user on page 1783*) for received REGISTER and INVITE attempts from remote voice users that fail to authenticate. SIP server authentication (refer to) and SIP register authentication (refer to) must be enabled to take advantage of the blacklist feature.

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example enters the SIP Security Remote User Configuration mode to enable the blacklist and set the attack threshold to **10** and the time to **4800** seconds:

(config)**#sip secure remote-user**
(config-secure-remote)**#blacklist**
(config-secure-remote)**#blacklist attack-threshold 10**
(config-secure-remote)**#blacklist time 4800**

sip session-timer

Use the **sip session-timer** command to configure the Session Initiation Protocol (SIP) session timer. This feature requires user agents (UAs) to periodically send re-INVITE requests (referred to as session refresh requests) to keep the session alive. Use the **no** form of this command to disable the SIP session timer. Variations of this command include:

sip session-timer
sip session timer min-se <*value*>
sip session timer session-expires <*value*>

Syntax Description

min-se <*value*>	Specifies the minimum session interval the unit will accept. The value of this parameter cannot be greater than the value of the **session-expires** parameter. Range is **90** to **3600** seconds.
session-expires <*value*>	Specifies the maximum amount of time that can occur between refresh requests before the session is considered timed out and is torn down. Range is **90** to **3600** seconds.

Default Values

By default, the SIP session timer is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

Entering **sip session-timer** without designating values for **session-expires** or **min-se** assigns the default values **1800** and **90** to **session-expires** and **min-se**, respectively.

Disabling the SIP session timer does not delete the stored values for **min-se** and **session-expires**; it only disables the SIP session timer.

Usage Examples

The following example enables the SIP session timer and sets the session expiration to **2600** seconds:

(config)**#sip session-timer session-expires 2600**

sip timer

Use the **sip timer** command to configure the Session Initiation Protocol (SIP) timers. These timers affect how long a SIP transaction resource is reserved once the final message in a transaction is received. Use the **no** form of this command to return to the default value. Variations of this command include:

sip timer d <*value*>
sip timer d t1-derived
sip timer j <*value*>
sip timer j t1-derived
sip timer T1 <*value*>
sip timer T2 <*value*>

Adtran does not recommend changing T1 and T2 timer values. T1 and T2 timers are base timers within the unit, and any changes will affect other timers which are based off of these timers.

Syntax Description

d <*value*>	Specifies the D timer. Valid range is **0** to **3200** ms.
j <*value*>	Specifies the J timer. Valid range is **0** to **3200** ms.
t1-derived	Specifies that the D or J timer is derived from the T1 timer value. This value is equal to 64*T1 value.
T1 <*value*>	Specifies the T1 timer. This timer is an estimate of network round trip time, and is used as the initial request retransmit interval. Several other SIP timers are derived from the T1 value. Valid range is **50** to **1000** ms.
T2 <*value*>	Specifies the T2 timer. This timer is the maximum retransmit interval for nonINVITE requests and INVITE responses. Valid range is **1000** to **32000** ms.

Default Values

By default, the T1 timer is set to **500** milliseconds, and the T2 timer is set to **4000** milliseconds.

By default, the D and J timers are set to **t1-derived**.

Command History

Release 13.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.
Release R10.10.0	Command was expanded to include the **d** and **j** timers. These parameters replace the **sip transaction fast-terminate** command.

Functional Notes

The D and J timers depend on the T1 timer value for operation. If a value is specified for the D or J timers, the dependence upon the T1 timer value is removed. When the D and J values are configured, timer updates are immediately recognized by the SIP stack. When the D and J timers depend on the T1 timer, they are updated when the T1 value changes.

Usage Examples

The following example configures the T1 timer to **1000** milliseconds:

(config)**#sip timer T1 1000**

sip timer registration-failure-retry *<value>*

Use the **sip timer registration-failure-retry** command to configure the time (in seconds) that will elapse before a Session Initiation Protocol (SIP) endpoint will retry registration with the SIP server after a registration failure has occurred. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies time in seconds. Range is **10** to **604800** seconds.

Default Values

By default, the registration-failure-retry timer is set to **60** seconds.

Command History

Release 11.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example allows a retry attempt to begin after **32** seconds:

(config)**#sip timer registration-failure-retry 32**

sip timer rollover *<value>*

Use the **sip timer rollover** command to specify the time period (in seconds) that the Session Initiation Protocol (SIP) proxy is set to wait for a response to a request before attempting to find an alternate destination. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the time period in seconds. Range is **1** to **32** seconds.

Default Values

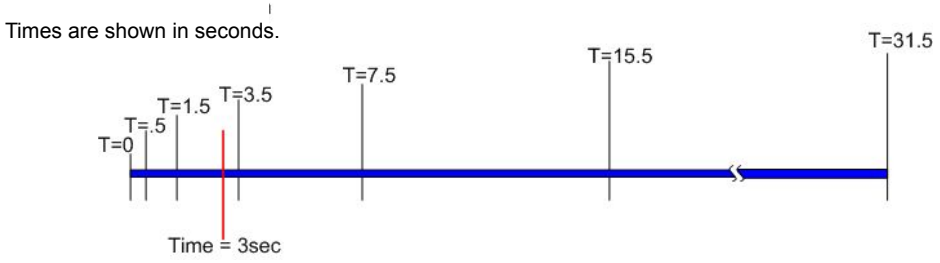
By default, the rollover timer is set to **3** seconds.

Command History

Release 11.1	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

The **sip timer rollover** command sets the SIP timer B value for Invite transactions originating from a SIP trunk. When originating a call, the SIP trunk attempts to send Invite messages to the primary SIP server and waits for a response. If there is no response, the SIP trunk waits for 0.5 seconds before attempting to send another Invite to the same SIP server. If no response, the SIP trunk waits for 1 second before attempting to send another Invite, then waits 2 seconds, and so on. These increasing intervals are shown in the diagram below.



The rollover timer allows the user to control how long to wait before trying the next server. In the diagram above, the red line indicates the rollover timer expiration. If there is no response after the timer expires, the SIP trunk will attempt to send Invite messages to the highest priority backup SIP server obtained via DNS service (SRV). The SIP trunk starts over at T=0 with the next server and doesn't send any more messages to the timed out server. As long as the SIP trunk does not receive a response, it will continue this cycle until it has attempted to contact all the SIP servers.

Usage Examples

The following example allows connection attempts to continue for up to **32** seconds before rolling over to another destination:

(config)**#sip timer rollover 32**

sip timer rollover register

Use the **sip timer rollover register** command to specify the time period (in seconds) that the Session Initiation Protocol (SIP) proxy waits for a response to a REGISTER request before attempting to find an alternate destination. Use the **no** form of this command to return to the default value. Variations of this command include:

sip timer rollover register <*value*>
sip timer rollover register follow-primary

Syntax Description

<*value*>	Specifies the rollover time period for REGISTER events in seconds. Range is **1** to **32** seconds.
follow-primary	Links the rollover timer for REGISTER events to the primary rollover timer specified by the **sip timer rollover** command.

Default Values

By default, the rollover timer for REGISTER events is set to **follow-primary**.

Command History

Release 18.2	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example allows REGISTER request attempts to continue without response for up to **32** seconds before rolling over to another destination:

(config)**#sip timer rollover register 32**

sip timer subscription-failure-retry <*value*>

Use the **sip timer subscription-failure-retry** command to specify the time period (in seconds) that will elapse before a subscription request will be resent to the Session Initiation Protocol (SIP) server after a subscription request failure has occurred. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the time period in seconds. Range is **10** to **604800** seconds.

Default Values

By default, the subscription failure retry timer is set to **60** seconds

Command History

Release R13.8.0	Command was introduced.

Usage Examples

The following example allows a retry to occur after **32** seconds:

(config)**#sip timer subscription-failure-retry 32**

sip tls

Use the **sip tls** command to enable Transport Layer Security (TLS) on the AOS device. Use the **no** form of this command to disable TLS. Variations of this command include:

sip tls
sip tls *<port>*

Syntax Description

<port>	Optional. Specifies the Transmission Control Protocol (TCP) port on which the Session Initiation Protocol (SIP) stack listens for TLS packets. Valid range is **1** to **65535**.

Default Values

By default, TLS is disabled. When enabled, the port is set to **5061** by default.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

TLS is a cryptographic protocol that provides communication security over the internet. TLS profiles are created and applied to SIP trunks to provide peer authentication through the exchange of symmetric keys and authentication certificates. Refer to the *SIP TLS Profile Command Set on page 4880* for more information about TLS configuration.

Usage Examples

The following example enables TLS on the AOS device:

(config)**#sip tls**

sip tone-file-prefix

Use the **sip tone-file-prefix** command to specify the file location (flash or CompactFlash) and location prefix of the call progress tone files that the unit should use for blind transfers over Session Initiation Protocol (SIP) trunks operating in local transfer mode. Use the **no** form of this command to return to the default value. Variations of this command include:

sip tone-file-prefix cflash *<location prefix>*
sip tone-file-prefix flash *<location prefix>*

Syntax Description

<location prefix>	Specifies the location prefix of the tone files to be used.
cflash	Specifies that the tone files are located in the unit's CompactFlash.
flash	Specifies that the tone files are located in the unit's flash memory.

Default Values

By default, AOS units with voice features that lack a digital signal processor (DSP) provide North American ringback and disconnect tones.

By default, AOS units with a DSP use the DSP to generate ringback tones based on the system country setting. For more information on how to configure the system country, refer to the command *voice system-country <name> on page 1970*.

Command History

Release R10.1.0	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Functional Notes

This command only designates the file location (flash or CompactFlash) and location prefix of call progress tones used during blind transfers over SIP trunks operating in local transfer mode. To fully configure international call progress tones during blind transfers, you must enable the AOS unit's File Transfer Protocol (FTP) server, upload the appropriate .wav files to the unit using an FTP client, and configure the unit to use the uploaded files. For more information on configuring call progress tones for blind transfers over SIP trunks operating in local transfer mode, refer to the *International Configuration Guide* available on Adtran's Support Forum at https://supportcommunity.adtran.com.

Below is a list of the available countries or regions and their corresponding location prefix.

Australia	**Adtran-UK**	Japan	**Adtran-JP**
Belgium	**Adtran-BE**	Luxembourg	**Adtran-DE**
Canada	**Adtran-NA**	Mexico	**Adtran-MX**
China	**Adtran-CN**	Netherlands	**Adtran-ETSI**
Denmark	**Adtran-ETSI**	Norway	**Adtran-ETSI**
Finland	**Adtran-FI**	Spain	**Adtran-ETSI**
France	**Adtran-FR**	Sweden	**Adtran-ETSI**
Germany	**Adtran-DE**	Switzerland	**Adtran-ETSI**
Hong Kong	**Adtran-HK**	UAE	**Adtran-UK**
India	**Adtran-IN**	UK	**Adtran-UK**
Ireland	**Adtran-IE**	USA	**Adtran-NA**
Italy	**Adtran-ETSI**		

Usage Examples

The following example configures the unit to use tone files stored in flash memory that have the Adtran-UK location prefix:

(config)**#sip tone-file-prefix flash Adtran-UK**

sip trunk-auth-name-source

Use the **sip trunk-auth-name-source** command to configure the authentication name source for the Session Initiation Protocol (SIP) trunks. Use the **no** form of this command to return to the default setting. Variations of this command include:

sip trunk-auth-name-source account-id
sip trunk-auth-name-source message

Syntax Description

account-id	Specifies using the corresponding account ID.
message	Specifies using the To or From user when selecting the authentication name and password.

Default Values

By default, the trunk authentication name source is **message**.

Command History

Release A2.03	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example configures the trunk authentication name source to use the account ID:

(config)**#sip trunk-auth-name-source account-id**

sip udp <*port*> secure remote-user

Use the **sip udp secure remote-user** command to enable remote user security on the specified User Datagram Protocol (UDP) port. This allows SIP traffic only from configured remote voice users, causing SIP traffic from unconfigured remote voice users to be dropped. Use the **no** form of this command to return to the default setting.

Syntax Description

<*port*>	Specifies the UDP port used by the gateway. Range is **1** to **65535**.

Default Values

By default, SIP traffic from any remote voice user is permitted through the UDP port, but if this command is entered, only traffic from configured remote voice users is allowed.

Command History

Release R10.7.0	Command was introduced.
Release R10.8.0	Command syntax was changed to remove the **ip** keyword.

Usage Examples

The following example enables remote user security for UDP port **25069**:

(config)**#sip udp 25069 secure remote-user**

snmp agent

Use the **snmp agent** command to enable the Simple Network Management Protocol (SNMP) agent. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, the SNMP agent is disabled.

Command History

Release 1.1	Command was introduced.
Release 18.2	Command was changed from **ip snmp agent** to **snmp agent** to incorporate Internet Protocol version 6 (IPv6) for Adtran internetworking products only.
Release R10.1.0	Command syntax was changed to remove the **ip** keyword in Adtran voice products.

Functional Notes

Allows a MIB browser to access standard MIBs within the product. This also allows the product to send traps to a trap management station.

SNMP can be used with either Internet Protocol version 4 (IPv4) or IPv6.

Usage Examples

The following example enables the IP SNMP agent:

(config)**#snmp agent**

snmp ifmib alias long

Use the **snmp ifmib alias long** command to configure the Simple Network Management Protocol (SNMP) IF.MIB alias settings to allow an alias string to be up to 255 characters long. Use the **no** form of this command to return to the default SNMP IF.MIB setting.

Syntax Description

No subcommands.

Default Values

By default, the maximum length of the SNMP IF.MIB alias is **64** characters.

Command History

Release 17.4	Command was introduced.

Usage Examples

The following example enables a longer SNMP IF.MIB alias length:

(config)**#snmp ifmib alias long**

snmp-server chassis-id "<*string*>"

Use the **snmp-server chassis-id** command to specify an identifier for the Simple Network Management Protocol (SNMP) server. Use the **no** form of this command to return to the default value.

Syntax Description

"<string>"	Identifies the product using an alphanumeric string enclosed in quotation marks (up to 32 characters in length).

Default Values

By default, the **snmp-server chassis-id** is set to **Chassis ID**.

Command History

Release 6.1	Command was introduced.

Usage Examples

The following example configures a chassis ID of **A432692**:

(config)**#snmp-server chassis-id A432692**

snmp-server community

Use the **snmp-server community** command to specify a community string to control access to the Simple Network Management Protocol (SNMP) information. Use the **no** form of this command to remove a specified community. Variations of this command include:

snmp-server community <*community*>
snmp-server community <*community*> **[ip access-class** <*ipv4 acl*>**] [ipv6 access-class** <*ipv6 acl*>**]**
snmp-server community <*community*> **[ip access-class** <*ipv4 acl*>**] [ipv6 access-class** <*ipv6 acl*>**]** **[any-vrf | vrf** <*name*>**]**
snmp-server community <*community*> **ro**
snmp-server community <*community*> **ro [ip access-class** <*ipv4 acl*>**] [ipv6 access-class** <*ipv6 acl*>**]**
snmp-server community <*community*> **ro [ip access-class** <*ipv4 acl*>**] [ipv6 access-class** <*ipv6 acl*>**]** **[any-vrf | vrf** <*name*>**]**
snmp-server community <*community*> **rw**
snmp-server community <*community*> **rw [ip access-class** <*ipv4 acl*>**] [ipv6 access-class** <*ipv6 acl*>**]**
snmp-server community <*community*> **rw [ip access-class** <*ipv4 acl*>**] [ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server community <*community*> **view** <*name*>
snmp-server community <*community*> **view** <*name*> **[ip access-class** <*ipv4 acl*>**]** **[ipv6 access-class** <*ipv6 acl*>**]**
snmp-server community <*community*> **view** <*name*> **[ip access-class** <*ipv4 acl*>**]** **[ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server community <*community*> **view** <*name*> **ro**
snmp-server community <*community*> **view** <*name*> **ro [ip access-class** <*ipv4 acl*>**]** **[ipv6 access-class** <*ipv6 acl*>**]**
snmp-server community <*community*> **view** <*name*> **ro [ip access-class** <*ipv4 acl*>**]** **[ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server community <*community*> **view** <*name*> **rw**
snmp-server community <*community*> **view** <*name*> **rw [ip access-class** <*ipv4 acl*>**]** **[ipv6 access-class** <*ipv6 acl*>**]**
snmp-server community <*community*> **view** <*name*> **rw [ip access-class** <*ipv4 acl*>**]** **[ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**

Syntax Description

<*community*>	Specifies the community string (a password to grant SNMP access).
ip access-class <*ipv4 acl*>	Optional. Specifies an Internet Protocol version 4 (IPv4) access control list (ACL) name used to limit access. Refer to *ip access-list extended <ipv4 acl name> on page 1344* and *ip access-list standard <ipv4 acl name> on page 1346* for more information on creating IPv4 ACLs
ipv6 access-class <*ipv6 acl*>	Optional. Specifies an Internet Protocol version 6 (IPv6) ACL name used to limit access. Refer to *ipv6 access-list extended <ipv6 acl name> on page 1500* and *ipv6 access-list standard <ipv6 acl name> on page 1502* for more information on creating IPv6 ACLs.
ro	Optional. Grants read-only access, allowing retrieval of MIB objects.

rw	Optional. Grants read-write access, allowing retrieval and modification of MIB objects.
view <*name*>	Optional. Specifies a previously defined view. Views define specific MIB objects available to the specified community string. For information on creating a new view, refer to *snmp-server view <name> <value> on page 1831*.
any-vrf	Optional. Specifies the ACL is applied to any virtual routing and forwarding (VRF) instance.
vrf <*name*>	Optional. Specifies the ACL is applied to a specific VRF instance.

*The parameters [**any-vrf** | **vrf** <name>] can only be entered if an **ip access-class** or **ipv6 access-class** is specified.*

Default Values

By default, there are no configured SNMP communities.

Command History

Release 1.1	Command was introduced.
Release 9.1	Command was expanded to include the **view** parameter.
Release 18.2	Command syntax was changed to include the **ip access-class** and **ipv6 access-class** parameters for IPv6 support in Adtran internetworking products only.
Release R10.1.0	Command syntax was changed to include the **ip access-class** and **ipv6 access-class** parameters for IPv6 support in Adtran voice products.
Release R10.8.0	Command was expanded to include the **any-vrf** and **vrf** <*name*> parameters.

Functional Notes

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

SNMP server communities can specify up to two ACLs to control access, one each for IPv4 and IPv6 protocols. When two ACLs are used, they must use the same VRF restriction (the default VRF, any VRF, or a specific VRF.) If no VRF is named, the default unnamed VRF is assumed.

Usage Examples

The following example specifies a community named **MyCommunity**, specifies a previously defined view named **blockinterfaces**, and assigns read-write access:

(config)**#snmp-server community MyCommunity view blockinterfaces rw**

snmp-server contact

Use the **snmp-server contact** command to specify Simple Network Management Protocol (SNMP) server contact information. Use the **no** form of this command to remove a configured contact. Variations of this command include:

snmp-server contact email <*address*>
snmp-server contact pager <*number*>
snmp-server contact phone <*number*>
snmp-server contact *"<string>"*

Syntax Description

email <*address*>	Specifies email address for the SNMP server contact.
pager <*number*>	Specifies pager number for the SNMP server contact.
phone <*number*>	Specifies phone number for the SNMP server contact.
"<string>"	Populates the sysContact string using an alphanumeric string enclosed in quotation marks (up to 32 characters in length).

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example specifies **6536999** for the pager number:

(config)**#snmp-server contact pager 6536999**

snmp-server context <*string*> vrf <*name*>

Use the **snmp-server context vrf** command to map the Simple Network Management Protocol (SNMP) context to the appropriate non-default virtual routing and forwarding (VRF) instance. Use the **no** form of this command to return to the default setting.

Syntax Description

context <*string*>	Specifies the SNMP context name.
vrf <*ame*>	Specifies the non-default VRF instance to which to map the SNMP context.

Default Values

By default, there are no VRF context mappings.

Command History

Release R10.11.0	Command was introduced.

Functional Notes

VRF context mapping is used to map the context of SNMP requests to the appropriate VRF instance. This is only necessary in multi-VRF installations where the content of the following four management information base (MIB) tables are used:

- IP-MIB::ipAddressTable
- IP-MIB::ipAddrTable
- IP-FORWARD-MIB::inetCidrRouteTable
- IP-FORWARD-MIB::ipCidrRouteTable

Context mapping does not apply to SNMP version 1 and version 2.

If your installation meets the above requirements, additional steps must be taken to ensure SNMP requests reach the correct destination.

- Define VRF instances on the AOS router. (Refer to *Configuring Multi-VRF in AOS* for more information.)
- Define a VRF context mapping to associate the VRF instance to the appropriate context name.
- Create an SNMP group for each non-default VRF instance. (Refer to the command *snmp-server group on page 1799* for more information.)
- Create an SNMP user and associate the user to appropriate SNMP group for each VRF instance. (Refer to *snmp-server user on page 1821* command for more information.)

Usage Examples

The following example maps the SNMP context **RED-CONTEXT** to the VRF instance **RED**:

(config)**#snmp-server context RED-CONTEXT vrf RED**

snmp-server enable traps

Use the **snmp-server enable traps** command to enable all Simple Network Management Protocol (SNMP) traps available on your system. Use the **no** form of this command to disable SNMP traps. Variations of this command include:

snmp-server enable traps
snmp-server enable traps application
snmp-server enable traps battery
snmp-server enable traps bgp
snmp-server enable traps delay track <*name*>
snmp-server enable traps dying-gasp
snmp-server enable traps entity
snmp-server enable traps eps
snmp-server enable traps fan
snmp-server enable traps frame-relay
snmp-server enable traps network-sync
snmp-server enable traps resource
snmp-server enable traps rps
snmp-server enable traps sfp
snmp-server enable traps snmp
snmp-server enable traps unit
snmp-server enable traps track
snmp-server enable traps voice
snmp-server enable traps vrrp

Syntax Description

application	Optional. Enables SNMP traps for applications (such as, Domain Naming System (DNS) traps).
battery	Optional. Enables traps for battery status.
bgp	Optional. Enables the Border Gateway Protocol (BGP) traps.
dying-gasp	Optional. Enables the dying-gasp traps. Refer to the **Functional Notes** below for more information on configuring a dying-gasp trap host.
delay track <*name*>	Optional. Enables SNMP traps to be buffered instead of sent immediately based on the status of the named track.
entity	Optional. Enables the entity sensor traps such as insertion and deletion of a small form-factor pluggable (SFP) interface module.
eps	Optional. Enables the external power supply (EPS) traps for connection state changes and failures.
fan	Optional. Enables the fan failure notification traps.
frame-relay	Optional. Enables the Frame Relay notification traps.
network-sync	Optional. Enables the network synchronization notification traps.
resource	Optional. Enables the resource utilization notification traps. This option is only available on AOS voice products.

rps	Optional. Enables the redundant power supply (RPS) traps for connection state changes and failures.
sfp	Optional. Enables the small form-factor pluggable (SFP) traps.
snmp	Optional. Enables the SNMP notification traps. The following SNMP traps are supported: **coldStart** **warmStart** **linkUp** **linkDown** **authenticationFailure**
track	Optional. Enables the network monitor track traps.
unit	Optional. Enables user login/logout traps for the unit.
voice	Optional. Enables voice notification traps.
vrrp	Optional. Enables Virtual Router Redundancy Protocol version 2 (VRRPv2) and version 3 (VRRPv3) traps.

Default Values

By default, there are no traps enabled.

Command History

Release 1.1	Command was introduced.
Release 17.3	Command was expanded to include the Frame Relay.
Release 17.6	Command was expanded to include **voice** traps.
Release A2.04	Command was expanded to include **resource** traps.
Release 18.1	Command was expanded to include **bgp** and **track** traps.
Release R10.3.0	Command was expanded to include **application** traps.
Release R10.8.0	Command was expanded to include **eps** and **rps** traps.
Release R10.11.0	Command was expanded to include **entity**, **fan** and **network-sync** traps.
Release R11.3.0	Command was expanded to include **vrrp** traps.
Release R11.6.0	Command was expanded to include **dying-gasp** traps.
Release R11.11.0	Command was expanded to include **battery** traps.
Release R13.3.0	Command was expanded to include **sfp** and **unit** traps. Added the ability to delay traps for tracks.

Functional Notes

Resource utilization traps are configured by using the command *resource-utilization on page 1684*.

If **dying-gasp** traps are enabled, the SNMP host must be configured separately to receive the traps using the **snmp-server host** [*<ip address>* | **vrf** *<name> <ip address>*] **dying-gasp-traps [1 | 2]** command. Refer to *snmp-server host dying-gasp-traps on page 1807* for more information.

Usage Examples

The following example enables SNMP traps:

(config)**#snmp-server enable traps snmp**

The following example enables all traps:

(config)**#snmp-server enable traps**

snmp-server engineID local <*hex string*>

Use the **snmp-server engineID local** command to change the default and manually set the Simple Network Management Protocol (SNMP) version 3 (v3) engine ID for the local machine. Use the **no** form of this command to return to the default engine ID.

Syntax Description

<hex string>	Defines the engine ID for the system. Engine IDs are the 12-octet hexadecimal representation (24 characters using 0 through 9 and/or a through f) defining a system on the management domain. Refer to the *Technology Review* for more detailed information on engine ID octet assignments.

SNMP v3 requires unique engine IDs for all systems in the management domain. Use the default engine ID when possible to ensure the uniqueness of the numbers. Problems can occur on a management network that contains duplicate engine IDs.

Default Values

By default, the local SNMP-server engine ID is **8000029803xxxxxxxxxxxx** (where the string of Xs represents the system medium access control (MAC) address).

Command History

Release 14.1	Command was introduced.

Usage Examples

The following example changes the default engine ID for the local system to **80 00 02 98 00 00 00 00 00 00 01** (where **80 00 02 98** represents the Internet Assigned Numbers Authority (IANA) ID for Adtran and **00 00 00 00 00 00 01** arbitrarily represents the first system on the management domain):

(config)**#snmp-server engineID local 800002980000000000000001**

Technology Review

The SNMP v3 engine ID is a unique identifier for a system on a management domain. The default engine ID contains 11 octets (in hexadecimal notation) that represent certain information about the system. The default engine ID format is as follows:

Octets 1 to 4	Octet 5	Octets 6 to 11
IANA ID for the product manufacturer	**03** Identifies that octets 6 through 11 contain a MAC address	System MAC address

The first 4 octets of the default engine ID for Adtran products is 80000298. Octets 1 through 4 represent the SNMP private enterprise number (assigned by the IANA) for the product manufacturer. The leading bit of octet 1 (the most significant bit) will always be a 1 for a default engine ID (making the leading character in the hex string an 8). Adtran products use the IANA ID of 664 (which is 02 98 in hexadecimal notation). Octet 5 is set to 03 to indicate that the engine ID uses a MAC address as the unique identifier. The last six octets of the default engine ID for Adtran routers contain the MAC address for the Ethernet 0/1 interface (for example, 00127905257c).

The **snmp-server engineID local** command overrides the default engine ID and replaces it with the first 24 characters of the user-entered string. Because the string is in hexadecimal notation, only numbers 0 through 9 and characters a through f are valid. If fewer than 24 characters are entered in the string, pad the end of the entered string with zeros (least significant bits) until the 24-character string is complete. For example, a user input of 8000029805 results in an engine ID of 800002980500000000000000.

snmp-server engineID remote

Use the **snmp-server engineID remote** command to identify a remote Simple Network Management Protocol (SNMP) entity's engine ID. The remote engine ID is necessary before SNMP version 3 (SNMPv3) inform notifications can be acknowledged. Refer to the command *snmp-server user on page 1821* for additional information about how it is used in conjunction with this command. Use the **no** form of this command to remove the remote SNMP entity's engine ID. Variations of this command include:

snmp-server engineID remote auto-link *<hex string>*
snmp-server engineID remote *<ip address> <hex string>*
snmp-server engineID remote vrf *<name> <ip address> <hex string>*

Syntax Description

auto-link	Specifies that the remote SNMP device Internet Protocol version 4 (IPv4) address follows the active auto-link server.
<ip address>	Specifies the IPv4 or Internet Protocol version 6 (IPv6) address for the remote SNMP device. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). IPv6 addresses should be expressed in colon hexadecimal format X:X:X:X::X, for example, **2001:DB8:1::1**.
<hex string>	Specifies the engine ID for the remote SNMP device.
vrf <name>	Specifies the VRF instance on which the remote SNMP device exists. If no VRF is specified, the SNMP device exists on the default unnamed VRF.

Default Values

By default, there are no remote engine IDs identified.

Command History

Release 14.1	Command was introduced.
Release R10.7.0	Command was expanded to include the **auto-link** parameter.
Release R10.8.0	Command was expanded to include the **vrf** *<name>* parameter.

Functional Notes

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Use the following requirements to avoid errors when configuring SNMP server and multi-VRF in AOS:

- For a remote engine ID with a VRF specified, a remote user with the same host address and VRF must be configured.
- If a VRF name is not specified for the remote engine ID and user, the default VRF will be used.
- A VRF associated with a remote address must be the same as the access class list (ACL) VRF and must match the remote engineID VRF. If they do not match, an error will display.

Usage Examples

The following example identifies a remote SNMP device with an IPv4 address of **10.10.12.2** and an engine ID of **80000298000000A0C8000001**:

(config)**#snmp-server engineID remote 10.10.12.2 80000298000000A0C8000001**

snmp-server group

Use the **snmp-server group** command to specify a new Simple Network Management Protocol (SNMP) server group to control access to SNMP information. Use the **no** form of this command to remove a specified group. Variations of this command include:

snmp-server group <*groupname*> **v1**
snmp-server group <*groupname*> **v1 [ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**]**
[notify <*name*>**] [read** <*name*>**] [write** <*name*>**] [any-vrf | vrf** <*name*>**]**
snmp-server group <*groupname*> **v2c**
snmp-server group <*groupname*> **v2c [ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**]**
[notify <*name*>**] [read** <*name*>**] [write** <*name*>**] [any-vrf | vrf** <*name*>**]**
snmp-server group <*groupname*> **v3 auth**
snmp-server group <*groupname*> **v3 auth context** <*string*>
snmp-server group <*groupname*> **v3 auth [ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**]**
[notify <*name*>**] [read** <*name*>**] [write** <*name*>**] [any-vrf | vrf** <*name*>**]**
snmp-server group <*groupname*> **v3 auth context** <*string*> **[ip access-class** <*ipv4 acl*> **| ipv6**
access-class <*ipv6 acl*>**] [notify** <*name*>**] [read** <*name*>**] [write** <*name*>**] [any-vrf | vrf** <*name*>**]**
snmp-server group <*groupname*> **v3 noauth**
snmp-server group <*groupname*> **v3 noauth context** <*string*>
snmp-server group <*groupname*> **v3 noauth [ip access-class** <*ipv4 acl*> **| ipv6 access-class**
<*ipv6 acl*>**] [notify** <*name*> | **read** <*name*> | **write** <*name*>**] [any-vrf | vrf** <*name*>**]**
snmp-server group <*groupname*> **v3 noauth context** <*string*> **[ip access-class** <*ipv4 acl*> **| ipv6**
access-class <*ipv6 acl*>**] [notify** <*name*> | **read** <*name*> | **write** <*name*>**] [any-vrf |**
vrf <*name*>**]**
snmp-server group <*groupname*> **v3 priv**
snmp-server group <*groupname*> **v3 priv context** <*string*>
snmp-server group <*groupname*> **v3 priv [ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**]**
[notify <*name*>**] [read** <*name*>**] [write** <*name*>**] [any-vrf | vrf** <*name*>**]**
snmp-server group <*groupname*> **v3 priv context** <*string*> **[ip access-class** <*ipv4 acl*> **| ipv6**
access-class <*ipv6 acl*>**] [notify** <*name*>**] [read** <*name*>**] [write** <*name*>**] [any-vrf | vrf** <*name*>**]**

Syntax Description

<*groupname*>	Specifies the name of the SNMP server group (32 characters maximum).
v1	Specifies using SNMP version 1 security model.
v2c	Specifies using SNMP version 2c security model.
v3	Specifies using SNMP version 3 user-based security model (USM).
auth	Optional. Only used in SNMP version 3. Indicates that authentication is used.
noauth	Optional. Only used in SNMP version 3. Indicates that no authentication is used.
priv	Optional. Only used in SNMP version 3. Indicates that privacy authentication is used.

context <*string*>	Optional. Only used in SNMP version 3 with multi-VRF installations. Specifies a context for VRF context mapping.
ip access-class <*ipv4 acl*>	Optional. Specifies an Internet Protocol version 4 (IPv4) access control list (ACL) entry.
ipv6 access-class <*ipv6 acl*>	Optional. Specifies an Internet Protocol version 6 (IPv6) ACL entry.
notify <*name*>	Optional. Specifies a previously configured SNMP view name to which the group has notify access (32 characters maximum). If a view is not specified, the system automatically assigned a default notify-view with no restrictions.
read <*name*>	Optional. Specifies a previously configured SNMP view name to which the group has read access (32 characters maximum). If a view is not specified, the system automatically assigned a default read-view with no restrictions.
write <*name*>	Optional. Specifies a previously configured SNMP view name to which the group has write access(32 characters maximum). If a write-view is not specified, write access is restricted for all users of the group.
any-vrf	Optional. Specifies the ACL is applied to any virtual routing and forwarding (VRF) instance.
vrf <*name*>	Optional. Specifies the ACL is applied to a specific non-default VRF instance.

Default Values

If no views are specified, the system automatically assigns default read- and notify-views that have no restrictions.

Command History

Release 13.1	Command was introduced.
Release 18.2	Command syntax was changed to include the **ip access-class** and **ipv6 access-class** parameters for IPv6 support in Adtran internetworking products only.
Release R10.1.0	Command syntax was changed to include the **ip access-class** and **ipv6 access-class** parameters for IPv6 support in Adtran voice products.
Release R10.8.0	Command was expanded to include the **any-vrf** and **vrf** <*name*> parameters.
Release R10.11.0	Command was expanded to include the **context** <*string*> parameter.

Functional Notes

SNMP groups are used to map SNMP users to SNMP views. To create a group, specify one or more views to which users will have access. A given view can be accessed by more than one group, as needed.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

SNMP context mapping is only used in conjunction with multi-VRF configurations to ensure proper delivery of SNMP requests. The SNMP context is mapped to a specific VRF instance to differentiate between the same IP address used across multiple VRFs.

SNMP server communities can specify up to two ACLs to control access, one each for IPv4 and IPv6 protocols. When two ACLs are used, they must use the same VRF restriction (the default VRF, any VRF, or a specific VRF.) If no VRF is named, the default unnamed VRF is assumed.

Usage Examples

The following example defines a group called **securityV3auth** using version 3 security model, authentication, and no ACL to verify:

(config)**#snmp-server group securityV3auth v3 auth**

snmp-server host auto-link dying-gasp-traps

Use the **snmp-server host auto-link dying-gasp-traps** command to configure the unit to send Simple Network Management Protocol (SNMP) dying-gasp traps messages to the active auto-link server. Use the **no** form of this command to disable the setting. Variations of this command include the following:

snmp-server host auto-link dying-gasp-traps 1 <*community*>
snmp-server host auto-linkdying-gasp-traps 1 version 1 <*community*>
snmp-server host auto-link dying-gasp-traps 1 version 2c <*community*>
snmp-server host auto-link dying-gasp-traps 1 version 3 auth <*user name*>
snmp-server host auto-link dying-gasp-traps 1 version 3 noauth <*user name*>
snmp-server host auto-link dying-gasp-traps 1 version 3 priv <*user name*>
snmp-server host auto-link dying-gasp-traps 2 <*community*>
snmp-server host auto-link dying-gasp-traps 2 version 1 <*community*>
snmp-server host auto-link dying-gasp-traps 2 version 2c <*community*>
snmp-server host auto-link dying-gasp-traps 2 version 3 auth <*user name*>
snmp-server host auto-link dying-gasp-traps 2 version 3 noauth <*user name*>
snmp-server host auto-link dying-gasp-traps 2 version 3 priv <*user name*>

Syntax Description

version 1	Specifies using SNMP version 1 security model.
version 2c	Specifies using SNMP version 2c security model.
version 3	Specifies using SNMP version 3 user-based security model (USM).
auth	Only used in SNMP version 3. Indicates that authentication is used.
noauth	Only used in SNMP version 3. Indicates that no authentication is used.
priv	Only used in SNMP version 3. Indicates that privacy authentication is used.
<*community*>	Specifies the community string (used as a password, 16 characters maximum) for authorized agents to obtain access to SNMP information.
<*user name*>	Specifies the user name for SNMP version 3 security.

Default Values

No default values are necessary for this command.

Command History

Release R11.6.0	Command was introduced.

Usage Examples

The following example configures an auto-link host as the first priority server to receive dying-gasp traps using SNMP **version 2c** and sets the community string to **MyCommunity**:

(config)**#snmp-server host auto-link dying-gasp-traps 1 version 2c MyCommunity**

snmp-server host auto-link informs

Use the **snmp-server host auto-link informs** command to configure the unit to send Simple Network Management Protocol (SNMP) INFORM messages to the active auto-link server. Use the **no** form of this command to disable the setting. Variations of this command include the following:

snmp-server host auto-link informs <*community*>
snmp-server host auto-link informs version 1 <*community*>
snmp-server host auto-link informs version 1 <*community*> **battery**
snmp-server host auto-link informs version 1 <*community*> **eps**
snmp-server host auto-link informs version 1 <*community*> **rps**
snmp-server host auto-link informs version 1 <*community*> **sfp**
snmp-server host auto-link informs version 1 <*community*> **snmp**
snmp-server host auto-link informs version 1 <*community*> **unit**
snmp-server host auto-link informs version 2c <*community*>
snmp-server host auto-link informs version 2c <*community*> **battery**
snmp-server host auto-link informs version 2c <*community*> **eps**
snmp-server host auto-link informs version 2c <*community*> **rps**
snmp-server host auto-link informs version 2c <*community*> **sfp**
snmp-server host auto-link informs version 2c <*community*> **snmp**
snmp-server host auto-link informs version 2c <*community*> **unit**
snmp-server host auto-link informs version 3 auth <*community*>
snmp-server host auto-link informs version 3 auth <*community*> **battery**
snmp-server host auto-link informs version 3 auth <*community*> **eps**
snmp-server host auto-link informs version 3 auth <*community*> **rps**
snmp-server host auto-link informs version 3 auth <*community*> **sfp**
snmp-server host auto-link informs version 3 auth <*community*> **snmp**
snmp-server host auto-link informs version 3 auth <*community*> **unit**
snmp-server host auto-link informs version 3 noauth <*community*>
snmp-server host auto-link informs version 3 noauth <*community*> **battery**
snmp-server host auto-link informs version 3 noauth <*community*> **eps**
snmp-server host auto-link informs version 3 noauth <*community*> **rps**
snmp-server host auto-link informs version 3 noauth <*community*> **sfp**
snmp-server host auto-link informs version 3 noauth <*community*> **snmp**
snmp-server host auto-link informs version 3 noauth <*community*> **unit**
snmp-server host auto-link informs version 3 priv <*community*>
snmp-server host auto-link informs version 3 priv <*community*> **battery**
snmp-server host auto-link informs version 3 priv <*community*> **eps**
snmp-server host auto-link informs version 3 priv <*community*> **rps**
snmp-server host auto-link informs version 3 priv <*community*> **sfp**
snmp-server host auto-link informs version 3 priv <*community*> **snmp**
snmp-server host auto-link informs version 3 priv <*community*> **unit**

Syntax Description

version 1	Specifies using SNMP version 1 security model.
version 2c	Specifies using SNMP version 2c security model.

version 3	Specifies using SNMP version 3 user-based security model (USM).
auth	Only used in SNMP version 3. Indicates that authentication is used.
noauth	Only used in SNMP version 3. Indicates that no authentication is used.
priv	Only used in SNMP version 3. Indicates that privacy authentication is used.
<*community*>	Specifies the community string (used as a password) (16 characters maximum) for authorized agents to obtain access to SNMP information.
battery	Optional. Allows battery trap informs.
eps	Optional. Allows external power supply (EPS) informs.
rps	Optional. Allows redundant power supply (RPS) informs.
sfp	Optional. Allows small form-factor pluggable (SFP) informs.
snmp	Optional. Allows SNMP informs.
unit	Optional. Allows unit informs for user login/logout.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.
Release R10.9.0	Command was expanded to include the **eps** and **rps** parameters.
Release R11.11.0	Command was expanded to include the **battery** parameter.
Release R13.2.0	Command was expanded to include the **sfp** and **unit** parameters.

Usage Examples

The following example sends all SNMP informs to the auto-link host and community string **MyCommunity** using SNMP **version 2c**:

(config)**#snmp-server host auto-link informs version 2c MyCommunity snmp**

snmp-server host auto-link traps

Use the **snmp-server host auto-link traps** command to configure the unit to send traps to the active auto-link server. Use the **no** form of this command to disable the setting. Variations of this command include the following:

snmp-server host auto-link traps <*community*>
snmp-server host auto-link traps version 1 <*community*> **[application] [battery] [bgp] [entity] [eps] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [rps] [sfp] [snmp] [track] [unit] [voice] [vrrp]**
snmp-server host auto-link traps version 2c <*community*> **[application] [battery] [bgp] [entity] [eps] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [rps] [sfp] [snmp] [track] [unit] [voice] [vrrp]**
snmp-server host auto-link traps version 3 auth <*community*> **[application] [battery] [bgp] [entity] [eps] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [rps] [sfp] [snmp] [track] [unit] [voice] [vrrp]**
snmp-server host auto-link traps version 3 noauth <*community*> **[application] [battery] [bgp] [entity] [eps] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [rps] [sfp] [snmp] [track] [unit] [voice] [vrrp]**
snmp-server host auto-link traps version 3 priv <*community*> **[application] [battery] [bgp] [entity] [eps] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [rps] [sfp] [snmp] [track] [unit] [voice] [vrrp]**

Syntax Description

version 1	Specifies using Simple Network Management Protocol (SNMP) version 1 security model.
version 2c	Specifies using SNMP version 2c security model.
version 3	Specifies using SNMP version 3 user-based security model (USM).
auth	Only used in SNMP version 3. Indicates that authentication is used.
noauth	Only used in SNMP version 3. Indicates that no authentication is used.
priv	Only used in SNMP version 3. Indicates that privacy authentication is used.
<*community*>	Specifies the community string (used as a password) (16 characters maximum) for authorized agents to obtain access to SNMP information.
application	Optional. Allows application traps (such as, Domain Naming System (DNS) traps).
battery	Optional. Enables battery status traps.
bgp	Optional. Allows Border Gateway Protocol (BGP) traps.
entity	Optional. Enables the entity sensor traps such as insertion and deletion of a small form-factor pluggable (SFP) interface module.
eps	Optional. Allows external power supply (EPS) traps.
fan	Optional. Enables the fan failure notification trap.
frame-relay	Optional. Allows Frame Relay traps.
network-sync	Optional. Enables the network synchronization notification traps.
over-temperature	Optional. Enables the over-temperature protection traps.

resource	Optional. Enables the resource utilization set of traps.
rps	Optional. Allows redundant power supply (RPS) traps.
sfp	Optional. Allows small form-factor pluggable (SFP) traps.
snmp	Optional. Allows SNMP traps.
unit	Optional. Allows unit traps for user login/logout.
track	Optional. Allows network monitor track traps.
voice	Optional. Allows voice traps.
vrrp	Optional. Allows Virtual Router Redundancy Protocol version 2 (VRRPv2) and version 3 (VRRPv3) traps.

Default Values

No default values are necessary for this command.

Command History

Release 1.1	Command was introduced.
Release 17.6	Command was expanded to include the **frame-relay** parameter.
Release 17.9	Command was expanded to include more **frame-relay** options, more **snmp** options, and the **voice** parameter. In addition, the **snmp-server host** <*ip address*> **traps version 3 priv** <*community*> version of the command was removed.
Release A2.04	Command was expanded to include **resource** traps.
Release 18.1	Command was expanded to include the **bgp** and **track** parameter.
Release R10.4.0	Command was expanded to include the **application** parameter.
Release R10.8.0	Command was expanded to include the **eps** and **rps** parameters.
Release R10.11.0	Command was expanded to include **entity, fan**, and **network-sync** traps.
Release R11.3.0	Command was expanded to include **vrrp** traps.
Release R11.6.0	Command was expanded to include the **over-temperature** protection.
Release R11.11.0	Command was expanded to include **battery** traps.
Release R13.2.0	Command was expanded to include the **sfp** and **unit** parameters.

Usage Examples

The following example sends all enabled traps to the auto-link host using SNMP **version 2c** and sets the community string to **MyCommunity**:

(config)**#snmp-server host auto-link traps version 2c MyCommunity**

snmp-server host dying-gasp-traps

Use the **snmp-server host dying-gasp-traps** command to configure the unit to send Simple Network Management Protocol (SNMP) dying-gasp traps messages to the specified SNMP host. Use the **no** form of this command to remove a specified host. Variations of this command include the following:

snmp-server host [<*ip address*> | <*name*>**] dying-gasp-traps 1** <*community*>
snmp-server host [<*ip address*> | <*name*>**] dying-gasp-traps 1 version 1** <*community*>
snmp-server host [<*ip address*> | <*name*>**] dying-gasp-traps 1 version 2c** <*community*>
snmp-server host [<*ip address*> | <*name*>**] dying-gasp-traps 1 version 3 auth** <*user name*>
snmp-server host [<*ip address*> | <*name*>**] dying-gasp-traps 1 version 3 noauth** <*user name*>
snmp-server host [<*ip address*> | <*name*>**] dying-gasp-traps 1 version 3 priv** <*user name*>
snmp-server host [<*ip address*> | <*name*>**] dying-gasp-traps 2** <*community*>
snmp-server host [<*ip address*> | <*name*>**] dying-gasp-traps 2 version 1** <*community*>
snmp-server host [<*ip address*> | <*name*>**] dying-gasp-traps 2 version 2c** <*community*>
snmp-server host [<*ip address*> | <*name*>**] dying-gasp-traps 2 version 3 auth** <*user name*>
snmp-server host [<*ip address*> | <*name*>**] dying-gasp-traps 2 version 3 noauth** <*user name*>
snmp-server host [<*ip address*> | <*name*>**] dying-gasp-traps 2 version 3 priv** <*user name*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] dying-gasp-traps 1** <*community*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] dying-gasp-traps 1 version 1** <*community*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] dying-gasp-traps 1 version 2c** <*community*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] dying-gasp-traps 1 version 3 auth** <*user name*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] dying-gasp-traps 1 version 3 noauth** <*user name*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] dying-gasp-traps 1 version 3 priv** <*user name*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] dying-gasp-traps 2** <*community*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] dying-gasp-traps 2 version 1** <*community*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] dying-gasp-traps 2 version 2c** <*community*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] dying-gasp-traps 2 version 3 auth** <*user name*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] dying-gasp-traps 2 version 3 noauth** <*user name*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] dying-gasp-traps 2 version 3 priv** <*user name*>

Syntax Description

<*ip address*>	Specifies the IP address (either Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6)) of the SNMP host that receives the SNMP information. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). IPv6 addresses should be expressed in colon hexadecimal format X:X:X:X::X, for example, **2001:DB8:1::1**.
<name>	Specifies the Fully Qualified Domain Name (FQDN) (e.g., **adtran.com**) of the SNMP host that receives the SNMP information.

vrf <*name*>	Optional. Specifies the VRF instance on which the host exists. If a VRF instance is not specified, the default unnamed VRF is assumed.
version 1	Specifies using SNMP version 1 security model.
version 2c	Specifies using SNMP version 2c security model.
version 3	Specifies using SNMP version 3 user-based security model (USM).
auth	Only used in SNMP version 3. Indicates that authentication is used.
noauth	Only used in SNMP version 3. Indicates that no authentication is used.
priv	Only used in SNMP version 3. Indicates that privacy authentication is used.
<*community*>	Specifies the community string (used as a password, 16 characters maximum) for authorized agents to obtain access to SNMP information.
<*user name*>	Specifies the user name for SNMP version 3 security.

Default Values

No default values are necessary for this command.

Command History

Release R11.6.0	Command was introduced.
Release R13.3.0	Command was expanded to allow the <*name*> of a FQDN server to be specified as the recipient of SNMP information.

Functional Notes

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the above mentioned commands without specifying a VRF will only affect the default unnamed VRF.

Usage Examples

The following example configures an SNMP server host at IPv4 address **190.3.44.69** as the first priority server to receive dying-gasp traps using SNMP **version 2c** and set the community string to **MyCommunity**:

(config)**#snmp-server host 190.3.44.69 dying-gasp-traps 1 version 2c MyCommunity**

snmp-server host informs

Use the **snmp-server host informs** command to configure the unit to send Simple Network Management Protocol (SNMP) INFORM messages to the specified SNMP host. Use the **no** form of this command to remove a specified host. Variations of this command include the following:

snmp-server host [<*ip address*> | <*name*>**] informs** <*community*>
snmp-server host [<*ip address*> | <*name*>**] informs version 1** <*community*>
snmp-server host [<*ip address*> | <*name*>**] informs version 1** <*community*> **[battery] [eps] [rps] [sfp] [snmp] [unit]**
snmp-server host [<*ip address*> | <*name*>**] informs version 2c** <*community*>
snmp-server host [<*ip address*> | <*name*>**] informs version 2c** <*community*> **[battery] [eps] [rps] [sfp] [snmp] [unit]**
snmp-server host [<*ip address*> | <*name*>**] informs version 3 auth** <*community*>
snmp-server host [<*ip address*> | <*name*>**] informs version 3 auth** <*community*> **[battery] [eps] [rps] [sfp] [snmp] [unit]**
snmp-server host [<*ip address*> | <*name*>**] informs version 3 noauth** <*community*>
snmp-server host [<*ip address*> | <*name*>**] informs version 3 noauth** <*community*> **[battery] [eps] [rps] [sfp] [snmp] [unit]**
snmp-server host [<*ip address*> | <*name*>**] informs version 3 priv** <*community*>
snmp-server host [<*ip address*> | <*name*>**] informs version 3 priv** <*community*> **[battery] [eps] [rps] [sfp] [snmp] [unit]**
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] informs** <*community*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] informs version 1** <*community*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] informs version 1** <*community*> **[battery] [sfp] [snmp] [unit]**
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] informs version 2c** <*community*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] informs version 2c** <*community*> **[battery] [sfp] [snmp] [unit]**
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] informs version 3 auth** <*community*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] informs version 3 auth** <*community*> **[battery] [sfp] [snmp] [unit]**
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] informs version 3 noauth** <*community*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] informs version 3 noauth** <*community*> **[battery] [sfp] [snmp] [unit]**
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] informs version 3 priv** <*community*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] informs version 3 priv** <*community*> **[battery] [sfp] [snmp] [unit]**

Syntax Description

<*ip address*>	Specifies the IP address (either Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6)) of the SNMP host that receives the SNMP information. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). IPv6 addresses should be expressed in colon hexadecimal format X:X:X:X::X, for example, **2001:DB8:1::1**.

<name>	Specifies the Fully Qualified Domain Name (FQDN) (e.g., **adtran.com**) of the SNMP host that receives the SNMP information.
vrf *<name>*	Optional. Specifies the VRF instance on which the host exists. If a VRF instance is not specified, the default unnamed VRF is assumed.
version 1	Specifies using SNMP version 1 security model.
version 2c	Specifies using SNMP version 2c security model.
version 3	Specifies using SNMP version 3 user-based security model (USM).
auth	Only used in SNMP version 3. Indicates that authentication is used.
noauth	Only used in SNMP version 3. Indicates that no authentication is used.
priv	Only used in SNMP version 3. Indicates that privacy authentication is used.
<community>	Specifies the community string (used as a password) (16 characters maximum) for authorized agents to obtain access to SNMP information.
battery	Optional. Allows battery trap informs.
eps	Optional. Allows external power supply (EPS) informs.
rps	Optional. Allows redundant power supply (RPS) informs.
sfp	Optional. Allows small form-factor pluggable (SFP) informs.
snmp	Optional. Allows SNMP informs.
unit	Optional. Allows unit informs for user login/logout.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.
Release 13.1	Command was expanded to include the **informs** options.
Release R10.8.0	Command was expanded to include the **vrf** *<name>* parameter.
Release R10.9.0	Command was expanded to include the **eps** and **rps** parameters on the default VRF instance.
Release R11.11.0	Command was expanded to include the **battery** parameter.
Release R13.2.0	Command was expanded to include the **sfp** and **unit** parameters.
Release R13.3.0	Command was expanded to allow the *<name>* of a FQDN server to be specified as the recipient of SNMP information.

Functional Notes

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the above mentioned commands without specifying a VRF will only affect the default unnamed VRF.

Usage Examples

The following example sends all SNMP informs to the host at IPv4 address **190.3.44.69** and community string **MyCommunity** using SNMP **version 2c**:

(config)**#snmp-server host 190.3.44.69 informs version 2c MyCommunity snmp**

snmp-server host traps

Use the **snmp-server host traps** command to configure the unit to send traps to the specified SNMP host. Use the **no** form of this command to remove a specified host. Variations of this command include the following:

snmp-server host [<*ip address*> | <*name*>**] traps** <*community*>
snmp-server host [<*ip address*> | <*name*>**] traps version 1** <*community*> **[application] [battery] [bgp] [eps] [entity] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [rps] [sfp] [snmp] [track] [unit] [voice] [vrrp]**
snmp-server host [<*ip address*> | <*name*>**] traps version 2c** <*community*> **[application] [battery] [bgp] [eps] [entity] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [rps] [sfp] [snmp] [track] [unit] [voice] [vrrp]**
snmp-server host [<*ip address*> | <*name*>**] traps version 3 auth** <*community*> **[application] [battery] [bgp] [eps] [entity] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [rps] [sfp] [snmp] [track] [unit] [voice] [vrrp]**
snmp-server host [<*ip address*> | <*name*>**] traps version 3 noauth** <*community*> **[application] [battery] [bgp] [eps] [entity] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [rps] [sfp] [snmp] [track] [unit] [voice] [vrrp]**
snmp-server host [<*ip address*> | <*name*>**] traps version 3 priv** <*community*> **[application] [battery] [bgp] [eps] [entity] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [rps] [sfp] [snmp] [track] [unit] [voice] [vrrp]**

snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] traps** <*community*>
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] traps version 1** <*community*> **[application] [battery] [bgp] [entity] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [sfp] [snmp] [track] [unit] [voice] [vrrp]**
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] traps version 2c** <*community*> **[application] [battery] [bgp] [entity] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [sfp] [snmp] [track] [unit] [voice] [vrrp]**
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] traps version 3 auth** <*community*> **[application] [battery] [bgp] [entity] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [sfp] [snmp] [track] [unit] [voice] [vrrp]**
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] traps version 3 noauth** <*community*> **[application] [battery] [bgp] [entity] [fan] [frame-relay] [network-sync] [over-temperature] [sfp] [snmp] [track] [unit] [voice] [vrrp]**
snmp-server host vrf <*name*> **[**<*ip address*> | <*name*>**] traps version 3 priv** <*community*> **[application] [battery] [bgp] [entity] [fan] [frame-relay] [network-sync] [over-temperature] [resource] [sfp] [snmp] [track] [unit] [voice] [vrrp]**

Syntax Description

<*ip address*>	Specifies the IP address (either Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6)) of the SNMP host that receives the SNMP information. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). IPv6 addresses should be expressed in colon hexadecimal format X:X:X:X::X, for example, **2001:DB8:1::1**.

<name>	Specifies the Fully Qualified Domain Name (FQDN) (e.g., **adtran.com**) of the SNMP host that receives the SNMP information.
traps	Enables traps to this host. If the version is not specified, version 1 is used.
vrf *<name>*	Optional. Specifies the VRF instance on which the host exists. If a VRF instance is not specified, the default unnamed VRF is assumed.
version 1	Specifies using SNMP version 1 security model.
version 2c	Specifies using SNMP version 2c security model.
version 3	Specifies using SNMP version 3 user-based security model (USM).
auth	Only used in SNMP version 3. Indicates that authentication is used.
noauth	Only used in SNMP version 3. Indicates that no authentication is used.
priv	Only used in SNMP version 3. Indicates that privacy authentication is used.
<community>	Specifies the community string (used as a password) (16 characters maximum) for authorized agents to obtain access to SNMP information.
application	Optional. Allows application traps (such as, Domain Naming System (DNS) traps).
battery	Optional. Enables battery status traps.
bgp	Optional. Allows Border Gateway Protocol (BGP) traps.
entity	Optional. Enables the entity sensor traps such as insertion and deletion of a small form-factor pluggable (SFP) interface module.
eps	Optional. Allows external power supply (EPS) traps.
fan	Optional. Enables the fan failure notification traps.
frame-relay	Optional. Allows Frame Relay traps.
network-sync	Optional. Enables the network synchronization notification traps.
over-temperature	Optional. Enables the over-temperature protection traps.
resource	Optional. Enables the resource utilization set of traps.
rps	Optional. Allows redundant power supply (RPS) traps.
sfp	Optional. Allows small form-factor pluggable (SFP) traps.
snmp	Optional. Allows SNMP traps.
unit	Optional. Allows unit traps for user login/logout.
track	Optional. Allows the network monitor track traps.
voice	Optional. Allows voice traps.
vrrp	Optional. Allows Virtual Router Redundancy Protocol version 2 (VRRPv2) and version 3 (VRRPv3) traps.

Default Values

No default values are necessary for this command.

Command History

Release 1.1	Command was introduced.
Release 17.6	Command was expanded to include the **frame-relay** parameter.
Release 17.9	Command was expanded to include more **frame-relay** options, more **snmp** options, and the **voice** parameter. In addition, the **snmp-server host** <*ip address*> **traps version 3 priv** <*community*> version of the command was removed.
Release A2.04	Command was expanded to include **resource** traps.
Release 18.1	Command was expanded to include the **bgp** and **track** parameter.
Release R10.4.0	Command was expanded to include the **application** parameter.
Release R10.8.0	Command was expanded to include the **eps**, **rps**, and **vrf** <*name*> parameter.
Release R10.11.0	Command was expanded to include **entity, fan**, and **network-sync** traps.
Release R11.3.0	Command was expanded to include **vrrp** traps.
Release R11.6.0	Command was expanded to include **over-temperature** protection.
Release R11.11.0	Command was expanded to include **battery** traps.
Release R13.2.0	Command was expanded to include **sfp** and **unit** parameters.
Release R13.3.0	Command was expanded to allow the <*name*> of a FQDN server to be specified as the recipient of SNMP information.

Functional Notes

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the above mentioned commands without specifying a VRF will only affect the default unnamed VRF.

Usage Examples

The following example sends all SNMP traps to the host at IPv4 address **190.3.44.69** and sets the community string to **MyCommunity** using SNMP **version 2c**:

(config)**#snmp-server host 190.3.44.69 traps version 2c MyCommunity snmp**

snmp-server inform

Use the **snmp-server inform** command to set the number of retry attempts for a response and set the amount of time to wait for a response before allowing a new request. Use the **no** form of this command to return to the default setting. Variations of this command include the following:

snmp-server inform retries <*number*>
snmp-server inform timeout <*value*>

Syntax Description

retries <*number*>	Specifies number of retries for a response. The range is from **1** to **100**.
timeout <*value*>	Specifies time (in seconds) to wait for a response. The range is from **1** to **1000** seconds.

Default Values

By default, the retry count is set to 3 and the timeout is set to 5 seconds.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example sets the retry count to **10**:

(config)**#snmp-server inform retries 10**

snmp-server location *“<string>”*

Use the **snmp-server location** command to specify the Simple Network Management Protocol (SNMP) system location string. Use the **no** form of this command to return to the default value.

Syntax Description

“<string>”	Populates the system location string using an alphanumeric string enclosed in quotation marks (up to 32 characters in length).

Default Values

By default, the **snmp-server location** is set to **Adtran**.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example specifies a location of **5th Floor Network Room**:

(config)**#snmp-server location “5th Floor Network Room”**

snmp-server management-url *<url>*

Use the **snmp-server management-url** command to specify the uniform resource locator (URL) for the device's management software. Use the **no** form of this command to remove the management URL.

Syntax Description

<url>	Specifies the URL for the management software.

Default Values

By default, no URL is defined.

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example specifies the URL **http://www.mywatch.com** as the device's management software:

(config)**#snmp-server management-url http://www.mywatch.com**

snmp-server management-url-label *<label>*

Use the **snmp-server management-url-label** command to specify a label for the uniform resource locator (URL) of the device's management software. Use the **no** form of this command to remove the label.

Syntax Description

<label>	Specifies a label for the URL of the management software (maximum length 255 characters).

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example specifies the label **watch** for the management software:

(config)**#snmp-server management-url-label watch**

snmp-server source-interface *<interface>*

Use the **snmp-server source-interface** command to specify a source interface for Simple Network Management Protocol (SNMP) traffic (including traps and get/set requests) originated by the unit. The IP address of the specified interface is used to source all SNMP traffic. The named Virtual Routing and Forwarding (VRF) instance further identifies the source interface when multiple VRF instances are configured on the router. Use the **no** form of this command to remove the specified interface.Variations of this command include:

snmp-server source-interface *<interface>*
snmp-server vrf *<name>* **source-interface** *<interface>*

Syntax Description

<interface>	Specifies the interface that should originate SNMP traffic. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **snmp-server source-interface ?** for a complete list of valid interfaces.
vrf *<name>*	Optional. Specifies the VRF instance on which the source interface exists.

Default Values

By default, there is no source-interface defined.

Command History

Release 7.1	Command was introduced.
Release 14.1	Command was expanded to include the tunnel interface.
Release 17.1	Command was expanded to include the asynchronous transfer mode (ATM) interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.8.0	Command was expanded to include the **vrf** <name> parameters.

Functional Notes

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the above mentioned command without specifying a VRF will only affect the default unnamed VRF.

Usage Examples

The following example specifies that the **ethernet 0/1** on VRF **RED** should be the source for all SNMP traps and get/set requests:

(config)**#snmp-server vrf RED source-interface ethernet 0/1**

snmp-server user

Use the **snmp-server user** command to configure Simple Network Management Protocol (SNMP) users to control access to SNMP information. Use the **no** form of this command to remove a user from the specified SNMP server group. Variations of this command include:

snmp-server user <*username*> <*groupname*> **v1**
snmp-server user <*username*> <*groupname*> **v1 [ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **v2c**
snmp-server user <*username*> <*groupname*> **v2c [ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **v3**
snmp-server user <*username*> <*groupname*> **v3 [ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **v3 auth md5** <*password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **v3 auth md5** <*password*> **priv des** <*password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **v3 auth sha** <*password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **v3 auth sha** <*password*> **priv des** <*password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**

NOTE *If **service password-encryption** is enabled, the running configuration changes to include the keyword **encrypted** before each password entry, which is masked. Refer to the command* *service password-encryption on page 1699**.*

Syntax Description

<*username*>	Specifies the name of the user.
<*groupname*>	Specifies the name of the group to which the user belongs.
v1	Specifies using the SNMP version 1 security model.
v2c	Specifies using the SNMP version 2c security model.
v3	Specifies using the SNMP version 3 (user-based) security model).
auth md5 <*password*>	Optional. Uses the HMAC-MD5-96 authentication level and a password string to build the key for the authentication level.
auth sha <*password*>	Optional. Uses the HMAC-SHA-96 authentication level and a password string to build the key for the authentication level.
priv des <*password*>	Optional. Uses the CBC-DES privacy authentication algorithm and a password string used for data encryption between the host and agent.
ip access-class <*ipv4 acl*>	Optional. Specifies an Internet Protocol version 4 (IPv4) access control list (ACL) entry.
ipv6 access-class <*ipv6 acl*>	Optional. Specifies an Internet Protocol version 6 (IPv6) ACL entry.

any-vrf	Optional. Specifies the ACL is applied to any virtual routing and forwarding (VRF) instance.
vrf <*name*>	Optional. Specifies the ACL is applied to a specific VRF instance. If no VRF is provided, the default unnamed VRF is assumed.

It is necessary to configure the SNMP engine ID before configuration of the remote users for a particular agent can be completed. Refer to the command *snmp-server engineID remote on page 1797* *for instructions in setting the engine ID with the remote option.*

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.
Release 18.2	Command syntax was changed to include the **ip access-class** and **ipv6 access-class** parameters for IPv6 support in Adtran internetworking products only.
Release R10.1.0	Command syntax was changed to include the **ip access-class** and **ipv6 access-class** parameters for IPv6 support in Adtran voice products.
Release R10.8.0	Command was expanded to include the **any-vrf** and **vrf** <*name*> parameters.

Functional Notes

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the above mentioned commands without specifying a VRF will only affect the default unnamed VRF.

The **snmp-server user** command can specify up to two ACLs to control access, one each for IPv4 and IPv6 protocols. When two ACLs are used, they must use the same VRF restriction (the default VRF, any VRF, or a specific VRF.) If no VRF is named, the default unnamed VRF is assumed.

Usage Examples

The following example enters a new user named **BobbyW** and assigns the user to a group called **securityV3auth** using version 3 security model, message digest 5 (MD5) authentication method with a password of **passWORD6243**, and no ACL to verify:

(config)#**snmp-server user BobbyW securityV3auth v3 auth md5 passWORD6243**

Technology Review

SNMP server users are configured and attached to a specified group with an SNMP version. The SNMP version defines the security model of the group, with SNMP version 1 (SNMPv1) being the least secure and SNMP version 3 (SNMPv3) the most secure. Groups also define the read, write, notify, and view access for each user that resides in the group.

Trap notifications in SNMP v1 and SNMP version 2 (SNMPv2) are sent once and do not require an acknowledgement upon receipt. With SNMPv3, a new form of notification type was introduced, called an inform. Unlike a trap sent with SNMPv1/v2, an inform requires a response be sent to the originating entity. If the originator of the inform notification does not receive the response before a specified timeout, the originator can resend until an acknowledgement response is received or a specified retry value is reached. Sending informs requires that the originator of the inform know the user, engine ID, security parameters, and belong to a group that grants access to the information.

SNMPv3 uses services, such as authentication, privacy, and ACLs to provide a higher level of security not present with v1 or v2. Of these new services, identifying an SNMP server user on a remote entity is necessary to receive and originate notifications, and also to generate and respond to commands.

snmp-server user <*username*> <*groupname*> remote <*host*> v3

Use the **snmp-server user remote v3** command to configure Simple Network Management Protocol version 3 (SNMPv3) users residing on a remote SNMP entity, to control access to SNMP information. The named Virtual Routing and Forwarding (VRF) instance further identifies the remote entity when multiple VRF instances are configured on the router. Use the **no** form of this command to remove a user from the specified SNMP group. Variations of this command include:

snmp-server user <*username*> <*groupname*> **remote** <*host*> **v3**
snmp-server user <*username*> <*groupname*> **remote** <*host*> **v3 [ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **remote** <*host*> **v3 auth md5** <*auth password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **remote** <*host*> **v3 auth md5** <*auth password*> **priv des** <*priv password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf <name>]**
snmp-server user <*username*> <*groupname*> **remote** <*host*> **v3 auth sha** <*auth password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **remote** <*host*> **v3 auth sha** <*auth password*> **priv des** <*priv password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **remote vrf** <*vrf name*> <*host*> **v3**
snmp-server user <*username*> <*groupname*> **remote vrf** <*vrf name*> <*host*> **v3 [ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **remote vrf** <*vrf name*> <*host*> **v3 auth md5** <*auth password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **remote vrf** <*vrf name*> <*host*> **v3 auth md5** <*auth password*> **priv des** <*priv password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **remote vrf** <*vrf name*> <*host*> **v3 auth sha** <*auth password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **remote vrf** <*vrf name*> <*host*> **v3 auth sha** <*auth password*> **priv des** <*priv password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**

*If **service password-encryption** is enabled, the running configuration changes to include the keyword **encrypted** before each password entry, which is masked. Refer to the command* *service password-encryption on page 1699**.*

Syntax Description

<*username*>	Specifies the name of the user.
<*groupname*>	Specifies the name of the group to which the user belongs.

<host>	Identifies the host name or Internet Protocol version4 (IPv4) or Internet Protocol version 6 (IPv6) address of a remote SNMP entity to which the user belongs. The remote host is necessary for acknowledgement of SNMP version 3 notifications. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). IPv6 addresses should be expressed in colon hexadecimal format X:X:X:X::X, for example, **2001:DB8:1::1**.
vrf *<vrf name>*	Optional. When used after the **remote** keyword, specifies the remote host exists on the named VRF. If no VRF is provided, the default unnamed VRF is assumed.
v3	Uses SNMP version 3 (user-based security model).
auth md5 *<auth password>*	Optional. Uses the HMAC-MD5-96 authentication level and a password string to build the key for the authentication level.
auth sha *<auth password>*	Optional. Uses the HMAC-SHA-96 authentication level and a password string to build the key for the authentication level.
priv des *<priv password>*	Optional. Uses the CBC-DES privacy authentication algorithm and a password string used for data encryption between the host and agent.
ip access-class *<ipv4 acl>*	Optional. Specifies an Internet Protocol version 4 (IPv4) access control list (ACL) entry.
ipv6 access-class *<ipv6 acl>*	Optional. Specifies an Internet Protocol version 6 (IPv6) ACL entry.
any-vrf	Optional. Specifies the ACL is applied to any virtual routing and forwarding (VRF) instance.
vrf *<name>*	Optional. Specifies the ACL is applied to a specific VRF instance. If no VRF is provided, the default unnamed VRF is assumed.

It is necessary to configure the SNMP engine ID before configuration of the remote users for a particular agent can be completed. Refer to the command *snmp-server engineID remote on page 1797* *for instructions in setting the engine ID with the remote option.*

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.
Release 14.1	Command was expanded to include the **remote** *<host>* parameter.
Release 18.2	Command syntax was changed to include the **ip access-class** and **ipv6 access-class** parameters for IPv6 support in Adtran internetworking products only.
Release R10.1.0	Command syntax was changed to include the **ip access-class** and **ipv6 access-class** parameters for IPv6 support in Adtran voice products.

Release R10.8.0	Command was expanded to include the **any-vrf** and **vrf** <*name*> parameters.

Functional Notes

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the above mentioned command without specifying a VRF will only affect the default unnamed VRF.

The **snmp-server user** command can specify up to two ACLs to control access, one each for IPv4 and IPv6 protocols. When two ACLs are used, they must use the same VRF restriction (the default VRF, any VRF, or a specific VRF.) If no VRF is named, the default unnamed VRF is assumed.

When configuring a remote engine ID with a VRF specified, a remote user with the same host address and VRF must be configured.

Usage Examples

The following example enters a new user named **BobbyW** and assigns the user to a group called **securityV3auth** on the remote host at IPv4 address **198.168.1.3**, using version 3 security model, message digest 5 (MD5) authentication method with a password of **passWORD6243**, and no ACL to verify:

(config)**#snmp-server user BobbyW securityV3auth remote 198.168.1.3 v3 auth md5 passWORD6243**

Technology Review

SNMP server users are configured and attached to a specified group with an SNMP version. The SNMP version defines the security model of the group, with SNMP version 1 (SNMPv1) being the least secure and SNMP version 3 (SNMPv3) the most secure. Groups also define the read, write, notify, and view access for each user that resides in the group.

Trap notifications in SNMP v1 and SNMP version 2 (SNMPv2) are sent once and do not require an acknowledgement upon receipt. With SNMPv3, a new form of notification type was introduced, called an inform. Unlike a trap sent with SNMPv1/v2, an inform requires a response be sent to the originating entity. If the originator of the inform notification does not receive the response before a specified timeout, the originator can resend until an acknowledgement response is received or a specified retry value is reached. Sending informs requires that the originator of the inform know the user, engine ID, security parameters, and belong to a group that grants access to the information.

SNMPv3 uses services, such as authentication, privacy, and ACLs to provide a higher level of security not present with v1 or v2. Of these new services, identifying an SNMP server user on a remote entity is necessary to receive and originate notifications, and also to generate and respond to commands.

Remote users are specified with an IP address or port number for the remote SNMP entity where the user resides. Configuration of the SNMP remote engine ID is necessary before SNMPv3 inform notifications can be acknowledged. This is accomplished using the **snmp-server engineID remote** command. The remote entity's SNMP engine ID is used for password authentication and privacy digests. The configuration acknowledgments of informs will fail if the remote engine ID is not configured first. A management device must know about the user, the engine ID of the device, and security parameters, such as authentication, passwords, and security level in order for the command to be processed by the receiving agent.

snmp-server user <*username*> <*groupname*> remote auto-link v3

Use the **snmp-server user remote auto-link v3** command to configure Simple Network Management Protocol version 3 (SNMPv3) users residing on a remote SNMP entity, to control access to SNMP information. The remote SNMP device Internet Protocol version 4(IPv4) address follows the active auto-link server. Refer to the command *auto-link on page 1214* for more information on enabling auto-link. Use the **no** form of this command to remove a user from the specified SNMP group. Variations of this command include:

snmp-server user <*username*> <*groupname*> **remote auto-link v3**
snmp-server user <*username*> <*groupname*> **remote auto-link v3 [ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **remote auto-link v3 auth md5** <*auth password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **remote auto-link v3 auth md5** <*auth password*> **priv des** <*priv password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **remote auto-link v3 auth sha** <*auth password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**
snmp-server user <*username*> <*groupname*> **remote auto-link v3 auth sha** <*auth password*> **priv des** <*priv password*> **[ip access-class** <*ipv4 acl*> **| ipv6 access-class** <*ipv6 acl*>**] [any-vrf | vrf** <*name*>**]**

*If **service password-encryption** is enabled, the running configuration changes to include the keyword **encrypted** before each password entry, which is masked. Refer to the command service password-encryption on page 1699.*

Syntax Description

<*username*>	Specifies the name of the user.
<*groupname*>	Specifies the name of the group the user belongs to.
remote auto-link	Specifies that the remote SNMP device IPv4 address follows the active auto-link server.
v3	Uses SNMP version 3 (user-based security model).
auth md5 <*auth password*>	Optional. Uses the HMAC-MD5-96 authentication level and a password string to build the key for the authentication level.
auth sha <*auth password*>	Optional. Uses the HMAC-SHA-96 authentication level and a password string to build the key for the authentication level.
priv des <*priv password*>	Optional. Uses the CBC-DES privacy authentication algorithm and a password string used for data encryption between the host and agent.
ip access-class <*ipv4 acl*>	Optional. Specifies an Internet Protocol version 4 (IPv4) access control list (ACL) entry.
ipv6 access-class <*ipv6 acl*>	Optional. Specifies an Internet Protocol version 6 (IPv6) ACL entry.
any-vrf	Optional. Specifies the ACL is applied to any virtual routing and forwarding (VRF) instance.
vrf <*name*>	Optional. Specifies the ACL is applied to a specific VRF instance. If no VRF is provided, the default unnamed VRF is assumed.

It is necessary to configure the SNMP engine ID before configuration of the remote users for a particular agent can be completed. Refer to the command snmp-server engineID remote on page 1797 for instructions in setting the engine ID with the remote option.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.
Release 14.1	Command was expanded to include the **remote** <*host*> parameter.
Release 18.2	Command syntax was changed to include the **ip access-class** and **ipv6 access-class** parameters for IPv6 support in Adtran internetworking products only.
Release R10.1.0	Command syntax was changed to include the **ip access-class** and **ipv6 access-class** parameters for IPv6 support in Adtran voice products.
Release R10.8.0	Command was expanded to include the **any-vrf** and **vrf** <*name*> parameters.

Functional Notes

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the above mentioned command without specifying a VRF will only affect the default unnamed VRF.

The **snmp-server user** command can specify up to two ACLs to control access, one each for IPv4 and IPv6 protocols. When two ACLs are used, they must use the same VRF restriction (the default VRF, any VRF, or a specific VRF.) If no VRF is named, the default unnamed VRF is assumed.

When configuring a remote engine ID with a VRF specified, a remote user with the same host address and VRF must be configured.

Usage Examples

The following example enters a new user named **BobbyW** and assigns the user to a group called **securityV3auth** using version 3 security model on a remote auto-link server and authentication method message digest 5 (MD5) with a password of **passWORD6243** and no ACL to verify:

(config)**#snmp-server user BobbyW securityV3auth remote auto-link v3 auth md5 passWORD6243**

Technology Review

SNMP server users are configured and attached to a specified group with an SNMP version. The SNMP version defines the security model of the group, with SNMP version 1 (SNMPv1) being the least secure and SNMP version 3 (SNMPv3) the most secure. Groups also define the read, write, notify, and view access for each user that resides in the group.

Trap notifications in SNMP v1 and SNMP version 2 (SNMPv2) are sent once and do not require an acknowledgement upon receipt. With SNMPv3, a new form of notification type was introduced, called an inform. Unlike a trap sent with SNMPv1/v2, an inform requires a response be sent to the originating entity. If the originator of the inform notification does not receive the response before a specified timeout, the originator can resend until an acknowledgement response is received or a specified retry value is reached. Sending informs requires that the originator of the inform know the user, engine ID, security parameters, and belong to a group that grants access to the information.

SNMPv3 uses services, such as authentication, privacy, and ACLs to provide a higher level of security not present with v1 or v2. Of these new services, identifying an SNMP server user on a remote entity is necessary to receive and originate notifications, and also to generate and respond to commands.

Remote users are specified with an IP address or port number for the remote SNMP entity where the user resides. Configuration of the SNMP remote engine ID is necessary before SNMPv3 inform notifications can be acknowledged. This is accomplished using the **snmp-server engineID remote** command. The remote entity's SNMP engine ID is used for password authentication and privacy digests. The configuration acknowledgments of informs will fail if the remote engine ID is not configured first. A management device must know about the user, the engine ID of the device, and security parameters, such as authentication, passwords, and security level in order for the command to be processed by the receiving agent.

snmp-server view <*name*> <*value*>

Use the **snmp-server view** command to create or modify a Simple Network Management Protocol (SNMP) view entry. Use the **no** form of this command to remove an entry. Variations of this command include:

snmp-server view <*name*> <*value*> **excluded**
snmp-server view <*name*> <*value*> **included**

Syntax Description

<*name*>	Specifies a label for the view record being created. The name is a record reference.
<*value*>	Specifies the object identifier (OID) to include or exclude from the view. To identify the subtree, specify a string using numbers, such as 1.4.2.6.8. Replace a single subidentifier with the asterisk (*) to specify a subtree family.
excluded	Specifies a view to be excluded.
included	Specifies a view to be included.

Default Values

No default values are necessary for this command.

Command History

Release 9.1	Command was introduced.

Usage Examples

The **snmp-server view** command can include or exclude a group of OIDs. The following example shows how to create a view (named **blockInterfaces**) to exclude the OID subtree family **1.3.3.1.2.1.2**:

(config)**#snmp-server view blockInterfaces 1.3.3.1.2.1.2.* excluded**

The following example shows how to create a view (named **block**) to include a specific OID:

(config)**#snmp-server view block 1.3.3.1.2.1.2. included**

sntp retry-timeout <*value*>

Use the **sntp retry-timeout** command to set the amount of time to wait for a response before allowing a new request. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies time (in seconds) to wait for a response before retrying. The range is from **3** to **2000000** seconds.

Default Values

By default, the retry timeout is set to **5** seconds.

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example sets the Simple Network Time Protocol (SNTP) retry timeout to **10** seconds:

(config)**#sntp retry-timeout 10**

sntp server

Use the **sntp server** command to set the host name of the Simple Network Time Protocol (SNTP) server, as well as the version of SNTP to use. SNTP is an abbreviated version of the Network Time Protocol (NTP). SNTP is used to set the time of the AOS product over a network. The SNTP server usually serves the time to many devices within a network. Use the **no** form of this command to return to the default setting. Variations of this command include:

sntp server [<*hostname*> **|** <*ip address*>**]**
sntp server [<*hostname*> **|** <*ip address*>**] version** <*number*>

Syntax Description

<*hostname*>	Specifies the host name of the SNTP server.
<*ip address*>	Specifies the IP address of the SNTP server. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
version <*number*>	Optional. Specifies which NTP version is used. Valid range is **1** to **3**.

Default Values

By default, NTP version is set to **1**.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example sets the SNTP server to **time.nist.gov** using SNTP version 1 (the default version):

(config)**#sntp server time.nist.gov**

The following example sets the SNTP server as **time.nist.gov**. All requests for time use version 2 of the SNTP:

(config)**#sntp server time.nist.gov version 2**

sntp wait-time <*value*>

Use the **sntp wait-time** command to set the time between updates from the time server. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies time (in seconds) between updates. Range is **10** to **2000000** seconds.

Default Values

By default, the wait time is set to **86400** seconds (1 day).

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example sets the Simple Network Time Protocol (SNTP) wait time to two days:

(config)**#sntp wait-time 172800**

spanning-tree edgeport bpdufilter default

Use the **spanning-tree edgeport bpdufilter default** command to enable the bridge protocol data unit (BPDU) filter on all ports by default. Use the **no** form of this command to disable the setting.

Syntax Description

No subcommands.

Default Values

By default, **spanning-tree edgeport bpdufilter default** is disabled.

Command History

Release 5.1	Command was introduced.

Functional Notes

The BPDU filter blocks any BPDUs from being transmitted and received on an interface. This can be overridden on an individual port.

Usage Examples

The following example enables the bpdufilter on all ports by default:

(config)**#spanning-tree edgeport bpdufilter default**

To disable the BPDU filter on a specific interface, issue the appropriate commands for the given interface using the following commands as an example:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#spanning-tree edgeport bpdufilter disable**

spanning-tree edgeport bpduguard default

Use the **spanning-tree edgeport bpduguard default** command to enable the bridge protocol data unit (BPDU) guard on all ports by default. Use the **no** form of this command to disable the setting.

Syntax Description

No subcommands.

Default Values

Disabled by default.

Command History

Release 5.1	Command was introduced.

Functional Notes

The bpduguard blocks any BPDUs from being received on an interface. This can be overridden on an individual port.

Usage Examples

The following example enables the BPDU guard on all ports by default.

(config)**#spanning-tree edgeport bpduguard default**

To disable the BPDU guard on a specific interface, issue the appropriate commands for the given interface using the following commands as an example:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#spanning-tree edgeport bpduguard disable**

spanning-tree edgeport default

Use the **spanning-tree edgeport default** command to configure all ports to be edgeports by default. Use the **no** form of this command to disable the setting. This command is overridden by the spanning-tree edgeport command configured in the interface configuration mode.

Syntax Description

No subcommands.

Default Values

Disabled by default.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example configures all interfaces running spanning tree to be edgeports by default:

(config)**#spanning-tree edgeport default**

An individual interface can be configured to not be considered an edgeport. For example:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#spanning-tree edgeport disable**

or

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#no spanning-tree edgeport**

spanning-tree edgeport rootguard default

Use the **spanning-tree edgeport rootguard default** command to enable root guard on all interfaces configured as an edgeport. Use the **no** form of this command to disable the setting.

Syntax Description

No subcommands.

Default Values

Disabled by default.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

Root guard blocks an interface from being elected to the root port role. If information about a superior root bridge is received, the interface will no longer forward traffic until superior root bridge proposals stop. If an interface has bridge protocol data unit (BPDU) filter or BPDU guard configured, configuring root guard will have no effect on the operation of the interface. The root guard setting can be overridden on an individual port basis.

Usage Examples

The following example enables the root guard on all ports by default.

(config)**#spanning-tree edgeport rootguard default**

To disable the root guard on a specific interface, issue the appropriate commands for the given interface. The following example disables the root guard on the gigabit switchport interface 0/3:

(config)**#interface gigabit-switchport 0/3**
(config-giga-swx 0/3)**#spanning-tree edgeport rootguard disable**

spanning-tree forward-time *<value>*

Use the **spanning-tree forward-time** command to specify the delay interval (in seconds) when forwarding spanning-tree packets. Use the **no** form of this command to return to the default interval.

Syntax Description

<value>	Specifies the forwarding delay interval in seconds. Range is **4** to **30** seconds.

Default Values

By default, the forwarding delay is set to **15** seconds.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example sets the forwarding time to **18** seconds:

(config)#**spanning-tree forward-time 18**

spanning-tree hello-time <*value*>

Use the **spanning-tree hello-time** command to specify the delay interval (in seconds) between hello bridge protocol data units (BPDUs). To return to the default interval, use the **no** form of this command.

Syntax Description

<*value*>	Specifies the delay interval (in seconds) between hello BPDUs. Range is **0** to **1000000** seconds.

Default Values

By default, the delay is set to **2** seconds.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example configures a **spanning-tree hello-time** interval of **10000** seconds:

(config)#**spanning-tree hello-time 10000**

spanning-tree max-age *<value>*

Use the **spanning-tree max-age** command to specify the interval (in seconds) the spanning tree will wait to receive bridge protocol data units (BPDUs) from the root bridge before assuming the network has changed (thus re-evaluating the spanning-tree topology). Use the **no** form of this command to return to the default interval.

Syntax Description

<value>	Specifies the wait interval (in seconds) between received BPDUs (from the root bridge). Range is **6** to **40** seconds.

Default Values

By default, the wait interval is set at **20** seconds.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example configures a wait interval of **35** seconds:

(config)**#spanning-tree max-age 35**

spanning-tree mode

Use the **spanning-tree mode** command to choose a spanning tree mode of operation. Use the **no** form of this command to return to the default setting. Variations of this command include:

spanning-tree mode rstp
spanning-tree mode stp

Syntax Description

rstp	Enables Rapid Spanning Tree Protocol (RSTP).
stp	Enables spanning-tree protocol.

Default Values

By default, **spanning-tree mode** is set to **rstp**.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example sets the spanning-tree mode to **rstp**:

(config)**#spanning-tree mode rstp**

spanning-tree pathcost method

Use the **spanning-tree pathcost method** command to select a short or long pathcost method used by the spanning-tree protocol. Use the **no** form of this command to return to the default setting. Variations of this command include:

spanning-tree pathcost method long
spanning-tree pathcost method short

Syntax Description

long	Specifies a long pathcost method.
short	Specifies a short pathcost method.

Default Values

By default, **spanning-tree pathcost** is set to **short**.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example specifies that the spanning-tree protocol use a **long** pathcost method:

(config)**#spanning-tree pathcost method long**

spanning-tree priority <*value*>

Use the **spanning-tree priority** command to set the priority for spanning-tree interfaces. The lower the priority value, the higher the likelihood the configured spanning-tree interface will be the root for the bridge group. To return to the default bridge priority value, use the **no** form of this command.

Syntax Description

<*value*>	Sets a priority value for the bridge interface. Configuring this value to a low number increases the interface's chance of being the root. Therefore, the maximum priority level would be 0. Range is **0** to **65535**.

Default Values

By default, the priority level is set to **32768**.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example sets **spanning-tree priority** to the maximum level:

(config)**#spanning-tree priority 0**

srtp-profile *<profile name>*

Use the **srtp-profile** command to enter the Secure Realtime Transfer Protocol (SRTP) Profile Configuration mode, from which the operation of SRTP is configured. Use the **no** form of this command to remove the profile.

Syntax Description

<profile name>	Specifies the name of the SRTP profile to create.

Default Values

By default, no SRTP profiles exist.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

Each entity on the AOS device that uses SRTP must have an SRTP profile applied in order to function. Many SRTP profiles can exist and be referenced by many entities using SRTP on the AOS device. The same SRTP profile can be used by as many entities using SRTP as required. The SRTP profile essentially operates as a template for SRTP operation and is applied on a per-trunk basis. For more information regarding SRTP configuration, refer to the *SRTP Profile Command Set on page 4888*.

Usage Examples

The following example creates the SRTP profile **SRTPPROFILE1** and enters the profile's configuration mode:

```
(config)#srtp-profile SRTPPROFILE1
(config-srtp-profile-SRTPPROFILE1)#
```

ssh-server <*TCP port*>

Use the **ssh-server** command to specify an alternate Transmission Control Protocol (TCP) port for secure shell (SSH) servers. Use the **no** form of this command to return to the default setting.

Syntax Description

<*port*>	Specifies the alternate TCP port for the SSH server.

Default Values

By default, the SSH server listens on TCP port **22**.

Command History

Release 18.2	Command was introduced. This command replaces the **ip ssh-server** <*port*> command for Adtran internetworking products only.
Release R10.1.0	Command was introduced. This command replaces the **ip ssh-server** <*port*> command for Adtran voice products.
Release R14.4.0	Command was introduced. This command is used to specify an alternate TCP port.

Functional Notes

SSH is a version of Telnet that allows you to run command line and graphical applications (as well as, transfer files) over an encrypted connection.

Usage Examples

The following example configures the SSH server to listen on TCP port **2200**, instead of the default port **22**:

(config)**#ip ssh-server 2200**

To return to the default setting, use the **no** form of the command. For example:

(config)**#no ip ssh-server 2200**

ssh-server authentication

Use the **ssh-server authentication** command to enable password and/or public key authentication for secure shell (SSH) connections to the system. Use the **no** form of this command to return to the default. Variations of this command include:

ssh-server authentication password
ssh-server authentication password pubkey
ssh-server authentication pubkey
ssh-server authentication pubkey password

Syntax Description

password	Allows password authentication for SSH connections.
pubkey	Allows public key authentication for SSH connections.

Default Values

By default, both password and pubkey authentication are enabled.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example enables public key authentication for SSH connections on the system:

>**enable**

#configure terminal

(config)**#ssh-server authentication password pubkey**

ssh-server cipher

Use the **ssh-server cipher** command to configure the secure shell (SSH) server cipher algorithm used in SSH connections to the system. Use the **no** form of this command to disable a cipher. Variations of this command include:

ssh-server cipher 3des-cbc
ssh-server cipher aes128-ctr
ssh-server cipher aes256-ctr

Syntax Description

3des-cbc	Enables 3des-cbc as a supported cipher for SSH connections.
aes128-ctr	Enables aes128-ctr as a supported cipher for SSH connections.
aes256-ctr	Enables aes256-ctr as a supported cipher for SSH connections.

Default Values

By default, **taes128-ctr** and **aes256-ctr** are enabled and **3des-cbc** is disabled.

Command History

Release R13.12.0	Command was introduced.

Usage Examples

The following example disables aes128-ctr for SSH connections on the system:

>**enable**

#configure terminal

(config)**#ssh-server cipher aes128-ctr**

ssh-server host-key

Use the ssh-server ssh-host-key command to configure the SSH server host-key algorithm used in SSH connections to the system. Use the **no** form of this command to disable an algorithm. Variations of this command include:

ssh-server host-key <*input*>

Syntax Description

host-key	Specifies the SSH client host-key algorithm.
ecdsa -sha2-nistp256	Enables ecdsa-sha2-nistp256 host key signature algorithm for signing and verifying sha256 message hash for securing SSH connections
ecdsa -sha2-nistp384	Enables ecdsa-sha2-nistp384 host key signature algorithm for signing and verifying sha256 message hash for securing SSH connections
ecdsa -sha2-nistp521	Enables ecdsa-sha2-nistp521 host key signature algorithm for signing and verifying sha256 message hash for securing SSH connections
rsa-sha2-512	Enables rsa-sha2-512 host key signature algorithm for signing and verifying sha512 message hash for securing SSH connections.
ssh-dss	Enables ssh-dss host key algorithm for signing and verifying sha1 message hash for securing SSH connections.
ssh-rsa	Enables ssh-rsa host key algorithm for signing and verifying sha1 message hash for securing SSH connections.

Default Values

By default ssh-rsa, ssh-dss are enabled, and rsa-sha2-512, ecdsa-sha2-nistp256, ecdsa-sha2-nistp521, ecdsa-sha2-nistp384 are disabled.

Command History

Release 14.4.0	Command was introduced.

Usage Examples

The following example configures various SSH client host-key algorithms.

>**enable**
#configure terminal
(config)**#ssh-server host-key ecdsa-sha2-nistp256**
(config)**#ssh-server host-key ecdsa-sha2-nistp384**
(config)**#ssh-server host-key ecdsa-sha2-nistp521**
(config)**#ssh-server host-key rsa-sha2-512**
(config)**#ssh-server host-key ssh-dss**
(config)**#ssh-server host-key ssh-rsa**

ssh-server kex

Use the **ssh-server kex** command to configure the secure shell (SSH) server key exchange (KEX) algorithm used in SSH connections to the system. Use the **no** form of this command to disable an algorithm. Variations of this command include:

ssh-server kex diffie-hellman-group-exchange-sha256
ssh-server kex diffie-hellman-group1-sha1
ssh-server kex diffie-hellman-group14-sha1
ssh-server kex diffie-hellman-group16-sha512
ssh-server kex ecdh-sha2-nistp256

Syntax Description

diffie-hellman-group-exchange -sha256	Enables the Diffie-Hellman Group Exchange key exchange, with SHA256 as the hash, as supported key exchange method for SSH connections.
diffie-hellman-group1-sha1	Enables the Diffie-Hellman Group 1 key exchange, with SHA-1 as the hash, as a supported key exchange method for SSH connections.
diffie-hellman-group14-sha1	Enables the Diffie-Hellman Group 14 key exchange, with SHA-1 as the hash, as a supported key exchange method for SSH connections.
diffie-hellman-group16-sha512	Enables the Diffie-Hellman Group 16 key exchange, with SHA512 as the hash, as a supported key exchange method for SSH connections.
ecdh-sha2-nistp256	Enables ECDH algorithm with SHA2 as the hash, as a supported key exchange method for SSH connections.

Default Values

By default, diffie-hellman-group1-sha1, diffie-hellman-group16-sha512, diffie-hellman-group-exchange-sha256, ecdh-sha2-nistp256 kex are disabled, and diffie-hellman-group14-sha1 is enabled.

Command History

Release R13.12.0	Command was introduced.
Release R14.4.0	Command was expanded to include diffie-hellman-group16-sha512, diffie-hellman-group-exchange-sha256, and ecdh-sha2-nistp256 kex options.

Usage Examples

The following examples are used for SSH key exchange connections using diffie-hellman and ECDH algorithms.

>**enable**
#configure terminal
config)**#ssh-server kex diffie-hellman-group-exchange-sha256**
(config)**#ssh-server kex diffie-hellman-group1-sha1**
(config)**#ssh-server kex diffie-hellman-group14-sha1**
(config)**#ssh-server kex diffie-hellman-group16-sha512**
(config)**#ssh-server kex ecdh-sha2-nistp256**

ssh-server mac

Use the **ssh-server mac** command to configure the secure shell (SSH) server message authentication code (MAC) algorithm used in SSH connections to the system. Use the **no** form of this command to disable an algorithm. Variations of this command include:

ssh-server mac hmac-sha1
ssh-server mac hmac-sha2-256

Syntax Description

hmac-sha1	Enables SHA-1 hash-based MAC (HMAC) encryption for securing SSH connections.
hmac-sha2-256	Enables SHA-256 HMAC encryption for securing SSH connections.

Default Values

By default, the SHA-1 HMAC algorithm (**hmac-sha1**) is disabled and the SHA-256 HMAC algorithm (**hmac-sha2-256**) is enabled.

Command History

Release R13.12.0	Command was introduced.

Usage Examples

The following example disables SHA-1 HMAC algorithm for SSH connections on the system:

(config)**#no ssh-server mac hmac-sha1**

ssh-server moduli

Use the **ssh-server moduli** command to configure the SSH server moduli values.Variations of this command include:

ssh-server moduli min <1024/1536/2048/3072/4096/6144> max <1536/2048/3072/4096/6144>

Syntax Description

moduli min	Sets the minimum moduli value. Optional values are: <1024/1536/2048/3072/4096/6144>
moduli max	Sets the maximum moduli value. Optional values are: <1536/2048/3072/4096/6144/8192>

Default Values

By default, ssh-server moduli min is set to 1024 and max is set to 8192.

Command History

Release R14.4.0	Command was introduced.

Usage Examples

The **min** and **max** moduli values must correspond. For example, a **min** value of 1024 must have a corresponding **max** value of 1536, 2048, 3072, 4096, 6144 or 8192. The reverse is also necessary. Any **max** value must have a corresponding **min** value.

The following examples set the minimum and maximum moduli values.

>**enable**
#configure terminal
(config)**#ssh-server moduli min 1024 max 1536**
(config)**#ssh-server moduli min 1536 max 3072**
(config)**#ssh-server moduli min 2048 max 6144**

ssh-server pubkey-chain

Use the **ssh-server pubkey-chain** command to enter the secure shell (SSH) Server Public Key Configuration mode and configure the SSH public key chain for public key based authentication. From within the SSH Server Public Key Configuration mode, a public key can be added for a remote device to gain access to the system through SSH connection. Use the **no** form of this command to remove the public key. Once **ssh-server pubkey-chain** command is entered into the system, the username and key type must follow with a subsequent command. To enter the SSH Server Public Key Configuration mode, enter the command as follows:

#ssh-server pubkey-chain

The following subcommands are available once you enter the SSH Server Public Key Configuration mode:

username <*username*> **key-hash ecdsa-sha2-nistp<256/384/521>** <*input*>
username <*username*> **key-hash ssh-<dss/rsa>** <*input*>
username <*username*> **key-hash ssh-rsa-sha2-512>** <*input*>
username <*username*> **key-hash ssh-rsa** <*input*>
username <*username*> **key-string**
username <*username*> **key-string sha2**
username <*username*> **privilege** <*level*> **key-hash ssh-hash** <*input*>
username <*username*> **privilege** <*level*> **key-hash ssh-rsa** <*input*>
username <*username*> **privilege** <*level*> **key-string** <*input*> **sha2**

Syntax Description

username <*username*>	Specifies the username of a remote device user to allow access through SSH connections. Only one key per user is allowed.
key-hash	Specifies adding a public key hash (SHA1 hash of Digital Signature Standard (DSS) or Rivest-Shamir-Adleman (RSA) formats) for the specified user.
e**cdsa-sha-nistp256**	Specifies SHA2 hash of ECDSA hash of 256 format.
e**cdsa-sha-nistp384**	Specifies SHA2 hash of ECDSA hash of 384format.
e**cdsa-sha-nistp521**	Specifies SHA2 hash of ECDSA hash of 521 format.
ssh-dss	Specifies SHA1 hash of DSS format.
ssh-rsa	Specifies SHA1 hash of RSA format.
ssh-sa-sha2-512	Specifies the SSH hash of RSA format.
sha2	Specifies the SSH hash of RSA format.
key-string	Specifies using a public key string (DSS or RSA format) for the specified user. Key strings can be entered in either open SSH or PEM format.
privilege <*level*>	Optional. Specifies a privilege level for this user at the time of authentication. Valid entries are **1** to **7**.

Default Values

By default, there are no SSH users authorized to gain access to the system using public keys.

Command History

Release R10.10.0	Command was introduced.
Release R10.11.0	Command was expanded to include the **privilege** parameter.
Release R12.2.0	Command was expanded to include support for RSA keys.
Release R14.4.0	Command was expanded to include support for RSA keys.

Functional Notes

Users can have one or both (DSS or RSA) key types at any given time. The system can store up to 100 user keys on the system at a time.

Once the command **username** <*username*> **key-string** is entered, a prompt results requesting the key string for the user be entered. After entering the key string, press **Enter** twice or type **quit** on a single line to end this function and return to the Global Configuration mode.

Usage Examples

The following example adds a public key for the remote user **ALPHA1** using a key-string in openSSH format:

(config)**#ssh-server pubkey-chain**
(config-ssh-pubkey-chain)**#username ALPHA1 key-string sha2**
(config-ssh-pubkey-ALPHA1)#
Enter user's public key (DSS). End with two consecutive carriage returns or the word “quit” on a line by itself:
ssh-dss
AAAB3NzaC1kc3MAAACBAOLniJWw39O5IXjm83M0DKOAKKa8wEB0zhr1SCnESmrnipCRagU2W

h9HjbKt/S2UuEh9+s3cKdV37ohbDKyQruU9vhw== ALPHA1@sample.adtran.com

Success!

The following example adds a public key for the remote user **ALPHA1** using a key string in PEM format:

(config)**#ssh-server pubkey-chain**
(config-ssh-pubkey-chain)**#username ALPHA1 key-string**
(config-ssh-pubkey-ALPHA1)#
Enter the user’s public key (DSS). End with two consecutive carriage returns or the word “quit” on a line by itself:
---- BEGIN SSH2 PUBLIC KEY ----

Comment: "dsa-key-20130916"

3L4=
---- END SSH2 PUBLIC KEY ----

Success!

The following example adds a public key for the remote user **CHARLIE3** using the hash key **A54568F4DA1BAB8BB53CF0ABD818FCDA**:

(config)**#ssh-server pubkey-chain**
(config-ssh-pubkey-chain)**#username CHARLIE3 key-hash ssh-dss**
A54568F4DA1BAB8BB53CF0ABD818FCDA
(config-ssh-pubkey-CHARLIE3)#

The following example removes the key string for the user **ALPHA1**:

(config-ssh-pubkey-ALPHA1)**#no ALPHA1 key-string**

The following example adds a privilege level 1 for the user **ALPHA**:

(config)**#ssh-server pubkey-chain**
(config-ssh-pubkey-chain)**#username ALPHA privilege 1 key-hash ssh-dss** *<key-hash for this user>*

ssh-server <TCP Port>

Use the **ssh-server TCP Port** command to listen on an alternate port. To access an alternate port, enter the command as follows:

#ssh-server port <*1-65535*>

Syntax Description

port <*1-65535*>	Specifies the alternate port.

Default Values

By default, there are no default values

Command History

Release R14.4.0	Command was expanded to include support for RSA keys.

Functional Notes

Usage Examples

The following example adds a TCP port:

>**enable**
#configure terminal
(config)**#ssh-server port** <*1-65535*>

ssh-client host-key

Use the ssh-client host-key command to configure the secure shell (SSH) client host-key algorithm used in SSH connections for the system. Use the **no** form of this command to disable an algorithm. Variations of this command include:

ssh-client host-key ecdsa-sha2-nistp256
ssh-client host-key ecdsa-sha2-nistp384
ssh-client host-key ecdsa-sha2-nistp521
ssh-client host-key ssh-dss
ssh-client host-key ssh-ed25519
ssh-client host-key ssh-rsa
ssh-client host-key ssh-rsa-sha2-256
ssh-client host-key ssh-rsa-sha2-512

Syntax Description

host-key	Specifies the SSH client host-key algorithm.
ecdsa -sha2-nistp256	Enables ecdsa-sha2-nistp256 host-key signature algorithm for signing and verifying sha256 hash for securing SSH connections.
ecdsa-sha2-nistp384	Enables ecdsa-sha2-nistp384 host-key signature algorithm for signing and verifying sha384 hash for securing SSH connections.
ecdsa-sha2-nistp521	Enables the ecdsa-sha2-nistp521 host-key signature algorithm for signing and verifying sha521 hash for securing SSH connections.
ssh-dss	Enables the ssh-dss host-key algorithm for signing and verifying sha1 message hash for securing SSH connections.
ssh-ed25519	Enables the ssh-ed25519 host-key algorithm for signing and verifying the SHA message hash for securing SSH connections.
ssh-rsa	Enables the ssh-rsa host-key algorithm for signing and verifying the SHA message hash for securing SSH connections.
ssh-rsa-sha2-256	Enables the ssh-rsa-sha2-256 host-key algorithm for signing and verifying the 256 message hash for securing SSH connections.
ssh-rsa-sha2-512	Enables the ssh-rsa-sha2-sha512 host-key signature algorithm for signing and verifying sha512 hash for securing SSH connections.

Default Values

By default, all the host-key algorithms are enabled and follows the following host-key priority order: ecdsa-sha2-nistp256, ecdsa-sha2-nistp384, ecdsa-sha2-nistp521, ssh-ed25519, rsa-sha2-512, rsa-sha2-256, ssh-rsa, ssh-dss

Command History

Release 14.3.0	Command was introduced.

Usage Examples

The following example configures various SSH client host-key algorithms.

>**enable**
#configure terminal
(config)**#ssh-client host-key ssh-ecdsa-sha2-nistp256**
(config)**#ssh-client host-key ssh-ecdsa-sha2-nistp384**
(config)**#ssh-client host-key ecdsa-sha2-nistp521**
(config)**#ssh-client host-key ssh-dss**
(config)**#ssh-client host-key ed25519**
(config)**#ssh-client host-key ssh-rsa**
(config)**#ssh-client host-key-rsa-sha2-512**

ssh-client kex

Use the ssh-client kex command to configure the secure shell (SSH) client KEX algorithms used in SSH connections from the system. Use the **no** form of this command to disable an algorithm. Variations of this command include:

ssh-client kex diffie-hellman-group-exchange-sha1
ssh-client kex diffie-hellman-group-exchange-sha256
ssh-client kex diffie-hellman-group1-sha1
ssh-client kex diffie-hellman-group14-sha1
ssh-client kex ecdh-sha2-nistp256
ssh-client kex ecdh-sha2-nistp384
ssh-client kex ecdh-sha2-nistp521
ssh-client kex ssh-curve25519-sha256
ssh-client kex ssh-curve25519-sha256-libssh

Syntax Description

kex	Specifies the KEX client host-ey Exchange algorithms.
diffie-hellman-group-exchange-sha1	Enables the Diffie-Hellman Group Exchange key exchange, with **SHA1** as a hash, as a supported key exchange method for SSH connections.
diffie-hellman-group-exchange-sha256	Enables the Diffie-Hellman Group Exchange key exchange, with **SHA256** as a hash, as a supported key exchange method for SSH connections.
diffie-hellman-group1-sha1	Enables the Diffie-Hellman **Group1** key exchange, with **SHA-1** as a hash, as a supported key exchange method for SSH connections.
diffie-hellman-group1-sha14	Enables the Diffie-Hellman **Group14** key exchange, with **SHA-1** as a hash, as a supported key exchange method for SSH connections.
ecdh-sha2-nistp256	Enables Elliptic Curve Diffie-Hellman key exchange, with SHA256 as a hash, as a supported key exchange method for SSH connections.
ecdh-sha2-nistp384	Enables Elliptic Curve Diffie-Hellman key exchange, with SHA384 as a hash, as a supported key exchange method for SSH connections.
ecdh-sha2-nistp521	Enables Elliptic Curve Diffie-Hellman key exchange, with SHA521 as a hash, as a supported key exchange method for SSH connections.
ecdh-curve25519-sha256	Enables Elliptic Curve25519 key exchange, with SHA256 as a hash, as a supported key exchange method for SSH connections.
ecdh-curve25519-sha256-libssh	Enables Elliptic Curve25519-sha256@libssh key exchange, with SHA256 as a hash, as a supported key exchange method for SSH connections.

Default Values

By default, all the Key Exchange algorithms are enabled. The order of default priority is as follows:

ecdh-sha2-nistp256
ecdh-sha2-nistp384
ecdh-sha2-nistp521
curve25519-sha256
curve25519-sha256@libssh.org
diffie-hellman-group-exchange-sha256
diffie-hellman-group-exchange-sha1
diffie-hellman-group14-sha1
diffie-hellman-group1-sha1

Command History

Release 14.3.0	Command was introduced.

Usage Examples

The following examples configure various SSH client kex algorithms.

>**enable**
>**configure terminal**
(config)#ssh-client kex diffie-hellman-group-exchange-sha1
(config)#ssh-client kex diffie-hellman-group-exchange-sha256
(config)#ssh-client kex diffie-hellman-group1-sha1

stack

Use the **stack** command to configure switch-stacking options. Use the **no** form of this command to disable this feature. Variations of this command include:

stack master
stack master *<vlan id>*
stack master *<vlan id> <ip address> <subnet mask>*
stack member *<mac address>*
stack member *<mac address> <unit id>*
stack vlan *<vlan id>*

Syntax Description

master	Specifies that the unit will be the master of the stack.
<vlan id>	Specifies the virtual local area network (VLAN) ID the stack will use for communication.
<ip address>	Configures the network mask of the private IP network. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
member	Adds a switch to the stack.
<mac address>	Specifies a valid 48-bit medium access control (MAC) address of the unit being added. MAC addresses should be expressed in the following format xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).
<unit id>	Specifies the unit ID of the switch being added.
vlan *<vlan id>*	Specifies the VLAN ID of the stack of which you are a member.

Default Values

By default, stack VLAN is **2386**, and the stack IP network is **169.254.0.0 /24**.

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example configures the unit to be the stack master and use the default stack VLAN and IP network.

(config)**#stack master 2000**

The following example configures the unit to be the stack master and use VLAN 2000 as the management VLAN and 192.168.1.0 /24 as the management network.

(config)**#stack master 2000 192.168.1.0 /24**

The following example adds the switch with the CPU MAC address 00:A0:C8:00:8C:20 to the stack; also assigns the number 2 as the new stack member's unit ID.

(config)**#stack member 00:A0:C8:00:8C:20 2**

The following example specifies that this unit is in the stack using VLAN 2000 as its management VLAN; also specifies that this unit is in stack member mode (not a stack-master).

(config)**#stack vlan 2000**

statistics rate-interval <*value*>

Use the **statistics rate-interval** command to specify the interval (in seconds) to receive interface statistics. Use the **no** form of this command to return to the default interval.

Syntax Description

<*value*>	Specifies the wait interval. Range is **30** to **600** seconds (in 30 second increments).

Default Values

By default, the wait interval is set at **300** seconds.

Command History

Release 17.4	Command was introduced.

Usage Examples

The following example configures a wait interval of **90** seconds:

(config)**#statistics rate-interval 90**

system-control-evc

Use the **system-control-evc** command to enter the system control Ethernet virtual connection (EVC) configuration mode. This configuration mode is used for dynamic provisioning and to separate the session control Point-to-Point Protocol over Ethernet (PPPoE) interface from regular customer services.

Syntax Description

No subcommands.

Default Values

By default, the system control EVC is always activated.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

The configuration commands for the system control EVC are outlined in the *System Control EVC Command Set on page 3745*.

Usage Examples

The following example enters the system control EVC configuration mode:

```
(config)#system-control-evc
(config-sys-cntrl-evc)#
```

system-management-evc

Use the **system-management-evc** command to enter the System Management Ethernet Virtual Connection (EVC) Configuration mode. This configuration mode is used to configure an inband IP network interface for the purposes of system management and control. The configuration commands for the system management EVC are outlined in the *System Management EVC Command Set on page 3843*.

Syntax Description

No subcommands.

Default Values

By default, the system management EVC is always activated.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example enters the system management EVC configuration mode:

```
(config)#system-management-evc
(config-sys-mgmt-evc)#
```

system mtu *<size>*

Use the **system mtu** command to set the maximum transmission unit (MTU) size for all ports on the AOS device and allow Ethernet frames larger than 1518 bytes (known as jumbo frames) to pass. Use the **no** form of this command to return to the default.

Syntax Description

<size>	Indicates the transmission size in bytes. The valid range is 1518 to the maximum byte size allowed for the unit being configured.

The MTU size specified does not include an 802.1Q virtual local area network (VLAN) tag. For example, if the MTU size is set to allow 1518 bytes, an 802.1Q tagged packet of 1522 bytes would still be accepted.

Default Values

By default, the MTU size is **1518**.

Changing the default value (1518) in a switch already installed in a network could cause traffic disruption.

Command History

Release 17.6	Command was introduced.

Usage Examples

The following example sets the maximum transmission unit size for all ports on the device to **9216** bytes:

(config)**#system mtu 9216**

tacacs-server

Use the **tacacs-server** command to configure several terminal access controller access-control system plus (TACACS+) parameters for all TACACS+ servers on the network. Most of these global settings can be overridden on a per-server basis (using the command *tacacs-server host on page 1868*). Use the **no** form of this command to return to the default setting. Variations of this command include the following:

tacacs-server key <*key*>
tacacs-server packet maxsize <*value*>
tacacs-server timeout <*value*>

Syntax Description

key <*key*>	Specifies the encryption key used by all TACACS+ servers. This is a global setting; however, it can be overridden on a per-server basis.
packet maxsize <*value*>	Specifies the maximum packet size that can be sent to any TACACS+ server. Packet maxsize range is **10240** to **65535** kilobytes.
timeout <*value*>	Specifies the time (in seconds) that the AOS unit will wait for the server's reply before declaring an error. The time range is **1** to **1000** seconds. This is a global setting; however, it can be overridden on a per-server basis.

Default Values

By default, there is no key specified for TACACS+ servers, the packet maxsize is set to **10240** kb, and the TACACS+ server timeout is set to **5** seconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets a timeout limit of **60** seconds for all TACACS+ servers:

(config)**#tacacs-server timeout 60**

tacacs-server host

Use the **tacacs-server host** command to specify the parameters for a terminal access controller access-control system plus (TACACS+) server. Specifying the virtual routing and forwarding (VRF) instance using the **vrf** <*name*> keyword applies the configuration to the named VRF instance. Omitting the **vrf** <*name*> keyword applies the configuration to the TACACS+ server for the default unnamed VRF. Use the **no** form of this command to return to the default setting. Variations of this command include the following:

tacacs-server host <*hostname*> **|** <*ip address*>
tacacs-server host <*hostname*> **|** <*ip address*> **key** <*key*>
tacacs-server host <*hostname*> **|** <*ip address*> **port** <*port*>
tacacs-server host <*hostname*> **|** <*ip address*> **timeout** <*value*>
tacacs-server vrf <*name*> **host** <*hostname*> **|** <*ip address*>
tacacs-server vrf <*name*> **host** <*hostname*> **|** <*ip address*> **key** <*key*>
tacacs-server vrf <*name*> **host** <*hostname*> **|** <*ip address*> **port** <*port*>
tacacs-server vrf <*name*> **host** <*hostname*> **|** <*ip address*> **timeout** <*value*>

Each parameter after <hostname | ip address> specifies the characteristics of the individual TACACS+ server. Parameters can be entered in a single command line, in any order, but each may only be used once.

Syntax Description

<*hostname*> **|** <*ip address*>	Specifies the server to configure. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). If a host name is used, a domain naming system (DNS) server should be learned by the AOS device using Dynamic Host Configuration Protocol (DHCP), Point-to-Point Protocol (PPP), or specified in the Global Configuration mode with the command *name-server on page 1622*.
key <*key*>	Specifies the encryption key used by the TACACS+ server. This command overrides the global TACACS+ key setting (set with the command *tacacs-server on page 1867*). This command must be entered last in the command line because everything after the **key** parameter is read as the new key.
port <*port*>	Specifies the Transmission Control Protocol (TCP) port used by the TACACS+ server. Range is **1** to **65535**.
timeout <*value*>	Specifies the time to wait (in seconds) for the server to reply to requests. Range is **1** to **1000** seconds.
vrf <*name*>	Specifies the name of the VRF to which to assign the association. If no VRF is specified, the association is applied to the default unnamed VRF.

Default Values

By default, the TACACS+ server uses TCP port **49**. By default, the key and timeout values are the values set by the command *tacacs-server on page 1867*.

Command History

Release 11.1	Command was introduced.
Release R10.7.0	Command was expanded to include the **vrf** <*name*> parameter.

Functional Notes

At a minimum, the address (IP or host name) of the server must be given. The other parameters can be entered in any order (except the **key** parameter) and, if the parameters are not specified, they will take default values or fall back on the global TACACS+ server's default settings (set using the command *tacacs-server on page 1867*).

If global password protection is enabled on the AOS device, encryption will be applied to the authentication key (**key** <*key*>). If global password protection is off, the authentication key will display as clear text. Refer to *service password-encryption on page 1699* for more information

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example specifies that the TACACS+ server at IP address **10.10.10.4** uses the global key setting (left unspecified), a timeout value of **10** seconds, and the default TCP port (left unspecified):

(config)**#tacacs-server host 10.10.10.4 timeout 10**

The following example specifies that the TACACS+ server at IP address **10.10.10.4** on VRF **RED**, uses the global key setting (left unspecified), a timeout value of **10** seconds, and the default TCP port (left unspecified):

(config)**#tacacs-server vrf RED host 10.10.10.4 timeout 10**

tcl run <*name*> track <*track name*>

Use the **tcl run track** command to initiate a tool command language (Tcl) script based on the result of monitoring the change of state of a track. Use the **no** form of this command to disable the track monitoring for the given script. This command is only available on platforms with Network Monitoring enabled. For more information on creating tracks, refer to *track <name> on page 1886* and the *Network Monitor Track Command Set on page 4098*. Variations of this command include:

tcl run <*name*> **track** <*track name*> **on-pass**
tcl run <*name*> **track** <*track name*> **on-fail**

Syntax Description

<*name*>	Specifies an inline Tcl script or Tcl script file.
<*track name*>	Specifies the name of the track to be monitored.
on-pass	Specifies the file should be run when the track meets the passing condition.
on-fail	Specifies the file should be run when the track meets the failure condition.

Default Values

No default values are necessary for this command.

Command History

Release 16.1	Command was introduced.
Release R11.11.1	Command was expanded to include inline scripts.

Usage Examples

The following example activates a Tcl script to be run when the failure condition is met on **track_a**:

(config)**#tcl run test1.tcl track track_a on-fail**

tcl script *<name> <delimiter>*

Use the **tcl script** command to create a new named tool command language (Tcl) script, and enter the input mode for the new script.

Syntax Description

<name>	Specifies the name of the inline Tcl script to be created.
<delimiter>	Specifies the delimiter character to be used to terminate the input mode for the inline Tcl script.

Default Values

No default values are necessary for this command.

Command History

Release R11.11.1	Command was introduced.

Usage Examples

The following example creates the **test1** inline Tcl script, with **@** specified as the delimiter character, enters the input mode for the script, enters a Tcl command, and then exits the input mode using the specified delimeter character:

(config)**#tcl script test1 @**
e**vent notice “TEST”**
@
(config)**#**

telnet

Use the **telnet** command to open a Telnet session (through AOS) to another system on the network. Variations of this command include the following:

telnet <*ip address* | *hostname*>
telnet <*ip address* | *hostname*> **port** <*tcp port*>
telnet vrf <*name*> <*ip address* | *hostname*>
telnet vrf <*name*> <*ip address* | *hostname*> **port** <*tcp port*>

Syntax Description

<*ip address* | *hostname*>	Specifies the IP address or host name of the remote system. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
port <*tcp port*>	Optional. Specifies the Transmission Control Protocol (TCP) port number to be used when connecting to a host through Telnet. Range is **1** to **65535**.
vrf <*name*>	Optional. Specifies the virtual routing and forwarding (VRF) where the IP address or host name exists.

Default Values

No default values are necessary for this command.

Command History

Release 1.1	Command was introduced.
Release 14.1	Command was expanded to specify the port number.
Release 16.1	Command was expanded to include the **vrf** parameter.

Functional Notes

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the above mentioned commands without specifying a VRF will only affect the default unnamed VRF.

Usage Examples

The following example opens a Telnet session with a remote system (**10.200.4.15**):

>**enable**
#telnet 10.200.4.15
User Access Login:
Password:

The following example opens a Telnet session with a remote system (**10.200.4.15**) on port **8010**:

>**enable**
#telnet 10.200.4.15 port 8010
User Access Login:
Password:

telnet-server <*port*>

Use the **telnet-server** command to specify an alternate Transmission Control Protocol (TCP) port for Telnet servers. Use the **no** form of this command to return to the default setting.

Syntax Description

<*port*>	Specifies the alternate TCP port for the Telnet server.

Default Values

By default, the Telnet server listens on TCP port **23**.

Command History

Release 18.2	Command was introduced. This command replaces the **ip telnet-server** <*port*> command for Adtran internetworking products only.
Release R10.1.0	Command was introduced. This command replaces the **ip telnet-server** <*port*> command for Adtran voice products.

Usage Examples

The following example configures the Telnet server to listen on TCP port **2323**, instead of the default port **23**:

(config)**#ip telnet-server 2323**

To return to the default setting, use the **no** form of the command. For example:

(config)**#no telnet-server 2200**

test template match <*string*> to <*pattern*>

Use the **test template match to** command to evaluate dial strings and regular expressions for template matching and substitution. Once the command is entered, a response is provided indicating if the match was successful. Variations of this command include the following:

test template match <*string*> **to** <*pattern*>
test template match <*string*> **to** <*pattern*> **substitute-using** <*pattern*>

Syntax Description

<*string*>	Specifies a specific dial string to match. Valid entries can include a combination of characters ***** and **0** through **9**.
<*pattern*>	Specifies a pattern using either traditional number matching or regular expression matching methods. Refer to the *Functional Notes* below for more information.
substitute-using	Optional. Displays the resulting substitution.

Default Values

No default values are necessary for this command.

Command History

Release A4.05	Command was introduced.

Functional Notes

The <*pattern*> parameter can be defined using traditional number matching or regular expression matching methods. Traditional number matching uses numbers and wildcard variables to enter a pattern.

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

In regular expressions number matching, the match strings are encapsulated by paired */* (slash) symbols. This indicates that the pattern is to be treated as a regular expression. Using regular expressions allows greater flexibility in matching multiple number templates with fewer expressions.

NOTE *AOS is compatible with Perl compatible regular expressions (PCREs). More information on understanding and using regular expressions is available at* http://www.pcre.org.

NOTE *The use of quotation marks in a command syntax, when entering a string is not necessary unless the string requires using a space or* **?***. Using either of these characters outside of quotation marks is interpreted by the command line interface (CLI) as a command and is not recognized as part of the string. The use of quotation marks in the following examples are provided to cover all possible user-entered strings. These examples can be entered without the quotation marks and function in the same manner.*

Usage Examples

The following is a sample response using the **test template match** command with traditional number matching:

(config)**#test template match “5551234” to “555XXXX”**
Match Result -> Match

The following is a sample response using the **test template match** command with regular expression matching:

(config)**#test template match “5551234” to “/555\d{4}/”**
Match Result -> Match

The following is a sample response using the **test template match** <*string*> **to** <*pattern*> **substitute-using** <*pattern*> command with traditional number matching:

(config)**#test template match “5551234” to “555XXXX” substitute-using “1359555XXXX”**
Substitute Result -> 13595551234

The following is a sample response using the **test template match** <*string*> **to** <*pattern*> **substitute-using** <*pattern*> command with regular expression matching:

(config)**#test template match “5552121DE” to “/(\d+).*/” substitute-using “/\1/”**
Substitute Result -> 5552121

tftp ip access-class <*ipv4 acl*> in

Use the **tftp ip access-class** class command to apply an Internet Protocol version 4 (IPv4) access control list (ACL) to all self-bound IPv4 Trivial File Transfer Protocol (TFTP) incoming connections. Use the **no** form of this command to remove the ACL. Variations of this command include:

tftp ip access-class <*ipv4 acl*> **in**
tftp ip access-class <*ipv4 acl*> **in any-vrf**
tftp ip access-class <*ipv4 acl*> **in vrf** <*name*>

Syntax Description

<*ipv4 acl*>	Specifies the IPv4 ACL to apply to the TFTP connections.
in	Specifies that the ACL is applied to incoming TFTP connections.
any-vrf	Optional. Allows incoming TFTP connections from any Virtual Routing and Forwarding (VRF) instance.
vrf <*name*>	Optional. Allows incoming TFTP connections from a specified VRF instance.

Default Values

By default, no ACLs are configured or applied to TFTP connections.

Command History

Release 18.2	Command was introduced.
Release R10.3.0	Command was expanded to include the **any-vrf** and **vrf** <*name*> parameters.

Usage Examples

The following example applies the previously configured IPv4 ACL **MatchAll** to inbound TFTP connections:

(config)**#tftp ip access-class MatchAll in**

tftp ipv6 access-class <*ipv6 acl*> in

Use the **tftp ipv6 access-class in** command to apply an Internet Protocol version 6 (IPv6) access control list (ACL) to all self-bound IPv4 Trivial File Transfer Protocol (TFTP) incoming connections. Use the **no** form of this command to remove the ACL. Variations of this command include:

tftp ipv6 access-class <*ipv6 acl*> **in**
tftp ipv6 access-class <*ipv6 acl*> **in any-vrf**
tftp ipv6 access-class <*ipv6 acl*> **in vrf** <*name*>

Syntax Description

<*ipv6 acl*>	Specifies the IPv6 ACL to apply to the TFTP connections.
in	Specifies that the ACL is applied to incoming TFTP connections.
any-vrf	Optional. Allows incoming TFTP connections from any Virtual Routing and Forwarding (VRF) instance.
vrf <*name*>	Optional. Allows incoming TFTP connections from a specified VRF instance.

Default Values

By default, no ACLs are configured or applied to TFTP connections.

Command History

Release 18.2	Command was introduced.
Release R10.3.0	Command was expanded to include the **any-vrf** and **vrf** <*name*> parameters.

Usage Examples

The following example applies the previously configured IPv6 ACL **MatchAll** to inbound TFTP connections:

(config)**#tftp ipv6 access-class MatchAll in**

tftp server

Use the **tftp server** command to enable the Trivial File Transfer Protocol (TFTP) server. The **default-filesystem** parameter specifies the default location for the TFTP server to retrieve and store files. Use the **no** form of this command to disable the TFTP server. Variations of this command include:

tftp server
tftp server overwrite
tftp server default-filesystem cflash
tftp server default-filesystem flash
tftp server default-filesystem usbdrive0

Syntax Description

overwrite	Enables the TFTP server to overwrite existing files.
default-filesystem cflash	Optional. Specifies that the TFTP server use CompactFlash® as the default file system.
default-filesystem flash	Optional. Specifies that the TFTP server use flash as the default file system.
default-filesystem usbdrive0	Optional. Specifies that the TFTP server use Universal Serial Bus (USB) flash drive memory as the default file system.

Default Values

By default, this command is disabled.

Command History

Release 9.3	Command was introduced.
Release 13.1	Command was expanded to include the **overwrite** feature.
Release 17.3	Command was expanded to include the **default-filesystem** parameter.
Release 18.2	Command was changed from **ip tftp server** to **tftp server** to accommodate Internet Protocol version 6 (IPv6) for Adtran internetworking products only. In addition, the command was expanded to include the **usbdrive0** parameter.
Release R10.1.0	Command was changed from **ip tftp server** to **tftp server** to accommodate Internet Protocol version 6 (IPv6) for Adtran voice products.

Usage Examples

The following example enables the TFTP server:

(config)**#tftp server**

The following example specifies CompactFlash as the default file system:

(config)**#tftp server default-filesystem cflash**

tftp source-interface *<interface>*

Use the **tftp source-interface** command to use the specified interface's IP address as the source IP address for Trivial File Transfer Protocol (TFTP) client traffic transmitted by the unit. Use the **no** form of this command if you do not wish to override the normal source IP address.

Syntax Description

<interface>	Specifies the interface to be used as the source IP address for TFTP traffic. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **tftp source-interface ?** for a complete list of valid interfaces.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.
Release 14.1	Command was expanded to include the tunnel interface.
Release 17.1	Command was expanded to include the asynchronous transfer mode (ATM) interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release 18.2	Command was changed from **ip tftp source-interface** to **tftp source-interface** to incorporate Internet Protocol version 6 (IPv6) for Adtran internetworking products only.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.1.0	Command was changed from **ip tftp source-interface** to **tftp source-interface** to incorporate Internet Protocol version 6 (IPv6) for Adtran voice products.

Functional Notes

This command allows you to override the *sender* field in the IP packet. If you have multiple interfaces in your unit, changing the *sender* tells the receiver where to send replies. This functionality can also be used to allow packets to get through firewalls that would normally block the flow.

Usage Examples

The following example configures the unit to use the **loopback 1** interface as the source IP for TFTP traffic:

(config)**#tftp source-interface loopback 1**

thresholds

Use the **thresholds** command to specify DS1 performance counter thresholds. Use the **no** form of this command to return to the default setting. Variations of this command include:

thresholds BES [15Min | 24Hr] <*number*>
thresholds CSS [15Min | 24Hr] <*number*>
thresholds DM [15Min | 24Hr] <*number*>
thresholds ES [15Min | 24Hr] <*number*>
thresholds LCV [15Min | 24Hr] <*number*>
thresholds LES [15Min | 24Hr] <*number*>
thresholds PCV [15Min | 24Hr] <*number*>
thresholds SEFS [15Min | 24Hr] <*number*>
thresholds SES [15Min | 24Hr] <*number*>
thresholds UAS [15Min | 24Hr] <*number*>

Threshold settings are applied to ALL DS1s.

Syntax Description

BES	Specifies the bursty errored seconds threshold.
CSS	Specifies the controlled slip seconds threshold.
DM	Specifies the degraded minutes threshold.
ES	Specifies the errored seconds threshold.
LCV	Specifies the line code violations threshold.
LES	Specifies the line errored seconds threshold.
PCV	Specifies the path coding violations threshold.
SEFS	Specifies the severely errored framing seconds threshold.
SES	Specifies the severely errored seconds threshold.
UAS	Specifies the unavailable seconds threshold.
15Min	Specifies that the threshold you are setting is for the counter's 15-minute statistics.
24Hr	Specifies that the threshold you are setting is for the counter's 24-hour statistics.
<*number*>	Specifies the maximum occurrences allowed for this error type. Once a threshold is exceeded, an event is sent to the console specifying the appropriate counter. Additionally, if Simple Network Management Protocol (SNMP) traps are enabled, the unit will send a trap with the same information as the console event.

Default Values

The default values for this command are as follows:

thresholds BES 15Min 10
thresholds BES 24Hr 100
thresholds CSS 15Min 1
thresholds CSS 24Hr 4
thresholds DM 15Min 1
thresholds DM 24Hr 4
thresholds ES 15Min 65
thresholds ES 24Hr 648
thresholds LCV 15Min 13340
thresholds LCV 24Hr 133400
thresholds LES 15Min 65
thresholds LES 24Hr 648
thresholds PCV 15Min 72
thresholds PCV 24Hr 691
thresholds SEFS 15Min 2
thresholds SEFS 24Hr 17
thresholds SES 15Min 10
thresholds SES 24Hr 100
thresholds UAS 15Min 10
thresholds UAS 24Hr 10

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the threshold for the 15-minute and 24-hour bursty errored seconds counter to **25** and **200**, respectively:

(config)**#thresholds BES 15Min 25**
(config)**#thresholds BES 24Hr 200**

timing-source

Use the **timing-source** command to configure the timing source used for reference timing. Use the **no** form of this command to return to the default setting. Variations of this command include the following:

timing-source e1 <*interface id*> **secondary**
timing-source e1 <*interface id*>
timing-source internal
timing-source internal secondary
timing-source t1 <*interface id*>
timing-source t1 <*interface id*> **secondary**

Syntax Description

e1 <*interface id*>	Recovers clocking from the specified E1 interface.
internal	Provides timing using the internal 1.544 MHz clock generator.
t1 <*interface id*>	Recovers clocking from the specified T1 or DSX-1 interface.
secondary	Optional. Signifies that the clock source specified in the command is to be the secondary clock source.

Default Values

By default, the primary clock source is set to **internal**.

Command History

Release 11.1	Command was introduced.
Release A5.01	Command was expanded to include the E1 interface.

Functional Notes

If both the primary and secondary clock sources fail, the unit automatically switches to internal timing.

Usage Examples

The following example configures the unit to use an internal timing source:

(config)**#timing-source internal**

The following examples set the t1 0/1 interface as the primary timing source and the t1 0/2 interface as the secondary timing source:

(config)**#timing-source t1 0/1**
(config)**#timing-source t1 0/2 secondary**

tls-profile *<profile name>*

Use the **tls-profile** command to enter the Transport Layer Security (TLS) Profile Configuration mode, from which the operation of TLS is configured. Use the **no** form of this command to remove the profile.

Syntax Description

<profile name>	Specifies the name of the TLS profile to create.

Default Values

By default, no TLS profiles exist.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

Each entity on the AOS device that uses TLS must have a TLS profile applied in order to function. Many TLS profiles can exist and be referenced by many entities using TLS on the AOS device. The same TLS profile can be used by as many entities using TLS as required. The TLS profile essentially operates as a template for TLS operation and is applied on a per-trunk basis. For more information regarding TLS configuration, refer to the *SIP TLS Profile Command Set on page 4880*.

Usage Examples

The following example creates the TLS profile **TLSPROFILE1** and enters the profile's configuration mode:

```
(config)#tls-profile TLSPROFILE1
(config-tls-profile-TLSPROFILE1)#
```

track *<name>*

Use the **track** command to create a track as part of network monitoring. This command is also used to enter into the Network Monitoring Track command set once a track is created. These additional commands are covered in *Network Monitor Track Command Set on page 4098*. Use the **no** form of this command to delete the track.

*Issuing the **shutdown** command once the track is configured will force the track to fail. Issuing the **no shutdown** command will enable the track.*

Syntax Description

<name>	Specifies the name of the track being created.

Default Values

By default, there are no tracks configured.

Command History

Release 13.1	Command was introduced.

Functional Notes

Track objects can be associated with probes to monitor their states. Upon a change in the probe state, the probe sends an event to any track registered with the probe. In response, the track performs the action indicated.

Track objects are associated with probes by using the commands *test if on page 4102* and *test list on page 4108*.

Usage Examples

The following example creates an track called **track_a**:

```
>enable
#configure terminal
(config)#track track_a
(config-track)#
```

Technology Review

Tracks are objects created to monitor other objects for a change in their state. The tracks can be configured to perform a specific action based upon the second object state detected. Association between a track and another object (for example, a probe, schedule, or interface) occurs through referencing the second object in the track's configuration. Once the track is registered with the second object, whenever a change occurs with that object's state, an event is sent to the track. Additional configuration commands are available for creating probes. These are explained in the *Network Monitor Probe Command Set on page 4062*.

username <*username*> password <*password*>

Use the **username password** command to configure the user name and password to use for all protocols requiring a user name-based authentication system, including File Transfer Protocol (FTP) server authentication, line (login local-user list), and Hypertext Transfer Protocol (HTTP) access. Using the **portal-list** parameter associates a portal list with the user. Using the **privilege** parameter specifies a privilege level for the user. Use the **no** form of this command to remove a user name and password. Variations of this command include:

username <*username*> **password** <*password*>
username <*username*> **portal-list** <*name*> **password** <*password*>
username <*username*> **portal-list** <*name*> **privilege** <*level*> **password** <*password*>
username <*username*> **privilege** <*level*> **password** <*password*>
username <*username*> **privilege** <*level*> **portal-list** <*name*> **password** <*password*>

Syntax Description

<*username*>	Specifies a user name using an alphanumerical string up to 30 characters in length (the user name is case sensitive).
password <*password*>	Specifies a password using an alphanumerical string up to 30 characters in length (the password is case sensitive).
portal-list <*name*>	Optional. Specifies the name of the portal list assigned to this user.
privilege <*level*>	Optional. Specifies privilege level for this user. Valid entries are **1** to **7**.

Default Values

By default, there is no established user name or password. By default, there is no portal list assigned to user names. If this command is entered without a privilege level specified, the default privilege level assigned to the user is level 7.

Command History

Release 1.1	Command was introduced.
Release 17.1	Command was expanded to include the **portal-list** parameter.
Release A1	Command was expanded to include the **password** parameter.
Release R10.11.0	Command was expanded to include the **privilege** parameter.

Functional Notes

All users defined using the **username/password** command are valid for access to the unit using the **login local-userlist** command.

Before a portal list can be associated with a user name, it must be defined using the command *portal-list <name> <portal1 portal2 portal3> on page 1655*.

Usage Examples

The following example creates a user name of **Adtran** with password **Adtran**:

(config)**#username Adtran password Adtran**

The following example associates the portal list **ENGINEERS** with the user name **Adtran** and the password **Adtran**:

(config)**#username Adtran portal-list ENGINEERS password Adtran**

The following example specifies a privilege level **4** with the user name **Adtran** and the password **Adtran**:

(config)**#username Adtran privilege 4 password Adtran**

vlan *<vlan id>*

Use the **vlan** command to enter the Virtual Local Area Network (VLAN) Configuration mode. Use the **no** form of this command to remove a VLAN ID. Refer to the *VLAN Command Set on page 3356* for more information.

Syntax Description

<vlan id>	Specifies a valid VLAN ID. Range is **1** to **4094**.

Default Values

No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example enters the VLAN Configuration mode for VLAN 1:

```
(config)#vlan 1
(config-vlan 1)#
```

voice alias *<name>* equals *<number>*

Use the **voice alias equals** command to configure the name and number for the call routing alias. This feature allows a single call destination to be reached by an alternate name and number. Use the **no** form of this command to disable this feature.

Syntax Description

<name>	Specifies the alias name to describe the call destination.
<number>	Assigns the alias number to mask the original number.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example activates the **Lobby** voice alias at extension **4100**:

(config)**#voice alias Lobby equals 4100**

voice ani-list <*name*>

Use the **voice ani-list** command to create a list of automatic number identification (ANI) information and enter the ANI list configuration mode. Use the **no** form of this command to remove the ANI list.

Additional subcommands are available once you have entered the ANI list configuration mode:

ani <*template*>

Syntax Description

<*name*>	Specifies the name of the ANI list.
ani <*template*>	Specifies the ANI digits of the calling party to add to the ANI list. Digits include a combination of wildcards and numerical digits. Refer to the *Functional Notes* of this command for more information on using wildcards.

Default Values

By default, no ANI lists are configured.

Command History

Release A2	Command was introduced.

Functional Notes

ANI lists are used to permit or deny specific calling parties from accessing trunk groups to which the ANI list is applied.

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example creates an ANI list called **TEST1** and specifies which numbers are included in the ANI list:

(config)**#voice ani-list TEST1**
(config-ani-list-TEST1)#ani 555-81xx

voice announcement trunk-unavailable

Use the **voice announcement trunk-unavailable** command to enable the playing of an announcement when a call is made and the trunk for that call is unavailable. Use the **no** form of this command to disable the option.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release R10.6.0	Command was introduced.

Usage Examples

The following example enables the trunk-unavailable announcement:

(config)**#voice announcement trunk-unavailable**

voice autoattendant

Use the **voice autoattendant** command to configure the auto attendant options for the system. Use the **no** form of the commands to disable the setting. For more voice auto attendant options, refer to *voice call-appearance-mode on page 1895*. Variations of this command include the following:

voice autoattendant <*name*>
voice autoattendant <*name*> **extension** <*number*>
voice autoattendant alias <*name*>
voice autoattendant did <*number*>
voice autoattendant extension <*number*>

Syntax Description

<*name*>	Specifies a name for this auto attendant.
alias <*name*>	Specifies an alias name to use as an alternate when accessing the auto attendant.
did <*number*>	Configures the direct inward dialing (DID) number to assign to the auto attendant.
extension <*number*>	Specifies the extension for auto attendant system login access.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example configures the **aOperator** as an alias for the auto attendant:

(config)**#voice autoattendant alias aOperator**

voice call-appearance-mode

Use the **voice call-appearance-mode** command to configure the unit to allow single or multiple call appearances to user account phones. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice call-appearance-mode multiple
voice call-appearance-mode single

Syntax Description

multiple	Allows multiple call appearances. For analog phones, this is limited to **2** call appearances; for Session Initiation Protocol (SIP) phones, **6** call appearances are allowed.
single	Allows only a single call appearance.

Default Values

By default, this is set to **multiple**.

Command History

Release 11.1	Command was introduced.

Functional Notes

Each incoming call is classified as a call appearance. For example, call waiting supports two call appearances simultaneously. Without call waiting, only one call appearance is supported at a time.

Usage Examples

The following example sets the unit to allow multiple call appearances:

(config)#**voice call-appearance-mode multiple**

voice caller-id timezone *<value>*

The **voice caller-id timezone** command sets the time zone used for the caller identification (ID) timestamp of an inbound call. This setting is independent of the clock timezone set by the command *clock timezone <value> on page 1234*. The caller ID timestamp is calculated using the system clock (*clock set <time> <day> <month> <year> on page 1233*) and the caller ID time zone offset. Use the **no** form of this command to disable this feature.

Syntax Description

<value>	Time zone values are specified in the *Functional Notes* section for this command.

Default Values

By default, the caller ID timezone is set to the current system time zone. For more information on the system time zone, refer to the command *clock timezone <value> on page 1234*.

Command History

Release R10.1.0	Command was introduced.

> NOTE *Depending on the **clock timezone** chosen, one-hour daylight savings time (DST) correction may be enabled automatically. Refer to the command clock on page 1232 for more information.*

Functional Notes

The following list shows sample cities and their time zone codes.

clock timezone +1-Amsterdam
clock timezone +1-Belgrade
clock timezone +1-Brussels
clock timezone +1-Sarajevo
clock timezone +1-West-Africa
clock timezone +10-Brisbane
clock timezone +10-Canberra
clock timezone +10-Guam
clock timezone +10-Hobart
clock timezone +10-Vladivostok
clock timezone +11
clock timezone +12-Auckland
clock timezone +12-Fiji
clock timezone +13
clock timezone +2-Athens
clock timezone +2-Bucharest
clock timezone +2-Cairo
clock timezone +2-Harare
clock timezone +8-Bejing
clock timezone +8-Irkutsk
clock timezone +8-Kuala-Lumpur
clock timezone +8-Perth
clock timezone +8-Taipei
clock timezone +9-Osaka
clock timezone +9-Seoul
clock timezone +9-Yakutsk
clock timezone +9:30-Adelaide
clock timezone +9:30-Darwin
clock timezone -1-Azores
clock timezone -1-Cape-Verde
clock timezone -10
clock timezone -11
clock timezone -12
clock timezone -2
clock timezone -3-Brasilia
clock timezone -3-Buenos-Aires

clock timezone +2-Helsinki
clock timezone +2-Jerusalem
clock timezone +3-Baghdad
clock timezone +3-Kuwait
clock timezone +3-Moscow
clock timezone +3-Nairobi
clock timezone +3:30
clock timezone +4-Abu-Dhabi
clock timezone +4-Baku
clock timezone +4:30
clock timezone +5-Ekaterinburg
clock timezone +5-Islamabad
clock timezone +5:30
clock timezone +5:45
clock timezone +6-Almaty
clock timezone +6-Astana
clock timezone +6-Sri-Jay
clock timezone +6:30
clock timezone +7-Bangkok
clock timezone +7-Kranoyarsk
clock timezone -3-Greenland
clock timezone -3:30
clock timezone -4-Atlantic-Time
clock timezone -4-Caracus
clock timezone -4-Santiago
clock timezone -5
clock timezone -5-Bogota
clock timezone -5-Eastern-Time
clock timezone -6-Central-America
clock timezone -6-Central-Time
clock timezone -6-Mexico-City
clock timezone -6-Saskatchewan
clock timezone -7-Arizona
clock timezone -7-Mountain-Time
clock timezone -8
clock timezone -9
clock timezone -0-Universal Coordinated Time (UTC)
clock timezone GMT-Casablanca
clock timezone GMT-Dublin

Usage Examples

The following example sets the caller ID time zone for Santiago, Chile.

>**enable**
(config)**#clock timezone -4-Santiago**

voice callerid-type *<method>*

Use the **voice callerid-type** command to specify the caller ID method for the system. Select the caller ID type that is required by your telecommunications provider. Use the **no** form of this command to disable the setting.

Syntax Description

<method>	Specifies the type of caller ID to use with the system. The available options are: • **Australia_FSK** • **Belgium_FSK** • **Canada_Stentor** • **Denmark_DTMF** • **Finland_DTMF** • **Italy_FSK** • **Mexico_FSK** • **Netherlands_DTMF** • **New Zealand_FSK** • **Norway_FSK** • **Sweden_DTMF** • **UK_BT** • **UK_CCA** • **United_Arab_Emirates_FSK** • **US_Bellcore**

Default Values

By default, the caller ID type is set to **US_Bellcore**.

Command History

Release 15.1	Command was introduced.
Release A2	Command was expanded to include **Australia_FSK**.
Release A4.05	Command was expanded to include **Mexico_FSK**.
Release A5.01	Command was expanded to include **United_Arab_Emirates_FSK**.
Release R14.2.0	Command was expanded to include **New Zealand_FSK**

Usage Examples

The following example specifies using the Italian method for the caller ID type:

(config)**#voice callerid-type Italy_FSK**

voice cause-code-map

Use the **voice cause-code-map** command to configure the cause code and Session Initiation Protocol (SIP) message numbers for the primary rate interface (PRI). Cause codes and SIP message numbers are associated with a particular connection failure, and notifies the system when problems occur. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice cause-code-map from-pri <*value*> <*value*>
voice cause-code-map to-pri <*value*> <*value*>

Syntax Description

from-pri <*value*> <*value*>	Enter the cause code number to map to the SIP message. The valid range is **1** to **127**. Next, enter the SIP message number to be used. The valid range is **400** to **606**.
to-pri <*value*> <*value*>	Enter the SIP message number to map to the PRI cause code map. The valid range is **400** to **606**. The second <*value*> is the PRI cause code number. The valid range is **1** to **127**.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example sets the cause code number to **28** to associate with SIP messages:

(config)**#voice cause-code-map from-pri 28**

voice class-of-service *<set name>*

Use the **voice class-of-service** command to create a voice class of service (CoS) rule set and to enter the Voice Class of Service command set. These additional commands are covered in *Voice CoS Command Set on page 4897*. Use the **no** form of this command to delete a configured CoS rule set.

Syntax Description

<set name>	Specifies the name of the CoS rule set.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example creates a new CoS rule set called **set1**:

```
(config)#voice class-of-service set1
Configuring New Level “set1”.
(config-cos-set1)#
```

voice codec-country <*name*>

Use the **voice codec-country** command to assign a country setting for the plain old telephone service (POTS) (analog) coder-decoders (CODECs). Use the **no** form of this command to delete a configured country setting.

Syntax Description

<*name*>	Specifies the CODEC country name. The available options are **Australia**, **Belgium**, **Canada**, **China_Hong_Kong**, **Denmark**, **Etsi**, **Finland**, **France**, **Germany**, **Ireland**, **Italy**, **Luxembourg**, **Mexico, Netherlands, New Zealand, Norway**, **Puerto_Rico**, **Spain**, **Sweden**, **Switzerland**, **United_Arab_Emirates**, **United_Kingdom**, and **United_States**.

Default Values

By default, the CODEC country setting is **United_States**.

Command History

Release 15.1	Command was introduced.
Release A2	Command was expanded to include **Australia**.
Release A2.04	Command was expanded to include **Belgium**, **France**, **Germany**, **Ireland**, **Italy**, **Luxembourg**, **Spain**, **Switzerland**, and **United_Kingdom**.
Release A4.05	Command was expanded to include **China_Hong_Kong**, **Denmark**, **Etsi**, **Finland**, **Mexico**, **Netherlands**, **Norway**, **Sweden**, and **United_Arab_Emirates**.
Release R14.2.0	Command expanded to include **New Zealand_FSK**

Usage Examples

The following example assigns **Canada** as the CODEC country:

(config)**#voice codec-country Canada**

voice codec-list <*name*>

Use the **voice codec-list** command to create a named coder-decoder (CODEC) list for call negotiation and to enter the CODEC list configuration mode. Use the **no** form of this command to delete a configured CODEC list.

Syntax Description

<*name*>	Specifies the CODEC list name.

Default Values

By default, there are no configured voice CODEC lists.

Command History

Release 9.3	Command was introduced.

Functional Notes

CODEC lists are list of CODECs arranged in preferred order with the first listed CODEC being the most preferred for call negotiation. Using the **voice codec-list** command enters the configuration mode for the CODEC list, where you can enter the types of CODECs to be used, and their order of preference. CODEC lists are then applied to interfaces, voice trunks, or voice accounts to be used for call negotiation. For more information on configuring and applying CODEC lists, refer to *Voice CODEC List Command Set on page 4893*.

Usage Examples

The following example creates a new CODEC list named **List1**:

```
(config)#voice codec-list List1
Configuring New Codec List “List1”.
(config-codec)#
```

voice codec-priority

Use the **voice codec-priority** command to specify which coder-decoder (CODEC) list is set as the priority. Use the **no** form of this command to disable the setting. Variations of this command include:

voice codec-priority trunk
voice codec-priority user
voice codec-priority offer-sdp

Syntax Description

trunk	Specifies using the trunk's CODEC list as the priority CODEC list.
user	Specifies using the user's CODEC list as the priority CODEC list.
offer-sdp	Specifies using Session Description Protocol (SDP) offer/answer exchanges to set CODEC priority.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.
Release A2	Command was expanded to include the **offer-sdp** parameter.

Functional Notes

The **voice codec-priority** command specifies the CODEC selection method at the unit's global level. Selections are made from preconfigured CODEC lists. For more information about configuring and applying CODEC lists, refer to the *Voice CODEC List Command Set on page 4893*.

Usage Examples

The following example specifies using the trunk's CODEC list as the priority CODEC list:

(config)**#voice codec-priority trunk**

voice compand-type

Use the **voice compand-type** command to set the companding type to match your telecommunications provider. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice compand-type a-law
voice compand-type u-law

Syntax Description

a-law	Specifies the A-law compand type. This compand type is mainly used in European telephone networks for the conversion between analog and digital signals in pulse-code modulation (PCM) applications, and is similar to the North American U-law standard.
u-law	Specifies the U-law compand type.This compand type is also known as Mu-law, and is the PCM quasi-logarithmic curve. It is the 64 kbps standard North America voice amplitude sample used for encoding and decoding.

Default Values

By default, the companding type is set to **u-law**.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example configures the companding type to **a-law**:

(config)**#voice compand-type a-law**

voice conference local

Use the **voice conference local** command to configure the local conference feature. The **voice conferencing-mode** command must be first set to **local** before these commands will take effect. Refer to *voice conferencing-mode on page 1907*. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice conference local max-sessions <*number*>
voice conference local originator flashhook drop
voice conference local originator flashhook ignore
voice conference local originator flashhook split
voice conference local originator onhook persist
voice conference local originator onhook terminate
voice conference local party-disconnect continue
voice conference local party-disconnect transfer

Syntax Description

max-sessions <*number*>	Specifies the maximum number of simultaneous 3-way conference sessions. If set to 0, the maximum number of sessions is defined by the capability of the hardware platform.
originator	Specifies the behavior of actions performed by the conference originator once the conference has been established.
flashhook drop	Indicates that when a flashhook is issued, the last party added to the 3-way conference will be dropped and the call will continue between the two remaining parties.
flashhook ignore	Indicates that when a flashhook is issued, it will be ignored. The 3-way conference will continue without interruption.
flashhook split	Indicates that when a flashhook is issued, the 3-way conference will be split into two calls, one between the originator and the first party and one between the originator and the second party. When a flashhook is issued after the split, it will toggle the originator between the two calls.
onhook persist	Indicates that when the originator goes on-hook, the two parties in the conference are connected together.
onhook terminate	Indicates that when the originator goes on-hook, the remaining parties are disconnected.
party-disconnect	Specifies the conference behavior after a member disconnects.
continue	Indicates the conference is maintained with the remaining parties.
transfer	Indicates the conference is dropped and a direct connection between the remaining parties is re-established.

Default Values

By default, the **max-sessions** is set to **3**, **originator onhook** is set to **persist**, **originator flashhook** is set to **drop**, and **party-disconnect** is set to **continue**.

Command History

Release A2	Command was introduced.

Functional Notes

The voice conference local settings are only valid when the **voice conferencing-mode** is set to **local**. Refer to *voice conferencing-mode on page 1907* for more information.

Usage Examples

The following example sets the unit to a maximum of 5 local conference sessions:

(config)**#voice conference local max-sessions 5**

The following example sets the behavior of the conference session to ignore a flash-hook issued by the conference originator:

(config)**#voice conference local originator flashhook ignore**

voice conferencing-mode

Use the **voice conferencing-mode** command to determine if voice conferencing bridging will be handled within the unit or from a far-end conferencing server. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice conferencing-mode local
voice conferencing-mode network

Syntax Description

local	Specifies voice conferencing will be handled within the unit.
network	Specifies voice conferencing will be handled by a far-end conferencing server.

Default Values

By default, the voice conferencing mode is set to **network**.

Command History

Release A1	Command was introduced.

Functional Notes

The voice conferencing mode is only valid when the flashhook mode is set to **interpreted**. Refer to the command *voice flashhook mode on page 1921* for more information.

Usage Examples

The following example sets the conferencing mode to handle conference bridging within the local unit:

(config)**#voice conferencing-mode local**

voice country-code *<number>*

Use the **voice country-code** command to enter the country code for this location. The country code is used to determine if an incoming call is international. If a call originates from the Session Initiation Protocol (SIP) wide area network (WAN) and it matches the specified voice country code number, the call is not considered international and the country code is stripped before passing the call to the customer premises equipment (CPE). Use the **no** form of this command to delete the country code.

Syntax Description

<number>	Specifies the country code of this location. One, two, and three (maximum) digit country codes are accepted.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.

Functional Notes

For a comprehensive list of numeric country codes for specific countries, refer to the *International Configuration Guide* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies a **voice country-code** of **44** (United Kingdom):

(config)**#voice country-code 44**

voice coverage *<name>*

Use the **voice coverage** command to create and modify a global call coverage list to be used to control call routing when a user's phone is not answered. This command also enters the global call coverage configuration mode. Use the **no** form of this command to remove a call coverage list.

Syntax Description

<name>	Specifies a name for the call coverage list.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Functional Notes

The **voice coverage** command creates a global call coverage list for the AOS product and enters the list's configuration mode. The configurable options for this list are detailed in *Call Coverage Command Set on page 4718*.

The global call coverage list can be overridden on a per-user or per-group basis using the **coverage** command from the appropriate configuration mode.

Usage Examples

The following example specifies that the call coverage list named **Absent** be used for global call coverage:

```
(config)#voice coverage Absent
    Configuring New Global Call Handling List "Absent"
(config-gch)#
```

voice current-mode

Use the **voice current-mode** command to activate a particular system mode on the unit. Variations of this command include:

voice current-mode custom1
voice current-mode custom2
voice current-mode custom3
voice current-mode default
voice current-mode lunch
voice current-mode night
voice current-mode override
voice current-mode weekend

Syntax Description

[custom1-custom3]	Specifies the custom system mode to use.
default	Specifies using the default system mode.
lunch	Specifies using the lunch time system mode.
night	Specifies using the night time system mode.
override	Specifies using the override system mode.
weekend	Specifies using the weekend system mode.

Default Values

By default, the system mode is set to **default**.

Command History

Release A1	Command was introduced.

Functional Notes

This command is used to put the unit into a specific system mode. The unit remains in the activated system mode until it is changed manually or a schedule change occurs triggering a transition to another system mode. Schedules are configured using the command *voice system-mode on page 1971*.

If the system is in override, the unit will ignore any schedule that exists. The unit will stay in override until manually changed. This command is saved into the dynvoice-config file to preserve the state of the unit in case of power failure.

Usage Examples

The following example sets the current system mode to **lunch**:

(config)**#voice current-mode lunch**

voice dial-plan

Use the **voice dial-plan** command to add a global number complete pattern. Use the **no** form of this command to delete configured dial plans. Variations of this command include:

voice dial-plan <*pattern id*> **900-number** <*pattern*>
voice dial-plan <*pattern id*> **900-number** <*pattern*> **[**<*ndt name*>**| default | none]**
voice dial-plan <*pattern id*> **always-permitted** <*pattern*>
voice dial-plan <*pattern id*> **always-permitted** <*pattern*> **[**<*ndt name*>**| default | none]**
voice dial-plan <*pattern id*> **extensions** <*pattern*>
voice dial-plan <*pattern id*> **extensions** <*pattern*> **[**<*ndt name*>**| default | none]**
voice dial-plan <*pattern id*> **internal-operator** <*pattern*>
voice dial-plan <*pattern id*> **internal-operator** <*pattern*> **[**<*ndt name*>**| default | none]**
voice dial-plan <*pattern id*> **international** <*pattern*>
voice dial-plan <*pattern id*> **international** <*pattern*> **[**<*ndt name*>**| default | none]**
voice dial-plan <*pattern id*> **local** <*pattern*>
voice dial-plan <*pattern id*> **local** <*pattern*> **[**<*ndt name*>**| default | none]**
voice dial-plan <*pattern id*> **long-distance** <*pattern*>
voice dial-plan <*pattern id*> **long-distance** <*pattern*> **[**<*ndt name*>**| default | none]**
voice dial-plan <*pattern id*> **operator-assisted** <*pattern*>
voice dial-plan <*pattern id*> **operator-assisted** <*pattern*> **[**<*ndt name*>**| default | none]**
voice dial-plan <*pattern id*> **specify-carrier** <*pattern*>
voice dial-plan <*pattern id*> **specify-carrier** <*pattern*> **[**<*ndt name*>**| default | none]**
voice dial-plan <*pattern id*> **toll-free** <*pattern*>
voice dial-plan <*pattern id*> **toll-free** <*pattern*> **[**<*ndt name*>**| default | none]**
voice dial-plan <*pattern id*> **[user1 | user2 | user3]** <*pattern*>
voice dial-plan <*pattern id*> **[user1 | user2 | user3]** <*pattern*> **[**<*ndt name*>**| default | none]**

Syntax Description

<*pattern id*>	Specifies dial pattern identification. Valid range is **1** to **255**.
900-number	Adds a pattern to the 900 number group.
always-permitted	Adds a pattern to the always permitted group.
extensions	Adds a pattern to the internal group.
internal-operator	Adds a pattern to the internal operator group.
international	Adds a pattern to the international group.
local	Adds a pattern to the local group.
long-distance	Adds a pattern to the long distance group.
operator-assisted	Adds a pattern to the operator assisted group.
specify-carrier	Adds a pattern to the specify carrier group.
toll-free	Adds a pattern to the toll free group.
user1	Adds a pattern to the user 1 group.
user2	Adds a pattern to the user 2 group.
user3	Adds a pattern to the user 3 group.

<pattern>	Specifies a dialing pattern. You can enter a complete phone number, or wildcards can be used to define the dialing pattern. Refer to *Functional Notes* of this command for more information on using wildcards.
<ndt name>	Optional. Specifies the named-digit-timeout to associate with this dial plan entry. The named-digit-timeout is assigned a timeout value with the **voice timeouts named-digit-timeout** command (refer to *voice timeouts on page 1972*).
default	Optional. Sets the named-digit-timeout to the default value. The default value is set with the **voice timeouts interdigit** command (refer to *voice timeouts on page 1972*).
none	Optional. Indicates that no named-digit-timeout is associated with this dial plan entry.

Default Values

By default, no dial plans are configured.

Command History

Release 9.3	Command was introduced.
Release A2	Command was expanded to include the named-digit-timeouts.

Functional Notes

Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example adds the pattern **8000** to the **local** group:

(config)**#voice dial-plan 1 local 8000**

The following example adds the pattern **NXX-XXXX** to the **local** group and associates it with the **short1** named-digit-timeout:

(config)**#voice dial-plan 2 local NXX-XXXX short1**

voice did <*number*> extension <*extension*>

Use the **voice did extension** command to add a direct inward dialing (DID) number. Use the **no** form of this command to delete a configured translation.

Syntax Description

<*number*>	Specifies the direct inward dial lookup number.
<*extension*>	Specifies the target account of the DID translation.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example directs DID number **5558123** to extension **8123**:

(config)**#voice did 5558123 extension 8123**

voice directory <*name*>

Use the **voice directory** command to create or modify a voice directory and enter the Voice Directory Configuration mode. Use the **no** form of this command to delete a configured voice directory. Variations of this command include:

voice directory <*name*>

The following additional subcommands are available once you have entered the Voice Directory Configuration mode:

directory-include <*number*> **first-name** <*name*>
directory-include <*number*> **first-name** <*name*> **last-name** <*name*>

Syntax Description

<*name*>	Specifies the name of the directory to create or modify.
directory-include <*number*>	Specifies the extension of the user to be added to the dial-by-name directory. Adding users to the directory allows them to call parties using a name stored in the system. Use the **no** form of this command to remove a user from the directory.
first-name <*name*>	Specifies the user's first name.
last-name <*name*>	Optional. Specifies the user's last name.

Default Values

By default, no voice directories are configured.

Command History

Release 14.1	Command was introduced.

Functional Notes

Adding a voice directory is useful when taking advantage of the dial-by-name feature. By default, a system directory is always available. All voice users are automatically added as members of the system directory.

Usage Examples

The following example creates a new **voice directory** with name **Engineering**:

(config)**#voice directory Engineering**

The following example adds **Jan Doe** to the **Engineering** dial-by-name directory:

(config)**#voice directory Engineering**
(config-dir)**#directory-include 5555 first-name Jan last-name Doe**

voice disconnect-mode

Use the **voice disconnect-mode** command to control the disconnect mode of the unit. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice disconnect-mode dialtone
voice disconnect-mode fast-busy

Syntax Description

dialtone	Specifies issuing dial tone after disconnect on the unit.
fast-busy	Specifies issuing fast-busy tone after disconnect on the unit.

Default Values

By default, this command is set to **dialtone**.

Command History

Release A2.03	Command was introduced.

Usage Examples

The following example configures the unit to disconnect issuing a **fast-busy** tone:

(config)**#voice disconnect-mode fast-busy**

voice emergency-services

Use the **voice emergency-services** command to enable the local emergency service numbers. Local emergency service numbers are configured automatically when the system country is specified. Use the **no** form of this command to disable the local emergency service numbers.

Syntax Description

No subcommands.

Default Values

By default, local emergency service numbers are enabled.

Command History

Release R10.3.0	Command was introduced.

Usage Examples

The following example disables local emergency service numbers:

(config)**#no voice emergency-services**

voice fax-tone

Use the **voice fax-tone** command to choose which tones initiate modem passthrough mode or T.38 mode. Use the **no** form of this command to inhibit a specified tone from initiating T.38 or modem passthrough call handling. Variations of this command include:

voice fax-tone default
voice fax-tone modem-passthrough default
voice fax-tone modem-passthrough t30-cng
voice fax-tone modem-passthrough v21-preamble
voice fax-tone modem-passthrough v25-ans
voice fax-tone modem-passthrough v25-ans-pr
voice fax-tone modem-passthrough v8-ansam
voice fax-tone modem-passthrough v8-ansam-pr
voice fax-tone t38 default
voice fax-tone t38 t30-cng
voice fax-tone t38 v21-preamble
voice fax-tone t38 v25-ans
voice fax-tone t38 v25-ans-pr
voice fax-tone t38 v8-ansam
voice fax-tone t38 v8-ansam-pr

Syntax Description

default	Restores the default tones for initiating modem passthrough mode or T.38 mode, depending on where it is used in the command syntax. For example, issuing **voice fax-tone default** restores defaults for both modes, while issuing **voice fax-tone t38 default** only restores defaults for T.38 mode.
modem-passthrough	Specifies modem passthrough mode.
t38	Specifies T.38 mode.
t30-cng	Specifies the T.30 calling tones.
v21-preamble	Specifies the V.21 preamble flag tones.
v25-ans	Specifies the V.25 answer tones.
v25-ans-pr	Specifies the V.25 answer tones with phase reversals.
v8-ansam	Specifies the V.8 answer tones with amplitude modulation.
v8-ansam-pr	Specifies the V.8 answer tones with amplitude modulation and phase reversals.

Default Values

By default, all tones are enabled for the **modem-passthrough** list. Only the **v21-preamble** is enabled by default for the T.38 list.

Command History

Release A2.04	Command was introduced.
Release A5.01	Command default was changed so that only the **v21-preamble** tone is enabled by default for the T.38 tone list.

Functional Notes

When a fax tone is enabled, the tone is eligible to initiate either modem-passthrough or T.38 handling, depending on the command entered. T.38 fax tone commands take priority over modem passthrough fax tone commands. For example, in the default configuration with all commands enabled, any detected tone on a call would cause a reINVITE to T.38, as long as T.38 is enabled on the user (or primary rate interface (PRI/CAS trunk). If T.38 is not enabled, the call would be reINVITED to G.711 in modem passthrough mode.

Usage Examples

The following example disables **t30-cng** fax tone for modem passthrough mode:

(config)**#no voice fax-tone modem-passthrough t30-cng**

voice feature-mode

Use the **voice feature-mode** command to configure control of the voice features. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice feature-mode local
voice feature-mode network

Syntax Description

local	Allows voice features to be handled by the local unit.
network	Allows voice features to be handled by the network.

Default Values

By default, the voice feature mode is set to **network**.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example sets the control of the voice features to the **local** unit:

(config)**#voice feature-mode local**

voice flashhook mode

Use the **voice flashhook mode** command to determine if flashhook events will be interpreted locally or will be forwarded to the far end. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice flashhook mode interpreted
voice flashhook mode transparent

Syntax Description

interpreted	Allows the local unit to interpret flashhook events.
transparent	Specifies flashhook events to be transparent to the provider.

Default Values

By default, the voice flashhook mode is set to **interpreted**.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example sets the flashhook mode to allow the local unit to interpret flashhook events:

(config)**#voice flashhook mode interpreted**

voice flashhook threshold *<min time> <max time>*

Use the **voice flashhook threshold** command to configure the minimum and maximum time the switch hook must be held to be interpreted as a flash. Use the **no** form of this command to return to the default setting.

Syntax Description

<min time>	Specifies minimum flashhook time in milliseconds. Valid range is from **300** to **1000** milliseconds.
<max time>	Specifies maximum flashhook time in milliseconds. Valid range is from **300** to **1000** milliseconds.

Default Values

By default, the flashhook threshold times are **300** milliseconds (minimum) and **1000** milliseconds (maximum).

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example configures the flashhook thresholds at a minimum of **400** to a maximum of **900**:

(config)**#voice flashhook threshold 400 900**

voice forward-mode

Use the **voice forward-mode** command to control the forwarding mode of the unit. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice forward-mode local
voice forward-mode network

Syntax Description

local	Allows forwards to be handled locally by the unit.
network	Allows forwards to be handled by the network.

Default Values

By default, this command is set to **network**.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example configures the unit to handle forwards locally:

(config)**#voice forward-mode local**

voice grouped-trunk *<name>*

Use the **voice grouped-trunk** command to create a grouped trunk and to enter the Grouped Trunk command set. Refer to *Voice Trunk Group Command Set on page 4704* for details. Use the **no** form of this command to delete a configured grouped trunk.

Syntax Description

<name>	Specifies the name of the trunk group.

Default Values

By default, there are no configured grouped trunks.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example creates the trunk group **trunk3**:

```
(config)#voice grouped-trunk trunk3
(config-TRUNK3)#
```

voice hold-reminder

Use the **voice hold-reminder** command to specify how long a call can be on hold before the hold reminder rings the phone again. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice hold-reminder <*value*>
voice hold-reminder <*value*> <*interval*>

Syntax Description

<*value*>	Specifies how long a call can be on hold before the hold reminder rings the phone again. Range is **5** to **30** seconds.
<*interval*>	Optional. Specifies the interval at which all subsequent reminder rings will occur. Range is **10** to **120** seconds.

Default Values

The defaults for this command are a **10**-second hold time before the first reminder ring with **30**-second intervals between subsequent rings.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the first reminder ring to occur after the call has been on hold for **20** seconds (with subsequent reminder rings occurring every **15** seconds until the call is picked up):

(config)**#voice hold-reminder 20 15**

voice international-prefix

Use the **voice international-prefix** command to configure the international prefix for this unit. Use the **no** form of this command to delete a configured prefix. Variations of this command include:

voice international-prefix <*prefix*>
voice international-prefix abbreviated

Syntax Description

abbreviated	Specifies the international prefix be replaced with a plus symbol (+) in the Session Initiation Protocol (SIP) header.
<*prefix*>	Specifies the up to four digits for the prefix.

Default Values

By default, there is no configured international prefix.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example configures **011** as the international prefix:

(config)**#voice international-prefix 011**

voice line *<name>*

Use the **voice line** command to create (or modify) a voice line and enter voice line's configuration mode. Use the **no** form of this command to delete a configured voice line.

Syntax Description

<name>	Specifies the name or description of the voice line.

Default Values

By default, there are no configured voice lines.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example creates the voice line **Public**, and enters its voice line configuration mode:

```
(config)#voice line Public
Configuring New Line “Public”.
(config-Public)#
```

voice logging smdr

Use the **voice logging smdr** command to enable local logging of station message detail records (SMDRs). Use the **no** form of this command to disable local logging of SMDR reporting.

Syntax Description

No subcommands.

Default Values

By default, SMDR reporting is disabled.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

SMDRs are used to log information about individual calls. The recorded information includes call timestamps, call lengths, participating parties, call origination and destination details, and other information related to calls made or received through the voice network system. Several programs are available that collect SMDR information in order to provide call accounting, find call trends, and supply network administrators with information about productivity. For more information about configuring SMDR in AOS, refer to the configuration guide *Configuring SMDR Reports for the NetVanta 7000 Series*, available online at https://supportofurms.adtran.com.

Usage Examples

The following example enables SMDR local logging:

(config)**#voice logging smdr**

voice logging smdr format

Use the **voice logging smdr format** command to specify the format of station message detail record (SMDR) logs. Use the **no** form of this command to return to the default SMDR format. Variations of this command include:

voice logging smdr format v1
voice logging smdr format v2

Syntax Description

v1	Specifies that SMDR version 1 is used.
v2	Specifies that SMDR version 2 is used.

Default Values

By default, **v1** SMDR formats are used.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

As of AOS firmware release R10.4.0, there are two SMDR versions. Both versions provide SMDRs in a single line of output that contains useful information about call activity. The first SMDR version (**v1**) provides the call date, time, duration, billing and origination codes, call originating and destination slot/port, calling and called party name and number, conference call flags, and special handling flags. The second SMDR version (**v2**) provides a unique ID for the call, the call date and start time, the call ring, hold, and billable time, the billing code, whether the call was internal or external, the originating and destination slot/port or trunk, calling and called party name and number, call destination name and ID, the dialed digits, the call status, and the SMDR version used to generate the call report. For more information about configuring SMDR in AOS, refer to the configuration guide *Configuring SMDR Reports for the NetVanta 7000 Series*, available online at https://supportofurms.adtran.com.

Usage Examples

The following example specifies that version 2 formatting is used for SMDR reporting:

(config)**#voice logging smdr format v2**

voice loopback *<number>*

Use the **voice loopback** command to configure the auto attendant options for the system. Use the **no** form of the commands to disable the setting. For more voice loopback account options, refer to *Voice Loopback Account Command Set on page 4546*.

Syntax Description

<number>	Specifies the extension for the loopback account.

Default Values

No default values are necessary for this command.

Command History

Release A1	Command was introduced.

Usage Examples

The following example creates a loopback with extension (account) number **5555**:

(config)**#voice loopback 5555**

voice mail

Use the **voice mail** command to configure voicemail options for the unit. Use the **no** form of this command to disable the setting. Refer to *voice mail check on page 1932* for additional arguments. Variations of this command include the following:

voice mail alias <*name*>
voice mail asterisk
voice mail class-of-service <*name*>
voice mail did <*number*>
voice mail extension <*extension*>
voice mail internal
voice mail leave-extension <*extension*>
voice mail max-login-attempts <*number*>

Syntax Description

alias <*name*>	Specifies an alias name to use as an alternate when accessing voicemail.
asterisk	Enables voicemail on an external Asterisk server.
class-of-service <*name*>	Configures the voicemail class of services.
did <*number*>	Configures the direct inward dialing (DID) number to assign to voicemail.
internal	Enables internal voicemail on the CompactFlash®.
extension <*extension*>	Specifies the extension users will dial to retrieve their voicemail.
leave-extension <*extension*>	Specifies the extension users will dial to leave a voicemail without ringing an extension. If a user forwards their phone to this extension, their calls will automatically forward to their voice mailbox.
max-login-attempts <*number*>	Specifies the maximum number login attempts to voicemail accounts. Range is **0** to **9** attempts.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.
Release 12.1	Command was expanded.

Usage Examples

The following example specifies extension **7500** for voicemail retrieval:

(config)**#voice mail extension 7500**

voice mail check

Use the **voice mail check** command to configure user parameters for the voicemail check extension. Use the **no** form of this command to disable the setting. Variations of this command include the following:

voice mail check alias <*name*>
voice mail check sip-identity <*station*> <*Txx*>
voice mail check sip-identity <*station*> <*Txx*> **register**
voice mail check sip-identity <*station*> <*Txx*> **register auth-name** <*username*> **password** <*password*>

Syntax Description

alias <*name*>	Specifies an alias name to use as an alternate when accessing the check extension.
sip-identity <*station*> <*Txx*>	Specifies the station to be used for Session Initiation Protocol (SIP) trunk (e.g., **station extension**). Also, specifies the SIP trunk through which to register the server. The trunk is specified in the format Txx (e.g., **T01**).
register	Registers the user to the server.
auth-name <*username*>	Sets the user name that will be required as authentication for registration to the SIP server.
password <*password*>	Sets the password that will be required as authentication for registration to the SIP server.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example configures the **voice mail check sip-identity** to use extension **6000** as its identity on trunk **T04**:

(config)**#voice mail check sip-identity 6000 T04**

voice mail leave

Use the **voice mail leave** command to configure user parameters for the voicemail leave extension. Use the **no** form of this command to disable the setting. Variations of this command include the following:

voice mail leave alias <*name*>
voice mail leave sip-identity <*station*> <*Txx*>
voice mail leave sip-identity <*station*> <*Txx*> **register**
voice mail leave sip-identity <*station*> <*Txx*> **register auth-name** <*username*> **password** <*password*>

Syntax Description

alias <*name*>	Specifies an alias name to use as an alternate when accessing the check extension.
sip-identity <*station*> <*Txx*>	Specifies the station to be used for Session Initiation Protocol (SIP) trunk (e.g., **station extension**). Also, specifies the SIP trunk through which to register the server. The trunk is specified in the format Txx (e.g., **T01**).
register	Registers the user to the server.
auth-name <*username*>	Sets the user name that will be required as authentication for registration to the SIP server.
password <*password*>	Sets the password that will be required as authentication for registration to the SIP server.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example configures the **voice mail leave sip-identity** to use extension **8000** as its identity on trunk **T06**:

(config)**#voice mail leave sip-identity 8000 T06**

voice mail sip-identity

Use the **voice mail sip-identity** command to configure Session Initiation Protocol (SIP) voicemail options for the unit. Use the **no** form of this command to disable the setting. Variations of this command include the following:

voice mail sip-identity <*sip ID*> <*sip trunk*>
voice mail sip-identity <*sip ID*> <*sip trunk*> **register**
voice mail sip-identity <*sip ID*> <*sip trunk*> **register auth-name** <*username*> **password** <*password*>

Syntax Description

<*sip ID*> <*sip trunk*>	Specifies a number to be used as the SIP ID (e.g., **station extension**) and the SIP trunk through which you will register to the server.
register	Registers the user to the server.
auth-name <*username*>	Sets the user name that will be required as AUTHENTICATION for registration to the SIP server.
password <*password*>	Sets the password that will be required as authentication for registration to the SIP server.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.
Release 12.1	Command was expanded.

Usage Examples

The following example specifies trunk **T02** and extension **5800** for **voice mail sip-identity**:

(config)**#voice mail sip-identity 5800 T02**

voice match ani <*template*> substitute <*template*>

Use the **voice match ani substitute** command to configure automatic number identification (ANI) substitution for inbound voice trunks. Use the **no** form of this command to remove the substitution. Variations of this command include:

voice match ani <*template*> **substitute** <*template*>

Syntax Description

ani <*template*>	Specifies the ANI information to be substituted. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
substitute <*template*>	Specifies the ANI information that is substituted for the original ANI information. This information is entered using wildcards and numerical digits. When using wildcards in the **match** and **substitute** template, both must be of the same type and position in the number template or AOS will not allow the substitution. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.

Default Values

By default, no ANI substitution is configured.

Command History

Release A2	Command was introduced.

Functional Notes

The convention for ANI templates is very similar to dial plan entries. Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits

5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example specifies that the ANI information from numbers **555-8111** to **555-8115** on all inbound trunks will be substituted by **555-8110**:

(config)**#voice match ani 555-811[1-5] substitute 555-8110**

Technology Review

The traditional ANI substitution feature operates at a global level on inbound trunks. The feature allows the substitution of calling party information with information determined by the user. This version of ANI substitution is applied only to internal caller ID at the inbound trunk, and only affects the number, not the name, of the calling party.

In this version of ANI substitution, DNIS substitution is also available. DNIS substitution is configured on a per-trunk basis for outbound trunks. DNIS substitution in this version only affects the number, not the name, of the called party.

voice mgcp-endpoint <*index*>

Use the **voice mgcp-endpoint** command to create a Media Gateway Control Protocol (MGCP) endpoint, assign it an index, and enter the endpoint configuration mode. Use the **no** form of this command to destroy the specified endpoint.

Syntax Description

<index>	Specifies the numerical value of the endpoint as part of the endpoint's default naming structure. Range is **1** to **255**.

Default Values

By default, no endpoints are configured.

Command History

Release A2	Command was introduced.

Functional Notes

By default, when endpoints are created and given an index number, they are named in the following format: **aaln/x**, where **x** is the index number. For example, an endpoint with an index of **4** will by default have the name **aaln/4**. The most common way of defining the index is to use the FXS port number, because the index is automatically appended to **aaln/** for the endpoint name.

Assigning an index is essential for creating an endpoint; however, endpoints can be renamed using the **name endpoint** command. Refer to *name <text> on page 4831* for more information.

Usage Examples

The following example creates an endpoint with an index of **1**, and enters the endpoint's configuration mode:

```
(config)#voice mgcp-endpoint 1
(config-mgcp-1)#
```

voice modem-passthrough-mode auto-disable-call-wait

Use the **voice modem-passthrough-mode auto-disable-call-wait** command to disable call waiting on fax and modem calls. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, automatic disabling of call waiting for fax/modem calls is disabled.

Command History

Release A2.04	Command was introduced.

Usage Examples

The following example disables call waiting on a fax call:

(config)**#voice modem-passthrough-mode auto-disable-call-wait**

voice music-on-hold mode

Use the **voice music-on-hold mode** command to configure the mode of the Music on Hold (MOH) feature. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice music-on-hold mode external
voice music-on-hold mode internal

Syntax Description

external	Specifies that on-hold music will play from a file stored locally on the unit.
internal	Specifies that on-hold music will play from an external device, such as an MP3 player or other device, plugged into the unit's MOH port.

Default Values

By default, this is set to **external**.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the MOH mode to **internal**:

(config)**#voice music-on-hold mode internal**

voice music-on-hold preferred-codec

Use the **voice music-on-hold preferred-codec** command to specify the coder-decoder (CODEC) format to use for the music on hold files. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice music-on-hold preferred-codec g711alaw
voice music-on-hold preferred-codec g711ulaw
voice music-on-hold preferred-codec g729

Syntax Description

g711alaw	Assigns the G.711 A-law CODEC (64000 bps) as the preferred CODEC for negotiation.
g711ulaw	Assigns the G.711 U-law CODEC (64000 bps) as the preferred CODEC for negotiation.
g729	Assigns the G.729 CODEC (8000 bps) as the preferred CODEC for negotiation.

Default Values

By default, the preferred CODEC is set to **g711ulaw**.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the preferred CODEC to **g711alaw**:

(config)**#voice music-on-hold preferred-codec g711alaw**

voice notify forward

Use the **voice notify forward** command to enable immediate call forwarding for analog voice users. This command causes the AOS device to play a certain stutter dial tone when the line is forwarded, alerting the subscriber that this line feature is enabled. Use the **no** form of this command to disable the feature. Variations of this command include:

voice notify forward disable-uri <*text*>
voice notify forward enable-uri <*text*>
voice notify forward parameter <*text*>

Syntax Description

disable-uri <*text*>	Specifies the Alert-Info uniform resource identifier (URI) that disables immediate call forwarding and produces the normal dialtone. When the disable URI is specified, the NOTIFY message is rejected and a 503 Service Unavailable response is generated. Specify the URI with a maximum of 256 characters.
enable-uri <*text*>	Specifies the Alert-Info URI that enables immediate call forwarding and produces the call forwarding dialtone. When the enable URI is specified, the NOTIFY message is accepted and a 200 OK response is generated. Specify the URI with a maximum of 256 characters.
parameter <*text*>	Specifies the Alert-Info parameter that indicates call forwarding is active. Specify the parameter with a maximum of 256 case-sensitive characters.

Default Values

By default, immediate call forwarding is disabled. When the feature is enabled, by default the normal and immediate call forwarding dial tones are set to an empty string, and the parameter value is set to an empty string.

Command History

Release R10.3.0	Command was introduced.

Functional Notes

The immediate call forwarding feature, when enabled, provides a specific dialtone which alerts the user that the feature is enabled. The specified dialtone occurs when the Alert-URI is matched in a NOTIFY message. For the feature to function, you must specify the Alert-URI that enables the feature and provides the feature dialtone (**enable-uri**), and you must specify the Alert-URI that disables the feature and provides the normal dialtone (**disable-uri**). If both parameters are not specified, the feature remains disabled.

This feature is available on all AOS voice platforms, and uses a country-specific dialtone when enabled. In all countries (excluding Mexico), the call forward indicator tone is equivalent to stutter-3. If both message waiting and call forwarding indication are enabled, stutter-3 is used for both features in all countries (excluding Mexico).

Usage Examples

The following example enables immediate call forwarding for analog users and specifies the normal and forwarding dial tones:

(config)**#voice notify forward enable-uri service:forward**
(config)**#voice notify forward disable-uri service:normal**

voice number-complete disable

Use the **voice number-complete disable** command to globally disable the default number-complete options. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice number-complete disable pound
voice number-complete disable star

Syntax Description

pound	Disables using the pound (#) key to indicate that a number is complete.
star	Disables using the star (*) key to indicate that a number is complete.

Default Values

By default, the pound (#) or star (*) key can be pressed to signify that the dialed number is complete.

Command History

Release A5.01	Command was introduced.

Functional Notes

When a user is dialing a phone number, the AOS unit will wait a configured amount of time (specified by the command *voice timeouts on page 1972*) after a digit is pressed before attempting to send the dialed set of digits. If the user does not want to wait for this timeout interval to elapse, the user can, by default, press either the pound (#) or star (*) key to indicate that the dialed number is complete.

Usage Examples

The following example disables using the pound (#) key to indicate that a number is complete:

(config)#**voice num-complete disable pound**

voice num-rings *<value>*

Use the **voice num-rings** command to globally specify the number of times a station will ring before beginning the coverage path that attempts to deliver a call to an available party. This setting can be overridden on a per-user basis using the **num-rings** command in the Voice User command set. Refer to *Voice User Account Command Set on page 4564* for more information. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the number of times a station can ring with no answer. Range is **0** to **9**. Setting to 0 allows unlimited rings.

Default Values

The default for this command is **0** (unlimited rings).

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets a limit on the number of times a station can ring:

(config)**#voice num-rings 8**

voice operator-group

Use the **voice operator-group** command to access the Voice Operator Group command mode. Refer to *Voice Operator Group Command Set on page 4664* for more information. Use the **no** form of this command to disable the setting.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example enters the Operator Group configuration mode:

```
(config)#voice operator-group
Configuring Operator Group.
(config-operator-group)#
```

voice overhead-paging connected-timeout <*value*>

Use the **voice overhead-paging connected-timeout** command to specify the timeout interval before an overhead paging call is terminated. Use the **no** form of this command to return to the default setting.

This setting does not affect calls placed into handset paging groups. It only affects calls to the overhead paging port on the back of the AOS unit.

Syntax Description

<*value*>	Specifies the timeout value in seconds. Set to **0** to disable the timeout.

Default Values

The default setting is **120** seconds.

Command History

Release A2.04	Command was introduced.

Usage Examples

The following example configures a connected timeout of **30** seconds for overhead paging:

(config)**#voice overhead-paging connected-timeout 30**

voice overhead-paging extension <*number*>

Use the **voice overhead-paging extension** command to specify the extension used for overhead paging. Use the **no** form of this command to disable the setting.

Syntax Description

<*number*>	Specifies the extension to use for overhead paging.

Default Values

No default values are necessary for this command.

Command History

Release 12.1	Command was introduced.

Usage Examples

The following example configures extension **3000** to be used for overhead paging:

(config)**#voice overhead-paging extension 3000**

voice paging-group <*extension*>

Use the **voice paging-group** command to create a new handset paging group and enter the paging group's configuration. Use the **no** form of this command to remove the paging group.

Syntax Description

<*extension*>	Specifies the numeric extension for the paging group.

Default Values

By default, no paging groups exist.

Command History

Release A2.04	Command was introduced.

Functional Notes

The **voice paging-group** command enters the configuration for a handset paging group. For more information about handset paging, refer to the *Handset Paging for the NetVanta 7000 Series* quick configuration guide available online at https://supportcommunity.adtran.com.

For more information about the commands used to configure handset paging, refer to the *Voice Paging Group Command Set on page 4680*.

Usage Examples

The following example creates a paging group using extension **8956** and enters the group's configuration mode:

```
(config)#voice paging-group 8956
  Configuring new paging group "8956".
(config-8956)#
```

voice park-return <*value*>

Use the **voice park-return** command to configure the time until a parked call returns. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies time in seconds until a call returns from park if not retrieved. Valid range is **15** to **360** seconds.

Default Values

By default, the **voice park-return** time is set to **60** seconds.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example sets the time a call returns from park to **30** seconds:

(config)**#voice park-return 30**

voice pickup-group *<name>*

Use the **voice pickup-group** command to create a new call pickup group and enter the group's configuration mode.

Syntax Description

<name>	Specifies the name of the call pickup group.

Default Values

By default, no call pickup groups exist.

Command History

Release A4.01	Command was introduced.

Functional Notes

There is a limit of 10 call pickup groups on an AOS unit.

For more information about call pickup group configuration commands, refer to the *Voice Call Pickup Group Command Set on page 4653*.

For more information about configuring the call pickup feature, refer to the *Configuring the Call Pickup Feature on AOS Voice Products* quick configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example creates the call pickup group **Sales** and enters the group's configuration mode:

```
(config)#voice pickup-group Sales
Configuring New Pickup Group "Sales"
(config-Sales)#
```

voice prompt-language <*language*>

Use the **voice prompt-language** command to specify the language to use for voice prompts (such as audios and voicemail menus) on the system. Use the **no** form of this command to disable the current language setting.

Syntax Description

<*language*>	Specifies the language to use for voice prompts. The available choices are **English** (American English), **FrenchCanadian, Irish** (Irish English), **LatinAmSpanish** (Latin American Spanish), and **UKEnglish** (United Kingdom English).

Default Values

The default value for this command is **English**.

Command History

Release 15.1	Command was introduced.
Release R10.2.0	The command was expanded to include the Irish language.

Usage Examples

The following example specifies the voice prompt language as Latin American Spanish:

(config)**#voice prompt-language LatinAMSpanish**

voice ring-group *<number>*

Use the **voice ring-group** command to create or modify ring group parameters. These additional commands are covered in *Voice Ring Group Command Set on page 4685*. Use the **no** form of this command to delete a configured ring group.

Syntax Description

<number>	Specifies the ring group's four-digit extension.

Default Values

By default, no ring groups are configured.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example creates a new ring group with extension **5678**:

(config)#**voice ring-group 5678**
Configuring New Group “5678”.
(config-5678)#

voice ring-option <*name*>

Use the **voice ring-option** command to create a ring option or modify an existing ring option. Once the ring option is configured, it can be applied to a shared line appearance (SLA) or shared call appearance (SCA). Use the **no** form of this command to delete a configured ring option. Additional subcommands are available once you have entered the Ring Option Configuration mode:

description <*text*>
ring-type delay-12-second
ring-type delay-24-second
ring-type immediate
ring-type silence
ring-type <*system mode*> **delay-12-second**
ring-type <*system mode*> **delay-24-second**
ring-type <*system mode*> **immediate**
ring-type <*system mode*> **silence**

Syntax Description

<*name*>	Specifies the name of the ring option. Limited to 10 characters.
description <*text*>	Optional. Provides a text description of the ring option. Limited to 40 characters.
ring-type <*system mode*>	Configures the ring behavior for the specified system mode. Not specifying a <*system mode*> implies changing the default system mode ring type. Enter one of the following to specify the system mode: **night**, **lunch**, **weekend**, **custom1**, **custom2**, **custom3**, or **override**. Enter a behavior to assign a ring type to the system mode:
immediate	Ring immediately.
silence	Visual ringing notification only.
delay-12-second	Ring after a 12 second delay.
delay-24-second	Ring after a 24 second delay.

Default Values

By default, the ring type is **immediate**.

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example creates a new ring option named **SALES** and enters the Ring Option Configuration mode:

(config)**#voice ring-option SALES**
Configuring New Group “SALES”.
(config-SALES)**#**

The following example sets the ring type for the **weekend** system mode to **silence** for the **SALES** ring option:

(config-sales)**#ring-type weekend silence**

voice service map isdn-to-sip forward

Use the **voice service map isdn-to-sip forward** command to configure integrated services digital networking (ISDN) to Session Initiation Protocol (SIP) mappings for the call forwarding voice feature on the AOS unit. Variations of this command include:

voice service map isdn-to-sip forward busy disable-code <*spre code*>
voice service map isdn-to-sip forward busy enable-code <*spre code*>
voice service map isdn-to-sip forward no-response disable-code <*spre code*>
voice service map isdn-to-sip forward no-response enable-code <*spre code*>
voice service map isdn-to-sip forward unconditional disable-code <*spre code*>
voice service map isdn-to-sip forward unconditional enable-code <*spre code*>

Syntax Values

busy	Specifies the call forwarding busy special prefix (SPRE) code is configured and mapped.
no-response	Specifies the call forwarding no response SPRE code is configured and mapped.
unconditional	Specifies the call forwarding unconditional SPRE code is configured and mapped.
disable-code <*spre code*>	Disables the call forwarding feature for the specified SPRE code. Refer to *Functional Notes* for information about entering SPRE codes.
enable-code <*spre code*>	Enables the call forwarding feature for the specified SPRE code. Refer to *Functional Notes* for information about entering SPRE codes.

Default Values

By default, the call forwarding voice feature is not mapped between ISDN and SIP.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

The **voice service map isdn-to-sip forward** command does not have a **no** version. To disable mapping of a specific call forwarding feature, enter the **disable-code** parameter at the end of the command.

SPRE codes for this command are entered in the <**NX*> format, where **N** matches numbers from **2** to **9**, and **X** matches numbers from **0** to **9**. For example, ***25**. Display the currently assigned voice SPRE codes, using the *show voice spre* command.

Usage Examples

The following example enables ISDN to SIP mapping for the call forwarding busy feature on SPRE code **25**:

(config)**#voice service map isdn-to-sip forward busy enable-code *25**

The following example disables ISDN to SIP mapping for the call forwarding no response feature on SPRE code **30**:

(config)**#voice service map isdn-to-sip forward no-response disable-code *30**

voice service-mode

Use the **voice service-mode** command to add a service mode transition. Variations of this command include:

voice service-mode day <*day*> <*time*>
voice service-mode lunch <*day*> <*time*>
voice service-mode night <*day*> <*time*>
voice service-mode weekend <*day*> <*time*>

Syntax Description

day	Specifies a transition to day mode.
lunch	Specifies a transition to lunch mode.
night	Specifies a transition to night mode.
weekend	Specifies a transition to weekend mode.
<*day*>	Specifies the day of week the transition occurs.
<*time*>	Specifies the time for transition to occur (24-hour format - hours:minutes (HH:MM)).

Default Values

By default, the **voice service-mode** is set to **day**.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example sets the voice service mode to **day** with a transition day of Monday and a transition time of 8:00 AM:

(config)**#voice service-mode day monday 08:00**

voice speed-dial *<unique id> <number> <name>*

Use the **voice speed-dial** command to create a list of IDs to be used as shortcuts to contact frequently called numbers. Use the **no** form of this command to return to the default setting.

Syntax Description

<unique id>	The speed-dial number that will be used to contact the *<number>* specified.
<number>	Phone number associated with the speed-dial entry (digits only).
<name>	Description of this speed-dial entry.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets a speed-dial number of **8** for extension **9654**:

(config)**#voice speed-dial 8 9654 3rdFloorLab**

voice spre *<pattern id> <pattern>*

Use the **voice spre** command to add a global special prefix (SPRE) complete pattern. This command allows users to enter a custom SPRE code. Use the **no** form of this command to delete a configured SPRE pattern.

Syntax Description

<pattern id>	Specifies the SPRE pattern ID. Valid range is **1** to **255**.
<pattern>	Specifies the SPRE pattern. Refer to *Functional Notes* below for more information.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Functional Notes

This command allows users to enter a SPRE code pattern. Patterns begin with ***** or **#**. If the pattern is followed by an **&**, then the dial plan number-complete templates are used to determine when the unit has enough digits to dial the number (for example, **67&**). However, if a dial plan does not exist for a particular code that is needed, then a SPRE code may be entered followed by an independent dial plan number-complete template (for example, ***67NXX-XXXX**).

Valid characters for patterns are as follows:

0 - **9** Match the exact digit(s) only
X Match any single digit 0 through 9
N Match any single digit 2 through 9
M Match any single digit 1 through 8
& Allows the use of the dial-plan number complete pattern
[] Match any digit in the list within the brackets (for example, [1,4,6])
,() Formatting characters that are ignored but allowed
- Use within brackets to specify a range, otherwise ignored

The following are example pattern entries using wildcards:
EX1: *70&
EX2: #12NXXXXXX
EX3: *[1-3,9]0&

SPRE complete pattern rules:

1) The pattern must begin with ***** or **#**.
2) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
3) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
4) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
5) The **&** wildcard is only allowed at the end of the number.

Usage Examples

The following sets the complete pattern for SPRE 1:

(config)**#voice spre 1 *67NXX-XXXX**

voice spre-map

Use the **voice spre-map** command to change the default mapping of special prefix (SPRE) codes on the AOS voice product. Functions and SPRE codes can be disabled by using the **none** keyword. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice spre-map all none
voice spre-map auto-answer-dnd *<*nx*>
voice spre-map auto-answer-dnd none
voice spre-map billing-code *<*nx*>
voice spre-map billing-code none
voice spre-map block-callid-delivery *<*nx*>
voice spre-map block-callid-delivery none
voice spre-map call-forward-cancel *<*nx*>
voice spre-map call-forward-cancel none
voice spre-map call-forward-extension *<*nx*>
voice spre-map call-forward-extension none
voice spre-map call-forward-remote *<*nx*>
voice spre-map call-forward-remote none
voice spre-map call-held/park-retrieve *<*nx*>
voice spre-map call-held/park-retrieve none
voice spre-map call-park-zone *<*nx*>
voice spre-map call-park-zone none
voice spre-map call-return *<*nx*>
voice spre-map call-return none
voice spre-map call-user-speed-dial *<*nx*>
voice spre-map call-user-speed-dial none
voice spre-map camp-on *<*nx*>
voice spre-map camp-on none
voice spre-map cancel-camp-on *<*nx*>
voice spre-map cancel-camp-on none

*Not all SPRE codes are supported by all AOS products. Type **voice spre-map ?** to view a list of supported SPRE codes.*

Syntax Description

all	Makes the SPRE code assignment for all functions.
none	Removes the SPRE code for the specified function.
***<*nx*>**	Specifies the SPRE code to assign to this function. Valid range for *n* is **2** to **9**. Valid range for *x* is **0** to **9**.
auto-answer-dnd	Specifies the automatic answer do-not-disturb (DND) function.
billing-code	Specifies the billing code function.
block-callid-delivery	Specifies the block caller-ID delivery function.
call-forward-cancel	Specifies the call forward cancel function.
call-forward-extension	Specifies the call forward + extension function.
call-forward-remote	Specifies the call forward remote function.
call-held/park-retrieve	Specifies the held call pickup and park retrieve function
call-park-zone	Specifies the call park + zone function.
call-return	Specifies the call return function.
call-user-speed-dial	Specifies the call user speed dial function.
camp-on	Specifies the camp-on function.
cancel-camp-on	Specifies the cancel camp-on function.
clear-message-waiting	Specifies the clear message waiting function.
conference	Specifies the 3-way conferencing function.
cos-override	Specifies the class of service (CoS) override function.
disable-call-waiting	Specifies the disable call waiting on a per-call basis function.
dnd-enable-disable	Specifies the DND enable/disable function.
door-phone	Specifies the door phone function.
door-unlock	Specifies the door unlock function.
fwd-notificatn-cancel	Specifies the forward notification cancel function.
group-login	Specifies the group login function.
group-logout	Specifies the group logout function.
hotel-login	Specifies the hotel login function.
hotel-logout	Specifies the hotel logout function.
maca-login	Specifies the multiple access with collision avoidance (MACA) login function.
maca-logout	Specifies the MACA logout function.
page-overhead	Specifies the overhead paging function.
permanent-hold	Specifies the permanent hold function.
program-speed-dial	Specifies the program user speed dial function.
redial	Specifies the call last dialed number function.
remote-call-fwd-cancel	Specifies the remote call forward cancel function.
send-to-vm	Specifies the send directly to voicemail function.
set-account-password	Specifies the set account password function.

set-message-waiting Specifies the set message waiting function.
system-mode Specifies the system mode function.
system-speed-dial Specifies the system speed dial function.
transfer Specifies the transfer function.
user-station-lock Specifies the user station lock function.
user-station-unlock Specifies the user station unlock function.

Default Values

Default mappings between functions and SPRE codes are as indicated in the following table:

SPRE Code	Function	SPRE Code	Function
*21	Billing Code	*55	Group Login
*67	Block Caller ID Delivery	*56	Group Logout
*97	Auto-Answer Do-Not-Disturb	*78	Held Call Pickup/Call Park Retrieve
*35	Call Forward Cancel	*46	Hotel Login
*33	Call Forward + Extension	*47	Hotel Logout
*34	Call Forward Remote	*63	MACA Login
*77	Call Park + Zone	*64	MACA Logout
*69	Call Return	*30	Page Overhead
*62	Call User Speed Dial	*44	Permanent Hold
*66	Camp-on	*61	Program User Speed Dial
*65	Cancel Camp-on	*72	Redial
*86	Clear Message Waiting	*36	Remote Call Forward Cancel
*22	Conference 3-way	*79	Set Account Password
*90	Class of Service Override	*85	Set Message Waiting
*70	Disable Call Waiting Per Call Basis	*20	System Mode
*39	Do Not Disturb Enable/Disable	*25	System Speed Dial
*37	Door Phone	*88	Transfer
*38	Door Unlock	*57	User Station Lock
*32	Forward Notification Cancel	*58	User Station Unlock

Command History

Release A2.03 Command was introduced.

Release A5.01	Command was expanded to include the **page-intercom** parameter.
Release R10.2.0	Command was expanded to include the **send-to-vm** parameter.
Release R10.6.0	Command was expanded to include the **call-held/park-retrieve** parameter.
Release R11.5.0	Command was altered to remove the **page-intercom** parameter.

Functional Notes

SPRE codes are used to map a sequence of digits to a particular functionality. For example, in a typical network, *67 is used to block caller ID. The codes and their functions are listed in the Default Values. Functions and SPRE codes can be disabled by using the **none** keyword.

Usage Examples

The following example sets the SPRE code for call return to ***79**:

(config)**#voice spre-map call-return *79**

voice spre-mode

Use the **voice spre-mode** command to control whether special prefix (SPRE) codes will be interpreted by the unit locally or forwarded to the network for interpretation. The **override** parameter indicates that the specified SPRE code is to be overridden. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice spre-mode local
voice spre-mode network
voice spre-mode override *<*nx*>

Syntax Description

local	Specifies that SPRE codes are interpreted locally by the unit.
network	Specifies the forwarding of SPRE codes to the network for handling.
override *<*nx*>	Indicates the configured SPRE processing mode is overridden for the specified SPRE code. Valid range for *n* is **2** to **9**. Valid range for *x* is **0** to **9**.

Default Values

By default, this command is set to forward SPRE codes to the network and no overrides are configured.

Command History

Release 11.1	Command was introduced.
Release A2.03	Command was expanded to include the **override** option.

Functional Note

SPRE codes are used to map a sequence of digits to a particular functionality. For example, in a typical network, *67 is used to block caller ID. When the AOS unit is configured to operate in **network** mode, the digits are collected and sent to the network for appropriate handling. Using the **override** parameter allows the unit to be configured so that certain SPRE codes are collected locally and the corresponding function is initiated.

Usage Examples

The following example configures the unit to interpret SPRE codes:

(config)**#voice spre-mode local**

The following example configures the unit, which is configured to use the **network** mode, to instead interpret the SPRE code ***67** locally:

(config)**#voice spre-mode network**
(config)**#voice spre-mode override *67**

voice status-group

Use the **voice status-group** command to create or modify a voice status group and enter the Voice Status Group Configuration mode. Use the **no** form of this command to delete a voice status group. Variations of this command include:

voice status-group <*name*>

The following additional subcommands are available once you have entered the Voice Status Group Configuration mode:

park-zone <*value*>
user <*number*>
user <*number*> **display-name** <*name*>
user <*number*> **dial-string** <*string*>
user <*number*> **display-name** <*name*> **dial-string** <*string*>
use-spre-entities

Syntax Description

<*name*>	Specifies the name of the voice status group to create, modify, or delete.
park-zone <*value*>	Specifies a new park zone number to add to this voice status group. The valid range is **0** to **9**.
user <*number*>	Specifies the extension of a user to add to this voice status group.
display-name <*name*>	Optional. Specifies an override name to appear as the user's name when displayed on the device (BLF). If the name includes spaces, it must be surrounded by quotation marks as shown in the *Usage Examples*.
dial-string <*string*>	Optional. Specifies a specific number to dial. Valid entries can include a combination of characters ***** and **0** through **9**.
use-spre-entities	Specifies that the system use special prefix (SPRE) codes for extensible markup language (XML) entities in Notify messages when applicable.

Default Values

By default, there are no voice status groups configured.

Unless the user explicitly enters a **display-name** or **dial-string**, these values will default to the user's extension number. The **dial-string** and **display-name** cannot be added or changed after a user is added to a status group. The user must first be removed from the status group with the **no user** <*number*> command, then re-added as a member with the appropriate **display-name** and/or **dial-string**. Refer to the *Usage Examples* section for further details.

Command History

Release 14.1	Command was introduced.

Release A2	Command was expanded to include the dial string entries.
Release A5.01	Command was expanded to include the **use-spre-entities** parameter.

Usage Examples

The following example creates a new voice status group with the name **Engineering**:

(config)**#voice status-group Engineering**
The following example adds park zone **4** to the Engineering status group directory:

(config)**#voice status-group Engineering**
(config-status-Engineering)**#park-zone 4**

The following example adds user **5555** to the Engineering status group directory, displaying the default name **5555** with the default dial string of **5555**:

(config)**#voice status-group Engineering**
(config-status-Engineering)**#user 5555**

The following example adds user **5555** to the Engineering status group directory, displaying the name **Test Lab** with the default dial string of **5555**:

(config)**#voice status-group Engineering**
(config-status-Engineering)**#user 5555 display-name “Test Lab”**

The following example adds user **5555** to the Engineering status group directory, displaying the default name **5555** with a handsfree dial string of ****5555**:

(config)**#voice status-group Engineering**
(config-status-Engineering)**#user 5555 dial-string **5555**

The following example adds user **5555** to the Engineering status group directory, displaying the name **Test Lab** with a handsfree dial string of ****5555**:

(config)**#voice status-group Engineering**
(config-status-Engineering)**#user 5555 display-name “Test Lab” dial-string **5555**

voice status-group expires

Use the **voice status-group expires** command to add a status group subscription time for status group clients. Any subscription time requests that fall between the minimum and maximum values will be instructed to use the default value instead. Variations of this command include:

voice status-group default-expires <*value*>
voice status-group max-expires <*value*>
voice status-group min-expires <*value*>

Syntax Description

default-expires <*value*>	Specifies a default subscription time. The valid range is **120** to **86400** seconds.
max-expires <*value*>	Specifies a maximum subscription time. The valid range is **120** to **86400** seconds.
min-expires <*value*>	Specifies a minimum subscription time. The valid range is **120** to **86400** seconds.

Default Values

By default, the voice status group **default-expires** value is set to **120** seconds, **max-expires** value is set to **3600**, and the **min-expires** is set to **86400**.

Command History

Release 14.1	Command was introduced.

Usage Examples

The following example sets the voice status group maximum subscription time to 2 hours:

(config)**#voice status-group max-expires 7200**

voice system-country *<name>*

Use the **voice system-country** command to specify the system country setting. Specifying the system country with this command automatically changes several default settings to match the standards of the specified country. Refer to the *Functional Notes* for details. Use the **no** form of this command to return to the default setting.

Syntax Description

<name>	Specifies the system country name. The available options are: **Australia**, **Belgium**, **Canada**, **China_Hong_Kong**, **Denmark**, **ETSI**, **Finland**, **France**, **Germany**, **Ireland**, **Italy**, **Luxembourg**, **Mexico**, **Netherlands**, **New Zealand**, **Norway**, **Puerto_Rico**, **Spain**, **Sweden**, **Switzerland**, **United_Arab_Emirates**, **United_Kingdom**, and **United_States**.

Default Values

The default system country code is **United_States**.

Command History

Release A2.04	Command was introduced.
Release A4.05	Command was modified to accept the country name instead of numbers.
Release R14.2.0	Command was expanded to include New **Zealand_FSK**

Functional Notes

The **voice system-country** command automatically sets the parameters for multiple settings on the AOS device to match the standards of the specified country. For example, Web-based graphical user interface (GUI) language, voice prompt language (if applicable), call progress tones, commanding type, caller ID type, and voice country code. The values for these parameters can be viewed using *show system on page 1036*.

The system country setting is not stored as part of the running configuration or startup configuration. Erasing the startup configuration will not change the system country. If a particular feature or configuration option is set to something other than the default, changing the system country will not effect that feature or option. For a comprehensive list of the features affected by the system country setting, refer to the *International Configuration Guide* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example sets the system country to **Canada**:

(config)**#voice system-country Canada**

voice system-mode

Use the **voice system-mode** command to configure the system mode schedules. When triggered by the system-clock, AOS units transition into a system mode based on the schedule. Use the **no** form of this command to disable the setting. Variations of this command include the following:

voice system-mode custom1 *<day> <time>*
voice system-mode custom2 *<day> <time>*
voice system-mode custom3 *<day> <time>*
voice system-mode default *<day> <time>*
voice system-mode lunch *<day> <time>*
voice system-mode night *<day> <time>*
voice system-mode weekend *<day> <time>*

Syntax Description

<day>	Specifies the day of the week. Choose from Sunday through Saturday.
<time>	Specifies the time of the day in a 24-hour format hours:minutes (HH:MM).
custom1 - custom3	Indicates the custom mode (1 through 3) to configure.
default	Indicates the default-time system mode to configure.
lunch	Indicates the lunch-time system mode to configure.
night	Indicates the night-time system mode to configure.
weekend	Indicates the weekend system mode to configure.

Default Values

By default, no system mode commands are configured, the unit will operate in the **default** mode.

Command History

Release A1	Command was introduced.

Usage Examples

The following example configures a typical 5-day business week:

(config)**#voice system-mode default Monday 8:00**
(config)**#voice system-mode night Monday 17:00**
(config)**#voice system-mode default Tuesday 8:00**
(config)**#voice system-mode night Tuesday 17:00**
(config)**#voice system-mode default Wednesday 8:00**
(config)**#voice system-mode night Wednesday 17:00**
(config)**#voice system-mode default Thursday 8:00**
(config)**#voice system-mode night Thursday 17:00**
(config)**#voice system-mode default Friday 8:00**
(config)**#voice system-mode weekend Friday 17:00**

voice timeouts

Use the **voice timeouts** command to configure the time limits for phases. Use the **no** form of this command to return to the default setting or remove the named digit timeout (NDT) and its value.

When removing an NDT and its value, if the NDT is assigned to a dial plan entry, then the deletion is not allowed. The dial plan must be removed first and added back into the system without the NDT association.

Variations of this command include:

voice timeouts alerting <*value*>
voice timeouts connected <*value*>
voice timeouts connecting <*value*>
voice timeouts emergency-callback <*value*>
voice timeouts interdigit <*value*>
voice timeouts named-digit-timeout <*ndt name*>
voice timeouts named-digit-timeout <*ndt name*> <*value*>
voice timeouts preconnected <*value*>
voice timeouts preconnecting <*value*>

Syntax Description

alerting <*value*>	Specifies the maximum time a call is allowed to remain in the alerting state. The shorter of this timeout or the configured maximum number of rings will determine how long a call is allowed to ring. The valid range is **0** (unlimited) to **60** minutes.
connected <*value*>	Specifies the maximum time a call is allowed to remain in the connected state. The valid range is **0** (unlimited) to **1000** hours.
connecting <*value*>	Specifies the maximum time a call is allowed to remain in the connecting state. The valid range is **0** (unlimited) to **60** minutes.
emergency-callback <*value*>	Specifies the maximum time to wait for an emergency callback. The valid range is **0** to **300** seconds.
interdigit <*value*>	Specifies the maximum time allowed between dialed digits. The valid range is **1** to **16** seconds.
named-digit-timeout	Creates a timeout with a name and a value to associate with a dial plan template.
<*ndt name*>	Specifies the name of the named-digit-timeout to be created.
<*value*>	Optional. Indicates the timeout value in seconds to allow after the last digit is dialed before routing the call. The valid range is **1** to **16** seconds.
preconnected <*value*>	Specifies the maximum time a call is allowed to stay in a preconnected state. The valid range is **0** (unlimited) to **60** minutes.
preconnecting <*value*>	Specifies the maximum time a call is allowed to stay in a preconnecting state. The valid range is **0** (unlimited) to **60** minutes.

Default Values

By default, the **alerting** timeout is 5 minutes, the **connected** timeout is 12 hours, and the **interdigit** timeout is 4 seconds. If no value is indicated for the NDT, 0 seconds is applied.

Command History

Release 14.1	Command was introduced.
Release A2	Command was expanded to include the **named-digit-timeouts** parameter.
Release R10.4.0	Command was expanded to include the **connecting**, **emergency-callback**, **preconnected**, and **preconnecting** parameters.

Functional Notes

The **named-digit-timeout** parameter allows multiple interdigit timeouts within the system. It provides a means for associating a specific amount of time to wait after a template match is made before routing a call. This added functionality allows short numbers and long numbers to coexist in the same system (for example, seven- and ten-digit patterns) without specifying additional characters (such as 1 or 9).

Usage Examples

The following example sets the alerting timeout to **30** seconds:

(config)**#voice timeouts alerting 30**

The following example creates a named-digit-timeout named **short1** and sets the timeout value to **2** seconds:

(config)**#voice timeouts named-digit-timeout short1 2**

voice transfer

Use the **voice transfer** command to set the unattended transfer for the system only. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice transfer blind
voice transfer unattended

Syntax Description

blind	Converts unattended transfer attempts to RFC 3891-compliant blind transfers.
unattended	Unattended transfer attempts are not modified.

Default Values

The default setting is **unattended**.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example configures the **voice transfer** type to **blind**:

(config)**#voice transfer blind**

voice transfer-mode

Use the **voice transfer-mode** command to specify whether transferred calls will be controlled by the unit locally, or if the network will control them. Use the **no** form of this command to return to the default setting. Variations of this command include:

voice transfer-mode local
voice transfer-mode network

Syntax Description

local	Specifies that call transferring is controlled locally by the unit.
network	Specifies that call transferring is controlled by the network.

Default Values

By default, the network controls call transfers.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures the unit to handle call transfers:

(config)**#voice transfer-mode local**

voice transfer-on-hangup

Use the **voice transfer-on-hangup** command to enable this feature. When transferring a call, hanging up initiates the transfer to the destination party. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is enabled.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example enables this feature:

(config)**#voice transfer-on-hangup**

voice trunk access-code

Use the **voice trunk access-code** command to modify the outbound trunk access code. Use the **no** form of this command to remove the trunk access code and return to the default. Variations of this command include:

voice trunk access-code <*number*>
voice trunk access-code none

Syntax Description

<*number*>	Specifies the digit to use as the outbound trunk access code. Valid entries are **0** through **9**.
none	Specifies that no trunk access code is required to place outbound calls.

Default Values

By default, the outbound trunk access code is **9**.

Command History

Release R10.8.0	Command was introduced.

Functional Notes

There are a number of considerations involved if the trunk access code is changed or omitted on a previously installed system using the **voice trunk access-code** command. The following items should be reviewed to confirm that the correct steering digit is configured in each of these areas of AOS:

- User account call forwarding
- External call coverage for user accounts, ring groups, operator groups, and globally
- User account FindMe-FollowMe refer actions
- SIP trunk account outbound match ANI Add/Replace Diversion/P-Asserted-Identity commands
- ISDN/SIP trunk account, outbound match ANI substitute commands
- ISDN/SIP/Analog trunk account, outbound match DNIS substitute/replace ani commands
- Shared line account, external call coverage
- Shared call appearance, external call coverage
- Voicemail session: returning a call to the sender of a message
- Auto attendant, transfers to external numbers
- Recording and playing audio prompts from an external number
- Auto attendant, dial-by-name directory entries
- Status group member, external dial strings
- Class of service, advanced permit/deny templates
- System dial plan templates
- Global inbound match ANI substitution

Usage Examples

The following example configures the outbound trunk access-code as **7**:

(config)**#voice trunk access-code 7**

voice trunk-list <*name*>

Use the **voice trunk-list** command to create a permit/deny trunk list and to enter the trunk list configuration mode. Use the **no** form of this command to remove the trunk list.

Additional subcommands are available once you have entered the trunk list configuration mode:

trunk <*Txx*>

Syntax Description

<*name*>	Specifies the name of the trunk list.
trunk <*Txx*>	Specifies the trunk to add to the trunk list. Trunks are specified by their 2-digit identifier. For example, **T01**.

Default Values

By default, no trunk lists are configured.

Command History

Release A2	Command was introduced.

Functional Notes

The trunk lists are permit/deny lists that operate in the same manner as automatic number identification (ANI) lists, and are used to specify trunks that will be permitted or denied access on specified voice trunk groups.

There is no limit on the number of trunks that can be added to the trunk list, and there is no limit on the number of trunk lists that can be applied to a voice trunk group. The trunk lists are applied to the trunk group in the order they are listed.

Although there is no limit on the number of trunks allowed in a trunk list, or the number of trunk lists applied to voice trunk groups, it is important to remember that the more lists that are applied to a trunk group, the more the runtime performance of call routing will be affected.

Usage Examples

The following example creates a trunk list called **TEST2** and specifies the trunks to be included in the list:

(config)**#voice trunk-list TEST2**
(config-trunk-list-TEST2)**#trunk T01**
(config-trunk-list-TEST2)**#trunk T03**

voice trunk <*trunk id*> type

Use the **voice trunk type** command to define a new trunk for use with a Session Initiation Protocol (SIP) or integrated services digital network (ISDN) interface. Executing this command activates the Voice Trunk Configuration mode for the individual trunk. Refer to *Voice ISDN Trunk Command Set on page 5008* for information on the commands in that mode. Other trunk types are explained in *voice trunk <trunk id> type analog supervision on page 1981*. Use the **no** form of this command to delete a configured voice trunk. Variations of this command include:

voice trunk <*trunk id*> **type isdn**
voice trunk <*trunk id*> **type sip**

Refer to the configuration guide Voice Traffic over SIP Trunks and Configuring the Total Access 900 Series PRI Interface guide for more information on voice trunks. These documents are available online at http://supportforums.adtran.com.

Syntax Description

<*trunk id*>	Specifies the trunk's two-digit identifier in the format Txx (for example, **T12**).
isdn	Configures the trunk for use with ISDN service.
sip	Configures this trunk for use with SIP.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.
Release 11.1	Command was expanded to include the analog and ISDN support.

Usage Examples

The following example creates the new trunk T12 for use with SIP and enters the Voice Trunk Configuration mode:

(config)**#voice trunk t12 type sip**
(config-T12)#

voice trunk *<trunk id>* type analog supervision

Use the **voice trunk type analog supervision** command to define a new trunk for an analog interface. Executing this command activates the Voice Trunk Analog Configuration mode for the individual trunk. Use the **no** form of this command to delete a configured voice trunk. Refer to *Voice Analog Trunk Command Set on page 4959* for information on the commands in that mode. Variations of this command include the following:

voice trunk *<trunk id>* **type analog supervision dpt**
voice trunk *<trunk id>* **type analog supervision ground-start**
voice trunk *<trunk id>* **type analog supervision loop-start**

Syntax Description

<trunk id>	Specifies the trunk's two-digit identifier in the format Txx (for example, **T01**).
dpt	Specifies dial pulse terminate (DPT) with an assumed user role.
ground-start	Specifies ground start (GS) with an assumed user role.
loop-start	Specifies loop start (LS) with an assumed user role.

Default Values

No default values are necessary for this command.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example creates the new trunk **T15** for use with an analog interface and enters the Voice Trunk Analog DPT Configuration mode:

(config)**#voice trunk t15 type analog supervision dpt**
(config-T15)#

voice trunk *<trunk id>* type t1-rbs supervision

Use the **voice trunk type t1-rbs supervision** command to define a new trunk for a T1 interface. Executing this command activates the Voice Trunk T1 Configuration mode for the individual trunk. Use the **no** form of this command to delete a configured voice trunk. Refer to *Voice T1 Trunk Command Set on page 5151* for information on the commands in that mode. Other trunk types are explained in *voice trunk <trunk id> type on page 1980*. Variations of this command include the following:

voice trunk *<trunk id>*
voice trunk *<trunk id>* **type t1-rbs supervision fgd role user**
voice trunk *<trunk id>* **type t1-rbs supervision ground-start role user**
voice trunk *<trunk id>* **type t1-rbs supervision immediate role network**
voice trunk *<trunk id>* **type t1-rbs supervision immediate role user**
voice trunk *<trunk id>* **type t1-rbs supervision loop-start role user**
voice trunk *<trunk id>* **type t1-rbs supervision tie-fgd**
voice trunk *<trunk id>* **type t1-rbs supervision wink role network**
voice trunk *<trunk id>* **type t1-rbs supervision wink role user**

Syntax Description

<trunk id>	Specifies the trunk's two-digit identifier in the format Txx (for example, **T01**).
fgd	Specifies feature group D (FGD) with an assumed user role.
ground-start	Specifies ground start (GS) with an assumed user role.
immediate	Specifies E&M immediate with an assumed network or user role.
loop-start	Specifies loop start (LS) with an assumed user role.
tie-fgd	Specifies tie trunk with FGD.
wink	Specifies wink with an assumed network or user role.
role network	Specifies the network role for this trunk.
role user	Specifies the user role for this trunk.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.
Release 12.1	Command was expanded.

Usage Examples

The following example creates the new trunk **T15** for use with a T1 interface and enters the Voice Trunk T1 Wink Configuration mode:

```
(config)#voice trunk t15 type t1-rbs supervision wink role network
(config-T15)#
```

voice user <*extension*>

Use the **voice user** command to create a new user extension and to enter the Voice User command set. Use the **no** form of this command to delete a configured extension or modify an existing extension's parameters. Refer to *Voice User Account Command Set on page 4564* for details.

Syntax Description

<*extension*>	Specifies user's extension.

Default Values

By default, there are no configured voice users.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example creates a new user with extension **9876**:

(config)#**voice user 9876**
Configuring New User "9876".
(config-9876)#

voip name-service host

Use the **voip name-service host** command to add a host to the Voice over Internet Protocol (VoIP) name service (VNS) cache table. Using the **no** form of this command removes the host from the cache. Variations of this command include:

voip name-service host <*hostname*> **mgcp**
voip name-service host <*hostname*> **mgcp tcp**
voip name-service host <*hostname*> **mgcp udp**
voip name-service host <*hostname*> **sip**
voip name-service host <*hostname*> **sip tcp**
voip name-service host <*hostname*> **sip tls**
voip name-service host <*hostname*> **sip tls srv** <*service-name-prefix*>
voip name-service host <*hostname*> **sip tls srv** <*service-name-prefix*> <*transport-name-prefix*>
voip name-service host <*hostname*> **sip udp**

Syntax Description

<*hostname*>	Specifies the fully qualified domain name (FQDN) of the added host.
mgcp	Specifies that Media Gateway Control Protocol (MGCP) is the service type for the VNS service request.
sip	Specifies that Session Initiation Protocol (SIP) is the service type for the VNS service request.
tcp	Optional. Specifies that Transmission Control Protocol (TCP) is the protocol used for the service request.
tls	Optional. Specifies that Transport Layer Security (TLS) is the protocol used for the service request.
srv	Optional. Specifies that service records (SRV) parameters are enabled. Available only when an FQDN has been specified.
<*service-name-prefix*>	Optional. Specifies the service name prefix for the domain naming system (DNS) service (SRV) request. Underscores are added automatically.
<*transport-name-prefix*>	Optional. Specifies the transport prefix for the DNS SRV request. Underscores are added automatically.
udp	Optional. Specifies that User Datagram Protocol (UDP) is the protocol used for the service request.

Default Values

By default, both MGCP and SIP VNS requests use UDP. By default, SIP TLS requests use **SIPS** as the service name prefix and **TCP** as the transport name prefix.

Functional Notes

Voice and media signaling protocols (such as SIP) often rely on DNS

in order to ease configuration and administration of endpoints and also to implement redundancy mechanisms provided by DNS service records. Because voice and media signaling protocols are often directly coupled to a user experience, applications are often very sensitive to latency introduced by the DNS mechanism.

AOS voice products rely on the ability to resolve names to one or more service or address records quickly in order to place a call or register to an external voice server. The DNS server is often not local to the AOS unit, and it is not guaranteed to be accessible, even when other mechanisms necessary for successful call completion may be available. A DNS request for a particular host name results in local caching by the AOS unit, after which the DNS information is quickly available without requiring additional requests. The cache remains populated until the cached record expires.

The VNS system in the AOS product implements preemptive and persistent caching of DNS records for voice signaling protocols. The VNS system maintains a table of DNS records in a cache for voice signaling protocols like SIP and MGCP. For example, if a request is generated from a SIP client (such as a SIP trunk or SIP proxy), for which there is a configured SIP server entity (such as a proxy address or SIP server address), the request is always serviced from the local DNS cache (rather than from an external DNS server). This ensures that SIP access to DNS is always available immediately, even during transient DNS outages.

The VNS system in AOS can be configured manually by adding a host to the cache (using the command *voip name-service host on page 1984*) and by specifying the number of attempts used by VNS to verify the DNS cache changes (using the command *voip name-service verification attempts <number> interval <seconds> on page 1986*). You can view the VNS cache by using the commands *show voip name-service cache on page 1108* and *show voip name-service name-table on page 1109*.

Configuring an FQDN using the **voip name-service host** command forces the FQDN resolution (using DNS) to never timeout from the DNS name table. Each DNS record has a time to live (TTL) value that specifies the amount of time to cache the record. After this time, the DNS table (by default) removes the record from the cache. VNS issues DNS queries in an attempt to keep voice-related records cached in the DNS name table, but if the DNS name servers are not available, the records can expire from the DNS name table. The records associated with configured VNS host FQDNs are not flushed from the cache regardless of the TTL or age of the record, but rather are permanently cached dynamic resolutions.

Command History

Release A4.03	Command was introduced.
Release R11.5.0	Command was expanded to include the **tls** and **srv** configuration parameters.

Usage Examples

The following example adds the SIP host **example.user.net** to the VNS/DNS cache, using **TCP** requests:

(config)**#voip name-service host example.user.net sip tcp**

The following example configures TLS as the transport protocol for a statically added VNS host:(config)#voip name-service host example.user.net sip tls

voip name-service verification attempts <*number*> interval <*seconds*>

Use the **voip name-service verification attempts interval** command to configure the Voice over Internet Protocol (VoIP) name service (VNS) to verify any domain naming system (DNS) changes to the VNS table. Using the **no** form of this command disables verification.

Syntax Description

attempts <*number*>	Specifies the number of consecutive DNS answers that validate a change to the VNS table. Valid range is **1** to **10**.
interval <*seconds*>	Specifies the time interval (in seconds) to wait between verification attempts. Valid range is **1** to **600** seconds.

Default Values

By default, the VNS system does not verify DNS changes.

Functional Notes

Voice and media signaling protocols (such as SIP) often rely on DNS in order to ease configuration and administration of endpoints and also to implement redundancy mechanisms provided by DNS service records. Because voice and media signaling protocols are often directly coupled to a user experience, applications are often very sensitive to latency introduced by the DNS mechanism.

AOS voice products rely on the ability to resolve names to one or more service or address records quickly in order to place a call or register to an external voice server. The DNS server is often not local to the AOS unit, and it is not guaranteed to be accessible, even when other mechanisms necessary for successful call completion may be available. A DNS request for a particular host name results in local caching by the AOS unit, after which the DNS information is quickly available without requiring additional requests. The cache remains populated until the cached record expires.

The VNS system in the AOS product implements preemptive and persistent caching of DNS records for voice signaling protocols. The VNS system maintains a table of DNS records in a cache for voice signaling protocols like Session Initiation Protocol (SIP) and Media Gateway Control Protocol (MGCP). For example, if a request is generated from a SIP client (such as a SIP trunk or SIP proxy), for which there is a configured SIP server entity (such as a proxy address or SIP server address), the request is always serviced from the local DNS cache (rather than from an external DNS server). This ensures that SIP access to DNS is always available immediately, even during transient DNS outages.

The VNS system in AOS can be configured manually by adding a host to the cache (using the command *voip name-service host on page 1984*) and by specifying the number of attempts used by VNS to verify the DNS cache changes (using the command *voip name-service verification attempts <number> interval <seconds> on page 1986*). You can view the VNS cache by using the commands *show voip name-service cache on page 1108* and *show voip name-service name-table on page 1109*.

Command History

Release A4.03	Command was introduced.

Usage Examples

In the following example, the VNS system is configured to use **3** attempts to validate a DNS change, with **30** seconds between each attempt:

(config)**#voip name-service verification attempts 3 interval 30**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an interface to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the interface from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an interface's VRF association will clear all IP-related settings on that interface.

Syntax Description

<name>	Specifies the name of the VRF to which to assign the interface.

Default Values

By default, interfaces are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release 17.8	The keyword **ip** was removed from this command.

Functional Notes

VRF instances must be created first before an interface can be assigned. An interface can only be assigned to one VRF, but multiple interfaces can be assigned to the same VRF.

An interface will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the **frame-relay 1.16** interface to the VRF instance named **RED**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#vrf forwarding RED**

vrf <*name*> route-distinguisher

Use the **vrf route-distinguisher** command to create a nondefault virtual routing and forwarding (VRF) instance and assign it a route distinguisher. Use the **no vrf** command to remove all VRF instances configured on the system. Use the **no vrf route-distinguisher** command to destroy the VRF instance and any commands configured on the VRF. Variations of this command include:

vrf <*name*> **route-distinguisher as-2byte** <*ASN:nn*>
vrf <*name*> **route-distinguisher as-4byte** <*ASN:nn*>
vrf <*name*> **route-distinguisher ip** <*ipv4 address:nn*>
vrf system-control route-distinguisher as-2byte 0:1
vrf system-management route-distinguisher as-2byte 0:2

Syntax Description

<*name*>	Specifies the name of the VRF instance. Valid range is up to **79** alphanumeric characters.
as-2byte <*ASN:nn*>	Specifies the autonomous system number (ASN)-relative route distinguisher as a 16-bit AS number *(ASN)* and a 32-bit arbitrary number (*nn*).
as-4byte <*ASN:nn*>	Specifies the ASN-relative route distinguisher as a 32-bit AS number (*ASN)* and a 16-bit arbitrary number (*nn*).
ip <*ipv4 address:nn*>	Specifies an IPv4 address-relative route distinguisher, which consists of an IPv4 address and a 16-bit arbitrary number (*nn*). IPv4 addresses should be expressed in decimal dotted notation (for example, **10.10.10.1**).
system-control	Specifies the system control VRF instance.
system-management	Specifies the system management VRF instance.

Default Values

No default values are necessary for this command.

Command History

Release 16.1	Command was introduced.
Release 18.3	Command syntax was changed to remove the **ip** keyword for IPv6 support in Adtran internetworking products. In addition, the **as-2byte**, **as-4byte**, and **ip** <*ipv4 address:nn*> parameters were added.
Release R10.1.0	Command syntax was changed to remove the **ip** keyword for IPv6 support in Adtran voice products. In addition, the **as-2byte**, **as-4byte**, and **ip** <*ipv4 address:nn*> parameters were added.
Release R10.10.0	Command was expanded to include the **system-control** and **system-management** options.

Functional Notes

The route distinguisher **0:0** or **0.0.0.0:0** is reserved for the default (unnamed) VRF instance and cannot be reassigned. Additionally, the VRF names **system-control** and **system-management** use route distinguishers **0:1** and **0:2** respectively, and cannot be reassigned. The system control and system management VRF instances exist by default and cannot be removed. These VRFs exist for the system control Ethernet virtual connection (EVC) and the system management EVC. Refer to *System Control EVC Command Set on page 3745* and *System Management EVC Command Set on page 3843* for more information.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Once a nondefault VRF is created, it must be assigned to the appropriate interfaces. Use the *voip name-service host on page 1984* to assign interfaces to the VRF. By default, interfaces are assigned to the default unnamed VRF. An interface can only be assigned to one VRF, but multiple interfaces can be assigned to the same VRF.

Usage Examples

The following example creates the VRF **Red** and assigns the 2-byte route distinguisher **2:2**:

(config)**#vrf RED route-distinguisher as-2byte 2:2**

APPLICATION COMMAND SETS

This section includes the following command sets:

NETWORK SYNC APPLICATION COMMAND SET

Use the network synchronization (Network Sync) application command set to aid in troubleshooting Network Sync configuration on the AOS unit. Network Sync application commands do not affect the configuration of the AOS unit, and they do not persist between reboots. To access the Network Sync application command set, enter the **application** command from the Enable mode prompt, and then enter the appropriate Network Sync application command as follows (refer to the command *application on page 98*):

```
>enable
#application
(app)#
```

The following command is common to multiple command sets and is covered in a centralized section of this guide. For more information, refer to the section listed below:

exit on page 83

Commands for this command set are described in this section in alphabetical order.

network-sync source-override on page 1993
network-sync transmit-ssm-override <input> on page 1994
network-sync wait-to-restore clear on page 1996

network-sync source-override

Use the **network-sync source-override** command to override the current clock source. When the clock source override is activated, there is a line displayed in the command **show network-sync** that indicates the override is active. Use the **no** form of this command to cancel the clock override. Variations of this command include:

network-sync source-override cancel
network-sync source-override internal
network-sync source-override primary
network-sync source-override primary force
network-sync source-override secondary
network-sync source-override secondary force

Syntax Description

cancel	Specifies that the source override is cancelled. This functions exactly the same as using the **no** command.
internal	Specifies that the internal oscillator is selected as the current clock source.
primary	Specifies that the primary clock source is overridden.
secondary	Specifies that the secondary clock source is overridden.
force	Optional. Specifies that the primary or secondary clock source should be selected as the current clock even if it is down.

Default Values

No default values are necessary for this command.

Command History

Release R10.11.0	Command was introduced.

Usage Examples

The following example overrides the secondary clock source:

#application
(app)**#network-sync source-override secondary**

network-sync transmit-ssm-override <*input*>

Use the **network-sync transmit-ssm-override** command to create an unconditional override of the synchronization status message (SSM) configuration for the clock. This command is used primarily for testing purposes. Use the **no** form of this command to remove the override.

Syntax Description

<*input*>	Specifies the SSM quality level override option. Refer to the Functional Notes of this command for specifics.

Default Values

By default, SSM override options are those provided by Ethernet equipment clock (EEC) option 2.

Command History

Release R10.11.0	Command was introduced.

Functional Notes

The various <*input*> parameters available for SSM override vary according to the EEC option selected in the Network Sync configuration (refer to *eec-option on page 4437*). If you have not specified an EEC option, option 2 is used by default. The following tables outline the <*input*> parameters for the **network-sync transmit-ssm-override** command.

Table 1. SSM Override Parameters for EEC Option 1

SSM Override Parameter	Description
q1-dnu	Do Not Use for Synchronization (0xF)
q1-eec1	Synchronous digital hierarchy (SDH) Equipment Clock (0xB)
q1-prc	Primary Reference Clock (0x2)
q1-ssu-a	Primary Level Synchronization Supply Unit (0x4)
q1-ssu-b	Second Level Synchronization Supply Unit (0x8)
<*input*>	Enter SSM as a decimal or hexadecimal value

Table 2. SSM Override Parameters for EEC Option 2

SSM Override Parameter	Description
q1-dus	Do Not Use for Synchronization (0xF)
q1-eec2	Stratum 3 Traceable (0xA)
q1-prov	Provisioned by Network Operator (0xE)

Table 2. SSM Override Parameters for EEC Option 2 (Continued)

SSM Override Parameter	Description
q1-prs	Stratum 1 Traceable (0x1)
q1-smc	SONET Minimum Clock Traceable (0xC)
q1-st2	Stratum 2 Traceable (0x7)
q1-st3e	Stratum 3E Traceable (0xD)
q1-stu	Synchronized Traceability Unknown (0x0)
q1-tnc	Transit Node Clock Traceable (0x4)
<input>	Enter SSM as a decimal or hexadecimal value

Usage Examples

The following example creates an unconditional SSM override:

#application
(app)**#network-sync transmit-ssm-override q1-dnu**

network-sync wait-to-restore clear

Use the **network-sync wait-to-restore clear** command to clear the wait-to-restore timers. Variations of this command include:

network-sync wait-to-restore clear primary
network-sync wait-to-restore clear secondary

Syntax Description

primary	Specifies the primary timers are cleared.
secondary	Specifies the secondary timers are cleared.

Default Values

No default values are necessary for this command.

Command History

Release R10.11.0	Command was introduced.

Usage Examples

The following example clears the primary wait-to-restore timers:

#application
(app)**#network-sync wait-to-restore clear primary**

Y.1731 Application Command Set

Use the Y.1731 application command set to configure and verify specifics of Y.1731 configuration on the AOS unit. Y.1731 applications are used in one- and two-way frame delay performance monitoring sessions, as well as frame loss monitoring sessions. To access the Y.1731 application command set, enter the **application** command from the Enable mode prompt, and then enter the appropriate Y.1731 application command as follows (refer to the command *application on page 98*):

```
>enable
#application
(app)#ethernet y1731 meg char-string MEG 3 100
(app-y1731 MEG)#
```

In AOS Release 17.1, output modifiers were introduced for all **show** commands. These modifiers help specify the information displayed in the **show** command output. The modifiers are appended to the end of the **show** command, preceded by the pipe character (|), and followed by the <*text*> to **exclude**, **include**, or with which to **begin** the display. The following output modifiers are common for all **show** commands:

| begin <*text*>	Produces output that begins with lines, including the specified text and every line thereafter.
| exclude <*text*>	Produces output that excludes any lines containing the specified text.
| include <*text*>	Produces output that only displays lines with the specified text.

The following command is common to multiple command sets and is covered in a centralized section of this guide. For more information, refer to the section listed below:

exit on page 83

All other commands for this command set are described in this section in alphabetical order:

frame-delay one-way on page 1998
frame-delay two-way on page 2000
frame-loss single-ended on page 2002
frame-loss synthetic single-ended on page 2004
linktrace <mep id | target mac address> on page 2007
loopback on page 2008
show frame-delay one-way on page 2010
show frame-delay two-way on page 2012
show frame-loss single-ended on page 2014
show frame-loss synthetic single-ended on page 2016
show loopback multicast on page 2018

frame-delay one-way

Use the **frame-delay one-way** command to configure a Y.1731 one-way frame delay performance monitoring session between maintenance entity group (MEG) endpoints (MEPs). Use the **no** form of this command to disable the frame delay monitoring session. Variations of this command include:

frame-delay one-way <*mep id* | *target mac address* | **multicast**>
frame-delay one-way <*mep id* | *target mac address* | **multicast**> **priority** <*value*>
frame-delay one-way <*mep id* | *target mac address* | **multicast**> **priority** <*value*> **count** <*value*>
frame-delay one-way <*mep id* | *target mac address* | **multicast**> **priority** <*value*> **count** <*value*> **interval** <*interval*>
frame-delay one-way <*mep id* | *target mac address* | **multicast**> **priority** <*value*> **count** <*value*> **interval** <*interval*> **size** <*bytes*>
frame-delay one-way <*mep id* | *target mac address* | **multicast**> **priority** <*value*> **count** <*value*> **interval** <*interval*> **size** <*bytes*> **data** <*data*>
frame-delay one-way <*mep id* | *target mac address* | **multicast**> **priority** <*value*> **count** <*value*> **interval** <*interval*> **size** <*bytes*> **data** <*data*> **verbose**

Syntax Description

<*mep id*>	Specifies the MEP ID of the target MEP. Valid MEP ID range is **1** to **8191.**
<*target mac address*>	Specifies the medium access control (MAC) address of the target MEP. Enter MAC addresses in hexadecimal format, for example: **xx:xx:xx:xx:xx:xx**.
multicast	Specifies the session is configured for multicast.
priority <*value*>	Optional. Specifies the virtual local area network (VLAN) priority of the target MEP. Valid range is **0** to **7**.
count <*value*>	Optional. Specifies the number of one-way delay measurement message frames (1DM) sent to the target MEP. Valid range is **2** to **1024**.
interval <*interval*>	Optional. Specifies the time (in milliseconds) between 1DM transmissions. Valid range is **100** to **900000** ms.
size <*bytes*>	Optional. Specifies the size of the 1DM frame in bytes. If no size is specified, 1DM fames are zero-padded up to 64 bytes. If the size is specified, a data type-length value (TLV) is used to ensure the 1DM frame is the correct length. Valid range is **0**, or **64** to **2000** bytes.
data <*data*>	Optional. Specifies a hex pattern used to fill the data TLV. Valid range is **0x0000** to **0xFFFF**.
verbose	Optional. Specifies details are given in the monitoring session.

Default Values

By default, no one-way frame delay monitoring sessions are configured. If a session is configured, it has an interval of **1000** ms, a size of **0** bytes, and a data pattern of **0x0000** by default.

Command History

Release R10.10.0	Command was introduced.
Release R11.10.0	Command was expanded to include the **multicast** parameter.

Usage Examples

The following example configures a one-way frame delay monitoring session for MEP **100** with a priority of **3**, a count of **100**, and the default interval, size, and data values:

#application
(app)**#ethernet y1731 meg char-string MEG 3 100**
(app-y1731 MEG)#f**rame-delay one-way 100 priority 3 count 100**

frame-delay two-way

Use the **frame-delay two-way** command to configure a Y.1731 two-way frame delay performance monitoring session between maintenance entity group (MEG) endpoints (MEPs). Use the **no** form of this command to disable the frame delay monitoring session. Variations of this command include:

frame-delay two-way <*mep id* | *target mac address* | **multicast**>
frame-delay two-way <*mep id* | *target mac address* | **multicast**> **count** <*count*>
frame-delay two-way <*mep id* | *target mac address* | **multicast**> **data** <*data*>
frame-delay two-way <*mep id* | *target mac address* | **multicast**> **interval** <*interval*>
frame-delay two-way <*mep id* | *target mac address* | **multicast**> **measurement-interval** <*measurement interval*>
frame-delay two-way <*mep id* | *target mac address* | **multicast**> **priority** <*priority*>
frame-delay two-way <*mep id* | *target mac address* | **multicast**> **repetition-time** <*repetition time*>
frame-delay two-way <*mep id* | *target mac address* | **multicast**> **size** <*size*>
frame-delay two-way <*mep id* | *target mac address* | **multicast**> **start-time [**<*start time*> **| immediate]**
frame-delay two-way <*mep id* | *target mac address* | **multicast**> **stop-time** <*stop time*>

NOTE *After specifying the MEP ID, MAC, or multicast address of the target MEP(s), the other parameters can be entered in any order.*

Syntax Description

<*mep id*>	Specifies the MEP ID of the target MEP. Valid MEP ID range is **1** to **8191**.
<*target mac address*>	Specifies the medium access control (MAC) address of the target MEP. Enter MAC addresses in hexadecimal format, for example: **xx:xx:xx:xx:xx:xx**.
multicast	Specifies the session is configured for multicast.
count <*count*>	Optional. Specifies the number of delay measurement messages (DMMs) sent to the target MEP. Cannot be used in conjunction with the **stop-time** parameter. Must be greater than or equal to the **measurement interval** divided by the **interval**. Valid range is **2** to **1024**.
data <*data*>	Optional. Specifies a hex pattern used to fill the data TLV. Valid range is **0x0000** to **0xFFFF**.
interval <*interval*>	Optional. Specifies the number of milliseconds between DMM transmissions. Valid range is **100** to **900000** ms.
measurement-interval <*measurement interval*>	Optional. Specifies the number of seconds over which frame delay statistics are generated. If used with the **repetition-time** parameter, must be in minute intervals (multiples of 60) and less than the repetition time. Valid range is **60** to **86400** seconds.
priority <*priority*>	Optional. Specifies the virtual local area network (VLAN) priority of the target MEP. Valid range is **0** to **7**.

repetition-time <*repetition time*>	Optional. Specifies the number of seconds between the start time of measurement intervals. The repetition time must be at least as long as the measurement interval and must be in minute intervals (multiples of 60). Valid range is **60** to **86400** seconds.
size <*size*>	Optional. Specifies the size in bytes of the DMM frame. If no size is specified, DMM fames are zero-padded up to 64 bytes. If the size is specified, a data type-length value (TLV) is used to ensure the DMM frame is the correct length. Valid range is **0**, or **64** to **2000** bytes.
start-time	Optional. Specifies the start time of the monitoring session.
<*start time*>	Specifies the absolute time of day after the initiation of the session that the measurement interval will begin. Specified in the format **HH:MM:SS**. For example, midnight is **00:00:00**.
immediate	Specifies that the session will start immediately.
stop-time <*stop-time*>	Optional. Specifies the duration in seconds of the frame delay monitoring session. Cannot be used in conjunction with the **count** parameter. Must be greater than or equal to the interval and must be large enough for one packet to be transmitted. If **stop-time** is not defined, then **count** will be used. Valid range is **0** to **15552000** seconds.

Default Values

By default, no two-way frame delay monitoring sessions are configured. If a session is configured, it has a count of **60**, an interval of **1000** ms, a measurement interval of **60** seconds, a size of **0** bytes, and a data pattern of **0x0000** by default.

Command History

Release R10.10.0	Command was introduced.
Release R11.6.0	Command was expanded to include the **repetition-time**, **start-time** and **stop-time** parameters.
Release R11.10.0	Command was expanded to include the **multicast** parameter.

Usage Examples

The following example configures a two-way frame delay monitoring session for MEP **100** with a priority of **3**, a start time of **02:00:00** (2:00 A.M.), a stop time of **3600** seconds (one hour), and the default interval, measurement interval, repetition time, size, and data values:

#application
(app)**#ethernet y1731 meg char-string MEG 3 100**
(app-y1731 MEG)**#frame-delay two-way 100 priority 3 start-time 02:00:00 stop-time 3600**

frame-loss single-ended

Use the **frame-loss single-ended** command to monitor single-ended frame loss across maintenance entity group (MEG) endpoints (MEPs). This commands uses actual data traffic to measure frame loss. To measure frame loss using synthetic frames, use the *frame-loss synthetic single-ended on page 2004*. Use the **no** form of this command to disable the monitoring feature. Variations of this command include:

frame-loss single-ended <*mep id* | *target mac address* | **multicast**>
frame-loss single-ended <*mep id* | *target mac address* | **multicast**> **count** <*count*>
frame-loss single-ended <*mep id* | *target mac address* | **multicast**> **data** <*data*>
frame-loss single-ended <*mep id* | *target mac address* | **multicast**> **interval** <*interval*>
frame-loss single-ended <*mep id* | *target mac address* | **multicast**> **measurement-interval** <*measurement interval*>
frame-loss single-ended <*mep id* | *target mac address* | **multicast**> **priority** <*priority*>
frame-loss single-ended <*mep id* | *target mac address* | **multicast**> **repetition-time** <*repetition time*>
frame-loss single-ended <*mep id* | *target mac address* | **multicast**> **size** <*size*>
frame-loss single-ended <*mep id* | *target mac address* | **multicast**> **start-time [**<*start time*> **| immediate]**
frame-loss single-ended <*mep id* | *target mac address* | **multicast**> **stop-time** <*stop time*>

After specifying the MEP ID, MAC, or multicast address of the target MEP(s), the other parameters can be entered in any order.

Syntax Description

<*mep id*>	Specifies the MEP ID of the target MEP. Valid MEP ID range is **1** to **8191**.
<*target mac address*>	Specifies medium access control (MAC) address of the target MEP. Enter MAC addresses in hexadecimal format, for example: **xx:xx:xx:xx:xx:xx**.
multicast	Specifies the session is configured for multicast.
count <*count*>	Optional. Specifies the number of loss measurement messages (LMMs) sent to the target MEP. Cannot be used in conjunction with the **stop-time** parameter. Must be greater than or equal to the **measurement interval** divided by the **interval**. Valid range is **2** to **1024**.
data <*data*>	Optional. Specifies a hex pattern used to fill the data TLV. Valid range is **0x0000** to **0xFFFF**.
interval <*interval*>	Optional. Specifies the number of milliseconds between DMM transmissions. Valid range is **100** to **900000** ms.
measurement-interval <*measurement interval*>	Optional. Specifies the number of seconds over which frame loss statistics are generated. If used with the **repetition-time** parameter, must be in minute intervals (multiples of 60) and less than the repetition time. Valid range is **60** to **86400** seconds.

priority <*priority*>	Optional. Specifies the virtual local area network (VLAN) priority of the target MEP. Valid range is **0** to **7**.
repetition-time <*repetition time*>	Optional. Specifies the number of seconds between the start time of measurement intervals. The repetition time must be at least as long as the measurement interval and must be in minute intervals (multiples of 60). Valid range is **60** to **86400** seconds.
size <*size*>	Optional. Specifies the size in bytes of the DMM frame. If no size is specified, DMM fames are zero-padded up to 64 bytes. If the size is specified, a data type-length value (TLV) is used to ensure the DMM frame is the correct length. Valid range is **0**, or **64** to **2000** bytes.
start-time	Optional. Specifies the start time of the monitoring session.
<*start time*>	Specifies the absolute time of day after the initiation of the session that the measurement interval will begin. Specified in the format **HH:MM:SS**. For example, midnight is **00:00:00**.
immediate	Specifies that the session will start immediately.
stop-time <*stop-time*>	Optional. Specifies the duration in seconds of the frame delay monitoring session. Cannot be used in conjunction with the **count** parameter. Must be greater than or equal to the interval and must be large enough for one packet to be transmitted. If **stop-time** is not defined, then **count** will be used. Valid range is **0** to **15552000** seconds.

Default Values

By default, no two-way frame delay monitoring sessions are configured. If a session is configured, it has a count of **60**, an interval of **1000** ms, a measurement interval of **60** seconds, a size of **0** bytes, and a data pattern of **0x0000** by default.

Command History

Release R10.10.0	Command was introduced.
Release R11.6.0	Command was expanded to include the **repetition-time**, **start-time** and **stop-time** parameters.
Release R11.10.0	Command was expanded to include the **multicast** parameter.

Usage Examples

The following example configures a frame-loss monitoring session for MEP **100** with a priority of **3**, a start time of **02:00:00** (2:00 A.M.), a stop time of **3600** seconds (one hour), and the default interval, measurement interval, repetition time, size, and data values:

#application
(app)**#ethernet y1731 meg char-string MEG 3 100**
(app-y1731 MEG)**#frame-loss single-ended 100 priority 3 start-time 02:00:00 stop-time 3600**

frame-loss synthetic single-ended

Use the **frame-loss synthetic single-ended** command to monitor frame loss across maintenance entity group (MEG) endpoints (MEPs). This commands uses synthetic frames to measure frame loss. To measure frame loss using actual data fames, use the *frame-loss single-ended on page 2002*.Use the **no** form of this command to disable the monitoring feature. Variations of this command include:

frame-loss synthetic single-ended <*mep id* | *target mac address* | **multicast**>
frame-loss synthetic single-ended <*mep id* | *target mac address* | **multicast**> **count** <*count*>
frame-loss synthetic single-ended <*mep id* | *target mac address* | **multicast**> **data** <*data*>
frame-loss synthetic single-ended <*mep id* | *target mac address* | **multicast**> **interval** <*interval*>
frame-loss synthetic single-ended <*mep id* | *target mac address* | **multicast**> **measurement-interval** <*measurement interval*>
frame-loss synthetic single-ended <*mep id* | *target mac address* | **multicast**> **priority** <*priority*>
frame-loss synthetic single-ended <*mep id* | *target mac address* | **multicast**> **repetition-time** <*repetition time*>
frame-loss synthetic single-ended <*mep id* | *target mac address* | **multicast**> **size** <*size*>
frame-loss synthetic single-ended <*mep id* | *target mac address* | **multicast**> **start-time [**<*start time*> **| immediate]**
frame-loss synthetic single-ended <*mep id* | *target mac address* | **multicast**> **stop-time** <*stop time*>

After specifying the MEP ID, MAC, or multicast address of the target MEP(s), the other parameters can be entered in any order.

Syntax Description

<*mep id*>	Specifies the MEP ID of the target MEP. Valid MEP ID range is **1** to **8191**.
<*target mac address*>	Specifies the medium access control (MAC) address of the target MEP. Enter MAC addresses in hexadecimal format, for example: **xx:xx:xx:xx:xx:xx**.
multicast	Specifies the session is configured for multicast.
count <*count*>	Optional. Specifies the number of synthetic loss messages (SLMs) sent to the target MEP. Cannot be used in conjunction with the **stop-time** parameter. Must be greater than or equal to the **measurement interval** divided by the **interval**. Valid range is **2** to **1024**.
data <*data*>	Optional. Specifies a hex pattern used to fill the data TLV. Valid range is **0x0000** to **0xFFFF**.
interval <*interval*>	Optional. Specifies the number of milliseconds between DMM transmissions. Valid range is **100** to **900000** ms.
measurement-interval <*measurement interval*>	Optional. Specifies the number of seconds over which frame loss statistics are generated. If used with the **repetition-time** parameter, must be in minute intervals (multiples of 60) and less than the repetition time. Valid range is **60** to **86400** seconds.

priority <*priority*>	Optional. Specifies the virtual local area network (VLAN) priority of the target MEP. Valid range is **0** to **7**.
repetition-time <*repetition time*>	Optional. Specifies the number of seconds between the start time of measurement intervals. The repetition time must be at least as long as the measurement interval and must be in minute intervals (multiples of 60). Valid range is **60** to **86400** seconds.
size <*size*>	Optional. Specifies the size in bytes of the DMM frame. If no size is specified, DMM fames are zero-padded up to 64 bytes. If the size is specified, a data type-length value (TLV) is used to ensure the DMM frame is the correct length. Valid range is **0**, or **64** to **2000** bytes.
start-time	Optional. Specifies the start time of the monitoring session.
<*start time*>	Specifies the absolute time of day after the initiation of the session that the measurement interval will begin. Specified in the format **HH:MM:SS**. For example, midnight is **00:00:00**.
immediate	Specifies that the session will start immediately.
stop-time <*stop-time*>	Optional. Specifies the duration in seconds of the frame delay monitoring session. Cannot be used in conjunction with the **count** parameter. Must be greater than or equal to the interval and must be large enough for one packet to be transmitted. If **stop-time** is not defined, then **count** will be used. Valid range is **0** to **15552000** seconds.

Default Values

By default, no two-way frame delay monitoring sessions are configured. If a session is configured, it has a count of **60**, an interval of **1000** ms, a measurement interval of **60** seconds, a size of **0** bytes, and a data pattern of **0x0000** by default.

Command History

Release R10.10.0	Command was introduced.
Release R11.6.0	Command was expanded to include the **repetition-time**, **start-time** and **stop-time** parameters.
Release R11.10.0	Command was expanded to include the **multicast** parameter.

Usage Examples

The following example configures a synthetic frame-loss monitoring session for MEP **100** with a priority of **3**, a start time of **02:00:00** (2:00 A.M.), a stop time of **3600** seconds (one hour), and the default interval, measurement interval, repetition time, size, and data values:

#application
(app)**#ethernet y1731 meg char-string MEG 3 100**
(app-y1731 MEG)**#frame-loss synthetic single-ended 100 priority 3 start-time 02:00:00 stop-time 3600**

linktrace *<mep id | target mac address>*

Use the **linktrace** command to trace the link between Y.1731 maintenance entity group (MEG) endpoints (MEPs). Use the **no** form of this command to disable the trace feature. Variations of this command include:

linktrace *<mep id | target mac address>*
linktrace *<mep id | target mac address>* **sorted**
linktrace *<mep id | target mac address>* **ttl** *<value>*
linktrace *<mep id | target mac address>* **ttl** *<value>* **mac-fdb-only**
linktrace *<mep id | target mac address>* **ttl** *<value>* **mac-fdb-only sorted**
linktrace *<mep id | target mac address>* **ttl** *<value>* **verbose**

Syntax Description

<mep id | target mac address>	Specifies the MEP ID or medium access control (MAC) address of the target MEP. Valid MEP ID range is **1** to **8191**. Enter MAC addresses in hexadecimal format, for example: **xx:xx:xx:xx:xx:xx**.
sorted	Optional. Sorts the results of the trace by MEP ID or MAC address.
ttl *<value>*	Optional. Specifies the number of mapped IP (MIP) address hops. Valid range is **1** to **255**.
mac-fdb-only	Optional. Specifies that only MAC addresses in the forwarding database (FDB) are traced.
verbose	Optional. Specifies that trace results are shown in detail.

Default Values

By default, link trace tests are not performed.

Command History

Release R10.10.0	Command was introduced.

Usage Example

The following example executes a trace of the link between MEP **100** and MEP **500**:

#application
(app)**#ethernet y1731 meg char-string MEG 3 100**
(app-y1731 MEG)**#linktrace 500**

loopback

Use the **loopback c**ommand to send loopback messages (LBMs) between Y.1731 maintenance entity group (MEG) endpoints (MEPs). The LBMs are used to verify bidirectional connectivity. Use the **no** form of this command to disable this feature. Variations of this command include:

loopback multicast
loopback multicast priority <*value*>
loopback multicast priority <*value*> **count** <*value*>
loopback multicast priority <*value*> **count** <*value*> **interval** <*interval*>
loopback multicast priority <*value*> **count** <*value*> **interval** <*interval*> **timeout** <*value*>
loopback multicast <*mep id* | *target mac address*> **priority** <*value*> **count** <*value*> **interval** <*interval*> **timeout** <*value*> **size** <*value*>
loopback multicast priority <*value*> **count** <*value*> **interval** <*interval*> **timeout** <*value*> **size** <*value*> **data [hex:4 | random]**
loopback multicast priority <*value*> **count** <*value*> **interval** <*interval*> **timeout** <*value*> **size** <*value*> **data [hex:4 | random] validate**
loopback multicast priority <*value*> **count** <*value*> **interval** <*interval*> **timeout** <*value*> **size** <*value*> **data [hex:4 | random] validate verbose**
loopback multicast priority <*value*> **count** <*value*> **interval** <*interval*> **timeout** <*value*> **size** <*value*> **data [hex:4 | random] verbose**

loopback unicast <*mep id* | *target mac address*>
loopback unicast <*mep id* | *target mac address*> **priority** <*value*>
loopback unicast <*mep id* | *target mac address*> **priority** <*value*> **count** <*value*>
loopback unicast <*mep id* | *target mac address*> **priority** <*value*> **count** <*value*> **interval** <*interval*>
loopback unicast <*mep id* | *target mac address*> **priority** <*value*> **count** <*value*> **interval** <*interval*> **timeout** <*value*>
loopback unicast <*mep id* | *target mac address*> **priority** <*value*> **count** <*value*> **interval** <*interval*> **timeout** <*value*> **size** <*value*>
loopback unicast <*mep id* | *target mac address*> **priority** <*value*> **count** <*value*> **interval** <*interval*> **timeout** <*value*> **size** <*value*> **data [hex:4 | random]**
loopback unicast <*mep id* | *target mac address*> **priority** <*value*> **count** <*value*> **interval** <*interval*> **timeout** <*value*> **size** <*value*> **data [hex:4 | random] validate**
loopback unicast <*mep id* | *target mac address*> **priority** <*value*> **count** <*value*> **interval** <*interval*> **timeout** <*value*> **size** <*value*> **data [hex:4 | random] validate verbose**
loopback unicast <*mep id* | *target mac address*> **priority** <*value*> **count** <*value*> **interval** <*interval*> **timeout** <*value*> **size** <*value*> **data [hex:4 | random] verbose**

Syntax Description

multicast	Specifies the session is configured for multicast.
unicast <*mep id* | *target mac address*>	Specifies the unicast MEP ID or medium access control (MAC) address of the target MEP. Valid MEP ID range is **1** to **8191**. Enter MAC addresses in hexadecimal format, for example: **xx:xx:xx:xx:xx:xx**.

priority *<value>*	Optional. Specifies the virtual local area network (VLAN) priority of the target MEP. Valid range is **0** to **7**.
count *<value>*	Optional. Specifies the number of LBMs sent to the target MEP. Valid range is **2** to **1024**.
interval *<interval>*	Optional. Specifies the time (in milliseconds) between LBM transmissions. Valid range is **100** to **10000** ms.
timeout *<value>*	Optional. Specifies the interval at which the loopback feature times out if there is no response to an LBM. Valid range is **100** to **5000** milliseconds.
size *<bytes>*	Optional. Specifies the size of the LBM frame in bytes. If no size is specified, LBM fames are zero-padded up to 64 bytes. If the size is specified, a data type-length value (TLV) is used to ensure the LBM frame is the correct length. Valid range is **64** to **9242** bytes.
data	Optional. Specifies a pattern used to fill the data TLV.
hex:4	Specifies any sequence of 4 hexadecimal digits.
random	Specifies a pseudo randomly generated number pattern
validate	Optional. Validates the connection between the MEPs.
verbose	Optional. Specifies that details are included in loopback test results.

Default Values

By default, no loopback tests are configured. If a test is configured, it has an interval of **1000** ms, a timeout of **100** seconds, a size of **0** bytes, and a data pattern of **0x0000** by default.

Command History

Release R10.10.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **random** parameter.
Release R11.7.0	The valid range of the **size** parameter was changed from **64** to **2000** bytes to **64** to **9242** bytes.
Release R11.10.0	Command was expanded to include the **multicast** parameter.

Functional Notes

When using the multicast loopback option, LBMs are sent a multicast MAC address. Up to 8 responding (LBR) MEPs/MAC addresses are recorded and displayed in the output of the command *show loopback multicast on page 2018*. The maximum count of LBMs supported for **multicast** is **60**, and the maximum for unicast is **1024**.

Usage Examples

The following example creates a loopback test between MEP **100** and MEP **500**:

#application
(app)**#ethernet y1731 meg char-string MEG 3 100**
(app-y1731 MEG)**#loopback unicast 500**

show frame-delay one-way

Use the **show frame-delay one-way** command to display statistics and configuration of one-way frame delay performance monitoring sessions. Variations of this command include:

show frame-delay one-way
show frame-delay one-way <*session id*>
show frame-delay one-way <*session id*> **realtime**

*The output of all **show** commands can be limited by appending the following modifiers to the end of the command: | **begin** <text>, | **exclude** <text>, and | **include** <text>. The **include** modifier limits output to lines that contain the specified text, the **exclude** modifier excludes any lines with the specified text, and the **begin** modifier displays the first line of output with the specified text and all lines thereafter.*

For specific instructions and examples regarding these modifiers, refer to the introduction of the Enable Mode Command Set on page 94.

Syntax Description

<*session id*>	Optional. Specifies that results for a specific frame delay monitoring session are displayed. Valid range is **1** to **n**.
realtime	Optional. Displays full-screen output in realtime. Information is continuously updated on the console.

Default Values

No default values are necessary for this command.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example displays the configuration of all one-way frame delay monitoring sessions:

```
#application
(app)#ethernet y1731 meg char-string MEG 3 100
(app-y1731 MEG)#show frame-delay one-way
Session 1 is Active
Source MAC                  : 00:a0:c8:00:00:01
VLAN Priority               : 7
Receive Interval            ms: 1000.12
Measurement Interval
Receive Count               Previous        Current
                            : 60            55
```

Delay		
Mean	ms: 0.08	0.09
Maximum	ms: 0.10	0.21
Minimum	ms: 0.07	0.07
Delay Variation Maximum		
Inter-packet	ms: 0.03	0.13
Reference-packet	ms:0.03	0.14

show frame-delay two-way

Use the **show frame-delay two-way** command to display statistics and configuration of two-way frame delay performance monitoring sessions. Variations of this command include:

show frame-delay two-way
show frame-delay two-way *<session id>*
show frame-delay two-way *<session id>* **realtime**

> *The output of all **show** commands can be limited by appending the following modifiers to the end of the command: | **begin** <text>, | **exclude** <text>, and | **include** <text>. The **include** modifier limits output to lines that contain the specified text, the **exclude** modifier excludes any lines with the specified text, and the **begin** modifier displays the first line of output with the specified text and all lines thereafter.*
>
> *For specific instructions and examples regarding these modifiers, refer to the introduction of the Enable Mode Command Set on page 94.*

Syntax Description

<session id>	Optional. Specifies that results for a specific frame delay monitoring session are displayed. Valid range is **1** to **n**.
realtime	Optional. Displays full-screen output in realtime. Information is continuously updated on the console.

Default Values

No default values are necessary for this command.

Command History

Release R10.10.0	Command was introduced.
Release R11.6.0	Command output was expanded to include the **Start-Time**, **Stop-Time**, **Repetition-Time**, and **Suspect Flag** fields.

Usage Examples

The following example displays the configuration of all two-way frame delay monitoring sessions:

#application
(app)**#ethernet y1731 meg char-string MEG 3 100**
(app-y1731 MEG)**#show frame-delay two-way**
MEP 100 Two-way Delay Session Results
Session 1 is Active

Session Type	: Proactive
Target MAC	: 00:a0:c8:01:00:00

Inter-packet	ms: 0.00	0.00

show frame-loss single-ended

Use the **show frame-loss single-ended** command to display statistics of single-ended frame loss monitoring sessions. Variations of this command include:

show frame-loss single-ended
show frame-loss single-ended <*session id*>
show frame-loss single-ended <*session id*> **realtime**

> *The output of all **show** commands can be limited by appending the following modifiers to the end of the command: | **begin** <text>, | **exclude** <text>, and | **include** <text>. The **include** modifier limits output to lines that contain the specified text, the **exclude** modifier excludes any lines with the specified text, and the **begin** modifier displays the first line of output with the specified text and all lines thereafter.*
>
> *For specific instructions and examples regarding these modifiers, refer to the introduction of the Enable Mode Command Set on page 94.*

> *Using the **realtime** argument for this command can adversely affect the performance or your unit.*

Syntax Description

<*session id*>	Optional. Specifies that results for a specific frame delay monitoring session are displayed. Valid range is **1** to **n**.
realtime	Optional. Displays full-screen output in real time. Information is updated on the console.

Default Values

No default values are necessary for this command.

Command History

Release R11.6.0	Command was introduced.

Functional Notes

Use the **realtime** argument for this command to display full-screen output in real time. Information is continuously updated on the console until you either freeze the data (by pressing the **F** key) or exit **realtime** mode (by pressing **Ctrl-C**). If there is not enough room on the screen for all available data, the information will truncate at the bottom of the screen. In order to maximize the amount of data displayed, increase the terminal length (using the **terminal length** command; refer to *terminal length <number> on page 1133*).

Usage Examples

The following example displays the statistics of frame loss monitoring for session **1**:

#application
(app)**#ethernet y1731 meg char-string MEG 3 1111**
(app-y1731 MEG)**#show frame-loss single-ended 1**
MEP 1111 Single-Ended Frame Loss Results

Session 1 is Active

Session Type	: Proactive	
Target MAC	: 00:a0:c8:01:00:00	
VLAN Priority	: 4	
Start Time	: 12:06:46 UTC Thu Jan 01 1970	
Stop Time	: Forever	
LMM Transmit Interval	: 1000	
LMM Measurement Interval	: 60	
Repetition Time	: 60	
LMM Size	: 0	
LMM Payload Data	: 0000	
Measurement Interval	Previous	Current
LMMs Transmitted	: 60	56
LMRs Received	: 60	56
Valid LMRs Received	: 60	56
Invalid LMRs Received	: 0	0
Out-of-order LMRs Received	: 0	0
Suspect Flag	: No	No
Frame Loss Near End	: 0	0
Frame Loss Far End	: 0	0
Frame Loss Ratio Near End	: 0.0000	0.0000
Frame Loss Ratio Far End	: 0.0000	0.0000
Min Frame Loss Ratio Near End	: 0.0000	0.0000
Min Frame Loss Ratio Far End	: 0.0000	0.0000
Max Frame Loss Ratio Near End	: 0.0000	0.0000
Max Frame Loss Ratio Far End	: 0.0000	0.0000
Max Consecutive Frame Loss	: 0	0

show frame-loss synthetic single-ended

Use the **show frame-loss synthetic single-ended** command to display statistics of synthetic single-ended frame loss monitoring sessions. Variations of this command include:

show frame-loss synthetic single-ended
show frame-loss synthetic single-ended <*session id*>
show frame-loss synthetic single-ended <*session id*> **realtime**

> *The output of all **show** commands can be limited by appending the following modifiers to the end of the command: | **begin** <text>, | **exclude** <text>, and | **include** <text>. The **include** modifier limits output to lines that contain the specified text, the **exclude** modifier excludes any lines with the specified text, and the **begin** modifier displays the first line of output with the specified text and all lines thereafter.*
>
> *For specific instructions and examples regarding these modifiers, refer to the introduction of the Enable Mode Command Set on page 94.*

> *Using the **realtime** argument for this command can adversely affect the performance or your unit.*

Syntax Description

<*session id*>	Optional. Specifies that results for a specific frame delay monitoring session are displayed. Valid range is **1** to **n**.
realtime	Optional. Displays full-screen output in realtime. Information is continuously updated on the console.

Default Values

No default values are necessary for this command.

Command History

Release R10.10.0	Command was introduced.
Release R11.6.0	Command output was expanded to include the **Start-Time**, **Stop-Time**, **Repetition-Time**, and **Suspect Flag** fields.

Usage Examples

The following example displays the statistics of synthetic frame loss monitoring for session **1**:

#application
(app)**#ethernet y1731 meg char-string MEG 3 1111**
(app-y1731 MEG)**#show frame-loss synthetic single-ended 1**
MEP 1111 Synthetic Single-Ended Frame Loss Results

Session 1 is Active

Session Type	: Proactive	
Target MAC	: 00:a0:c8:01:00:00	
VLAN Priority	: 4	
Start Time	: 12:06:46 UTC Thu Jan 01 1970	
Stop Time	: Forever	
SLM Transmit Interval	: 1000	
SLM Measurement Interval	: 60	
Repetition Time	: 60	
SLM Size	: 0	
SLM Payload Data	: 0000	
Measurement Interval	Previous	Current
SLMs Transmitted	: 60	56
SLRs Received	: 60	56
Valid SLRs Received	: 60	56
Invalid SLRs Received	: 0	0
Out-of-order SLRs Received	: 0	0
Suspect Flag	: No	No
Frame Loss Near End	: 0	0
Frame Loss Far End	: 0	0
Frame Loss Ratio Near End	: 0.0000	0.0000
Frame Loss Ratio Far End	: 0.0000	0.0000
Min Frame Loss Ratio Near End	: 0.0000	0.0000
Min Frame Loss Ratio Far End	: 0.0000	0.0000
Max Frame Loss Ratio Near End	: 0.0000	0.0000
Max Frame Loss Ratio Far End	: 0.0000	0.0000
Max Consecutive Frame Loss	: 0	0

show loopback multicast

Use the **show loopback multicast** command to display a detailed report of all remote Y.1731 maintenance entity group (MEG) endpoints (MEPs) that responded to the last issuance of the **loopback multicast** command (refer to *loopback on page 2008*).

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release R11.10.0	Command was introduced.

Functional Notes

The output of this command is reset with every new issuance of the **loopback multicast** command (refer to *loopback on page 2008*). Only eight responding remote devices are displayed in the output of the **show loopback multicast** command, regardless of how many remote devices are configured or have learned medium access control (MAC) addresses.

Usage Examples

The following example displays output from the **show loopback multicast** command:

```
#application
(app)#ethernet y1731 meg char-string MEG 3 100
(app-y1731 MEG)#show loopback multicast
```

MacAddress	RMEP ID	Success	Out Of Order	Data Mismatch	Out	Timed Incomplete
00:00:12:AB:12:12	416	60	0	0	0	0
00:A0:C8:01:ED:A5	3416	60	0	0	0	0

INTERFACE COMMAND SETS

The interface command sets are divided into the following sections:

LINE INTERFACE COMMAND SETS

This section includes the following command sets:

LINE (CONSOLE) INTERFACE COMMAND SET

To activate the Line (Console) Interface Configuration mode, enter the **line console 0** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#line console 0
(config-con 0)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

access-attempts on page 2022
accounting commands begin on page 2023
authorization commands begin on page 2026
databits <value> on page 2028
flowcontrol on page 2029
line-timeout <value> on page 2030
login on page 2031
login authentication <listname> on page 2032
login local-userlist on page 2033
parity on page 2034
password <password> on page 2035
speed <rate> on page 2036
stopbits <value> on page 2037

access-attempts

Use the **access-attempts** command to specify the number of failed access attempts allowed on the line console before the session is locked. Use the **no** form of this command to disable this feature. Variations of this command include:

access-attempts <*number*>
access-attempts <*number*> **lock-period** <*number*>

Syntax Description

<*number*>	Specifies the number of failed access attempts allowed before the session is locked. The session remains locked for the lock period. Valid range is **1** to **10** attempts; a value of **0** disables the feature.
lock-period <*number*>	Optional. Specifies the lock period. Valid range is **1** to **30** seconds, with a default value of **3** seconds.

Default Values

By default, this feature is disabled and multiple access attempts are allowed. When enabled, the default lock period is **3** seconds.

Command History

Release R11.10.2	Command was introduced.

Usage Examples

The following example specifies that **5** failed login attempts are allowed before the session is locked, and that the session remains locked for **10** seconds:

(config)**#line console 0**
(config-con 0)**#access-attempts 5 lock-period 10**

accounting commands <*level*> <*listname*>

Use the **accounting commands** command to assign authentication, authorization, and accounting (AAA) command accounting method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA command accounting method list from the interface. Variations of this command include:

accounting commands <*level*> **default**
accounting commands <*level*> <*listname*>

Syntax Description

<*level*>	Specifies whether the list applies to Level **1** (unprivileged) or Level **15** (privileged) commands.
default	Applies the default AAA command accounting method list to the interface.
<*listname*>	Applies the specified AAA command accounting method list to the interface.

Default Values

By default, no AAA command accounting method list is applied to the line interface.

Command History

Release 11.1	Command was introduced.

Functional Notes

AAA command accounting method lists are used to specify the types of information recorded when users access specified command levels. For more information about configuring command accounting lists, refer to the command *aaa accounting connection on page 1157*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA command accounting list **Accounting1** is applied to all Level **15** commands on all console lines:

(config)**#line console 0**
(config-con 0)**#accounting commands 15 Accounting1**

accounting connection <*listname*>

Use the **accounting connection** command to assign authentication, authorization, and accounting (AAA) connection accounting method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA connection accounting method list from the interface. Variations of this command include:

accounting connection default
accounting connection <*listname*>

Syntax Description

default	Applies the default AAA connection accounting method list to the interface.
<*listname*>	Applies the specified AAA connection accounting method list to the interface.

Default Values

By default, no AAA command accounting method list is applied to the line interface.

Command History

Release 13.1	Command was introduced.

Functional Notes

AAA connection accounting method lists are used to specify the types of information recorded about outbound connections made from the AOS unit. For more information about configuring connection accounting lists, refer to the command *aaa accounting connection on page 1157*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA connection accounting list **AcctConn1** is applied to all console lines:

(config)**#line console 0**
(config-con 0)**#accounting connection AcctConn1**

accounting exec <*listname*>

Use the **accounting exec** command to assign authentication, authorization, and accounting (AAA) executive accounting method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA executive accounting method list from the interface. Variations of this command include:

accounting exec default
accounting exec <*listname*>

Syntax Description

default	Applies the default AAA connection accounting method list to the interface.
<*listname*>	Applies the specified AAA connection accounting method list to the interface.

Default Values

By default, no AAA command accounting method list is applied to the line interface.

Command History

Release 13.1	Command was introduced.

Functional Notes

AAA executive accounting method lists are used to specify the types of information recorded about inbound connections made by connecting to the line interfaces and creating a terminal session. For more information about configuring executive accounting lists, refer to the command *aaa accounting exec on page 1160*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA executive accounting list **Inboundacct1** is applied to the console line:

(config)**#line console 0**
(config-con 0)**#accounting exec Inboundacct1**

authorization commands *<level> <listname>*

Use the **authorization commands** command to assign authentication, authorization, and accounting (AAA) command authorization method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA command authorization method list from the interface. Variations of this command include:

authorization commands *<level>* **default**
authorization commands *<level> <listname>*

Syntax Description

<level>	Specifies whether the list applies to Level **1** (unprivileged) or Level **15** (privileged) commands.
default	Applies the default AAA command authorization method list to the interface.
<listname>	Applies the specified AAA command authorization method list to the interface.

Default Values

By default, no AAA command authorization method list is applied to the line interface.

Command History

Release 11.1	Command was introduced.

Functional Notes

AAA command authorization method lists are used to allow or restrict the use of certain commands on a per-user basis. For more information about configuring command authorization lists, refer to the command *aaa authorization commands <level> on page 1176*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA command authorization list **Authorization1** is applied to the Level **15** commands on all console line:

(config)**#line console 0**
(config-con 0)**#authorization commands 15 Authorization1**

authorization exec <*listname*>

Use the **authorization exec** command to assign authentication, authorization, and accounting (AAA) Enable mode authorization method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA Enable mode authorization method list from the interface. Variations of this command include:

authorization exec default
authorization exec <*listname*>

Syntax Description

default	Applies the default AAA Enable mode authorization method list to the interface.
<*listname*>	Applies the specified AAA Enable mode authorization method list to the interface.

Default Values

By default, no AAA Enable mode authorization method list is applied to the line interface.

Command History

Release 13.1	Command was introduced.

Functional Notes

AAA Enable mode authorization method lists are used to allow or restrict user access to the privileged command line interface (CLI) mode (Enable mode). For more information about configuring Enable mode authorization lists, refer to the command *aaa authorization exec on page 1181*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA Enable mode authorization list **ExecList1** is applied to the console line:

(config)**#line console 0**
(config-con 0)**#authorization exec ExecList1**

databits *<value>*

Use the **databits** command to set the number of databits per character for a terminal session. This value must match the configuration of your VT100 terminal or terminal emulator software. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the data bits per character. Select from **7** or **8** databits per character.

Default Values

By default, the databits are set to **8**.

Command History

Release 1.1	Command was introduced.
Release R12.1.0	Command was made unavailable for virtual AOS (vAOS) instances.

Functional Notes

This command is not available for vAOS instances.

Usage Examples

The following example configures **7** databits per character for the console terminal session:

(config)**#line console 0**
(config-con 0)**#databits 7**

flowcontrol

Use the **flowcontrol** command to set flow control for the line console. Use the **no** form of this command to return to the default setting. Variations of this command include:

flowcontrol none
flowcontrol software in

Syntax Description

none	Specifies no flow control.
software in	Configures AOS to derive flow control from the attached device.

Default Values

By default, flow control is set to **none**.

Command History

Release 3.1	Command was introduced.
Release R12.1.0	Command was made unavailable for virtual AOS (vAOS) instances.

Functional Notes

This command is not available for vAOS instances.

Usage Examples

The following example configures no flow control for the line console:

(config)**#line console 0**
(config-con 0)**#flowcontrol none**

line-timeout <*value*>

Use the **line-timeout** command to specify the number of minutes a line session may remain inactive before AOS terminates the session. Use the **no** form of this command to return to the default value. Variations of this command include:

line-timeout <*value*>
line-timeout <*value*> **any-activity**

Syntax Description

<*value*>	Specifies the number of minutes a line session may remain inactive before AOS terminates the session. Valid range: **0** to **35791**. Entering a **line-timeout** value of 0 disables the feature.
any-activity	Optional. Specifies that the SSH session does not time out until the specified value when the client is receiving or sending information with the AOS device.

Default Values

By default, the **line-timeout** is set to **15** minutes.

Command History

Release 11.1	Command was introduced.
Release R11.10.2	Command was expanded to include the **any-activity** parameter.

Functional Notes

The session timer is typically reset if data is sent from the client to the AOS device, but not if data is sent from the AOS device to the client. The optional **any-activity** parameter of this command prevents the session from timing out when the client is in a passive mode (only receiving data from the AOS device).

Usage Examples

The following example specifies a timeout of **2** minutes for all console sessions:

(config)**#line console 0**
(config-con 0)**#line-timeout 2**

login

Use the **login** command to enable security login on the line session. Additionally, it is necessary to configure the password using the command *password <password> on page 2035*. Use the **no** form of this command to disable the login feature.

Syntax Description

No subcommands.

Default Values

By default, secure login is disabled.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example enables the security login feature and specifies a password (**mypassword**) on the available console session:

(config)**#line console 0**
(config-console 0)**#login**
(config-con 0)**#password mypassword**

login authentication <*listname*>

Use the **login authentication** command to apply the named authentication, authorization, and accounting (AAA) login method list to the line interface for authenticating users connecting to the interface. Use the **no** form of this command to remove the authentication method list from the interface.

Syntax Description

<*listname*>	Specifies the AAA login authentication method list to use for authentication.

Default Values

By default, no AAA login authentication method list is specified. If AAA is enabled (using the command *aaa on on page 1187*), but no login authentication method list is specified, the **default** login authentication method list is used. If the default list is used, but the default list has not been configured, console interfaces will automatically grant access (to prevent a lockout situation).

Command History

Release 5.1	Command was introduced.

Functional Notes

AAA login authentication method lists are used to verify user logins on the line interface. For more information about configuring login authentication method lists, refer to the command *aaa authentication login on page 1169*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the AAA login authentication method list **AuthList1** is applied to the console line:

```
(config)#line console 0
(config-con 0)#login authentication AuthList1
```

login local-userlist

Use the **login local-userlist** command to enable security login for the terminal session. It is required to configure user names and passwords using the **username/password** command from the Global Configuration mode (refer to *username <username> password <password> on page 1887*). Use the **no** form of this command to disable the login local-userlist feature.

*All user properties assigned using the **username/password** command are valid when using the **login local-userlist** command.*

Syntax Description

No subcommands.

Default Values

By default, there is no login password set to access the unit.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example displays creating a local userlist and enabling the security login feature on the **CONSOLE** port:

(config)**#username my_user password my_password**
(config)**#line console 0**
(config-con 0)**#login local-userlist**

When connecting to the unit, the following prompts are displayed:

User Access Login
Username: **Adtran**
Password:
Router#

parity

Use the **parity** command to specify the type of parity used as error correction. This value must match the configuration of your VT100 terminal or terminal emulator software. Use the **no** form of this command to return to the default value. Variations of this command include:

parity even
parity mark
parity none
parity odd
parity space

Syntax Description

even	Sets the parity bit to 0 if the number of 1 bits in the data sequence is odd, or set to 1 if the number of 1 bits is even.
mark	Always sets the parity bit to 1.
none	No parity bit used.
odd	Sets the parity bit to 1 if the number of 1 bits in the data sequence is even, or set to 1 if the number is odd.
space	Always sets the parity bit to 0.

Default Values

By default, the parity option is set to **none**.

Command History

Release 1.1	Command was introduced.
Release R12.1.0	Command was made unavailable for virtual AOS (vAOS) instances.

Functional Notes

Parity is the process used to detect whether characters have been altered during the data transmission process. Parity bits are appended to data frames to ensure that parity (whether it be odd or even) is maintained.

This command is not available for vAOS instances.

Usage Examples

The following example specifies **mark** parity for the console terminal session:

(config)**#line console 0**
(config-con 0)**#parity mark**

password *<password>*

Use the **password** command to configure the password (with optional encryption) required on the line session when security login is enabled (using the command *login on page 2031*). Use the **no** form of this command to remove a configured password. Variations of this command include:

password *<password>*
password md5 *<password>*

Syntax Description

<password>	Specifies the password for the line session using an alphanumeric character string (up to 16 characters).
md5	Specifies message digest 5 (MD5) as the encryption protocol to use when displaying the enable password during show commands. If the MD5 keyword is not used, encryption is not used when displaying the enable password during show commands.

Default Values

By default, there is no login password set for access to the unit.

Command History

Release 1.1	Command was introduced.
Release 6.1	Encryption was added.

Usage Examples

The following example enables the security login feature and specifies a password on the **CONSOLE** port:

(config)**#line console 0**
(config-con 0)**#login**
(config-con 0)**#password mypassword**

To provide extra security, AOS can encrypt the enable password when displaying the current configuration. For example, the following is a **show configuration** printout (password portion) with an unencrypted enable password (Adtran):

!
enable password Adtran
!

Alternately, the following is a **show configuration** printout (password portion) with an enable password of Adtran using md5 encryption:

!
enable password md5 encrypted 5aa5fbae7d01a90e79fb57705ce74676
!

speed *<rate>*

Use the **speed** command to specify the data rate for the **CONSOLE** port. This setting must match your VT100 terminal emulator or emulator software. Use the **no** form of this command to restore the default value.

Syntax Description

<rate>	Specifies rate of data transfer on the interface (2400; 4800; 9600; 19200; 38400; 57600; or 115200 bps).

Default Values

By default, the speed is set to **9600** bps.

Command History

Release 1.1	Command was introduced.
Release R12.1.0	Command was made unavailable for virtual AOS (vAOS) instances.

Functional Notes

This command is not available for vAOS instances.

Usage Examples

The following example configures the **CONSOLE** port for **19200** bps:

(config)**#line console 0**
(config-con 0)**#speed 19200**

stopbits *<value>*

Use the **stopbits** command to set the number of stopbits per character for a terminal session. This value must match the configuration of your VT100 terminal or terminal emulator software. The default is 1 stopbit per character. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the stopbits per character. Select from 1 or 2 stopbits per character.

Default Values

By default, the **stopbits** are set to **1**.

Command History

Release 1.1	Command was introduced.
Release R12.1.0	Command was made unavailable for virtual AOS (vAOS) instances.

Functional Notes

This command is not available for vAOS instances.

Usage Examples

The following example configures **2** stopbits per character for the console terminal session:

(config)**#line console 0**
(config-con 0)**#stopbits 2**

LINE (SSH) INTERFACE COMMAND SET

To activate the Line Secure Shell (SSH) Interface Configuration mode, enter the **line ssh** command specifying a SSH session(s) at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#line ssh 0 4
(config-ssh0-4)#
```

You can select a single line by entering the **line ssh** command followed by the line number (0-4). For example:

```
>enable
#configure terminal
(config)#line ssh 2
(config-ssh2)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

accounting commands begin on page 2039
authorization commands begin on page 2042
ip access-class <ipv4 acl name> in on page 2044
ip access-policy <ipv4 acp name> on page 2046
ipv6 access-class <ipv6 acl name> in on page 2048
line-timeout <value> on page 2050
login on page 2051
login authentication <listname> on page 2052
login local-userlist on page 2053

accounting commands <*level*> <*listname*>

Use the **accounting commands** command to assign authentication, authorization, and accounting (AAA) command accounting method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA command accounting method list from the interface. Variations of this command include:

accounting commands <*level*> **default**
accounting commands <*level*> <*listname*>

Syntax Description

<*level*>	Specifies whether the list applies to Level **1** (unprivileged) or Level **15** (privileged) commands.
default	Applies the default AAA command accounting method list to the interface.
<*listname*>	Applies the specified AAA command accounting method list to the interface.

Default Values

By default, no AAA command accounting method list is applied to the line interface.

Command History

Release 11.1	Command was introduced.

Functional Notes

AAA command accounting method lists are used to specify the types of information recorded when users access specified command levels. For more information about configuring command accounting lists, refer to the command *aaa accounting connection on page 1157*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA command accounting list **Accounting1** is applied to all Level **15** commands on all secure shell (SSH) lines:

(config)**#line ssh 0 4**
(config-ssh0-4)**#accounting commands 15 Accounting1**

accounting connection <*listname*>

Use the **accounting connection** command to assign authentication, authorization, and accounting (AAA) connection accounting method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA connection accounting method list from the interface. Variations of this command include:

accounting connection default
accounting connection <*listname*>

Syntax Description

default	Applies the default AAA connection accounting method list to the interface.
<*listname*>	Applies the specified AAA connection accounting method list to the interface.

Default Values

By default, no AAA command accounting method list is applied to the line interface.

Command History

Release 13.1	Command was introduced.

Functional Notes

AAA connection accounting method lists are used to specify the types of information recorded about outbound connections made from the AOS unit. For more information about configuring connection accounting lists, refer to the command *aaa accounting connection on page 1157*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA connection accounting list **AcctConn1** is applied to all secure shell (SSH) lines:

(config)**#line ssh 0 4**
(config-ssh0-4)**#accounting connection AcctConn1**

accounting exec <*listname*>

Use the **accounting exec** command to assign authentication, authorization, and accounting (AAA) executive accounting method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA executive accounting method list from the interface. Variations of this command include:

accounting exec default
accounting exec <*listname*>

Syntax Description

default	Applies the default AAA connection accounting method list to the interface.
<*listname*>	Applies the specified AAA connection accounting method list to the interface.

Default Values

By default, no AAA command accounting method list is applied to the line interface.

Command History

Release 13.1	Command was introduced.

Functional Notes

AAA executive accounting method lists are used to specify the types of information recorded about inbound connections made by connecting to the line interfaces and creating a terminal session. For more information about configuring executive accounting lists, refer to the command *aaa accounting exec on page 1160*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA executive accounting list **Inboundacct1** is applied to all secure shell (SSH) lines:

(config)**#line ssh 0 4**
(config-ssh0-4)**#accounting exec Inboundacct1**

authorization commands *<level> <listname>*

Use the **authorization commands** command to assign authentication, authorization, and accounting (AAA) command authorization method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA command authorization method list from the interface. Variations of this command include:

authorization commands *<level>* **default**
authorization commands *<level> <listname>*

Syntax Description

<level>	Specifies whether the list applies to Level **1** (unprivileged) or Level **15** (privileged) commands.
default	Applies the default AAA command authorization method list to the interface.
<listname>	Applies the specified AAA command authorization method list to the interface.

Default Values

By default, no AAA command authorization method list is applied to the line interface.

Command History

Release 11.1	Command was introduced.

Functional Notes

AAA command authorization method lists are used to allow or restrict the use of certain commands on a per-user basis. For more information about configuring command authorization lists, refer to the command *aaa authorization commands <level> on page 1176*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA command authorization list **Authorization1** is applied to all Level **15** commands on all secure shell (SSH) lines:

(config)**#line ssh 0 4**
(config-ssh0-4)**#authorization commands 15 Authorization1**

authorization exec *<listname>*

Use the **authorization exec** command to assign authentication, authorization, and accounting (AAA) Enable mode authorization method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA Enable mode authorization method list from the interface. Variations of this command include:

authorization exec default
authorization exec *<listname>*

Syntax Description

default	Applies the default AAA Enable mode authorization method list to the interface.
<listname>	Applies the specified AAA Enable mode authorization method list to the interface.

Default Values

By default, no AAA Enable mode authorization method list is applied to the line interface.

Command History

Release 13.1	Command was introduced.

Functional Notes

AAA Enable mode authorization method lists are used to allow or restrict user access to the privileged command line interface (CLI) mode (Enable mode). For more information about configuring Enable mode authorization lists, refer to the command *aaa authorization exec on page 1181*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA Enable mode authorization list **ExecList1** is applied to all secure shell (SSH) lines:

(config)**#line ssh 0 4**
(config-ssh0-4)**#authorization exec ExecList1**

ip access-class <*ipv4 acl name*> in

Use the **ip access-class in** command to restrict Internet Protocol version 4 (IPv4) secure shell (SSH) access using a configured access control list (ACL). Received IPv4 packets passed by the ACL will be allowed. Use the ACL configuration to deny hosts or entire networks or to permit specified IPv4 addresses. Use the **no** form of this command to disable this feature. Refer to *ip access-list standard <ipv4 acl name> on page 1346* and *ip access-list extended <ipv4 acl name> on page 1344* for more information about configuring ACLs. Variations of this command include:

ip access-class <*ipv4 acl name*> **in**
ip access-class <*ipv4 acl name*> **in any-vrf**
ip access-class <*ipv4 acl name*> **in vrf** <*name*>

Syntax Description

<*ipv4 acl name*>	Identifies the configured IPv4 ACL using an alphanumeric descriptor (all ACL descriptors are case sensitive).
any-vrf	Optional. Allows incoming connections from any virtual routing and forwarding (VRF) instance based on the parameters set in the ACL. Without this keyword, the ACL only applies to the default VRF and all SSH connections on nondefault VRFs will be ignored.
vrf <*name*>	Optional. Allows incoming connections from a specified VRF instance based on the parameters set in the access class list.

Default Values

By default, there are no configured IPv4 ACLs associated with SSH sessions.

Command History

Release 11.1	Command was introduced.
Release 16.1	Command was expanded to include the **any-vrf** parameter.
Release 18.2	Command was changed to include the **ip** parameter to accommodate Internet Protocol version 6 (IPv6) support for Adtran internetworking products only.
Release R10.1.0	Command was changed to include the **ip** parameter to accommodate Internet Protocol version 6 (IPv6) support for Adtran voice products.
Release R10.2.0	Command was expanded to include the **vrf** <*name*> parameter.

Functional Notes

When using the **ip access-class in** command to associate an ACL with an SSH session, remember to duplicate the **ip access-class in** command for all configured SSH sessions 0 through 4. SSH access to the unit using a specific SSH session is not possible. Users will be assigned the first available SSH session.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example associates the IPv4 ACL **Trusted** (to allow SSH sessions from the 192.22.56.0 /24 network) with all SSH sessions (0 through 4) on all VRF instances:

Create the IPv4 ACL:

(config)**#ip access-list standard Trusted**
(config)**#permit 192.22.56.0 0.0.0.255**

Enter the line (SSH):

(config)**#line ssh 0 4**

Associate the ACL with the SSH session:

(config-ssh0-4)**#ip access-class Trusted in any-vrf**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to an interface. IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

> NOTE *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an interface.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the Ethernet interface 0/1:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the interface:

(config)**#line ssh 0 4**
(config-ssh0-4)**#ip access-policy PRIVATE**

ipv6 access-class <*ipv6 acl name*> in

Use the **ipv6 access-class in** command to restrict Internet Protocol version 6 (IPv6) secure shell (SSH) access using a configured access control list (ACL). Received IPv6 packets passed by the ACL will be allowed. Use the ACL configuration to deny hosts or entire networks or to permit specified IPv4 addresses. Use the **no** form of this command to disable this feature. Refer to *ipv6 access-list standard <ipv6 acl name> on page 1502* and *ipv6 access-list extended <ipv6 acl name> on page 1500* for more information about configuring ACLs. Variations of this command include:

ipv6 access-class <*ipv6 acl name*> **in**
ipv6 access-class <*ipv6 acl name*> **in any-vrf**
ipv6 access-class <*ipv6 acl name*> **in vrf** <*name*>

Syntax Description

<*ipv6 acl name*>	Identifies the configured IPv6 ACL using an alphanumeric descriptor (all ACL descriptors are case sensitive).
any-vrf	Optional. Allows incoming connections from any virtual routing and forwarding (VRF) instance based on the parameters set in the ACL. Without this keyword, the ACL only applies to the default VRF and all SSH connections on nondefault VRFs will be ignored.
vrf <*name*>	Optional. Allows incoming connections from a specified VRF instance based on the parameters set in the access class list.

Default Values

By default, there are no configured ACLs associated with SSH sessions.

Command History

Release 18.2	Command was introduced.
Release R10.2.0	Command was expanded to include the **vrf** <*name*> parameter.

Functional Notes

When using the **ipv6 access-class in** command to associate an ACL with an SSH session, remember to duplicate the **ipv6 access-class in** command for all configured SSH sessions 0 through 4. SSH access to the unit using a specific SSH session is not possible. Users will be assigned the first available SSH session.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example associates the IPv6 ACL **Trustedv6** (to allow SSH sessions from the **2001:DB8:3F::/64** network) with all SSH sessions (0 through 4) on all VRF instances:

Create the IPv6 ACL:

(config)**#ipv6 access-list extended Trustedv6**
(config-ext6-nacl)**#permit ipv6 2001:DB8:3F::/64 any**

Enter the line (SSH):

(config)**#line ssh 0 4**

Associate the ACL with the SSH session:

(config-ssh0-4)**#ipv6 access-class Trustedv6 in any-vrf**

line-timeout <*value*>

Use the **line-timeout** command to specify the number of minutes a line session may remain inactive before AOS terminates the session. Use the **no** form of this command to return to the default value. Variations of this command include:

line-timeout <*value*>
line-timeout <*value*> **any-activity**

Syntax Description

<*value*>	Specifies the number of minutes a line session may remain inactive before AOS terminates the session. Valid range: **0** to **35791**. Entering a **line-timeout** value of 0 disables the feature.
any-activity	Optional. Specifies that the SSH session does not time out until the specified value when the client is receiving or sending information with the AOS device.

Default Values

By default, the **line-timeout** is set to **15** minutes.

Command History

Release 11.1	Command was introduced.
Release R11.10.2	Command was expanded to include the **any-activity** parameter.

Functional Notes

The session timer is typically reset if data is sent from the client to the AOS device, but not if data is sent from the AOS device to the client. The optional **any-activity** parameter of this command prevents the session from timing out when the client is in a passive mode (only receiving data from the AOS device).

Usage Examples

The following example specifies a timeout of **2** minutes for all secure shell (SSH) sessions:

(config)**#line ssh 0 4**
(config-ssh0-4)**#line-timeout 2**

login

Use the **login** command to enable security login on the line session requiring the password configured using the **password** command. Use the **no** form of this command to disable the login feature.

Syntax Description

No subcommands.

Default Values

By default, secure login is disabled.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example enables the security login feature and specifies a password (**mypassword**) on all the available secure shell (SSH) sessions (0 through 4):

(config)**#line ssh 0 4**
(config-ssh0-4)**#login**
(config-ssh0-4)**#password mypassword**

login authentication <*listname*>

Use the **login authentication** command to apply the named authentication, authorization, and accounting (AAA) login method list to the line interface for authenticating users connecting to the interface. Use the **no** form of this command to remove the authentication method list from the interface.

Syntax Description

<*listname*>	Specifies the AAA login authentication method list to use for authentication.

Default Values

By default, no AAA login authentication method list is specified. If AAA is enabled (using the command *aaa on on page 1187*), but no login authentication method list is specified, the **default** login authentication method list is used. If the default list is used, but the default list has not been configured, secure shell (SSH) interfaces use the local user database for authentication.

Command History

Release 5.1	Command was introduced.

Functional Notes

AAA login authentication method lists are used to verify user logins on the line interface. For more information about configuring login authentication method lists, refer to the command *aaa authentication login on page 1169*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the AAA login authentication method list **AuthList1** is applied to all SSH lines:

(config)**#line ssh 0 4**
(config-ssh0-4)**#login authentication AuthList1**

login local-userlist

Use the **login local-userlist** command to check the local list of user names and passwords configured using the **username/password** Global Configuration command (refer to *username <username> password <password> on page 1887*).

> NOTE *All user properties assigned using the **username/password** command are valid when using the **login local-userlist** command.*

Syntax Description

No subcommands.

Default Values

By default, there is no login password set for access to the unit.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example creates a local userlist and enables the security login feature:

(config)**#username my_user password my_password**
(config)**#line ssh 0**
(config-ssh0)**#login local-userlist**

When connecting to the unit, the following prompts are displayed:

User Access Login
Username: **my_user**
Password:
#

LINE (TELNET) INTERFACE COMMAND SET

To activate the Line (Telnet) Interface Configuration mode, enter the **line telnet** command specifying a Telnet session(s) at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#line telnet 0 4
(config-telnet0-4)#
```

You can select a single line by entering the **line telnet** command followed by the line number (0-4). For example:

```
>enable
#configure terminal
(config)#line telnet 2
(config-telnet2)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

accounting commands begin on page 2055
authorization commands begin on page 2058
ip access-class <ipv4 acl name> in on page 2060
ip access-policy <ipv4 acp name> on page 2062
ipv6 access-class <ipv6 acl name> in on page 2064
line-timeout <value> on page 2066
login on page 2067
login authentication <listname> on page 2068
login local-userlist on page 2069
password <password> on page 2070

accounting commands <*level*> <*listname*>

Use the **accounting commands** command to assign authentication, authorization, and accounting (AAA) command accounting method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA command accounting method list from the interface. Variations of this command include:

accounting commands <*level*> **default**
accounting commands <*level*> <*listname*>

Syntax Description

<*level*>	Specifies whether the list applies to Level **1** (unprivileged) or Level **15** (privileged) commands.
default	Applies the default AAA command accounting method list to the interface.
<*listname*>	Applies the specified AAA command accounting method list to the interface.

Default Values

By default, no AAA command accounting method list is applied to the line interface.

Command History

Release 11.1	Command was introduced.

Functional Notes

AAA command accounting method lists are used to specify the types of information recorded when users access specified command levels. For more information about configuring command accounting lists, refer to the command *aaa accounting connection on page 1157*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA command accounting list **Accounting1** is applied to all Level **15** commands on all Telnet lines:

(config)**#line telnet 0 4**
(config-telnet0-4)**#accounting commands 15 Accounting1**

accounting connection <*listname*>

Use the **accounting connection** command to assign authentication, authorization, and accounting (AAA) connection accounting method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA connection accounting method list from the interface. Variations of this command include:

accounting connection default
accounting connection <*listname*>

Syntax Description

default	Applies the default AAA connection accounting method list to the interface.
<*listname*>	Applies the specified AAA connection accounting method list to the interface.

Default Values

By default, no AAA command accounting method list is applied to the line interface.

Command History

Release 13.1	Command was introduced.

Functional Notes

AAA connection accounting method lists are used to specify the types of information recorded about outbound connections made from the AOS unit. For more information about configuring connection accounting lists, refer to the command *aaa accounting connection on page 1157*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA connection accounting list **AcctConn1** is applied to all Telnet lines:

(config)**#line telnet 0 4**
(config-telnet0-4)**#accounting connection AcctConn1**

accounting exec <*listname*>

Use the **accounting exec** command to assign authentication, authorization, and accounting (AAA) executive accounting method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA executive accounting method list from the interface. Variations of this command include:

accounting exec default
accounting exec <*listname*>

Syntax Description

default	Applies the default AAA connection accounting method list to the interface.
<*listname*>	Applies the specified AAA connection accounting method list to the interface.

Default Values

By default, no AAA command accounting method list is applied to the line interface.

Command History

Release 13.1	Command was introduced.

Functional Notes

AAA executive accounting method lists are used to specify the types of information recorded about inbound connections made by connecting to the line interfaces and creating a terminal session. For more information about configuring executive accounting lists, refer to the command *aaa accounting exec on page 1160*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA executive accounting list **Inboundacct1** is applied to all Telnet lines:

(config)**#line telnet 0 4**
(config-telnet0-4)**#accounting exec Inboundacct1**

authorization commands *<level> <listname>*

Use the **authorization commands** command to assign authentication, authorization, and accounting (AAA) command authorization method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA command authorization method list from the interface. Variations of this command include:

authorization commands *<level>* **default**
authorization commands *<level> <listname>*

Syntax Description

<level>	Specifies whether the list applies to Level **1** (unprivileged) or Level **15** (privileged) commands.
default	Applies the default AAA command authorization method list to the interface.
<listname>	Applies the specified AAA command authorization method list to the interface.

Default Values

By default, no AAA command authorization method list is applied to the line interface.

Command History

Release 11.1	Command was introduced.

Functional Notes

AAA command authorization method lists are used to allow or restrict the use of certain commands on a per-user basis. For more information about configuring command authorization lists, refer to the command *aaa authorization commands <level> on page 1176*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA command authorization list **Authorization1** is applied to all Level **15** commands on all Telnet lines:

(config)**#line telnet 0 4**
(config-telnet0-4)**#authorization commands 15 Authorization1**

authorization exec <*listname*>

Use the **authorization exec** command to assign authentication, authorization, and accounting (AAA) Enable mode authorization method lists to line interfaces. You must first turn AAA on for this command to become available (using the command *aaa on on page 1187*). Use the **no** form of this command to remove the AAA Enable mode authorization method list from the interface. Variations of this command include:

authorization exec default
authorization exec <*listname*>

Syntax Description

default	Applies the default AAA Enable mode authorization method list to the interface.
<*listname*>	Applies the specified AAA Enable mode authorization method list to the interface.

Default Values

By default, no AAA Enable mode authorization method list is applied to the line interface.

Command History

Release 13.1	Command was introduced.

Functional Notes

AAA Enable mode authorization method lists are used to allow or restrict user access to the privileged command line interface (CLI) mode (Enable mode). For more information about configuring Enable mode authorization lists, refer to the command *aaa authorization exec on page 1181*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that AAA Enable mode authorization list **ExecList1** is applied to all Telnet lines:

(config)**#line telnet 0 4**
(config-telnet0-4)**#authorization exec ExecList1**

ip access-class *<ipv4 acl name>* in

Use the **ip access-class in** command to restrict Internet Protocol version 4 (IPv4) telnet access using a configured access control list (ACL). Received IPv4 packets passed by the ACL will be allowed. Use the ACL configuration to deny hosts or entire networks or to permit specified IPv4 addresses. Use the **no** form of this command to disable this feature. Refer to *ip access-list standard <ipv4 acl name> on page 1346* and *ip access-list extended <ipv4 acl name> on page 1344* for more information about configuring ACLs. Variations of this command include:

ip access-class *<ipv4 acl name>* **in**
ip access-class *<ipv4 acl name>* **in any-vrf**
ip access-class *<ipv4 acl name>* **in vrf** *<name>*

Syntax Description

<ipv4 acl name>	Identifies the configured IPv4 ACL using an alphanumeric descriptor (all ACL descriptors are case sensitive).
any-vrf	Optional. Allows incoming connections from any virtual routing and forwarding (VRF) instance based on the parameters set in the ACL. Without this keyword, the ACL only applies to the default VRF and all telnet connections on nondefault VRFs will be ignored.
vrf *<name>*	Optional. Allows incoming connections from a specified VRF instance based on the parameters set in the access class list.

Default Values

By default, there are no configured IPv4 ACLs associated with telnet sessions.

Command History

Release 11.1	Command was introduced.
Release 16.1	Command was expanded to include the **any-vrf** parameter.
Release 18.2	Command was changed to include the **ip** parameter to accommodate Internet Protocol version 6 (IPv6) support for Adtran internetworking products only.
Release R10.1.0	Command was changed to include the **ip** parameter to accommodate Internet Protocol version 6 (IPv6) support for Adtran voice products.
Release R10.2.0	Command was expanded to include the **vrf** *<name>* parameter.

Functional Notes

When using the **ip access-class in** command to associate an ACL with a telnet session, remember to duplicate the **ip access-class in** command for all configured telnet sessions 0 through 4. Telnet access to the unit using a specific telnet session is not possible. Users will be assigned the first available telnet session.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example associates the IPv4 ACL **Trusted** (to allow telnet nsessions from the 192.22.56.0 /24 network) with all telnet sessions (0 through 4) on all VRF instances:

Create the IPv4 ACL:

(config)**#ip access-list standard Trusted**
(config)**#permit 192.22.56.0 0.0.0.255**

Enter the line (Telnet):

(config)**#line telnet 0 4**

Associate the ACL with the SSH session:

(config-telnet0-4)**#ip access-class Trusted in any-vrf**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to an interface. IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

> NOTE *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an interface.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the Ethernet interface 0/1:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the interface:

(config)**#line telnet 0 4**
(config-telnet0-4)**#ip access-policy PRIVATE**

ipv6 access-class *<ipv6 acl name>* in

Use the **ipv6 access-class in** command to restrict Internet Protocol version 6 (IPv6) telnet access using a configured access control list (ACL). Received IPv6 packets passed by the ACL will be allowed. Use the ACL configuration to deny hosts or entire networks or to permit specified IPv4 addresses. Use the **no** form of this command to disable this feature. Refer to *ipv6 access-list standard <ipv6 acl name> on page 1502* and *ipv6 access-list extended <ipv6 acl name> on page 1500* for more information about configuring ACLs. Variations of this command include:

ipv6 access-class *<ipv6 acl name>* **in**
ipv6 access-class *<ipv6 acl name>* **in any-vrf**
ipv6 access-class *<ipv6 acl name>* **in vrf** *<name>*

Syntax Description

<ipv6 acl name>	Identifies the configured IPv6 ACL using an alphanumeric descriptor (all ACL descriptors are case sensitive).
any-vrf	Optional. Allows incoming connections from any virtual routing and forwarding (VRF) instance based on the parameters set in the ACL. Without this keyword, the ACL only applies to the default VRF and all telnet connections on nondefault VRFs will be ignored.
vrf *<name>*	Optional. Allows incoming connections from a specified VRF instance based on the parameters set in the access class list.

Default Values

By default, there are no configured ACLs associated with telnet sessions.

Command History

Release 18.2	Command was introduced.
Release R10.2.0	Command was expanded to include the **vrf** *<name>* parameter.

Functional Notes

When using the **ipv6 access-class in** command to associate an ACL with a telnet session, remember to duplicate the **ipv6 access-class in** command for all configured telnet sessions 0 through 4. Telnet access to the unit using a specific SSH session is not possible. Users will be assigned the first available telnet session.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example associates the IPv6 ACL **Trustedv6** (to allow telnet sessions from the **2001:DB8:3F::/64** network) with all telnet sessions (0 through 4) on all VRF instances:

Create the IPv6 ACL:

(config)**#ipv6 access-list extended Trustedv6**
(config-ext6-nacl)**#permit ipv6 2001:DB8:3F::/64 any**

Enter the line (telnet):

(config)**#line telnet 0 4**

Associate the ACL with the telnet session:

(config-telnet0-4)**#ipv6 access-class Trustedv6 in any-vrf**

line-timeout <*value*>

Use the **line-timeout** command to specify the number of minutes a line session may remain inactive before AOS terminates the session. Use the **no** form of this command to return to the default value. Variations of this command include:

line-timeout <*value*>
line-timeout <*value*> **any-activity**

Syntax Description

<*value*>	Specifies the number of minutes a line session may remain inactive before AOS terminates the session. Valid range: **0** to **35791**. Entering a **line-timeout** value of 0 disables the feature.
any-activity	Optional. Specifies that the SSH session does not time out until the specified value when the client is receiving or sending information with the AOS device.

Default Values

By default, the **line-timeout** is set to **15** minutes.

Command History

Release 11.1	Command was introduced.
Release R11.10.2	Command was expanded to include the **any-activity** parameter.

Functional Notes

The session timer is typically reset if data is sent from the client to the AOS device, but not if data is sent from the AOS device to the client. The optional **any-activity** parameter of this command prevents the session from timing out when the client is in a passive mode (only receiving data from the AOS device).

Usage Examples

The following example specifies a timeout of **2** minutes for all telnet sessions:

(config)**#line telnet 0**
(config-telnet0)**#line-timeout 2**

login

Use the **login** command to enable security login on the line session requiring the password configured using the **password** command. Use the **no** form of this command to disable the login feature.

Syntax Description

No subcommands.

Default Values

By default, secure login is disabled.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example enables the security login feature and specifies a password on all the available Telnet sessions (0 through 4):

(config)**#line telnet 0 4**
(config-telnet0-4)**#login**
(config-telnet0-4)**#password mypassword**

login authentication <*listname*>

Use the **login authentication** command to apply the named authentication, authorization, and accounting (AAA) login method list to the line interface for authenticating users connecting to the interface. Use the **no** form of this command to remove the authentication method list from the interface.

Syntax Description

<*listname*>	Specifies the AAA login authentication method list to use for authentication.

Default Values

By default, no AAA login authentication method list is specified. If AAA is enabled (using the command *aaa on on page 1187*), but no login authentication method list is specified, the **default** login authentication method list is used. If the default list is used, but the default list has not been configured, Telnet interfaces use the local user database for authentication.

Command History

Release 5.1	Command was introduced.

Functional Notes

AAA login authentication method lists are used to verify user logins on the line interface. For more information about configuring login authentication method lists, refer to the command *aaa authentication login on page 1169*.

For more information about configuring AAA on your network, refer to the configuration guide *Configuring AAA in AOS* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the AAA login authentication method list **AuthList1** is applied to all Telnet lines:

(config)**#line telnet 0 4**
(config-telnet0-4)**#login authentication AuthList1**

login local-userlist

Use the **login local-userlist** command to enable security login for the terminal session requiring the user names and passwords configured using the **username/password** Global Configuration command. Use the **no** form of this command to disable the login local-userlist feature.

*All user properties assigned using the **username/password** command are valid when using the **login local-userlist** command.*

Syntax Description

No subcommands.

Default Values

By default, there is no login password set for access to the unit.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example displays creating a local userlist and enabling the security login feature:

(config)**#username my_user password my_password**
(config)**#line telnet 0**
(config-telnet0)**#login local-userlist**

When connecting to the unit, the following prompts are displayed:

User Access Login
Username: **my_user**
Password:
Router#

password *<password>*

Use the **password** command to configure the password (with optional encryption) required on the line session when security login is enabled (using the **login** command). Use the **no** form of this command to remove a configured password. Variations of this command include:

password *<password>*
password md5 *<password>*

Syntax Description

<password>	Specifies the password for the line session using an alphanumeric character string (up to 16 characters).
md5	Optional. Specifies message digest 5 (MD5) as the encryption protocol to use when displaying the enable password during show commands. If the MD5 keyword is not used, encryption is not used when displaying the enable password during show commands.

Default Values

By default, there is no login password set for access to the unit.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example enables the security login feature and specifies a password for the Telnet session 0:

(config)**#line telnet 0**
(config-telnet0)**#login**
(config-telnet0)**#password mypassword**

To provide extra security, AOS can encrypt the enable password when displaying the current configuration. For example, the following is a **show configuration** printout (password portion) with an unencrypted enable password (Adtran):

!
enable password Adtran
!

Alternately, the following is a **show configuration** printout (password portion) with an enable password of Adtran using md5 encryption:

!
enable password md5 encrypted 5aa5fbae7d01a90e79fb57705ce74676
!

PHYSICAL INTERFACE COMMAND SETS

This section includes the following command sets:

ADSL INTERFACE COMMAND SET

To activate the ADSL Interface Configuration mode, enter the **interface adsl** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface adsl 0/1
(config-adsl 0/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

interop-flag on page 2073
phy-flag on page 2074
retrain on page 2075
snr-margin on page 2076
training-mode on page 2077

interop-flag

This command is for future configuration and should not be modified.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release A4.05	Command was introduced.

phy-flag

This command is for future configuration and should not be modified.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release A4.05	Command was introduced.

retrain

Use the **retrain** command to force the modem to retrain.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example forces a modem retrain:

(config)**#interface adsl 0/1**
(config-adsl 0/1)**#retrain**

snr-margin

Use the **snr-margin** command to enable monitoring and set the minimum signal-to-noise ratio (SNR) during training and showtime. Use the **no** form of this command to disable monitoring. Variations of this command include:

snr-margin <*margin*>
snr-margin showtime monitor
snr-margin training monitor

Syntax Description

<*margin*>	Sets the minimum SNR margin value in dB. The range is from **1** to **15** dB.
showtime monitor	Enables margin monitoring to retrain the asymmetric digital subscriber line (ADSL) interface if the specified minimum margin is violated during showtime.
training monitor	Enables margin monitoring to retrain the ADSL interface if the specified minimum margin is violated during training.

Default Values

By default, SNR margin monitoring is disabled.

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example enables SNR margin monitoring during showtime with a minimum level of **7** dB:

(config)**#interface adsl 0/1**
(config-adsl 0/1)**#snr-margin showtime monitor 7**

training-mode

Use the **training-mode** command to configure the asymmetric digital subscriber line (ADSL) training mode. Use the **no** form of this command to disable a specific training mode. Variations of this command include:

training-mode ADSL2
training-mode ADSL2+
training-mode ADSL2+ANNEX-M
training-mode G.DMT
training-mode G.LITE
training-mode Multi-Mode
training-mode Multi-Mode-no-T1413
training-mode READSL2
training-mode T1.413

Syntax Description

ADSL2	Specifies International Telecommunication Union (ITU) G.992.3 mode.
ADSL2+	Specifies ITU G.992.5 mode.
ADSL2+ANNEX-M	Specifies ITU G.992.5 Annex M mode.
G.DMT	Specifies ANSI full-rate mode.
G.LITE	Specifies ANSI splitterless mode.
Multi-Mode	Specifies auto detect mode. When set to multi-mode, the ADSL interface attempts to train to the DSLAM using each of the supported training modes until a match is found.
Multi-Mode-no-T1413	Specifies auto detect mode without ANSI T1.413 capability.
READSL2	Specifies ITU G.992.3 Annex L mode.
T1.413	Specifies ANSI T1.413 mode.

Default Values

By default, the training mode is set to **Multi-Mode**.

Command History

Release 8.1	Command was introduced.
Release 13.1	Command was expanded to include the ITU G.992.5 Annex M mode.
Release A4.05	Command was expanded to include the **Multi-Mode-no-T1413** parameter.

Functional Notes

Some of the listed training modes (G.LITE, T1.413, ADSL2, ADSL2+, READSL2) are currently supported for ADSL over plain old telephone service (POTS) (Annex A) and are not valid for ADSL over integrated services digital network (ISDN) (Annex B) modules.

Usage Examples

The following example sets the training mode to **T1.413**:

(config)**#interface adsl 0/1**
(config-adsl 0/1)**#training-mode T1.413**

BRI INTERFACE COMMAND SET

To activate the BRI Interface Configuration mode, enter the **interface bri** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface bri 1/2
(config-bri 1/2)#
```

*The BRI number in the example above is shown as **bri 1/2**. This number is based on the interface's location (slot/port) and could vary depending on the unit's configuration. Use the **do show interfaces** command to determine the appropriate interface number.*

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

All other commands for this command set are described in this section in alphabetical order.

caller-id-override

Use the **caller-id-override** command to configure the unit to replace caller ID information with a user-specified number. Use the **no** form of this command to disable any caller ID overrides. Variations of this command include:

caller-id-override always <*number*>
caller-id-override if-no-cid <*number*>

Syntax Description

always <*number*>	Always forces replacement of the incoming caller ID number with the number given.
if-no-cid <*number*>	Replaces the incoming caller ID number with the number given only if there is no caller ID information available for the incoming call.

Default Values

By default, this command is disabled.

Command History

Release 6.1	Command was introduced.

Functional Notes

This command forces a replacement of the incoming caller ID number with the number given. The received caller ID, if any, is discarded, and the given override number is used to connect the incoming call to a circuit of the same number.

Usage Examples

The following example configures the unit to always provide the given number as the caller ID number:

(config)**#interface bri 1/2**
(config-bri 1/2)**#caller-id-override always 5551000**

calling-party

Use the **calling-party** command to configure and control the basic rate interface (BRI) outgoing caller ID information. Use the **no** form of this command to disable this feature. Variations of this command include:

calling-party name <*name*>
calling-party number <*number*>
calling-party override always
calling-party override if-no-CID
calling-party presentation allowed
calling-party presentation not-available
calling-party presentation restricted
calling-party screening auto
calling-party screening network-provided

Syntax Description

name <*name*>	Configures the calling party name for the BRI.
number <*number*>	Configures the calling party number for the BRI.
override always	Enables the calling party to be replaced with the override number.
override if-no-CID	Enables the calling party to be replaced if caller ID number is not received.
presentation allowed	Enables the presentation of caller ID to always be allowed.
presentation not-available	Sets the calling party number to not available.
presentation restricted	Restricts the delivery on the caller ID information.
screening auto	Specifies that the calling party screening indicator is automatically determined.
screening network-provided	Specifies that the calling party screening indicator is provided by the network.

Default Values

By default, the command is disabled and the calling party screening indicator is set to **auto**.

Command History

Release 11.1	Command was introduced.
Release R10.5.0	Command was added to the BRI and the **screening auto** and **screening network-provided** parameters were added.

Usage Examples

The following example configures the calling party outgoing information to always provide the given number and name:

(config)**#interface bri 1/2**
(config-bri 1/2)**#calling-party override always**
(config-bri 1/2)**#calling-party presentation 555-8000**
(config-bri 1/2)**#calling-party name Company, Inc.**

clock source

Use the **clock source** command to configure the source timing used for the interface. Use the **no** form of this command to return to the default value. Variations of this command include:

clock source line
clock source system

Syntax Description

line	Configures the unit to recover clocking from the basic rate interface (BRI) circuit.
system	Configures the unit to provide clocking using the system clock.

Default Values

By default, the clock source is set to **system**.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example configures the unit to recover clocking from the circuit:

(config)**#interface bri 1/2**
(config-bri 1/2)**#clock source line**

isdn activation-timer <*value*>

Use the **isdn activation-timer** command to set the integrated services digital network (ISDN) T3 activation timer setting for the basic rate interface (BRI). This value is based upon the International Telecommunication Union Telecommunication Standardization Sector (ITU-T) recommendation 1.430. Use the **no** form of this command to return the timer to the default value.

Syntax Description

<*value*>	Specifies the ISDN activation timer in seconds. Valid range is **0** to **60** seconds. Using a value of **0** disables the timer.

Default Values

By default, the ISDN activation timer is set to **10** seconds.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example sets the ISDN activation timer to **20** seconds for the BRI:

(config)**#interface bri 1/2**
(config-bri 1/2)**#isdn activation-timer 20**

isdn channel-flag

Use the **isdn channel-flag** to specify the integrated services digital network (ISDN) channel selection setting for the basic rate interface (BRI). Use the **no** form of this command to return to the default setting. Variations of this command include:

isdn channel-flag auto
isdn channel-flag exclusive
isdn channel-flag preferred

Syntax Description

auto	Specifies that the ISDN channel ID is automatically set to preferred or exclusive.
exclusive	Specifies that the ISDN channel ID is always set to exclusive.
preferred	Specifies that the ISDN channel ID is always set to preferred.

Default Values

By default, the ISDN channel ID is set to **auto**.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example specifies the ISDN channel selection for the interface as **exclusive**:

(config)**#interface bri 1/2**
(config-bri 1/2)**#isdn channel-flag exclusive**

isdn disconnect progress-tone

Use the **isdn disconnect progress-tone** command to specify that calls are disconnected with a progress tone. Use the **no** form of this command to disable the feature.

Syntax Description

No subcommands.

Default Values

By default, call progress tones are not used.

Command History

Release R10.5.0	Command was introduced.

Usage Example

The following example enables the use of progress tones when calls are disconnected on the BRI:

(config)**#interface bri 1/2**
(config-bri 1/2)**#isdn disconnect progress-tone**

isdn l2-disconnect <*value*>

Use the **isdn l2-disconnect** command to specify the disconnect delay of integrated services digital network (ISDN) Layer 2 functionality when there are no active calls. Use the **no** form of this command to disable the feature.

Syntax Description

<*value*>	Specifies the Layer 2 deactivation delay (in seconds). Valid range is **0** to **65535** seconds. Specifying a value of **0** disables the deactivation delay.

Default Values

By default, the Layer 2 disconnect feature is disabled.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example configures the Layer 2 disconnect delay as **500** seconds:

(config)**#interface bri 1/2**
(config-bri 1/2)**#isdn l2-disconnect 500**

isdn ldn

Use the **isdn ldn** command to specify the local directory numbers (LDNs) for the basic rate interface (BRI). This information should be supplied by your service provider. Use the **no** form of this command to remove a configured LDN. Variations of this command include:

isdn ldn1 *<ldn number>*
isdn ldn2 *<ldn number>*

*The BRI module requires all incoming calls to be directed to the LDN associated with the service profile identifier (SPID) programmed using the **isdn spid1** command. All calls to the LDN associated with SPID 2 will be rejected (unless part of a bonding call).*

Syntax Description

ldn1	Specifies the LDN associated with the SPID entered as **spid1**.
ldn2	Specifies the LDN associated with the SPID entered as **spid2**.
<ldn number>	Specifies the LDN assigned to the circuit by the service provider. The LDN is the number used by remote callers to dial into the integrated services digital network (ISDN) circuit.

Default Values

By default, there are no configured LDNs.

Command History

Release 12.1	Command was introduced.

Functional Notes

Inbound calls are not accepted on interfaces without programmed LDNs. LDNs can also be entered using the **isdn spid** command. The **isdn spid** and **isdn ldn** commands overwrite the existing programmed LDN; therefore, the latest LDN programmed takes precedence.

Usage Examples

The following example defines an LDN of **555-1111**:

(config)**#interface bri 1/2**
(config-bri 1/2)**#isdn ldn1 5551111**

isdn line-termination

Use the **isdn line-termination** command to enable the integrated services digital network (ISDN) line termination resistor for the interface. Use the **no** form of this command to disable the feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example enables the ISDN termination resistor on the BRI:

(config)**#interface bri 1/2**
(config-bri 1/2)**#isdn line-termination**

isdn name-delivery

Use the **isdn name-delivery** command to enable the delivery of the name associated with the basic rate interface (BRI). Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, **isdn name-delivery** is disabled.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example enables the delivery of calling party information on the BRI:

(config)**#interface bri 1/2**
(config-bri 1/2)**#isdn name-delivery**

isdn overlap-receive

Use the **isdn overlap-receive** command to enable overlap receiving mode on the basic rate interface (BRI). Use the **no** form of this command to return to the default setting. Variations of this command include:

isdn overlap-receive timeout <*value*>
isdn overlap-receive digits-transferred <*value*>

Syntax Description

timeout <*value*>	Specifies how long the interface will attempt to match direct inward dialing (DID) digits received in INFO messages to entries in the voice dial-plan. If no matching entry is found, the interface will deliver the message when the timeout period expires. Valid range is **1** to **15** seconds.
digits-transferred <*value*>	Specifies how many DID digits the interface will collect before delivering the call. Valid range is **1** to **64** digits

Default Values

By default, **isdn overlap-receive** is disabled.

Command History

Release R10.7.0	Command was introduced.

Functional Notes

When **isdn overlap-receive** is enabled, the interface will accept a SETUP message where the Called Party Number (CPN) information element is either missing or does not have enough DID digits. When more digits are received in subsequent INFO messages, the number is matched against entries in the voice dial-plan to determine when there are enough digits to deliver the call.

If no matching voice dial-plan entry is found, the interface will deliver the call when configuration the **isdn overlap-receive timeout** expires.

When **isdn overlap-receive did-length** is configured, no voice dial-plan look-up occurs. The interface will deliver the call as soon as the specified number of DID digits has been collected.

If at any time an INFO message is received with CPN information element containing **#** or a Sending Complete information element is received, the interface will deliver the call immediately.

Usage Examples

The following example enables overlap receiving with a timeout value of **7** seconds on the BRI:

(config)**#interface bri 1/2**
(config-bri 1/2)**#isdn overlap-receiving timeout 7**

isdn setup enable

Use the **isdn setup enable** command to enable progress indicators in the integrated services digital network (ISDN) setup message and redirecting numbers for ISDN calls on the basic rate interface (BRI). The redirecting number is used to insert the caller's number when a call is diverted by a blind transfer or forward that both occurs on an ISDN trunk in local mode and proceeds out of an ISDN trunk. Use the **no** form of this command to disable this feature. Variations of this command include:

isdn setup enable called
isdn setup enable calling
isdn setup enable pi-1
isdn setup enable pi-3
isdn setup enable redirecting-number

Syntax Description

called	Enables the called number in ISDN setup messages.
calling	Enables the calling number in ISDN setup messages.
pi-1	Enables progress indicator 1 for ISDN setup messages. Progress indicator 1 indicates that the call is not end-to-end ISDN and further call progress information may be available in-band.
pi-3	Enables progress indicator 3 for ISDN setup messages. Progress indicator 3 indicates that the origination address is non-ISDN.
redirecting-number	Enables redirecting numbers for ISDN calls.

Default Values

By default, the called and calling numbers are included in ISDN setup messages.

Command History

Release A4.01	Command was introduced.
Release A4.03	Command was expanded to include the **redirecting-number** parameter.
Release R10.5.0	Command was expanded to include the BRI and the **called** and **calling** parameters.

Usage Examples

The following example enables redirecting numbers for ISDN calls on the BRI:

(config)**#interface bri 1/2**
(config-bri 1/2)**#isdn setup enable redirecting-number**

isdn spid

Use the **isdn spid** command to specify the service profile identifiers (SPIDs) and the local directory numbers (LDNs) for the basic rate interface (BRI). This information should be supplied by your service provider. Use the **no** form of this command to remove a configured SPID. Variations of this command include:

isdn spid1 <*spid number*> <*ldn number*>
isdn spid2 <*spid number*> <*ldn number*>

*The BRI module requires all incoming calls to be directed to the LDN associated with the SPID programmed using the **isdn spid1** command. All calls to the LDN associated with SPID 2 will be rejected (unless part of a bonding call).*

Syntax Description

spid1	Specifies the primary SPID.
spid2	Specifies the secondary SPID.
<*spid number*>	Specifies the 8- to 14-digit number identifying your BRI line in the central office switch. A SPID is generally created using the area code and phone number associated with the line and a four-digit suffix. For example, the following SPIDs may be provided on a BRI line with phone numbers 555-1111 and 555-1112: SPID 1: 701 555 1111 0101 SPID 2: 701 555 1112 0101
<*ldn number*>	Optional. Specifies the LDN assigned to the circuit by the service provider. An LDN programmed using the **isdn spid1** command is automatically associated with SPID 1. An LDN programmed using the **isdn spid2** command is automatically associated with SPID 2. The LDN is the number used by remote callers to dial into the integrated services digital network (ISDN) circuit. Inbound calls are not accepted on interfaces without programmed LDNs. LDNs can also be entered using the **isdn ldn** command. The **isdn spid** and **isdn ldn** commands overwrite the existing programmed LDN; therefore, the latest LDN programmed takes precedence.

Default Values

By default, there are no configured SPIDs or LDNs.

Command History

Release 1.1	Command was introduced.

Functional Notes

AOS does not support “SPID-less” 5ESS signaling. SPIDs are required for all configured BRI endpoints using 5ESS signaling.

For European applications, a SPID is not necessary. Use the **isdn ldn** command to configure the LDN for European applications.

Usage Examples

The following example defines a SPID of **704 555 1111 0101** with an LDN of **555 1111**:

(config)**#interface bri 1/2**
(config-bri 1/2)**#isdn spid1 70455511110101 5551111**

isdn static-tei <*value*>

Use the **isdn static-tei** command to configure a static integrated services digital network (ISDN) Layer 2 terminal endpoint identifier (TEI). Use the **no** form of this command to remove the TEI.

Syntax Description

<*value*>	Specifies the TEI. Valid range is **0** to **63**.

Default Values

By default, no static TEI exists.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example creates a static ISDN TEI of **5**:

(config)**#interface bri 1/2**
(config-bri 1/2)**#isdn static-tei 5**

isdn switch-type

Use the **isdn switch-type** command to specify the integrated services digital network (ISDN) signaling type configured on the basic rate interface (BRI). The type of ISDN signaling implemented on the BRI does not always match the manufacturer of the central office switch. Use the **no** form of this command to return to the default value. Variations of this command include:

isdn switch-type basic-5ess
isdn switch-type basic-dms
isdn switch-type basic-net3
isdn switch-type basic-ni

Syntax Description

basic-5ess	Specifies Lucent/AT&T 5ESS signaling.
basic-dms	Specifies Nortel DMS-100 custom signaling.The **basic-dms** signaling type is not compatible with proprietary SL-1 DMS signaling.
basic-net3	Specifies Net3 Euro-ISDN signaling.
basic-ni	Specifies National ISDN-1 signaling.

Default Values

By default, the ISDN signaling is set to National ISDN-1 (**basic-ni**).

Command History

Release 1.1	Command was introduced.

Functional Notes

The **isdn switch-type** command specifies the type of ISDN signaling implemented on the BRI, not the manufacturer of the central office switch. It is quite possible to have a Lucent Central Office switch providing National ISDN signaling on the BRI.

Usage Examples

The following example configures a BRI for a circuit with Lucent 5ESS (custom) signaling:

(config)**#interface bri 1/2**
(config-bri 1/2)**#isdn switch-type basic-5ess**

loopback local

Use the **loopback local** command to enable a local loopback of the interface (towards the router). Use the **no** form of this command to disable the loopback. Variations of this command include:

loopback local all
loopback local b1
loopback local b2
loopback local both

Syntax Description

all	Loops the entire interface back towards the router (including the D-channel). With an active **loopback active all**, the established D-channel between the integrated services digital network (ISDN) module and the central office switch drops.
b1	Loops the data on B1 back towards the router. A B1 loopback does not disrupt D-channel signaling.
b2	Loops the data on B2 back towards the router. A B2 loopback does not disrupt D-channel signaling.
both	Loops the data on B1 and B2 back towards the router, but does not disrupt D-channel signaling.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example enables a B2 loopback of the basic rate interface (BRI) 1/2 interface:

(config)**#interface bri 1/2**
(config-bri 1/2)**#loopback local b2**

loopback network

Use the **loopback network** command to enable a loopback of the interface (towards the network). Use the **no** form of this command to disable the loopback. Variations of this command include:

loopback network b1
loopback network b2
loopback network both

Syntax Description

b1	Loops the data on B1 back towards the network. A B1 loopback does not disrupt D-channel signaling.
b2	Loops the data on B2 back towards the network. A B2 loopback does not disrupt D-channel signaling.
both	Loops the data on B1 and B2 back towards the network, but does not disrupt D-channel signaling.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example enables a B2 loopback of the basic rate interface (BRI) 1/2 interface:

(config)**#interface bri 1/2**
(config-bri 1/2)**#loopback network b2**

maintenance

Use the **maintenance** command to force a reset of the interface (initiating the SABME/UA process) or to reset the D-channel (by sending a RESTART message). Variations of this command include:

maintenance reset
maintenance restart-d

*The **maintenance** command disrupts data flow on the integrated services digital network (ISDN) interface. All active calls will drop when the reset or restart process begins.*

Syntax Description

reset	Forces a complete reset of the interface by initiating the SABME/UA process.
restart-d	Resets the D-channel by sending a Q.931 RESTART message to the central office switch.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example resets the basic rate interface (BRI) 1/2 interface:

(config)**#interface bri 1/2**
(config-bri 1/2)**#maintenance reset**

resource pool-member <*name*>

Use the **resource pool-member** command to assign the interface to a resource pool, making it a demand routing resource. Use the **no** form of this command to return to the default value. Variations of this command include:

resource pool-member <*name*>
resource pool-member <*name*> <*priority*>

Syntax Description

<*name*>	Specifies the name of the resource pool to which this interface is assigned.
<*priority*>	Optional. Specifies the priority value of using this interface versus other interfaces contained in the specified resource pool using a number **1** to **255**. Lower numbers indicate higher priority. Interfaces with the same priority are selected in alphabetical order by interface name.

Default Values

By default, the interface is not assigned to any resource pool.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures a basic rate interface (BRI) as a member of resource pool **MyPool**:

(config)**#interface bri 1/2**
(config-bri 1/2)**#resource pool-member MyPool**

role

Use the **role** command to configure the interface protocol to use on the basic rate interface (BRI). This setting controls the functional mode of the interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

role network
role user

Syntax Description

network	Sets the port to operate in network termination (NT) mode.
user	Sets the port to operate in terminal equipment (TE) mode.

Default Values

By default, the role is set to **network**.

Command History

Release 11.1	Command was introduced.
Release R10.5.0	Command was expanded to include the BRI.

Usage Examples

The following example configures the interface protocol as **user** on the BRI:

(config)**#interface bri 1/2**
(config-bri 1/2)**#role user**

system-timing

Use the **system-timing** command to configure the Rx clock as the primary or secondary timing source for the system. Use the **no** form of this command to disable this feature.Variations of this command include:

system-timing primary
system-timing secondary

Syntax Description

primary	Specifies the Rx clock as the primary timing source.
secondary	Specifies the Rx clock as the secondary timing source.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.
Release R10.5.0	Command was expanded to include the basic rate interface (BRI).

Usage Examples

The following example configures the BRI interface to provide its Rx clock as the primary timing source for the system:

(config)**#interface bri 1/2**
(config-bri 1/2)**#system timing primary**

test-call

Use the **test-call** command to initiate a test call on the basic rate interface (BRI) to test integrated services digital network (ISDN) connectivity without disrupting the primary interface for which the BRI interface is a backup. Use the **no** form of this command to disable this feature. Variations of this command include:

test-call answer
test-call dial <*number*>
test-call dial <*number*> **speed** [**56** | **64**]
test-call hangup
test-call hangup channels <*number*>

Syntax Description

answer	Places the unit in answer mode for test calls.
dial <*number*>	Specifies a test number to dial. No special characters are allowed. For example, **12125551212** is accepted, but **1-212-555-1212** and **1 (212) 555-1212** are not accepted.
speed [**56** | **64**]	Optional. Specifies the channel speed (in kilobytes per second) of the call. Valid speeds are **56** and **64**.
hangup	Terminates all test calls on all channels.
channels <*number*>	Optional. Specifies a single channel on which to terminate a test call. For a list of available channels, enter **test-call hangup channels ?** at the prompt.

Default Values

No default values are necessary for this command.

Command History

Release 18.1	Command was introduced.

Functional Notes

To successfully place a test call, a remote unit must be configured to answer the test call using the **test-call answer** command, and a separate local unit must be used to dial the test call number using the **test-call dial** <*number*> command.

Usage Examples

The following example places a test call over **bri 1/1** to **5555300**:

(config-bri 1/1)**#test-call dial 5555300**

2011.02.11 14:58:10 ISDN.INTERFACE BRI 1/1 Entering test-call mode.
2011.02.11 14:58:10 ISDN.INTERFACE BRI 1/1 Placing test-call to 5555300

CELLULAR INTERFACE COMMAND SET

To create a cellular interface and activate the Cellular Interface Configuration mode, enter the **interface cellular** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface cellular 1/1
(config-cellular 1/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order:

apn <name> on page 2106
cdma activate oma-dm on page 2107
cdma activate otasp on page 2108
cdma msl <number> on page 2109
custom-profile ha-shared-secret on page 2110
custom-profile home-address <ip address> on page 2111
custom-profile primary-ha-address <ip address> on page 2112
custom-profile secondary-ha-address <ip address> on page 2113
custom-profile username <username> on page 2114
match ani <template> substitute <template> on page 2115
reset on page 2117
resource pool-member <name> on page 2118
retry-throttling on page 2119
usb-id <value> on page 2120

apn <*name*>

Use the **apn** command to change the name of the access point associated with your universal serial bus (USB) cellular modem. Use the **no** version of this command to remove the name.

Syntax Description

<*name*>	Specifies the modem's access point name (APN) that is supplied by your service provider.

Default Values

By default, the APN is set to the name provided by the cellular service provider.

Command History

Release 18.2	Command was introduced.

Functional Notes

If you purchased your USB cellular modem in the Unites States, your APN is automatically set correctly. Adtran recommends that you do not change this setting. In countries other than the United States, where modems and cellular service are sold separately, the APN may not be defined. If the APN is not defined or incorrect, contact your service provider.

Usage Examples

In the following example, the APN is specified as **isp.cingular**:

(config)**#interface cellular 1/1**
(config-cellular 1/1)**#apn isp.cingular**

cdma activate oma-dm

Use the **cdma activate oma-dm** command to activate the cellular interface for connection to the Sprint wireless network.

Syntax Description

No subcommands.

Default Values

By default, the cellular interface is deactivated.

Command History

Release 17.4	Command was introduced.

Usage Examples

The following example activates cellular interface 1/1:

(config)**#interface cellular 1/1**
(config-cellular-1/1)**#cdma activate oma-dm**

cdma activate otasp

Use the **cdma activate otasp** command to activate the cellular interface for connection to the Verizon wireless network.

Syntax Description

No subcommands.

Default Values

By default, the cellular interface is disabled.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example activates cellular interface 1/1:

(config)**#interface cellular 1/1**
(config-cellular 1/1)**#cdma activate otasp**

cdma msl *<number>*

Use the **cdma msl** command to enter the 6-digit Sprint Master Subsidy Lock (MSL) code. Use the **no** form of this command to remove the code.

Syntax Description

<number>	Specifies the 6-digit Sprint MSL code.

Default Values

By default, no MSL code is activated.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example enters MSL code **526510** on cellular interface 1/1:

(config)**#interface cellular 1/1**
(config-cellular-1/1)**#cdma msl 526510**

custom-profile ha-shared-secret

Use the **custom-profile ha-shared-secret** command to specify the home agent shared secret for the cellular custom profile. Use the **no** form of this command to remove the shared secret from the custom profile configuration. Variations of this command include:

custom-profile ha-shared-secret ascii <*shared secret*>
custom-profile ha-shared-secret hexadecimal <*shared secret*>

Syntax Description

ascii <*shared secret*>	Specifies a plain text secret. Secret can be up to **16** characters in length.
hexadecimal <*shared secret*>	Specifies a hexadecimal secret. Secret can be up to **32** characters in length.

Default Values

By default, no custom profile is configured.

Command History

Release 17.5	Command was introduced.

Functional Notes

Cellular custom profile settings are useful for services that require manual activation or for services that allow remote access to private networks over the 3G network. For more information about custom profile settings, refer to the *3G CDMA NIM and the Cellular Interface* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example creates a plain text home agent shared secret (**sharedsecret**) for the custom profile:

(config)**#interface cellular 1/1**
(config-cellular 1/1)**#custom-profile ha-shared-secret ascii sharedsecret**

custom-profile home-address *<ip address>*

Use the **custom-profile home-address** command to specify the home address for the cellular custom profile. Use the **no** form of this command to remove the home address from the custom profile settings.

Syntax Description

<ip address>	Specifies the IP address of the home address. Enter IP addresses in dotted decimal notation (**XX.XX.XX.XX**).

Default Values

By default, no custom profile is configured.

Command History

Release 17.5	Command was introduced.

Functional Notes

Cellular custom profile settings are useful for services that require manual activation or for services that allow remote access to private networks over the 3G network. For more information about custom profile settings, refer to the *3G CDMA NIM and the Cellular Interface* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example creates the home address for the custom profile:

(config)**#interface cellular 1/1**
(config-cellular 1/1)**#custom-profile home-address 192.168.1.1**

custom-profile primary-ha-address *<ip address>*

Use the **custom-profile primary-ha-address** command to specify the primary home agent IP address for the cellular custom profile. Use the **no** form of this command to remove the primary home agent IP address from the custom profile settings.

Syntax Description

<ip address>	Specifies the IP address of the primary home agent. Enter IP addresses in dotted decimal notation (**XX.XX.XX.XX**).

Default Values

By default, no custom profile is configured.

Command History

Release 17.5	Command was introduced.

Functional Notes

Cellular custom profile settings are useful for services that require manual activation or for services that allow remote access to private networks over the 3G network. For more information about custom profile settings, refer to the *3G CDMA NIM and the Cellular Interface* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the primary home agent IP address for the custom profile:

(config)**#interface cellular 1/1**
(config-cellular 1/1)**#custom-profile primary-ha-address 192.168.1.5**

custom-profile secondary-ha-address *<ip address>*

Use the **custom-profile secondary-ha-address** command to specify the secondary home agent IP address for the cellular custom profile. Use the **no** form of this command to remove the secondary home agent IP address from the custom profile settings.

Syntax Description

<ip address>	Specifies the IP address of the secondary home agent. Enter IP addresses in dotted decimal notation (**XX.XX.XX.XX**).

Default Values

By default, no custom profile is configured.

Command History

Release 17.5	Command was introduced.

Functional Notes

Cellular custom profile settings are useful for services that require manual activation or for services that allow remote access to private networks over the 3G network. For more information about custom profile settings, refer to the *3G CDMA NIM and the Cellular Interface* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the secondary home agent IP address for the custom profile:

(config)**#interface cellular 1/1**
(config-cellular 1/1)**#custom-profile secondary-ha-address 192.168.1.6**

custom-profile username <*username*>

Use the **custom-profile username** command to specify the username and password for the cellular custom profile. Use the **no** form of this command to remove the username and password from the custom profile settings. Variations of this command include:

custom-profile username <*username*>
custom-profile username <*username*> **password ascii** <*password*>
custom-profile username <*username*> **password hexadecimal** <*password*>

Syntax Description

username <*username*>	Specifies the user name for the custom profile. The user name is equivalent to network address identifier (NAI) user identification. User names can be up to **72** characters in length.
password ascii <*password*>	Specifies the plain text password. Passwords are equivalent to authentication, authorization, and accounting (AAA) shared secrets. Passwords can be up to **16** characters in length.
password hexadecimal <*password*>	Specifies the hexadecimal password. Passwords are equivalent to AAA shared secrets. Passwords can be up to **32** characters in length.

Default Values

By default, no custom profile is configured.

Command History

Release 17.5	Command was introduced.

Functional Notes

Cellular custom profile settings are useful for services that require manual activation or for services that allow remote access to private networks over the 3G network. For more information about custom profile settings, refer to the *3G CDMA NIM and the Cellular Interface* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the user name and plain text password for the custom profile:

(config)**#interface cellular 1/1**
(config-cellular 1/1)**#custom-profile username USERNAME password ascii PASSWORD**

match ani <*template*> substitute <*template*>

Use the **match ani substitute** command to configure automatic number identification (ANI) substitution for outbound voice trunks. Use the **no** form of this command to remove the substitution. Variations of this command include:

match ani <*template*> **substitute** <*template*>
match ani <*template*> **substitute** <*template*> **name** <*name*>

Syntax Description

ani <*template*>	Specifies the ANI information to be substituted. This information is entered using wildcards and numerical digits. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
substitute <*template*>	Specifies the ANI information that is substituted for the original ANI information. This information is entered using wildcards and numerical digits. When using wildcards in the **match** and **substitute** template, both must be of the same type and position in the number template or AOS will not allow the substitution. Refer to the *Functional Notes* of this command for available wildcards and proper data entry.
name <*name*>	Optional. Specifies the name associated with the ANI information. This option is only available on trunks that support ANI name information (integrated services digital network (ISDN) trunks, Session Initiation Protocol (SIP) trunks, T1 loop start (LS) network trunks, and T1 ground start (GS) network trunks).

Default Values

By default, no ANI substitution is configured.

Command History

Release A2	Command was introduced.

Functional Notes

The convention for ANI templates is very similar to dial plan entries. Valid characters for templates are as follows:

0 - 9	Match the exact digit(s) only
X	Match any single digit 0 through 9
N	Match any single digit 2 through 9
M	Match any single digit 1 through 8
$	Match any number string dialed
[]	Match any digit in the list within the brackets (for example, [1,4,6])
,()	Formatting characters that are ignored but allowed
-	Use within brackets to specify a range, otherwise ignored

The following are example template entries using wildcards:

1) NXX-XXXX	Match any 7-digit number beginning with 2 through 9
2) 1-NXX-NXX-XXXX	Match any number with a leading 1, then 2 through 9, then any 2 digits, then 2 through 9, then any 6 digits
3) 555-XXXX	Match any 7-digit number beginning with 555
4) XXXX$	Match any number with at least 5 digits
5) [7,8]$	Match any number beginning with 7 or 8
6) 1234	Match exactly 1234

Some template number rules:

1) All brackets must be closed with no nesting of brackets and no wildcards within the brackets.
2) All brackets can hold digits and commas, for example: [1239]; [1,2,3,9]. Commas are implied between numbers within brackets and are ignored.
3) Brackets can contain a range of numbers using a hyphen, for example: [1-39]; [1-3,9].
4) The $ wildcard is only allowed at the end of the template, for example: 91256$; XXXX$.

Usage Examples

The following example specifies that the ANI information from numbers **555-8111** to **555-8115** will be substituted by **555-8110** for outbound calls on interface 1/1:

(config)**#interface cellular 1/1**
(config-cellular 1/1)**#match ani 555-811[125] substitute 555-8110**

reset

Use the **reset** command to reboot the cellular network interface module (NIM).

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example reboots the NIM associated with cellular interface 1/1:

(config)**#interface cellular 1/1**
(config-cellular 1/1)**#reset**

resource pool-member <*name*>

Use the **resource pool-member** command to configure the cellular interface as a resource pool member for the demand interface to draw upon when connecting to the cellular network. Use the **no** form of this command to remove the interface from the resource pool. Variations of this command include:

resource pool-member <*name*>
resource pool-member <*name*> <*priority*>

Syntax Description

<*name*>	Specifies the resource pool to which the cellular interface is assigned.
<*priority*>	Optional. Specifies the priority this interface is given over other interfaces in the same pool. Range is **1** to **255**.

Default Values

By default, the cellular interface is not associated with any resource pools.

Command History

Release 17.2	Command was introduced.

Functional Notes

Lower priority values indicate a higher priority. Interfaces within the same resource pool with the same priority are selected as resources in alphabetical order by interface name.

Usage Examples

The following example configures interface **cellular 1/1** as a member of the **cellular** resource pool:

(config)**#interface cellular 1/1**
(config-cellular 1/1)**#resource pool-member cellular**

retry-throttling

Use the **retry-throttling** command to enable retry throttling. Use the **no** form of this command to disable retry throttling.

Syntax Description

No subcommands.

Default Values

In the Verizon cellular network, the retry throttle is enabled and cannot be disabled.

In the Sprint cellular network, the retry throttle is disabled by default but can be enabled by using this command.

Command History

Release 17.5	Command was introduced.

Functional Notes

When the retry throttle is enabled, it will disable the cellular interface for 15 minutes if a data call fails.

Usage Examples

The following example enables retry throttling:

(config)**#interface cellular 1/1**
(config-cellular 1/1)**#retry-throttling**

usb-id <*value*>

Use the **usb-id** command to specify which universal serial bus (USB) device the network interface module (NIM) will use. The USB ID is a combination of the vendor and product IDs. These values are displayed in the *show usb attached-devices on page 1061*.

Syntax Description

<*value*>	Specifies the identifying information for the USB device in the format <*vendor ID*> *:* <*product id*>. Each ID value is a 16-bit hexadecimal value, for example, **1234:ABCD**.

Default Values

No default values are necessary for this command.

Command History

Release R10.6.0	Command was introduced.

Functional Notes

The USB ID is a combination of the vendor and product ID. To view these values, enter the **show usb attached-devices** command as follows:

>**enable**
#show usb attached-devices
Device inserted in slot 1 on bus 0
Device Address: 1
Association: USB Cellular Interface /
Vendor: 0x1410 (Novatel Wireless Inc.)
Product: 0x6000 (Novatel Wireless CDMA)
Serial Number: 091165297381000
Device Class: 0x00 (NULL (PER INTERFACE))

The vendor ID (0x1410) and the product ID (0x6000) create the USB ID of **1410:6000**. This value is then entered as the USB ID using the **usb-id** command.

Usage Examples

The following example creates a USB ID of **1410:6000** on the cellular interface:

(config)**#interface cellular 1/1**
(config-cellular 1/1)**#usb-id 1410:6000**

DDS INTERFACE COMMAND SET

To activate the DDS Interface Configuration mode, enter the **interface dds** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface dds 1/1
(config-dds 1/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

clock rate on page 2122
clock source on page 2123
data-coding scrambled on page 2124
loopback on page 2125
remote-loopback on page 2126
snmp trap on page 2127
snmp trap link-status on page 2128

clock rate

Use the **clock rate** command to configure the data rate used as the operating speed for the interface. This rate should match the rate required by the digital data service (DDS) service provider. Use the **no** form of this command to return to the default value. Variations of this command include:

clock rate auto
clock rate bps56k
clock rate bps64k

Syntax Description

auto	Automatically detects the clock rate and sets to match.
bps56k	Sets the clock rate to **56** kbps.
bps64k	Sets the clock rate to **64** kbps.

Default Values

By default, the rate is set to **auto**.

Command History

Release 1.1	Command was introduced.

Functional Notes

When operating at 64 kbps (clear channel operation), the data terminal equipment (DTE) data sequences may mimic network loop maintenance functions and erroneously cause other network elements to activate loopbacks. Use the **data-coding scrambled** command to prevent such occurrences. Refer to *data-coding scrambled on page 2124* for related information.

Usage Examples

The following example configures the clock rate for **56** kbps operation:

(config)**#interface dds 1/1**
(config-dds 1/1)**#clock rate bps56k**

clock source

Use the **clock source** command to configure the source timing used for the interface. The clock specified using the **clock source** command is also the system master clock. Use the **no** form of this command to return to the default value. Variations of this command include:

clock source internal
clock source line

Syntax Description

internal	Configures the unit to provide clocking using the internal oscillator.
line	Configures the unit to recover clocking from the digital data service (DDS) circuit.

Default Values

By default, the clock source is set to **line**.

Command History

Release 1.1	Command was introduced.

Functional Notes

When operating on a DDS network, the clock source should be **line**. On a point-to-point private network, one unit must be **line** and the other **internal**.

Usage Examples

The following example configures the unit to recover clocking from the circuit:

(config)**#interface dds 1/1**
(config-dds 1/1)**#clock source line**

data-coding scrambled

Use the **data-coding scrambled** command to enable the digital data service (DDS) OS scrambler to combine user data with pattern data to ensure user data does not mirror standard DDS loop codes. The scrambler may only be used on 64 kbps circuits without Frame Relay signaling (clear channel). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, the scrambler is disabled.

Command History

Release 1.1	Command was introduced.

Functional Notes

When operating at 64 kbps (clear channel operation), there is a possibility the data terminal equipment (DTE) data sequences may mimic network loop maintenance functions and erroneously cause other network elements to activate loopbacks. Use the **data-coding scrambled** command to prevent such occurrences. Do not use this command if using Frame Relay or if using Point-to-Point Protocol (PPP) to another device other than an AOS product also running scrambled.

Usage Examples

The following example enables the DDS OS scrambler:

(config)**#interface dds 1/1**
(config-dds 1/1)**#data-coding scrambled**

loopback

Use the **loopback** command to initiate a specified loopback on the interface. Use the **no** form of this command to deactivate the loop. Variations of this command include:

loopback dte
loopback line
loopback remote

Syntax Description

dte	Initiates a loop to connect the transmit and receive path through the unit.
line	Initiates a loop of the digital data service (DDS) circuit toward the network by connecting the transmit path to the receive path.
remote	Transmits a DDS loop code over the circuit to the remote unit. In response, the remote unit should initiate a line loopback.

Default Values

No default values are necessary for this command.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example activates a line loopback on the DDS interface:

(config)**#interface dds 1/1**
(config-dds 1/1)**#loopback line**

remote-loopback

Use the **remote-loopback** command to configure the interface to respond to loopbacks initiated by a remote unit (or the service provider). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, all interfaces respond to remote loopbacks.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example enables remote loopbacks on the digital data service (DDS) interface:

(config)**#interface dds 1/1**
(config-dds 1/1)**#remote-loopback**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.

Usage Examples

The following example enables SNMP capability on the digital data service (DDS) interface:

(config)**#interface dds 1/1**
(config-dds 1/1)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all supported interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the digital data service (DDS) interface:

(config)**#interface dds 1/1**
(config-dds 1/1)**#no snmp trap link-status**

DSX-1 INTERFACE COMMAND SET

To activate the DSX-1 Interface Configuration mode, enter the **interface t1** command (and specify the DSX-1 port) at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface t1 1/2
(config-t1 1/2)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

coding on page 2130
framing on page 2131
line-length <value> on page 2132
loopback network on page 2133
loopback remote line inband on page 2134
remote-loopback on page 2135
signaling-mode on page 2136
snmp trap link-status on page 2137
test-pattern on page 2138

coding

Use the **coding** command to configure the line coding for a DSX-1 physical interface. This setting must match the line coding supplied on the circuit by the PBX. Use the **no** form of this command to return to the default setting. Variations of this command include:

coding ami
coding b8zs

Syntax Description

ami	Configures the line coding for alternate mark inversion (AMI).
b8zs	Configures the line coding for bipolar eight zero substitution (B8ZS).

Default Values

By default, all DSX-1 interfaces are configured with **b8zs** line coding.

Command History

Release 1.1	Command was introduced.

Functional Notes

The line coding configured in the unit must match the line coding of the DSX-1 circuit. A mismatch will result in line errors (e.g., bipolar violations (BPVs)).

Usage Examples

The following example configures the DSX-1 interface for **ami** line coding:

(config)**#interface t1 1/2**
(config-t1 1/2)**#coding ami**

framing

Use the **framing** command to configure the framing format for the DSX-1 interface. This parameter should match the framing format set on the external device. Use the **no** form of this command to return to the default value. Variations of this command include:

framing d4
framing esf

Syntax Description

d4	Specifies D4 superframe (SF) format.
esf	Specifies extended superframe (ESF) format.

Default Values

By default, the framing format is set to **esf**.

Command History

Release 1.1	Command was introduced.

Functional Notes

A frame is comprised of a single byte from each of the T1's timeslots; there are 24 timeslots on a single T1 circuit. Framing bits are used to separate the frames and indicate the order of information arriving at the receiving equipment. D4 and ESF are two methods of collecting and organizing frames over the circuit.

Usage Examples

The following example configures the DSX-1 interface for **d4** framing:

(config)**#interface t1 1/2**
(config-t1 1/2)**#framing d4**

line-length <*value*>

Use the **line-length** command to set the line build out (LBO) (in feet or dB) for the DSX-1 interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Configures the LBO for the DSX-1 interface. Valid options include: **-7.5** dB or **0** to **655** feet. Use the -7.5 dB option for maximum attenuation.

Default Values

By default, the LBO is set to **0** feet.

Command History

Release 1.1	Command was introduced.

Functional Notes

The **line-length** value represents the physical distance between DSX equipment (measured in cable length). Based on this setting, the AOS device increases signal strength to compensate for the distance the signal must travel. Valid distance ranges are listed below:

- 0 to 133 feet
- 134 to 265 feet
- 266 to 399 feet
- 400 to 533 feet
- 534 to 655 feet

Usage Examples

The following example configures the DSX-1 interface **line-length** for **300** feet:

(config)**#interface t1 1/2**
(config-t1 1/2)**#line-length 300**

loopback network

Use the **loopback network** command to initiate a loopback on the interface toward the network. Use the **no** form of this command to deactivate the loopback. Variations of this command include:

loopback network line
loopback network payload

Syntax Description

line	Initiates a metallic loopback of the physical DSX-1 network interface.
payload	Initiates a loopback of the T1 framer (CSU portion) of the DSX-1 network interface.

Default Values

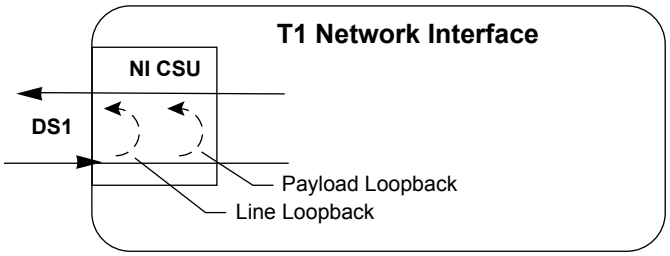
No default values are necessary for this command.

Command History

Release 1.1	Command was introduced.

Functional Notes

The following diagram depicts the difference between a line and payload loopback.



Usage Examples

The following example initiates a payload loopback of the DSX-1 interface:

(config)**#interface t1 1/2**
(config-t1 1/2)**#loopback network payload**

loopback remote line inband

Use the **loopback remote line inband** command to send a loopback code to the remote unit to initiate a line loopback. Use the **no** form of this command to send a loopdown code to the remote unit to deactivate the loopback.

Syntax Description

inband	Uses the inband channel to initiate a full 1.544 Mbps physical (metallic) loopback of the signal received by the remote unit from the network.

Default Values

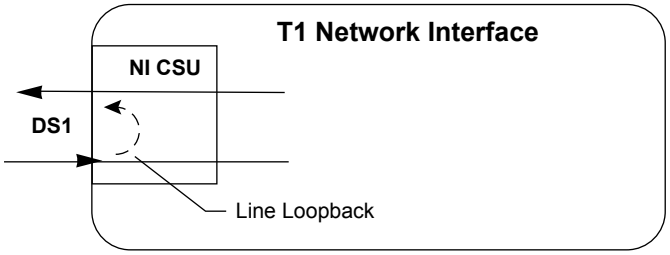
No default values are necessary for this command.

Command History

Release 1.1	Command was introduced.

Functional Notes

A remote loopback can only be issued if a cross connect does not exist on the interface and if the signaling mode is set to **none**. The following diagram depicts the difference between a line and payload loopback.



Usage Examples

The following example initiates a remote line loopback using the inband channel:

(config)**#interface t1 1/2**
(config-t1 1/2)**#loopback remote line inband**

remote-loopback

Use the **remote-loopback** command to configure the interface to respond to loopbacks initiated by a remote unit (or the service provider). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, all interfaces respond to remote loopbacks.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example enables remote loopbacks on the DSX-1 interface:

(config)**#interface t1 1/2**
(config-t1 1/2)**#remote-loopback**

signaling-mode

Use the **signaling-mode** command to configure the signaling type (robbed-bit for voice or clear channel for data) for the level zero digital signals (DS0s) mapped to the DSX-1 port. Use the **no** form of this command to return to the default setting. Variations of this command include:

signaling-mode message-oriented
signaling-mode none
signaling-mode robbed-bit

Syntax Description

message-oriented	Specifies clear channel signaling on Channel 24 only. Use this signaling type with QSIG installations.
none	Specifies clear channel signaling on all 24 DS0s. Use this signaling type with data-only or primary rate interface (PRI) DSX-1 installations.
robbed-bit	Specifies robbed bit signaling on all DS0s. Use this signaling type for voice-only DSX-1 applications.

Default Values

By default, the signaling mode is set to **robbed-bit**.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example configures the DSX-1 port for PRI compatibility:

(config)**#interface t1 1/2**
(config-t1 1/2)**#signaling-mode none**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the DSX-1 interface:

(config)**#interface t1 1/2**
(config-t1 1/2)**#no snmp trap link-status**

test-pattern

Use the **test-pattern** command to activate the built-in pattern generator and begin sending the specified test pattern. This pattern generation can be used to verify a data path when used in conjunction with an active loopback. Use the **no** form of this command to cease pattern generation. Variations of this command include:

test-pattern ones
test-pattern zeros

Syntax Description

ones	Generates a test pattern of continuous ones.
zeros	Generates a test pattern of continuous zeros.

Default Values

No default values are necessary for this command.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example activates the pattern generator for a stream of continuous ones:

(config)**#interface t1 1/2**
(config-t1 1/2)**#test-pattern ones**

E1 INTERFACE COMMAND SET

To activate the E1 Interface Configuration mode, enter the **interface e1** command (and specify the E1 port) at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface e1 1/1
(config-e1 1/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

clock source on page 2140
coding on page 2141
framing crc4 on page 2142
loop-alarm-detect on page 2143
loopback network on page 2144
loopback remote v54 on page 2145
remote-loopback on page 2146
sa4tx-bit <value> on page 2147
snmp trap line-status on page 2148
snmp trap link-status on page 2149
snmp trap threshold-reached on page 2150
system-timing on page 2151
tdm-group <number> on page 2152
test-pattern on page 2153
timing-domain <domain> on page 2154
ts16 on page 2155

clock source

Use the **clock source** command to configure the source timing used for the interface. Use the **no** form of this command to return to the default value. Variations of this command include:

clock source internal
clock source line
clock source system
clock source through

Syntax Description

internal	Configures the unit to provide clocking using the internal oscillator.
line	Configures the unit to recover clocking from the E1 circuit.
system	Configures the unit to provide clocking from the chassis selection.
through	Configures the unit to recover clocking from the circuit connected to the G.703 interface.

Default Values

By default, the unit is configured to recover clocking from the primary circuit.

Command History

Release 5.1	Command was introduced.
Release A2	Command was expanded to include the **system** parameter.

Functional Notes

When operating on a circuit that is providing timing, setting the **clock source** to **line** can avoid errors, such as clock slip seconds (CSS).

Usage Examples

The following example configures the unit to recover clocking from the primary circuit:

(config)**#interface e1 1/1**
(config-e1 1/1)**#clock source line**

coding

Use the **coding** command to configure the line coding for the E1 physical interface. This setting must match the line coding supplied on the circuit by the service provider. Use the **no** form of this command to return to the default setting. Variations of this command include:

coding ami
coding hdb3

Syntax Description

ami	Configures the line coding for alternate mark inversion (AMI).
hdb3	Configures the line coding for high-density bipolar 3 (HDB3).

Default Values

By default, all E1 interfaces are configured with **hdb3** line coding.

Command History

Release 5.1	Command was introduced.

Functional Notes

The line coding configured in the unit must match the line coding of the E1 circuit. A mismatch will result in line errors (e.g., bipolar violations (BPVs)).

Usage Examples

The following example configures the E1 interface for **ami** line coding:

(config)**#interface e1 1/1**
(config-e1 1/1)**#coding ami**

framing crc4

Use the **framing crc4** command to configure the framing format for the E1 interface. This parameter should match the framing format provided by the service provider or external device. Use the **no** form of this command to return to the default value.

Syntax Description

crc4	Enables CRC4 bits to be transmitted in the outgoing data stream. Also, the received signal is checked for CRC4 errors.

Default Values

By default, CRC4 is disabled.

Command History

Release 5.1	Command was introduced.

Functional Notes

The framing value must match the configuration of the E1 circuit. A mismatch will result in a loss of frame alarm.

Usage Examples

The following example configures the E1 interface for CRC4 framing:

(config)**#interface e1 1/1**
(config-e1 1/1)**#framing crc4**

loop-alarm-detect

The **loop-alarm-detect** command enables detection of a loop alarm on the E1 interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is enabled.

Command History

Release 6.1	Command was introduced.

Functional Notes

This command enables the detection of a loopback alarm. This alarm works in conjunction with the **sa4tx-bit** command setting. The loopback condition is detected by comparing the transmitted **sa4tx-bit** value to the received Sa4 bit value. If the bits match, a loopback is assumed. This detection method only works with a network in which the far end is transmitting the opposite value for Sa4.

Usage Examples

The following example enables detection of a loop alarm on the E1 interface:

(config)**#interface e1 1/1**
(config-e1 1/1)**#loop-alarm-detect**

loopback network

Use the **loopback network** command to initiate a loopback on the interface toward the network. Use the **no** form of this command to deactivate the loopback. Variations of this command include:

loopback network line
loopback network payload

Syntax Description

line	Initiates a metallic loopback of the physical E1 network interface.
payload	Initiates a loopback of the E1 framer (CSU) portion of the E1 network interface.

Default Values

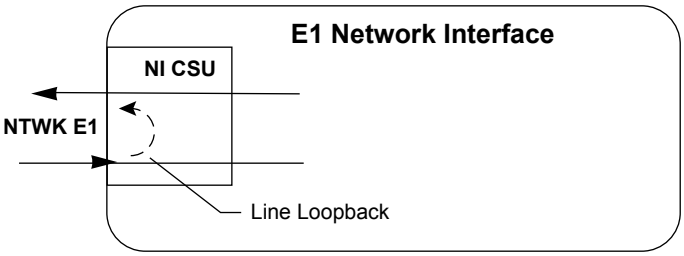
No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.

Functional Notes

The following diagram depicts a line loopback.



Usage Examples

The following example initiates a line loopback of the E1 interface:

(config)**#interface e1 1/1**
(config-e1 1/1)**#loopback network line**

loopback remote v54

The **loopback remote v54** command initiates an E1 remote loopback test (with a V.54 loopback pattern). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.

Functional Notes

This command causes a V.54 inband loop code to be sent in the payload towards the far end.

Usage Examples

The following example sends a V.54 inband loop code to the far end:

(config)**#interface e1 1/1**
(config-e1 1/1)**#loopback remote v54**

remote-loopback

Use the **remote-loopback** command to configure the interface to respond to loopbacks initiated by a remote unit (or the service provider). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, all interfaces respond to remote loopbacks.

Command History

Release 1.1	Command was introduced.

Functional Notes

This controls the acceptance of any remote loopback requests. When enabled, remote loopbacks are detected and cause a loopback to be applied. When disabled, remote loopbacks are ignored.

Usage Examples

The following example enables remote loopbacks on the E1 interface:

(config)**#interface e1 1/1**
(config-e1 1/1)**#remote-loopback**

sa4tx-bit <*value*>

The **sa4tx-bit** command selects the Tx value of Sa4 in this E1 interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies a **0** or a **1** for the transmit value of the SA4 bit on the E1.

Default Values

The default value for this command is **1**.

Command History

Release 6.1	Command was introduced.

Functional Notes

This command assigns a value to the Tx spare bit in position 4. The odd-numbered frames of TS0 are not used for frame alignment. Bits in position 4 through 8 are called spare bits. Values of 0 or 1 are accepted.

TS0 odd frame

Bit position	1	2	3	4	5	6	7	8
Bit use	0	1	RAI = 1	S	S	S	S	S

Usage Examples

The following example sets the Tx value of Sa4 to **0**:

(config)**#interface e1 1/1**
(config-e1 1/1)**#sa4tx-bit 0**

snmp trap line-status

Use the **snmp trap line-status** command to control the Simple Network Management Protocol (SNMP) variable dsx1LineStatusChangeTrapEnable (RFC 2495) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the dsx1LineStatusChangeTrapEnable object identifier (OID) is set to enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 11.1	Command was introduced.

Functional Notes

The **snmp trap line-status** command is used to control the RFC 2495 dsx1LineStatusChangeTrapEnable OID (OID number 1.3.6.1.2.1.10.18.6.1.17.0).

Usage Examples

The following example disables the line-status trap on the T1 interface:

(config)**#interface e1 1/1**
(config-t1 1/1)**#no snmp trap line-status**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the E1 interface:

(config)**#interface e1 1/1**
(config-e1 1/1)**#no snmp trap link-status**

snmp trap threshold-reached

Use the **snmp trap threshold-reached** command to control the Simple Network Management Protocol (SNMP) variable adGenAOSDs1ThresholdReached (adGenAOSDs1-Ext MIB) to enable the interface to send SNMP traps when a DS1 performance counter threshold is reached. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the adGenAOSDs1ThresholdReached object identifier (OID) is disabled for all interfaces.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example disables SNMP threshold reached trap on the E1 interface:

(config)**#interface e1 1/1**
(config-e1 1/1)**#no snmp trap threshold-reached**

system-timing

Use the **system-timing** command to configure the system timing to use the E1 interface as the system clock source. Use the **no** form of this command to return to the default value. Variations of this command include:

system-timing primary
system-timing secondary

Syntax Description

primary	Configures the unit to use the E1 interface as the source of the primary system clock.
secondary	Configures the unit to use the E1 interface as the source of the secondary system clock.

Default Values

By default, the unit is configured to recover clocking from the primary circuit.

Command History

Release A2	Command was introduced.

Usage Examples

The following example configures the unit to use the E1 interface as the primary system timing source:

(config)**#interface e1 1/1**
(config-e1 1/1)**#system-timing primary**

tdm-group <*number*>

Use the **tdm-group** command to create a group of contiguous channels on this interface to be used during the **cross-connect** process. Use the **no** form of this command to remove configured time division multiplexing (TDM) groups. Refer to *cross-connect on page 76* for related information. Variations of this command include:

tdm-group <*number*> **timeslots** <*value*>
tdm-group <*number*> **timeslots** <*value*> **speed [56 | 64]**

*Changing **tdm-group** settings could result in service interruption.*

Syntax Description

<*number*>	Identifies the created TDM group. Valid range is **1** to **255**.
timeslots <*value*>	Specifies the channels to be used in the TDM group. Valid range is **1** to **31**. The timeslot value can be entered as a single number representing one of the 31 E1 channel timeslots or as a contiguous group of channels. (For example, **1-10** specifies the first 10 channels of the E1.)
speed [56 | 64]	Optional. Specifies the individual channel rate on the E1 interface to be 56 or 64 kbps. The default speed is 64 kbps. 56 kbps operation is not available on all E1 interfaces. Refer to the quick start guide provided with your E1 module to determine whether 56 kbps is valid.

Default Values

By default, there are no configured TDM groups.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example creates a TDM group (labeled **5**) of 10 channels at 64 kbps each:

(config)**#interface e1 1/1**
(config-e1 1/1)**#tdm-group 5 timeslots 1-10 speed 64**

test-pattern

Use the **test-pattern** command to activate the built-in pattern generator and begin sending the specified test pattern. This pattern generation can be used to verify a data path when used in conjunction with an active loopback. Use the **no** form of this command to cease pattern generation. Variations of this command include:

test-pattern clear
test-pattern errors
test-pattern insert
test-pattern ones
test-pattern p215
test-pattern p220
test-pattern p511
test-pattern qrss
test-pattern zeros

Syntax Description

clear	Clears the test pattern error count.
errors	Displays the test pattern error count.
insert	Inserts an error into the currently active test pattern.
ones	Generates test pattern of continuous ones.
p215	Generates a pseudorandom test pattern sequence based on a 15-bit shift register.
p220	Generates a pseudorandom test pattern sequence based on a 20-bit shift register.
p511	Generates a test pattern of repeating ones and zeros.
qrss	Generates a test pattern of random ones and zeros.
zeros	Generates test pattern of continuous zeros.

Default Values

No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example activates the pattern generator for a stream of continuous ones:

(config)**#interface e1 1/1**
(config-e1 1/1)**#test-pattern ones**

timing-domain <*domain*>

Use the **timing-domain** command to assign the interface to a system-wide voice timing domain. Use the **no** form of this command to return to the default.

Syntax Description

<*domain*>	Assigns the interface to a system-wide timing domain. Valid domains are **1** and **2**.

Default Values

By default, interfaces are assigned to timing domain **1**.

Command History

Release A5.01	Command was introduced.

Usage Examples

The following example assigns the interface to timing domain **2**:

(config)**#interface e1 1/1**
(config-e1 1/1)**#timing-domain 2**

ts16

Use the **ts16** command to enable timeslot 16 multiframe to be checked on the receive signal. Use the **no** form of this command to disable timeslot 16.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.

Functional Notes

If timeslot 16 is used on the incoming E1, do not map timeslot 16 using the **tdm-group** command. By default, all timeslots not physically mapped using the **tdm-group** command are passed through to the G.703 interface. Leaving timeslot 16 unmapped makes it available for multiframe signaling by the connected E1 device.

Usage Examples

The following example enables timeslot 16 multiframing:

(config)**#interface e1 1/1**
(config-e1 1/1)**#ts16**

ETHERNET INTERFACE COMMAND SET

There are multiple types of Ethernet interfaces associated with AOS:

- Basic Ethernet interfaces (e.g., eth 0/1)
- Gigabit Ethernet interfaces (e.g., giga-eth 0/3)
- Gigabit Ethernet subinterfaces associated with Layer 3 services (eg., giga-eth 0/1.1)
- Ethernet subinterfaces associated with a virtual local area network (VLAN) (e.g., eth 0/1.1)
- Ethernet subinterfaces associated with Layer 3 services (eg., eth 0/1.1)
- Switchport interfaces which are only available on specific platforms (e.g., swx 0/1)
- Gigabit switchport interfaces which are only available on specific platforms (e.g., giga-swx 0/1)
- 10 gigabit switchport interfaces which are only available on specific platforms (e.g., xgiga-swx 1/1)

Not all platforms have Ethernet subinterfaces, Gigabit Ethernet, switchport, or gigabit switchport interfaces available. To see if your unit has this capability, type ***show interfaces*** *at the enable prompt.*

To activate the basic Ethernet Interface Configuration mode, enter the **interface ethernet** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface ethernet 0/1
(config-eth 0/1)#
```

To activate the Ethernet Subinterface Configuration mode, enter the **interface ethernet** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface ethernet 0/1.1
(config-eth 0/1.1)#
```

To activate the Ethernet Subinterface Configuration mode for Layer 3 services, enter the **interface ethernet** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface ethernet 0/1.1
(config-eth 0/1.1)#
```

To activate the Gigabit Ethernet Interface Configuration mode, enter the **interface gigabit-ethernet** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface gigabit-ethernet 0/3
(config-giga-eth 0/3)#
```

To activate the Gigabit Ethernet Subinterface Configuration mode, enter the **interface gigabit-ethernet** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface gigabit-ethernet 0/3.1
(config-giga-eth 0/3.1)#
```

To activate the Gigabit Switchport Interface Configuration mode, enter the **interface gigabit-switchport** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface gigabit-switchport 0/3
(config-giga-swx 0/3)#
```

To activate the Switchport Interface Configuration mode, enter the **interface switchport** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface switchport 0/1
(config-swx 0/1)#
```

To activate the Ethernet Configuration mode for a range of Ethernet interfaces, enter the **interface range** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface range ethernet 0/1, 0/8
(config-eth 0/1, 0/8)#
```

To activate the 10 Gigabit Switchport Interface Configuration mode, enter the **interface xgigabit-switchport** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface xgigabit-switchport 1/1
(config-xgiga-swx 1/1)#
```

*Not all Ethernet commands apply to all Ethernet types. Use the **?** command to display a list of valid commands. For example:*

*>**enable***
*Password:**xxxxx***
#config term
*(config)#**interface ethernet 0/1***
*(config-eth 0/1)#**?***

alias	*- A text name assigned by an SNMP NMS*
arp	*- Set ARP commands*
awcp	*- Enables Adtran Wireless Control Protocol on this interface*
bandwidth	*- Set bandwidth parameter*
etc.	

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

arp arpa on page 2161
awcp on page 2162
bandwidth <value> on page 2163
bridge-group <number> on page 2165
bridge-group <number> vlan-transparent on page 2166
ce-vlan-id <vlan id> on page 2167
channel-group <number> mode on on page 2168
connect evc <name> on page 2169

arp arpa

Use the **arp arpa** command to set ARPA as the standard Address Resolution Protocol (ARP) on this interface. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

The default for this command is **arpa**.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Usage Examples

The following example enables standard ARP for the Ethernet interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#arp arpa**

awcp

Use the **awcp** command to enable Adtran Wireless Control Protocol (AWCP) on this interface. The AWCP is an Adtran proprietary protocol used by an access controller (AC) to communicate with an access point (AP). Use the **no** form of this command to disable AWCP for this interface.

Syntax Description

No subcommands.

Default Values

By default, AWCP is enabled on the interface.

Command History

Release 15.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

When the global-level command **dot11ap access-point-controller** (refer to *dot11ap access-point-control on page 1268* for more information) is enabled, the AWCP function can be disabled on a specific interface by using the **no** form of this command from the desired interface. When the global-level command **dot11ap access-point-controller** is disabled, it overrides the **awcp** command setting for the interface.

Usage Examples

The following example disables AWCP on Ethernet interface 0/1:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#no awcp**

bandwidth <*value*>

Use the **bandwidth** command to provide the bandwidth value of an interface to the higher level protocols. This value is used in cost calculations. Use the **no** form of this command to restore the default value.

Syntax Description

<*value*>	Specifies bandwidth in kbps. Range is **1** to **4294967295** kbps.

Default Values

To view default value, use the **show interfaces** command.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

The **bandwidth** command is an informational value that is communicated to the higher level protocols to be used in cost calculations. While this is a routing parameter that does not affect the physical interface, it does affect the amount of bandwidth available for use in Quality of Service (QoS) configurations.

It is important to note that there is an order of precedence in determining the interface bandwidth reported by the router for QoS. Under normal circumstances, the Layer 1 bandwidth is reported based on the interface type. For example, a T1 interface will report the available bandwidth as 1.536 Mbps. This can be misleading in QoS configurations if the **bandwidth** command has been applied to the IP interface for routing purposes because the command overrides the reported available bandwidth that can be utilized for QoS. Using the **bandwidth** command can severely disrupt the configuration of QoS on the interface, therefore, use the **max-reserved-bandwidth** command (*page 2272*) to adjust the bandwidth appropriately for QoS configurations.

When configuring QoS for an Ethernet or VLAN interface, the interface **traffic-shape rate** command can be used to configure traffic shaping without applying a QoS map. If traffic shaping is applied to the same interface that will also have a QoS map applied to it, the amount of bandwidth available for the QoS policy is reduced to the value set with the **traffic-shape rate** command (*page 2348*). This value should be set to match the upload speed of the circuit. For example, under normal circumstances, an Ethernet interface can negotiate to 100 Mbps. However, the throughput of the upstream equipment is usually significantly less than the negotiated rate. The **traffic-shape rate** command is used to define the limit of when QoS policies containing the commands *bandwidth on page 4466* or *priority on page 4481* should be enforced according to the upload speed of the circuit. If the **bandwidth** <*value*> command is also entered on the same IP interface as the **traffic-shape rate** command, it will overwrite the value of the **traffic-shape rate** command for QoS purposes. It is not recommended to use the **bandwidth** <*value*> command for QoS. Instead, use the **max-reserved-bandwidth** command (*page 2272*) to adjust the bandwidth appropriately because the **traffic-shape rate** command is required for QoS to function properly on VLAN and Ethernet WAN IP interfaces.

Usage Examples

The following example sets bandwidth of the Ethernet 0/1 interface to 10 Mbps:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#bandwidth 10000**

bridge-group *<number>*

Use the **bridge-group** command to assign an interface to the specified bridge group. Use the **no** form of this command to remove the interface from the bridge group.

Syntax Description

<number>	Specifies the bridge group (by number) to which to assign this interface. Range is **1** to **255**.

Default Values

By default, there are no configured bridge groups.

Command History

Release 1.1	Command was introduced.

Functional Notes

A bridged network can provide excellent traffic management to reduce collisions and limit the amount of bandwidth wasted with unnecessary transmissions when routing is not necessary. Any two interfaces can be bridged (e.g., Ethernet to T1 bridge, Ethernet to Frame Relay subinterface).

Usage Examples

The following example assigns the Ethernet interface to bridge-group **17**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#bridge-group 17**

bridge-group <*number*> vlan-transparent

Use the **bridge-group vlan-transparent** command to prevent an interface from removing the virtual local area network (VLAN) tag. Use the **no** form of this command to allow the interface to remove the VLAN tag from the packet.

*The **bridge-group vlan-transparent** command is not a global command. The command must be applied on all interfaces of the bridge group.*

Syntax Description

<number>	Specifies the bridge group number. Valid range is **1** to **255**.

Default Values

By default, VLAN tags are removed from the data.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the high level data link control (HDLC) interface and Frame Relay subinterface.

Usage Examples

The following example removes the VLAN tags from the packets on the Ethernet interface 0/1:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#bridge-group 1 vlan-transparent**

ce-vlan-id <*vlan id*>

Use the **ce-vlan-id** command to set a customer-edge (CE) virtual local area network (VLAN) ID for Layer 3 service subinterfaces used as the Metro Ethernet network (MEN) port. Use the **no** form of this command to remove the CE VLAN ID configuration from the subinterface. Variations of this command include:

ce-vlan-id <*vlan id*>
ce-vlan-id <*vlan id*> **untagged**

Syntax Description

<*vlan id*>	Specifies a valid CE VLAN interface ID number. Range is **1** to **4095**.
untagged	Optional. Specifies that all untagged packets are identified with this subinterface.

Default Values

By default, all Layer 3 service subinterface traffic is unspecified, which prevents the subinterface from becoming active.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example configures a CE VLAN of **100** for the Gigabit Ethernet subinterface 0/1.1:

(config)**#interface gigabit-ethernet 0/1.1**
(config-giga-eth 0/1.1)**#ce-vlan-id 100**

channel-group <*number*> mode on

Use the **channel-group mode on** command to statically add the interface to a channel group. To remove an interface from a channel group, use the **no** form of this command.

Syntax Description

<*number*>	Specifies the channel-group number. Range is **1** to **6**.

Default Values

By default, the interface is not part of a channel group.

Command History

Release 5.1	Command was introduced.

Functional Notes

There can be up to six channel groups with 2 to 8 interfaces per group. Dynamic protocols are not yet supported (only static). A physical interface can be a member of only one channel group.

Usage Examples

The following example adds the Ethernet 0/1 interface to channel group **1**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#channel-group 1 mode on**
(config-eth 0/1)#

connect evc *<name>*

Use the **connect evc** command to associate the Ethernet virtual connection (EVC) with the subinterface for Layer 3 Metro Ethernet network (MEN) to CPU communication. Use the **no** form of this command to remove the connection.

Syntax Description

<name>	Specifies the EVC to which the matching traffic is mapped.

Default Values

By default, no EVC components are connected to the subinterface.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

The EVC's connected MEN port must match the parent interface of the Layer 3 subinterface for the subinterface to be active. This command is required if the parent interface is a network-to-network interface (NNI) and will not function if the parent interface is a user network interface (UNI).

Usage Examples

The following example specifies that EVC **CustomerSVC** is associated with Gigabit Ethernet subinterface 1/1.1:

(config)**#interface gigabit-ethernet 1/1.1**
(config-giga-eth-1/1.1)**#connect evc CustomerSVC**

dynamic-dns

Use the **dynamic-dns** command to configure Dynamic DNS service provided by Dynamic Network Services, Inc. (www.dyndns.org). Use the **no** form of this command to disable this feature. Variations of this command include:

dynamic-dns custom <*hostname*> <*minutes*>
dynamic-dns dyndns <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-custom <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-static <*hostname*> <*username*> <*password*>

Syntax Description

<*hostname*>	Specifies the host name for the server that updates the dynamic domain naming system (DNS).
<*minutes*>	Specifies the intervals in minutes to update the server with information (updates also occur when the interface's IP address changes regardless of the update intervals).
<*username*>	Specifies the user name.
<*password*>	Specifies the password.
	Refer to *Functional Notes* below for additional argument descriptions.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.
Release 12.1	Command was expanded.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

custom - Constanttime.com's Custom Dynamic DNS^{SM} service allows you complete access and management control over your domain name regardless of where you purchased/registered it. This allows you to manage IP address mappings (A records), domain aliases (CNAME records), and mail servers (mail exchange (MX) records).

dyndns - The Dynamic DNS^{SM} offered by Dynamic Network Services, Inc. (DynDNS.org) allows you to alias a dynamic IP address to a static host name in various domains. This allows your unit to be more easily accessed from various locations on the Internet. This service is provided for up to five host names.

dyndns-custom - DynDNS.org's Custom DNS^{SM} service provides a full DNS solution, giving you complete control over an entire domain name. A Web-based interface provides two levels of control over your domain, catering to average or advanced users. Five globally redundant DNS servers ensure that your domain will always resolve.

A choice of two interfaces is available. The basic interface is designed for most users. It comes preconfigured for most common configurations and allows for easy creation of most common record types. The advanced interface is designed for system administrators with a solid DNS background, and provides layout and functionality similar to a BIND zone file allowing for the creation of nearly any record type.

Custom DNS^{SM} can be used with both static and dynamic IPs, and has the same automatic update capability through Custom DNS-aware clients as Dynamic DNS.

dyndns-static - The Static DNS service is similar to DynDNS.org's Dynamic DNS^{SM} service in that it allows a host name, such as yourname.dyndns.org, to point to your IP address. Unlike a Dynamic DNS host, a Static DNS host does not expire after 35 days without updates, but updates take longer to propagate through the DNS system. This service is provided for up to five host names.

If your IP address does not change often or at all, but you still want an easy name to remember it by (without having to purchase your own domain name), Static DNS service is ideal for you.

If you would like to use your own domain name (such as yourname.com), you need Custom DNS service that also provides full dynamic and static IP address support.

Usage Examples

The following example sets the Dynamic DNS to **dyndns-custom** with host name **host**, user's name **user**, and password **pass**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#dynamic-dns dyndns-custom host user pass**

egress-queue

Use the **egress-queue** command to specify the output queue used by the Ethernet virtual connection (EVC) for traffic egressing this Layer 3 interface towards the user network interface (UNI). Use the **no** form of this command to return to the default setting. Variations of this command include:

egress-queue inherit
egress-queue <*value*>

Syntax Description

inherit	Specifies that traffic egressing the subinterface is mapped to the UNI queue based on the packet's outer tag value.
<*value*>	Specifies the queue to which the traffic is mapped. Valid range is **0** to **7**.

Default Values

By default, egressing traffic inherits the queue information.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies that egress traffic from the Layer 3 Ethernet subinterface 1/1.1 is mapped to egress queue **5**:

(config)**#interface ethernet 1/1.1**
(config-eth-1/1.1)**#egress queue 5**

encapsulation 802.1q

Use the **encapsulation 802.1q** command to put the interface into 802.1q virtual local area network (VLAN) mode.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Usage Examples

The following example puts Ethernet interface 0/1 in 802.1q mode and configures a subinterface for VLAN usage:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#encapsulation 802.1q**
(config-eth 0/1)**#interface ethernet 0/1.1**
(config-eth 0/1.1)**#vlan-id 3**

ethernet-cfm down

Use the **ethernet-cfm down** command to enable Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) on the Ethernet interface. Use the **no** form of this command to disable Ethernet OAM CFM on this interface.

Syntax Description

No subcommands.

Default Values

By default, Ethernet OAM CFM is disabled.

Command History

Release 17.4	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

For more information about Ethernet OAM CFM and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

For more information regarding specific Ethernet OAM CFM configuration commands on the Ethernet interface, refer to the *Ethernet OAM CFM Command Set on page 4405*.

Usage Examples

The following example enables Ethernet OAM CFM on Ethernet interface **0/1**:

(config)**#interface eth 0/1**
(config-eth 0/1)**#ethernet-cfm down**

ethernet-cfm mep

Use the **ethernet-cfm mep** command to create an Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) maintenance endpoint (MEP) on the Ethernet interface. Use the **no** form of this command to remove the MEP from the interface. Variations of this command include:

ethernet-cfm mep *<name>* *<name>* *<mep id>* **down**
ethernet-cfm mep none *<name>* *<mep id>* **down**

Syntax Description

<name>	Specifies the MEP's maintenance domain.
<name>	Specifies the MEP's maintenance association.
<mep id>	Specifies the unique numerical ID for this MEP. Range is **1** to **8191**.
none	Optional. Specifies no domain name is used.
down	Specifies the direction of the MEP.

Default Values

By default, no MEPs exist on the interface.

Command History

Release 17.4	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

For more information about Ethernet OAM CFM and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

For more information about specific MEP configuration commands, refer to the *Ethernet OAM CFM Command Set on page 4405*.

Usage Examples

The following example creates an MEP, with the MEP ID **100**, on Ethernet interface **eth 0/1**. The MEP is associated with maintenance domain **Domain1** and association **association1**:

```
(config)#interface eth 0/1
(config-eth 0/1)#ethernet-cfm mep Domain1 association1 100 down
(config-eth 0/1-mep)
```

ethernet lmi

Use the **ethernet lmi** command to enable Ethernet local management interface (E-LMI) on the Gigabit Ethernet interface. Use the **no** form of this command to disable the feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled. When enabled, the interface is in the provider edge (PE) mode.

Command History

Release R11.5.0	Command was introduced.
Release R11.6.0	Support for monitoring Y.1731 alarms and conditions was added.

Functional Notes

E-LMI is a feature used by AOS to provide user network interface (UNI) and Ethernet virtual connection (EVC) status information to the customer edge (CE) device. Status information is gathered from E-LMI messages exchanged between the PE and CE devices, and is stored in the AOS device.

The **no** form of this command disables E-LMI on the interface and also automatically removes the configured E-LMI bandwidth threshold for the interface, if configured. Refer to the command *ethernet lmi interface <interface> bandwidth-threshold on page 2177*.

Usage Examples

The following example enables the E-LMI feature:

(config)**#interface gigabit-ethernet 0/2**
(config-giga-eth 0/2)**#ethernet lmi**

ethernet lmi interface <*interface*> bandwidth-threshold

Use the **ethernet lmi interface** <*interface*> **bandwidth-threshold** command to monitor the bandwidth of an interface to determine the status of the Ethernet virtual connection (EVC). If the bandwidth of the interface drops below the specified amount, Ethernet local management interface (E-LMI) will indicate that the EVC status is NOT ACTIVE. Use the **no** form of this command to disable the feature. Variations of this command include:

ethernet lmi interface <*interface*> **bandwidth-threshold downspeed** <*value*>
ethernet lmi interface <*interface*> **bandwidth-threshold upspeed** <*value*>
ethernet lmi interface <*interface*> **bandwidth-threshold downspeed** <*value*> **upspeed** <*value*>

Syntax Description

<*interface*>	Specifies the Layer 2 interface to monitor for reduced bandwidth.
downspeed <*value*>	Specifies the bandwidth threshold for traffic moving from the Metro Ethernet network (MEN) to the UNI. If the interface's bandwidth in this direction drops below the specified value, E-LMI will indicate that the EVC is down. Valid range is **0** to **4294967295** kbps. Specifying a value of **0** disables the bandwidth monitoring.
upspeed <*value*>	Specifies the bandwidth threshold for traffic moving from the UNI to the MEN. If the interface's bandwidth in this direction drops below the specified value, E-LMI will indicate that the EVC is down. Valid range is **0** to **4294967295** kbps. Specifying a value of **0** disables the bandwidth monitoring.

Default Values

By default, this feature is disabled.

Command History

Release R11.6.0	Command was introduced.

Functional Notes

E-LMI is a feature used by AOS to provide UNI and EVC status information to the customer edge (CE) device. Status information is gathered from E-LMI messages exchanged between the provider edge (PE) and CE devices, and is stored in the AOS device.

If the actual bandwidth for the specified interface drops below the specified bandwidth, E-LMI indicates that the EVC is active. If the actual bandwidth is greater than or equal to the specified bandwidth, E-LMI indicates that the EVC is active. If both downspeed and upspeed are specified, and if the bandwidth in either direction falls below the specified threshold, E-LMI indicates that the EVC is inactive.

Only one interface can be specified using this command. Entering a different interface over-writes the existing configuration.

Using the **no** version of the command *ethernet lmi on page 2176* also removes the configured E-LMI bandwidth threshold on the interface.

Usage Examples

The following example monitors the downspeed bandwidth for the interface:

(config)**#interface gigabit-ethernet 0/2**
(config-giga-eth 0/2)**#ethernet lmi interface efm-group 1/1 bandwidth-threshold downspeed 400000**

ethernet lmi forwarding

Use the **ethernet lmi forwarding** command to enable transparent forwarding of E-LMI messages from UNI to NNI. Use the **no** form of this command to disable transparent forwarding of E-LMI messages.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled. When enabled, the interface transparently forwards E-LMI messages.

Command History

Release R13.11.0	Command was introduced.

Usage Examples

The following example enables Gigabit Ethernet interface 0/2 to transparently forward E-LMI messages:

(config)**#interface gigabit-ethernet 0/2**
(config-giga-eth 0/2)**#ethernet lmi forwarding**

ethernet oam enable

Use the **ethernet oam enable** command to enable Ethernet Link operations, administration, and management (OAM) on the interface. Use the **no** form of this command to disable Ethernet Link OAM on this interface.

Syntax Description

No subcommands.

Default Values

By default, Ethernet Link OAM is disabled when an interface is created. However, some products have Ethernet OAM enabled in their factory default configuration (for example, the NetVanta 4660).

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example enables Ethernet Link OAM on Gigabit Ethernet interface **0/1**:

(config)**#interface gigabit-ethernet 0/1**
(config-giga-eth 0/1)**#ethernet oam enable**

ethernet oam mode passive

Use the **ethernet oam mode passive** command to specify the Ethernet Link operations, administration, and management (OAM) mode on the interface. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, Ethernet Link OAM operates in active mode.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

When Ethernet Link OAM is in active mode (default setting), the interface attempts to initiate the OAM discovery process once Ethernet Link OAM is enabled. When Ethernet Link OAM is operating in passive mode, the interface waits for an active peer to initiate OAM discovery, as outlined in IEEE 802.3ah.

Usage Examples

The following example places Ethernet Link OAM in **passive** mode on Gigabit Ethernet interface **0/1**:

(config)**#interface gigabit-ethernet 0/1**
(config-giga-eth 0/1)**#ethernet oam mode passive**

ethernet oam link-monitor

Use the **ethernet oam link monitor** command to allow the interface to receive Ethernet Link operations, administration, and maintenance (OAM) Protocol Data Unit (PDU) Event Notifications on the interface. Use the **no** form of this command to disable OAM PDU Event Notifications on this interface.

Syntax Description

No subcommands.

Default Values

By default, Ethernet Link OAM PDU support is enabled on the interface.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

By default, support for OAM PDUs is advertised during OAM discovery. When OAM is enabled, the interface can receive OAM PDU Event Notifications, OAM PDUs with the Critical Link Event flags set, and Link Event time, length, value (TLV) notifications.

When link events are received by the interface, it keeps a record of the last two unique events on a per-event type basis. This includes critical link events, such as critical events, dying gasps, and link fault notifications, as well as regular link events, such as Errored Symbol Period, Errored Frames, Errored Frame Period, and Errored Frame Seconds Summary TLVs. You can view the recorded local and remote OAM link events using the **show ethernet oam statistics** command as described on *page 634*. You can clear the recorded events using the **clear ethernet oam statistics** command, as described on *page 136*.

Usage Examples

The following example disables support for receiving Ethernet Link OAM PDUs on Gigabit Ethernet interface **0/1**:

(config)**#interface gigabit-ethernet 0/1**
(config-giga-eth 0/1)**#no ethernet oam link-monitor**

ethernet oam mib-retrieval

Use the **ethernet oam mib-retrieval** command to enable Ethernet Link operations, administration, and management (OAM) Protocol Data Unit (PDU) Variable Responses and Variable Requests on the interface. Us the **no** form of this command to disable Variable Response and Request support for this interface.

Syntax Description

No subcommands.

Default Values

By default, Ethernet Link OAM PDU Variable Request and Response support is enabled on the interface.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

By default, support for OAM PDUs is advertised during OAM discovery. When OAM is enabled, the interface can receive OAM PDU Event Notifications, OAM PDUs with the Critical Link Event flags set, and Link Event time, length, value (TLV) notifications.

When link events are received by the interface, it keeps a record of the last two unique events on a per-event type basis. This includes critical link events, such as critical events, dying gasps, and link fault notifications, as well as regular link events, such as Errored Symbol Period, Errored Frames, Errored Frame Period, and Errored Frame Seconds Summary TLVs. You can view the recorded local and remote OAM link events using the **show ethernet oam statistics** as described on *page 634*. You can clear the recorded events using the **clear ethernet oam statistics** command, as described on *page 136*.

Usage Examples

The following example disables support for receiving Ethernet Link OAM PDUs on Gigabit Ethernet interface **0/1**:

(config)**#interface gigabit-ethernet 0/1**
(config-giga-eth 0/1)**#no ethernet oam link-monitor**

flowcontrol receive

Use the **flowcontrol receive** command to enable incoming flow control for the Ethernet interface. If **flowcontrol receive** is enabled, the unit will honor received pause frames. Use the **no** form of this command to disable flow control.

Syntax Description

No subcommands.

Default Values

By default, flow control is disabled.

Command History

Release 18.2	Command was introduced.

Usage Examples

The following example specifies that Ethernet interface **giga-eth 0/1** honors received pause frames:

(config)**#interface gigabit-ethernet 0/1**
(config-giga-eth 0/1)**#flowcontrol receive**

full-duplex

Use the **full-duplex** command to configure the Ethernet interface for full-duplex operation. This allows the interface to send and receive simultaneously. Use the **no** form of this command to return to the default **half-duplex** operation.

Syntax Description

No subcommands.

Default Values

By default, all Ethernet interfaces are configured for half-duplex operation.

Command History

Release 1.1	Command was introduced.
Release R12.1.0	Command was made unavailable for Ethernet interfaces on virtual AOS (vAOS) instances.

Functional Notes

Full-duplex Ethernet is a variety of Ethernet technology currently being standardized by the IEEE. Because there is no official standard, vendors are free to implement their independent versions of full-duplex operation. Therefore, it is not safe to assume that one vendor's equipment will work with another.

Devices at each end of a full-duplex link have the ability to send and receive data simultaneously over the link. Theoretically, this simultaneous action can provide twice the bandwidth of normal (half-duplex) Ethernet. To deploy full-duplex Ethernet, each end of the link must only connect to a single device (a workstation or a switched hub port). With only two devices on a full-duplex link, there is no need to use the medium access control mechanism (to share the signal channel with multiple stations) and listen for other transmissions or collisions before sending data.

Some Ethernet equipment (though rare) is unable to negotiate duplex if speed is manually determined. To avoid incompatibilities, manually set the duplex if the speed is manually set. Refer to *speed on page 2321* *for more information.*

The 10Base-T, 100Base-TX, and 100Base-FX signaling systems support full-duplex operation (because they have transmit and receive signal paths that can be simultaneously active).

This command is not available for Ethernet interfaces on vAOS instances.

Usage Examples

The following example configures the Ethernet interface for **full-duplex** operation:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#full-duplex**

half-duplex

Use the **half-duplex** command to configure the Ethernet interface for half-duplex operation. This setting allows the Ethernet interface to either send or receive at any given moment, but not simultaneously. Use the **no** form of this command to disable half-duplex operation.

Syntax Description

No subcommands.

Default Values

By default, all Ethernet interfaces are configured for half-duplex operation.

Command History

Release 1.1	Command was introduced.
Release R12.1.0	Command was made unavailable for Ethernet interfaces on virtual AOS (vAOS) instances.

Functional Notes

Half-duplex Ethernet is the traditional form of Ethernet that employs the carrier sense multiple access/collision detect (CSMA/CD) protocol to allow two or more hosts to share a common transmission medium while providing mechanisms to avoid collisions. A host on a half-duplex link must “listen” on the link and only transmit when there is an idle period. Packets transmitted on the link are broadcast (so it will be “heard” by all hosts on the network). In the event of a collision (two hosts transmitting at once), a message is sent to inform all hosts of the collision and a backoff algorithm is implemented. The backoff algorithm requires the station to remain silent for a random period of time before attempting another transmission. This sequence is repeated until a successful data transmission occurs.

Some Ethernet equipment (though rare) is unable to negotiate duplex if speed is manually determined. To avoid incompatibilities, manually set the duplex if the speed is manually set. Refer to *speed on page 2321* *for more information.*

This command is not available for Ethernet interfaces on vAOS instances.

Usage Examples

The following example configures the Ethernet interface for **half-duplex** operation:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#half-duplex**

ip access-group *<ipv4 acl name>*

Use the **ip access-group** command to apply an Internet Protocol version 4 (IPv4) access control list (ACL) to be used for IPv4 packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ip access-group *<ipv4 acl name>* **in**
ip access-group *<ipv4 acl name>* **out**

Syntax Description

<ipv4 acl name>	Applies the named IPv4 ACL to the interface.
in	Enables access control on IPv4 packets received on the specified interface.
out	Enables access control on IPv4 packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

When this command is enabled, the IPv4 destination address of each packet must be validated before being passed through. If the packet is not acceptable per these settings, it is dropped.

Usage Examples

The following example configures the router to only allow IPv4 Telnet traffic (as defined in the user-configured **TelnetOnly** ACL) into the Ethernet interface:

(config)**#ip access-list extended TelnetOnly**
(config-ext-nacl)**#permit tcp any any eq telnet**
(config-ext-nacl)**#interface ethernet 0/1**
(config-eth 0/1)**#ip access-group TelnetOnly in**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to an interface. IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

> NOTE *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an interface.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the Ethernet interface 0/1:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the Ethernet interface 0/1:

(config)**#interface eth 0/1**
(config-eth 0/1)**#ip access-policy PRIVATE**

ip address dhcp

Use the **ip address dhcp** command to use Dynamic Host Configuration Protocol (DHCP) to obtain an address on the interface. Use the **no** form of this command to remove a configured IP address (using DHCP) and disable DHCP operation on the interface. Variables that may be used with this command to further define the DHCP configuration include:

ip address dhcp class-id [ascii *<string>* **| hex** *<value>***] [client-id [***<interface>* **|** *<identifier>***]] [hostname** *<"string">***] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp client-id [*<interface>* **|** *<identifier>***] [hostname** *<"string">***] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp hostname *"<string>"* **[no-default-route | no-domain-name | no-nameservers] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp [no-default-route | no-domain-name | no-nameservers] [track *<name>***] [***<administrative distance>***]**
ip address dhcp track *<name>* **[***<administrative distance>***]**

Syntax Description

<administrative distance>	Optional. Specifies the administrative distance to use when adding the DHCP gateway into the route table. It is used to determine the best route when multiple routes to the same destination exist. The lower the administrative distance, the more reliable the route. Range is **1** to **255**.
class-id	Optional. Specifies the vendor class identifier for the interface.
ascii *<string>*	Specifies the vendor class identifier in an ASCII string of up to **255** bytes.
hex *<value>*	Specfies the vendor class identifier in hexadecimal format. Valid range is up to **510** hexadecimal numbers. An even number of digits is required.
client-id	Optional. Specifies the client identifier used when obtaining an IP address from a DHCP server.
<interface>	Specifies an interface, thus defining the client identifier as the hexadecimal medium access control (MAC) address of the specified interface (including a hexadecimal number added to the front of the MAC address to identify the media type). For example, specifying the **client-id ethernet 0/1** (where the Ethernet interface has a MAC address of d217.0491.1150) defines the client identifier as **01:d2:17:04:91:11:50** (where 01 defines the media type as Ethernet). Refer to *hardware-address on page 4344* for a detailed listing of media types.
<identifier>	Specifies a custom client-identifier using a text string (that is converted to a hexadecimal equivalent) or 7 to 28 hexadecimal numbers (with colon delimiters). For example, a custom client identifier of **0f:ff:ff:ff:ff:51:04:99:a1** may be entered using the *<identifier>* option.
hostname *<"string">*	Optional. Specifies a text string (to override the global router name) to use as the name in the DHCP option 12 field. The string is enclosed in quotation marks and can consist of up to 35 characters.

no-default-route Optional. Specifies that no default route is obtained via DHCP.

no-domain-name Optional. Specifies that no domain name is obtained via DHCP.

no-nameservers Optional. Specifies that no domain naming system (DNS) servers are obtained via DHCP.

track *<name>* Optional. Attaches a network monitoring track to the DHCP client. The DHCP gateway route for this client will only reside in the route table while the track is in the pass state. For more information on configuring track objects, refer to *track <name> on page 1886*.

Default Values

<administrative distance> By default, the administrative distance value is 1.

class-id Optional. By default, no vendor class identifier is configured.

client-id Optional. By default, the client identifier is populated using the following formula:

TYPE: INTERFACE SPECIFIC INFO : MAC ADDRESS

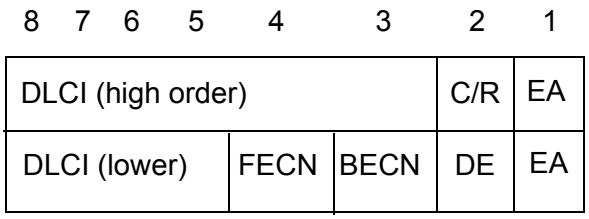
Where TYPE specifies the media type in the form of one hexadecimal byte (refer to *hardware-address on page 4344* for a detailed listing of media types), and the MAC ADDRESS is the medium access control (MAC) address assigned to the first Ethernet interface in the unit in the form of six hexadecimal bytes. (For units with a single Ethernet interface, the MAC ADDRESS assigned to Ethernet 0/1 is used in this field.)

INTERFACE SPECIFIC INFO is only used for Frame Relay interfaces and can be determined using the following:

FR_PORT#: Q.922 ADDRESS

Where the FR_PORT# specifies the label assigned to the virtual Frame Relay interface using four hexadecimal bytes. For example, a virtual Frame Relay interface labeled 1 would have a FR_PORT# of 00:00:00:01.

The Q.922 ADDRESS field is populated using the following:



Where the FECN, BECN, C/R, DE, and high order extended address (EA) bits are assumed to be 0 and the lower order EA bit is set to 1.

The following list provides a few example DLCIs and associated Q.922 address:

DLCI (decimal) / Q.922 address (hex)

16 / 0x0401
50 / 0x0C21
60 / 0x0CC1
70 / 0x1061
80 / 0x1401

hostname *“<string>”* By default, the host name is the name configured using the Global Configuration **hostname** command.

Command History

Release 2.1	Command was introduced.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 13.1	Command was expanded to include the track and administrative distance.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.10.0	Command was expanded to include the **class-id** parameter in support of DHCP Option 60.

Functional Notes

DHCP allows interfaces to acquire a dynamically assigned IP address from a configured DHCP server on the network. Many service providers require the use of DHCP when connecting to their services. Using DHCP reduces the number of dedicated IP addresses the ISP must obtain. Consult your ISP to determine the proper values for the **client-id** and **hostname** fields.

The vendor class identifier is sent to the DHCP server in DHCP discover and request messages via DHCP Option 60. This option gives the DHCP server details regarding DHCP client configuration and also allows the server to send any vendor-specific information to the client in DHCP offer messages via Option 43.

Usage Examples

The following example enables DHCP operation on the Ethernet interface 0/1:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip address dhcp**

The following example enables DHCP operation on the Ethernet interface 0/1 utilizing host name **adtran** and does not allow obtaining a default route, domain name, or name servers. It also sets the administrative distance as **5**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip address dhcp hostname “adtran” no-default-route no-domain-name no-nameservers 5**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the specified interface (only one primary address is allowed). Use the optional **secondary** keyword to define a secondary IPv4 address. Use the **no** form of this command to remove a configured IPv4 address. Variations of this command include:

ip address <*ipv4 address*> <*subnet mask*>
ip address <*ipv4 address*> <*subnet mask*> **secondary**

Syntax Description

<*ipv4 address*>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*subnet mask*>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the specified interface.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IP addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a secondary IPv4 address of **192.22.72.101 /30**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip address 192.22.72.101 /30 secondary**

ip address range *<start ip address> <end ip address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the specified interface. Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip crypto map *<name>*

Use the **ip crypto map** command to associate Internet Protocol version 4 (IPv4) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

> NOTE *When you apply a map to an interface, you are applying all crypto maps with the given map name. This allows you to apply multiple crypto maps if you have created maps that share the same name, but have different map index numbers.*

Syntax Description

<name>	Specifies the IPv4 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

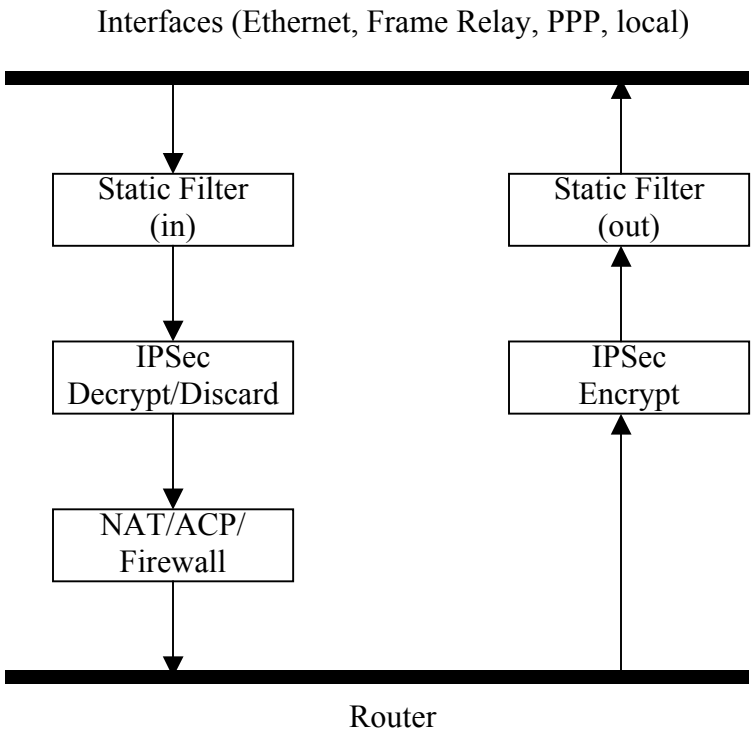
Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 9.1	Command was expanded to include the High-Level Data Link Control (HDLC) interface.
Release 11.1	Command was expanded to include the demand interface.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.7.0	Command syntax was changed to require the **ip** keyword.

Functional Notes

When configuring a system to use both the stateful inspection firewall and Internet key exchange (IKE) negotiation for VPN, keep the following notes in mind.

When defining the IPv4 policy class and associated access control lists (ACLs) that describe the behavior of the IPv4 firewall, do not forget to include the traffic coming into the system over a VPN tunnel terminated by the system. The firewall should be set up with respect to the unencrypted traffic that is destined to be sent or received over the VPN tunnel. The following diagram represents typical AOS data-flow logic.



As shown in the diagram above, data coming into the product is first processed by the static filter associated with the interface on which the data is received. This access group is a true static filter and is available for use regardless of whether the IPv4 firewall is enabled or disabled. Next (if the data is encrypted), it is sent to the IPSec engine for decryption. The decrypted data is then processed by the stateful inspection firewall. Therefore, given a terminating VPN tunnel, only unencrypted data is processed by the firewall.

The IPv4 ACLs for a crypto map on an interface work in reverse logic to the ACLs for a policy class on an interface. When specifying the ACLs for a crypto map, the source information is the private local side, unencrypted source of the data. The destination information will be the far-end, unencrypted destination of the data. However, ACLs for a policy class work in reverse. The source information for the ACL in a policy class is the far end. The destination information is the local side.

Usage Examples

The following example applies all IPv4 crypto maps with the name **MyMap** to the Ethernet interface:

(config)**#ethernet 0/1**
(config-eth 0/1)**#ip crypto map MyMap**

ip dhcp

Use the **ip dhcp** command to release or renew the Dynamic Host Configuration Protocol (DHCP) Internet Protocol version 4 (IPv4) address. This command is only applicable when using DHCP for IP address assignment. Variations of this command include:

ip dhcp release
ip dhcp renew

Syntax Description

release	Releases the DHCP IPv4 address.
renew	Renews the DHCP IPv4 address.

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.
Release 8.1	Command was added to the asynchronous transfer mode (ATM) subinterface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release R10.1.0	Command was added to the bridged virtual interface (BVI).

Usage Examples

The following example releases the IPv4 address assigned (by DHCP) on the Ethernet interface 0/1:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip dhcp release**

ip dhcp relay destination *<ipv4 address>*

Use the **ip dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 4 (IPv4) and to specify the IPv4 address for the DHCPv4 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv4 relay functionality is disabled on the interface.

Syntax Description

<ipv4 address>	Specifies the IPv4 address for the DHCPv4 messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.

Usage Examples

The following example enables DHCPv4 relay agent functionality and specifies the destination address as **192.33.4.251**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip dhcp relay destination 192.33.4.251**

ip directed-broadcast

Use the **ip directed-broadcast** command to allow reception/forwarding of directed broadcasts. Use the **no** form of this command to disable this feature. Variations of this command include:

ip directed-broadcast
ip directed-broadcast <*name*>

Syntax Description

<*name*>	Optional. Specifies an IP access control list (ACL) to filter traffic.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

A directed broadcast is a packet intended for all nodes on a nonlocal network. For example, the broadcast address 255.255.255.255 reaches all nodes on a network; the directed broadcast address 128.1.255.255 is intended for all nodes whose network address is 128.1.0.0. A router not directly attached to 128.1.0.0 simply forwards the directed broadcast packet to the next hop. A router on network 128.1.0.0 that has **ip directed-broadcast** enabled, accepts and forwards the packet to all nodes whose network address is 128.1.0.0. Routers connecting subnets of 128.1.0.0 also accept and forward the packet to the nodes on their respective subnets. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is distributed as a broadcast on the destination subnet. The packet is then sent as a link-layer broadcast.

The **ip directed-broadcast** command controls the distribution of directed broadcasts when they reach their target subnets. Only the final transmission of the directed broadcast on its ultimate destination subnet is affected. It does not affect the transit unicast routing of IP directed broadcasts.

If **ip directed-broadcast** is enabled for this interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which this interface is attached will be forwarded as broadcasts on that subnet. Forwarding of the packets can be limited by specifying an ACL with this command. In this case, only directed broadcasts that are permitted by the specified ACL will be forwarded, and all other directed broadcasts directed to this interface subnet will be dropped.

Disabling the **ip directed-broadcast** command will cause directed broadcasts destined for the subnet to which this interface is attached to be dropped.

This option is a requirement for routers as described in RFC 1812, section 4.2.2.11. Furthermore, it is disabled by default (RFC 2644), with the intended goal of reducing the efficacy of certain types of denial of service (DoS) attacks.

Usage Examples

The following example enables forwarding of directed broadcasts on the interface **ethernet 0/1**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip directed-broadcast**

ip ffe

Use the **ip ffe** command to enable the RapidRoute fast forwarding engine (FFE) on this Internet Protocol version 4 (IPv4) interface with the default number of entries. Use the **no** form of this command to disable this feature. Variations of this command include:

ip ffe
ip ffe max-entries <*value*>

Issuing this command will cause all RapidRoute entries to be cleared from this IPv4 interface.

Syntax Description

max-entries <*value*>	Optional. Specifies the maximum number of entries stored in the flow table. Valid range is from **1** to **500000**.

Default Values

By default, the RapidRoute Engine is enabled. The default number of **max-entries** is **4096**.

Command History

Release 13.1	Command was introduced.
Release 17.6	Command was expanded to include the high level data link control (HDLC) and tunnel interfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.4.0	Maximum number of stored entries was expanded to **500000** and RapidRoute is now enabled by default.

Functional Notes

RapidRoute can be used to help reduce routing overhead, and thus reduce overall routing times. Routing times are reduced by the creation of a flow table on the ingress interface. The maximum number of entries that can be stored in the flow table at any one time may be specified by using the **max-entries** parameters.

Usage Examples

The following example disables RapidRoute on the IPv4 interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#no ip ffe**

Technology Review

The RapidRoute system goal is to increase IP packet throughput by moving as much of the packet processing into the engine as possible. Packets are classified into flows based upon the IP protocol (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol (ICMP), etc.), the source and destination IP addresses, IP type of service (ToS), and the protocol-specific information, such as the source and destination port numbers. Flows are defined as the unidirectional representation of a conversation between two IP hosts. Each ingress interface keeps its own flow table, a collection of flow entries.

The first packet in a flow that is forwarded through the unit will build a flow entry. When a flow entry is looked up but no entry is found, a RapidRouteBuilder object is allocated and attached to the packet. As the packet passes through the various processing layers, each subsystem will add processing to the RapidRouteBuilder. When packet is about to be forwarded out of the egress interface, the RapidRouteBuilder will be finalized. That is, the flow entry being built will be checked for completeness and committed to the flow table on the ingress interface. Subsequent flow matches can then bypass the normal processing layers.

ip flow

Use the **ip flow** command to enable integrated traffic monitoring (ITM) for all traffic received or forwarded on an interface. Use the **no** form of this command to disable traffic monitoring. Variations of this command include:

ip flow egress
ip flow egress <*name*>
ip flow ingress
ip flow ingress <*name*>

Syntax Description

egress	Specifies that all outgoing traffic be monitored.
ingress	Specifies that all incoming traffic be monitored.
<*name*>	Optional. Specifies the name of an access control list (ACL) to use for filtering traffic.

Default Values

By default, no traffic monitoring is enabled.

Command History

Release 16.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Usage Examples

The following example enables traffic monitoring on an **Ethernet** interface to monitor **incoming** traffic through an ACL called **myacl**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip flow ingress myacl**

ip helper-address *<ip address>*

Use the **ip helper-address** command to configure AOS to forward User Datagram Protocol (UDP) broadcast packets received on the interface. Use the **no** form of this command to disable forwarding packets.

*The **ip helper-address** command must be used in conjunction with the **ip forward-protocol** command to configure AOS to forward UDP broadcast packets.*

Syntax Description

<ip address>	Specifies the destination IP address for the forwarded UDP packets. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, broadcast UDP packets are not forwarded.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

When used in conjunction with the **ip forward-protocol** command, the **ip helper-address** feature allows you to customize which broadcast packets are forwarded.

To implement the helper address feature, assign helper address(es) (specifying the device that needs to receive the broadcast traffic) to the interface closest to the host that transmits the broadcast packets. When broadcast packets (of the specified type forwarded using the **ip forward-protocol** command) are received on the interface, they will be forwarded to the device that needs the information.

Only packets meeting the following criteria are considered eligible by the **ip helper-address** feature:

1. The packet IP protocol is UDP.

2. Any UDP port specified using the **ip forward-protocol** command.

3. The medium access control (MAC) address of the frame is an all-ones broadcast address (ffff.ffff.ffff).

4. The destination IP address is broadcast defined by all ones (**255.255.255.255**) or a subnet broadcast (for example, **192.33.4.251** for the **192.33.4.248 /30** subnet).

Usage Examples

The following example forwards all domain naming system (DNS) broadcast traffic to the DNS server with IP address **192.33.5.99**:

(config)**#ip forward-protocol udp domain**
(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip helper-address 192.33.5.99**

ip igmp

Use the **ip igmp** command to configure multicasting related functions for the interface. Variations of this command include:

ip igmp immediate-leave
ip igmp last-member-query-interval <*milliseconds*>
ip igmp querier-timeout <*seconds*>
ip igmp query-interval <*seconds*>
ip igmp query-max-response-time <*seconds*>
ip igmp static-group <*address*>
ip igmp version [1 | 2]

Syntax Description

immediate-leave	Specifies that if only one host (or Internet Group Management Protocol (IGMP) snooping switch) is connected to the interface, when a leave is received, multicast of that group is immediately terminated as opposed to sending a group query and timing out the group if no device responds. Works in conjunction with **ip igmp last-member-query-interval**. Applies to all groups when configured. Use the **no** form of this command to disable the **immediate-leave** feature.
last-member-query-interval <*milliseconds*>	Controls the timeout (in milliseconds) used to detect whether any group receivers remain on an interface after a receiver leaves a group. If a receiver sends a leave-group message (IGMP Version 2), the router sends a group-specific query on that interface. After twice the time specified by this command plus as much as one second longer, if no receiver responds, the router removes that interface from the group and stops sending that group's multicast packets to the interface. Range is **100** to **65535** ms. Use the **no** form of this command to return to the default setting.
querier-timeout <*seconds*>	Specifies the interval (in seconds) that the router waits after the current querier's last query before it takes over as querier (IGMP V2). Range is **60** to **300** seconds. Use the **no** form of this command to return to the default setting.
query-interval <*seconds*>	Specifies the interval (in seconds) at which IGMP queries are sent on an interface. Host query messages are addressed to the all-hosts multicast group with an IP time to live (TTL) of 1. The router uses queries to detect whether multicast group members are on the interface and to select an IGMP designated router (DR) for the attached segment (if more than one multicast router exists). Only the DR for the segment sends queries. For IGMP V2, the DR is the router with the lowest IP address on the segment. Range is **0** to **65535** seconds. Use the **no** form of this command to return to the default setting.
query-max-response-time <*seconds*>	Specifies the maximum response time (in seconds) advertised by this interface in queries when using IGMP V2. Hosts are allowed a random time within this period to respond, reducing response bursts. Use the **no** form of this command to return to the default setting.

Syntax Description

static-group <*address*>	Configures the router's interface to be a statically connected member of the specified group. Packets received on the correct reverse path forwarding (RPF) interface are forwarded to this interface regardless of whether any receivers have joined the specified group using IGMP. Use the **no** form of this command to remove a configured static group.
version [1 | 2]	Sets the interface's IGMP version. Use the **no** form of this command to return to the default setting.

Default Values

The defaults for this command are:

last-member-query-interval	**1000** milliseconds
querier-timeout	2x the **query-interval** value
query-interval	**60** seconds
query-max-response-time	**10** seconds
version	Version **1**

There are no default values for **immediate-leave** and **static-group**.

Command History

Release 7.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Usage Examples

The following example sets the query message interval on the interface to **200** milliseconds:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip igmp last-member-query-interval 200**

ip mcast-stub downstream

Use the **ip mcast-stub downstream** command to enable multicast forwarding and Internet Group Management Protocol (IGMP) (router mode) on an interface, and to place it in multicast stub downstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub upstream** commands. Downstream interfaces connect to segments with multicast hosts. Multiple interfaces may be configured in downstream mode; however, interfaces connecting to the multicast network (upstream) should not be configured in downstream mode. Interfaces configured as downstream should have the lowest IP address of all IGMP-capable routers on the connected segment in order to be selected as the designated router (DR) and ensure proper forwarding. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub upstream on page 2210* for more information.

Usage Examples

The following example enables multicast forwarding and IGMP on the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip mcast-stub downstream**

ip mcast-stub fixed

Use the **ip mcast-stub fixed** command to allow forwarding of multicast traffic on a selected interface after enabling multicast routing. Use the **no** form of this command to disable this mode.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 12.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Multicast routing must be enabled prior to setting **ip mcast-stub fixed** on the selected interface. Also, use the **ip igmp static-group** <*ip address*> command to receive multicast traffic without host-initiated Internet Group Management Protocol (IGMP) activity on the selected interface. Otherwise, all host-initiated IGMP transactions will enter multicast routes on the router's interface involved with IGMP activities.

Usage Examples

The following example enables multicast traffic forwarding and IGMP on the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip mcast-stub fixed**

ip mcast-stub helper-enable

Use the **ip mcast-stub helper-enable** command to assign the **ip mcast-stub helper-address** as the Internet Group Management Protocol (IGMP) proxy. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 8.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address**, **ip mcast-stub upstream**, and **ip mcast-stub downstream** commands. When enabled, the interface becomes a helper forwarding interface. The IGMP host function is dynamically enabled and the interface becomes the active upstream interface, enabling the unit to perform as an IGMP proxy. Refer to *ip mcast-stub helper-address <ip address> on page 1418*, *ip mcast-stub downstream on page 2207*, and *ip mcast-stub upstream on page 2210* for more information.

Usage Examples

The following example sets the helper address as the IGMP proxy:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip mcast-stub helper-enable**

ip mcast-stub upstream

Use the **ip mcast-stub upstream** command to enable multicast forwarding on an interface and place it in multicast stub upstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub downstream** commands. When enabled, the interface becomes a candidate to be a helper forwarding interface. If chosen as the best path toward the helper address by the router's unicast route table, the Internet Group Management Protocol (IGMP) host function is dynamically enabled and the interface becomes the active upstream interface, enabling the router to perform as an IGMP proxy. Though multiple interfaces may be candidates, no more than one interface will actively serve as the helper forwarding interface. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub downstream on page 2207* for more information.

Usage Examples

The following example enables multicast forwarding on the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip mcast-stub upstream**

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces (all types)	1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

OSPFv2 will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the Ethernet interface 0/1:

(config)**#interface eth 0/1**
(config-eth 0/1)**#ip mtu 1200**

ip ospf

Use the **ip ospf** command to customize Open Shortest Path First version 2 (OSPFv2) settings (if needed). Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **area** <*area id*>
ip ospf <*process id*> **authentication-key** <*password*>
ip ospf <*process id*> **cost** <*value*>
ip ospf <*process id*> **dead-interval** <*seconds*>
ip ospf <*process id*> **hello-interval** <*seconds*>
ip ospf <*process id*> **message-digest-key [1 | 2] md5** <*key*>
ip ospf <*process id*> **priority** <*value*>
ip ospf <*process id*> **retransmit-interval** <*seconds*>
ip ospf <*process id*> **shutdown**
ip ospf <*process id*> **transmit-delay** <*seconds*>

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
area <*area id*>	Specifies the ID of the area to which this interface is assigned for the specified OSPFv2 process. Valid range is **0** to **4294967295**.
authentication-key <*password*>	Assigns a simple-text authentication password to be used by other routers using the OSPF simple password authentication.
cost <*value*>	Specifies the OSPF cost of sending a packet on the interface. This value overrides any computed cost value. Range is **1** to **65535**.
dead-interval <*seconds*>	Sets the maximum interval (in seconds) allowed between hello packets. If the maximum is exceeded, neighboring devices will determine that the device is down. Range is **0** to **32767** seconds.
hello-interval <*seconds*>	Specifies the interval (in seconds) between hello packets sent on the interface. Range is **0** to **32767** seconds.
message-digest-key [1 | 2] md5 <*key*>	Configures OSPF message digest 5 (MD5) authentication (16 byte maximum) keys.
priority <*value*>	Sets the OSPF priority. The value set in this field helps determine the designated router (DR) for this network. Range is **0** to **255**.
retransmit-interval <*seconds*>	Specifies the interval (in seconds) between link state advertisements (LSAs). Range is **0** to **32767** seconds.

shutdown	Disables the OSPFv2 process on the interface. When this keyword is used, the OSPFv2 settings remain in place, but logically it appears to the interface as though the process has been removed from the configuration. This parameter can be useful in troubleshooting.
transmit-delay <*seconds*>	Sets the estimated time (in seconds) required to send a link state advertisement (LSA) on the interface. Range is **0** to **32767** seconds.

Default Values

The defaults for this command are:

dead-interval <*seconds*>	40 seconds
hello-interval <*seconds*>	10 seconds: Ethernet, Frame Relay, and Point-to-Point Protocol (PPP)
priority <*value*>	1
retransmit-interval <*seconds*>	5 seconds
transmit-delay <*seconds*>	1 second

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.3.0	Command was expanded to include the <*process id*>, **area** <*area id*>, and **shutdown** parameters.

Usage Examples

The following example specifies an OSPFv2 priority of **120** on the Ethernet interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip ospf 1 priority 120**

ip ospf <*process id*> authentication

Use the **ip ospf authentication** command to authenticate an interface that is performing open shortest path first (OSPF) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **authentication**
ip ospf <*process id*> **authentication message-digest**
ip ospf <*process id*> **authentication null**

Syntax Description

<process id>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
message-digest	Optional. Selects message digest authentication type.
null	Optional. Specifies that no authentication be used.

Default Values

By default, **ip ospf authentication** is set to **null** (meaning no authentication is used).

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Usage Examples

The following example specifies that no authentication will be used on the Ethernet interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip ospf 1 authentication null**

ip ospf <*process id*> network

Use the **ip ospf network** command to specify the type of network on this interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **network broadcast**
ip ospf <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
broadcast	Sets the network type for broadcast.
point-to-point	Sets the network type for point-to-point.

Default Values

By default, Ethernet defaults to **broadcast**. Point-to-Point Protocol (PPP) and Frame Relay default to **point-to-point**.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Functional Notes

A point-to-point network will not elect designated routers.

Usage Examples

The following example designates a broadcast network type:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip ospf 1 network broadcast**

ip pim sparse-mode

Use the **ip pim sparse-mode** command to enable protocol-independent multicast (PIM) sparse mode for this interface. Use the **no** form of this command to disable PIM sparse mode.

Syntax Description

No subcommands.

Default Values

By default, PIM sparse mode for this interface is disabled.

Command History

Release 11.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

PIM sparse mode is a multicast routing protocol that makes use of the unicast forwarding table. It builds unidirectional shared trees rooted at a rendezvous point (RP) for a multicast group or a shortest path tree rooted at a specific source for a multicast group.

Usage Examples

The following example enables PIM sparse mode on the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip pim sparse-mode**

ip pim-sparse dr-priority <*value*>

Use the **ip pim-sparse dr-priority** command to specify the priority for the designated router (DR). This command modifies the router's priority in the DR election process. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the priority of this interface (to be used when determining the DR). Valid range is **1** to **4294967295**.

Default Values

By default, the priority of all protocol-independent multicast (PIM) interfaces is **1**.

Command History

Release 11.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Interfaces advertise their configured priority values in the hello messages transmitted on the interface. Routers use the priority values to determine the appropriate DR. The router on the network segment with the highest priority is selected as the DR. If a hello message is received on the interface from a router on the network segment and it does not contain a priority, the entire network segment defaults to DR selection based on IP addresses instead of priority. In this instance, the DR is selected as the router on the network segment that has the highest IP address. AOS will always include a priority in all transmitted hello messages. If no priority is specifically designated by the user, the priority is set as the default of 1.

Usage Examples

The following example specifies a priority of **100** on the Ethernet 0/1 interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip pim-sparse dr-priority 100**

ip pim-sparse hello-timer <*value*>

Use the **ip pim-sparse hello-timer** command to specify protocol-independent multicast (PIM) sparse hello timer period. This is the time interval at which periodic hellos are sent out on all interfaces of a PIM-capable router. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the interval (in seconds) at which periodic hellos are sent out of the interface. Valid range is **10** to **3600** seconds.

Default Values

By default, the hellos are transmitted on PIM interfaces every **60** seconds.

Command History

Release 11.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Hello messages are used to inform neighbors of a router's presence. Hello messages normally generate a small amount of traffic on an interface. Setting the **hello-timer** to a small interval increases the number of hellos sent (thus increasing the amount of traffic). Set the **hello-timer** to a reasonable value, taking into consideration the bandwidth available on the interface.

Usage Examples

The following example specifies hellos be sent on the Ethernet 0/1 interface every **3600** seconds:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip pim-sparse hello-timer 3600**

ip pim-sparse nbr-timeout <*value*>

Use the **ip pim-sparse nbr-timeout** command to specify protocol-independent multicast (PIM) sparse neighbor timeout. This is the time interval after which a PIM-capable router will consider a neighbor not present. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the time interval in seconds after which a neighbor is considered not present. Valid range is **30** to **10800** seconds.

Default Values

By default, the nbr-timeout is set to **105** seconds.

Command History

Release 11.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Usage Examples

The following example sets the neighbor timeout to **300** seconds:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip pim-sparse nbr-timeout 300**

ip pim-sparse override-interval <*value*>

Use the **ip pim-sparse override-interval** command to specify the protocol-independent multicast (PIM) sparse join/prune override interval. This delay interval is the period after a join/prune that another router on the local area network (LAN) may override a join/prune. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the delay time in milliseconds. Valid range is **0** to **65535** milliseconds.

Default Values

By default, the override interval is set to **2500** milliseconds.

Command History

Release 11.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Usage Examples

The following example sets the override interval to **3000** milliseconds:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip pim-sparse override-interval 3000**

ip pim-sparse propagation-delay *<value>*

Use the **ip pim-sparse propagation-delay** command to specify the expected propagation delay for join/prune messages. Set the propagation delay (in milliseconds) to estimate the amount of delay found in the local link. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the expected propagation delay in the local link in milliseconds. Valid range is **0** to **32767** milliseconds.

Default Values

By default, the propagation delay is set to **500** milliseconds.

Command History

Release 11.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Usage Examples

The following example sets the propagation delay to **300** milliseconds:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip pim-sparse propagation-delay 300**

ip policy route-map *<name>*

Use the **ip policy route-map** command to assign a policy route-map to this interface. Use the **no** form of this command to remove the route-map policy.

Syntax Description

<name>	Specifies the name of the policy route map to assign to this interface.

Default Values

By default, no policy route map is assigned to this interface.

Command History

Release 11.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Usage Examples

The following example assigns the policy route map **policy1** to the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip policy route-map policy1**

ip proxy-arp

Use the **ip proxy-arp** command to enable proxy Address Resolution Protocol (ARP) on the interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, proxy ARP is enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

In general, the principle of proxy ARP allows a router to insert its IP address in the source IP address field of a packet (if the packet is from a host on one of its subnetworks). This allows hosts to reach devices on other subnetworks without implementing routing or specifying a default gateway.

If proxy ARP is enabled, AOS will respond to all ARP requests with its specified medium access control (MAC) address and forward packets accordingly.

Enabling proxy ARP on an interface may introduce unnecessary ARP traffic on the network.

Usage Examples

The following example enables proxy ARP on the Ethernet interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip proxy-arp**

ip rip receive version

Use the **ip rip receive version** command to configure the Routing Information Protocol (RIP) version the unit accepts in all RIP packets received on the interface. Variations of this command include:

ip rip receive version 1
ip rip receive version 2

Syntax Description

1	Accepts only RIP version 1 packets received on the interface.
2	Accepts only RIP version 2 packets received on the interface.

Default Values

By default, all interfaces implement RIP version **1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Use the **ip rip receive version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only accepts one version (either **1** or **2**) on a given interface.

Usage Examples

The following example configures the Ethernet interface to accept only RIP version **2** packets:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip rip receive version 2**

ip rip send version

Use the **ip rip send version** command to configure the Routing Information Protocol (RIP) version the unit sends in all RIP packets transmitted on the interface. Variations of this command include:

ip rip send version 1
ip rip send version 2

Syntax Description

1	Transmits only RIP version 1 packets on the interface.
2	Transmits only RIP version 2 packets on the interface.

Default Values

By default, all interfaces transmit RIP version **1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Use the **ip rip send version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only transmits one version (either **1** or **2**) on a given interface.

Usage Examples

The following example configures the Ethernet interface to transmit only RIP version **2** packets:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip rip send version 2**

ip rip summary-address *<ip address> <subnet mask>*

Use the **ip rip summary-address** command to manually summarize the routes Routing Information Protocol (RIP) will advertise and send out a specified interface. Use the **no** form of this command to disable this mode.

Syntax Description

<ip address>	Specifies the summarized network IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.0**).
<subnet mask>	Specifies the subnet mask that corresponds to the range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no manual summarization is applied by RIP.

Command History

Release 12.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Unlike the automatic summarization on classful network boundaries, only specific network advertisements are made by RIP using the **ip rip summary-address** command. This command is only effective if RIP version 2 is configured.

Usage Examples

The following example enables manual summarization on the specified IP address:

(config)**#interface eth 0/1**
(config-eth 0/1)**#ip rip summary-address 10.10.123.0 255.255.255.0**

ip route-cache

Use the **ip route-cache** command to enable Internet Protocol version 4 (IPv4) fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

*Using network address translation (NAT) or the AOS firewall capabilities on an interface requires process switching mode (using the **no ip route-cache** command).*

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Fast switching allows an IPv4 interface to provide optimum performance when processing IPv4 traffic.

Usage Examples

The following example enables IPv4 fast switching on the Ethernet interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip route-cache**

ip unnumbered *<interface>*

Use the **ip unnumbered** command to use the IP address assigned to the specified interface for all IP processing on the active interface. Use the **no** form of this command to remove the unnumbered configuration.

Syntax Description

<interface>	Specifies the interface that contains the IP address to use as the source address for all packets transmitted on this interface. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip unnumbered ?** for a list of valid interfaces.

Default Values

By default, all interfaces are configured to use a specified IP address (using the **ip address** command).

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 11.1	Command was expanded to include the demand interfaces.

Functional Notes

If **ip unnumbered** is enabled on an interface, all IP traffic from the interface will use a source IP address taken from the specified interface. For example, specifying **ip unnumbered ppp 1** while in the Ethernet Interface Configuration mode configures the Ethernet interface to use the IP address assigned to the Point-to-Point Protocol (PPP) interface for all IP processing. In addition, AOS uses the specified interface information when sending route updates over the unnumbered interface.

Usage Examples

The following example configures the Ethernet interface 0/1 to use the IP address assigned to the PPP interface (**ppp 1**):

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip unnumbered ppp 1**

ip urlfilter *<name>*

Use the **ip urlfilter** command to apply a universal resource locator (URL) filter to the interface for all inbound or outbound traffic. Use the **no** form of this command to remove the URL filter from an interface. Variations of this command include:

ip urlfilter *<name>* **in**
ip urlfilter *<name>* **out**

Syntax Description

<name>	Specifies the URL filter name to use on the interface.
in	Applies the filter to the inbound traffic.
out	Applies the filter to the outbound traffic.

Default Values

By default, there are no URL filters applied to any interfaces.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be created by using the **ip urlfilter** *<filtername>* **http** command before applying it to the interface. Refer to *ip urlfilter allowmode on page 1493* for more information on using this command.

Usage Examples

The following example performs URL filtering on all traffic entering through the Ethernet interface and matches the URL filter named **MyFilter**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip urlfilter MyFilter in**

ipv6

Use the **ipv6** command to enable Internet Protocol version 6 (IPv6) processing and create a link-local address on an interface. Use the **no** form of this command to disable IPv6 processing and remove all IPv6 configuration on the interface.

Syntax Description

No subcommands.

Default Values

By default, IPv6 is not enabled on the interface.

Command History

Release 18.1	Command was introduced.

Functional Notes

Because AOS uses the dual-stack for IPv6 implementation, IPv6 features must be enabled for the supported IPv6 features to be used. Enabling IPv6 in AOS is completed by using an IPv6 address or using the **ipv6** keyword with specific commands. For example, to enable IPv6 on an interface and cause the interface to join the link scoped all-nodes and all-routers multicast group, enter an IPv6 address on the interface.

Use the **ipv6** command to enable IPv6 processing and create a link-local address on an interface when other unicast IPv6 addresses are not needed on the interface. This command is not necessary nor effectual when any other form of an IPv6 address command is also present on the interface.

Usage Examples

The following example enables IPv6 and creates a link-local IPv6 address on the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6**

ipv6 access-group *<ipv6 acl name>*

Use the **ipv6 access-group** command to apply an Internet Protocol version 6 (IPv6) access control list (ACL) to be used for IPv6 packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ipv6 access-group *<ipv6 acl name>* **in**
ipv6 access-group *<ipv6 acl name>* **out**

Syntax Description

<ipv6 acl name>	Applies the named IPv6 ACL to the interface.
in	Enables access control on IPv6 packets received on the specified interface.
out	Enables access control on IPv6 packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 18.1	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.

Functional Notes

Only one IPv6 ACL can be applied in each traffic direction.

Unlike in IPv4, IPv6 traffic filters include an implicit **permit** for neighbor solicitation and advertisement packets in an ACL before the traditional implicit **deny** at the end of the ACL. This prevents blocking of address resolution and unreachability detection, although this can be overridden by entering explicit **deny** commands in the IPv6 ACL.

Usage Examples

The following example applies the IPv6 ACL **Privatev6** to incoming IPv6 traffic on the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 access-group Privatev6 in**

ipv6 access-policy *<ipv6 acp>*

Use the **ipv6 access-policy** command to assign a specified Internet Protocol version 6 (IPv6) access control policy (ACP) to an interface. IPv6 ACPs are applied to IPv6 traffic entering an interface. Use the **no** form of this command to remove an ACP association.

Syntax Description

<ipv6 acp>	Identifies the configured IPv6 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv6 ACPs associated with an interface.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example applies the IPv6 ACP **PRIVATEv6** to the interface:

Enable the AOS security features:
(config)**#ipv6 firewall**

Associate the ACP with the Ethernet interface 0/1:

(config)**#interface eth 0/1**
(config-eth 0/1)**#ipv6 access-policy PRIVATEv6**

ipv6 address autoconfig

Use the **ipv6 address autoconfig** command to enable Internet Protocol version 6 (IPv6) processing on the interface, create a local-link IPv6 address for the interface, and allow the interface to automatically configure itself based on advertisements from other routers on the link. Use the **no** form of this command to remove all autoconfigured addresses, prefixes, and any resulting routes from the interface and also causes the interface to cease processing received router advertisements (RAs).Variations of this command include:

ipv6 address autoconfig
ipv6 address autoconfig default
ipv6 address autoconfig default metric <*value*>

Syntax Description

default	Optional. Specifies that the interface maintain a list of advertising routers that are willing to be IPv6 default routers.
metric <*value*>	Optional. Specifies the administrative distance for a default router maintained in the default router list. Range is **1** to **255**. Routes with lower administrative distance are favored.

Default Values

By default, no IPv6 addresses are configured for the interface and IPv6 processing is not enabled. When an IPv6 address is configured automatically, the administrative distance for default routers is **2** by default.

Command History

Release 18.1	Command was introduced.

Functional Notes

When autoconfiguration is enabled, the interface listens for RA messages that tell the interface how it should be configured. The interface then creates addresses for advertised 64-bit prefixes with the A flag in the IPv6 address set using stateless address autoconfiguration (SLAAC). The addresses use the EUI-64 interface ID in the lower 64 bits of the address. A route type of *Connected* is added to the route table if the L flag on the prefix advertisement (on-link flag) is also set.

Usage Examples

The following example enables IPv6 processing on the interface, creates a link-local IPv6 address for the interface, and allows the interface to automatically configure itself for IPv6:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 address autoconfig**

ipv6 address *<ipv6 address/prefix-length>*

Use the **ipv6 address** command to assign a unicast Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<ipv6 address/prefix-length>	Specifies the IPv6 unicast address to add to the interface. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

Default Values

By default, no IPv6 address is configured on the interface and IPv6 processing is not enabled on the interface.

Command History

Release 18.1	Command was introduced.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the interface using the command *ipv6 address <ipv6 link-local address> link-local on page 2237*.

The address created by this command is a manually configured IPv6 address, which must have all parts (prefix and host bits) specified.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example adds a unicast IPv6 address to the interface and enables IPv6 processing on the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 address 2001:DB8::/32**

ipv6 address *<ipv6 prefix/prefix-length>* eui-64

Use the **ipv6 address eui-64** command to assign a unicast Internet Protocol version 6 (IPv6) address and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<ipv6 prefix/prefix-length>	Specifies the IPv6 prefix. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
eui-64	Specifies that the IPv6 address is constructed using the specified prefix in the high-order bits and followed by the EUI-64 Interface ID in the lower 64 bits.

Default Values

By default, no IPv6 address is configured on the interface and IPv6 processing is not enabled on the interface.

Command History

Release 18.1	Command was introduced.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the interface using the command *ipv6 address <ipv6 link-local address> link-local on page 2237*.

The address created by this command is an EUI-64 unicast address. For this type of address, the EUI-64 interface ID is automatically placed in the IPv6 address. Any manually configured bits beyond the address's prefix length are set to **0**; however, any manually configured bits within the prefix length that extend into the lower 64 bits take precedence over the Interface ID bits.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example adds a unicast IPv6 address with an EUI-64 Interface ID to the interface and enables IPv6 processing on the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 address 2001:DB8:3F::/48 eui-64**

ipv6 address <*ipv6 link-local address*> link-local

Use the **ipv6 address link-local** command to manually assign a link-local Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<*ipv6 link-local address*>	Specifies the link-local IPv6 address. Link-local addresses are specified in colon hexadecimal notation, and begin with **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since link-local addresses have no prefix, the bits entered form the entire IPv6 address.
link-local	Specifies this is a manually configured link-local address. Manually configured link-local addresses replace automatically configured link-local addresses on the interface.

Default Values

By default, no IPv6 address is configured for the interface and IPv6 processing is not enabled.

Command History

Release 18.1	Command was introduced.

Functional Notes

A single link-local address can be manually configured on an interface. The lower 64 bits of the specified address become the Interface ID for the interface, overriding the default interface ID. Any other address that uses the EUI-64 parameter to automatically place the interface ID in the lower 64 bits of the IPv6 address use the new value for the interface ID.

The <*ipv6 address*> for a link-local IPv6 address is specified in the format **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since this form of address has no prefix, the bits entered form the entire IPv6 address. These bits also become the new interface ID for the interface and can be derived from the interface's medium access control (MAC) address.

The **link-local** parameter specifies this is a manually configured link-local address. Any manually configured link-local address will replace an automatically configured link-local address for the interface.

Using the **no** form of this command with a specified IPv6 address removes that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example manually creates a link-local IPv6 address on the interface and enables IPv6 processing:

(config)**#interface eth 0/1**
(config-eth 0/1)**#ipv6 address FE80::220:8FF:FE54:F9D8 link-local**

ipv6 crypto map *<name>*

Use the **ipv6 crypto map** command to associate Internet Protocol version 6 (IPv6) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

Syntax Description

<name>	Specifies the IPv6 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

Command History

Release R10.7.0	Command was introduced.

Functional Notes

Only one IPv6 crypto map can be specified per interface, and the crypto map is applied within the virtual routing and forwarding (VRF) instance to which the interface belongs. To apply the IPv6 crypto map, the interface must have IPv6 enabled. In addition, the interface must have an IPv6 address of appropriate scope to allow connectivity to peer's addresses as specified in the crypto map's entries.

Usage Examples

The following example applies all IPv6 crypto maps with the name **MyMap** to the Ethernet interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6**
(config-eth 0/1)**#ipv6 crypto map MyMap**

ipv6 address dhcp

Use the **ipv6 address dhcp** command to enable Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) on the interface, place the interface in DHCPv6 client mode, and configure the address parameters of the DHCPv6 client. Use the **no** form of this command to disable the DHCPv6 client on the interface. Variations of this command include:

ipv6 address dhcp
ipv6 address dhcp hostname *<partial fqdn>*
ipv6 address dhcp hostname fqdn *<fqdn>*
ipv6 address dhcp no-domain-name
ipv6 address dhcp no-nameservers
ipv6 address dhcp no-ntp
ipv6 address dhcp no-sntp-server
ipv6 address dhcp rapid-commit

Syntax Description

hostname <*partial fqdn*>	Optional. Specifies the name to be sent to the DHCPv6 server as the host portion of its fully qualified domain name (FQDN). FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
fqdn <*fqdn*>	Optional. Specifies a name to be sent to the DHCPv6 server as the system's FQDN. FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
no-domain-name	Optional. Specifies that no domain names are obtained using this DHCPv6 client.
no-nameservers	Optional. Specifies that no domain naming server (DNS) addresses are obtained through DHCPv6.
no-ntp	Optional. Specifies that no Network Time Protocol (NTP) server values are obtained through this DHCPv6 client.
no-sntp-server	Optional. Specifies that no Simple Network Time Protocol (SNTP) server values are obtained through this DHCPv6 client.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Functional Notes

To enable an interface as a DHCPv6 client, you must first enable IPv6 on the interface using the command *ipv6 on page 2231*.

Enabling the interface as a DHCPv6 client using the **ipv6 address dhcp** command places the interface into DHCPv6 client mode. DHCPv6 modes (**client**, **server**, **relay**) are mutually exclusive at the interface. Any existing mode must be removed before a different mode can be applied. For example, if the interface is configured as a DHCPv6 relay agent, you must first disable the **relay** mode before you can specify the interface is in **client** mode.

Usage Examples

The following example enables the interface as a DHCPv6 client and specifies the client's host name:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 address 2001:DB8:1::1/64**
(config-eth 0/1)**#ipv6 address dhcp fqdn client@company.com**

ipv6 dhcp client pd <*prefix name*>

Use the **ipv6 dhcp client pd** command to enable the Dynamic Control Host Protocol for Internet Protocol version 6 (DHCPv6) client on the interface and specify that the interface acquires an IPv6 prefix for the DHCPv6 client. Use the **no** form of this command to disable this feature. Variations of this command include:

ipv6 dhcp client pd <*prefix name*>
ipv6 dhcp client pd <*prefix name*> **no-aggregate-route**
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*>
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*> **tag** <*value*>
ipv6 dhcp client pd <*prefix name*> **rapid-commit**

Syntax Description

<*prefix name*>	Specifies the variable of the prefix stored on the AOS system. Variables are expressed in ASCII text of up to **80** characters.
no-aggregate-route	Optional. Specifies that a route to the null 0 interface is not injected into the route table for the prefixes assigned.
distance <*distance*>	Optional. Specifies the administrative distance to assign to the injected route. Valid range is **1** to **255** with a default distance of **1**.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.
tag <*value*>	Optional. Specifies a number to use as a tag for labeling and filtering routers. Valid range is **1** to **65535**.

Default Values

By default, the DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Usage Examples

The following example enables the DHCPv6 client on the interface and assigns the prefix **PREFIX1**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)#ipv6 dhcp client pd PREFIX1

ipv6 dhcp relay destination *<ipv6 address>*

Use the **ipv6 dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 6 (IPv6) and to specify the IPv6 address or Ethernet virtual circuit (EVC) for the DHCPv6 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv6 relay functionality is disabled on the interface. Variations of this command include:

ipv6 dhcp relay destination *<ipv6 address>*
ipv6 dhcp relay destination *<ipv6 address>* *<interface>*
ipv6 dhcp relay destination *<ipv6 address>* **mef-ethernet** *<slot/port>*
ipv6 dhcp relay destination *<ipv6 address>* **system-control-evc**
ipv6 dhcp relay destination *<ipv6 address>* **system-management-evc**

Syntax Description

<ipv6 address>	Specifies the IPv6 address for the DHCPv6 messages. IPv6 addresses should be specified in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<interface>	Optional. Specifies an output interface to use when sending messages to the DHCPv6 server. If no interface is specified, the interface is selected by the routing table. This parameter is only required when the IPv6 address is a link-scoped address. Interfaces are specified in the *<interface type> <slot/port | interface id>* format. For example, for an Ethernet interface, use **eth 0/1**. Type **ipv6 dhcp relay destination** *<ipv6 address>* **?** to display a list of valid interfaces.
mef-ethernet *<slot/port>*	Specifies the Metro Ethernet Forum (MEF) Ethernet interface.
system-control-evc	Optional. Specifies the DHCPv6 messages are sent to the IPv6 address on the system control EVC.
system-management-evc	Optional. Specifies the DHCPv6 messages are sent to the IPv6 address on the system management EVC.

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.
Release R10.5.0	Command was expanded to include the loopback interface.
Release R10.10.0	Command was expanded to include the **system-control-evc** and **system-management-evc** for the Layer 3 Ethernet and Gigabit Ethernet subinterfaces.
Release R10.11.0	Command was expanded to include the MEF Ethernet interface.
Release R13.7.0	Command was expanded to include the VLAN interface.

Functional Notes

To configure an interface to function as a DHCPv6 relay agent, you must first enable IPv6 on the interface using the command *ipv6 on page 2231*.

Usage Examples

The following example enables DHCPv6 relay agent functionality and specifies the destination IPv6 address as **2001:DB8:2::1**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6**
(config-eth 0/1)**#ipv6 dhcp relay destination 2001:DB8:2::1**

Technology Review

DHCPv6, like DHCP in IPv4, is used in IP networks to supply hosts with IP addresses and other networking information. DHCPv6, however, functions slightly differently than DHCPv4 by providing relay agents with the ability to send relay-forward and relay-reply messages. In addition, in DHCPv4, when DHCP messages are sent to a DHCP server whose address is not known, the IPv4 client uses the broadcast address. In DHCPv6, the IPv6 client sends messages using the link-scoped multicast address. This address is the All DHCP Relay Agents and Servers link, designated as **FF02::1:2**.

In AOS, DHCPv6 relay agents are used when the DHCP server is not on the same link as the DHCP client. The relay is typically a router on the same link as the client, which acts as an intermediary to help the client's DHCP messages reach the DHCP server. DHCPv6 relay agents operate transparently to the DHCP client, and can be configured in chains, meaning that information about each agent encountered is encapsulated into the relay message. Relay agents add fields to the DHCP message as they send these messages to the server, thus providing a method to properly manage the DHCP client.

For more information about DHCPv6 functionality in AOS, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

ipv6 dhcp server

Use the **ipv6 dhcp server** command to enable Internet Protocol version 6 (IPv6) Dynamic Host Control Protocol (DHCP) on the interface and specify that the interface is functioning as a DHCPv6 server. This command not only enables the DHCPv6 server on the interface, it also configures specific parameters of the DHCPv6 server. Hence, the parameters of this command can be entered multiple times and in any order. Use the **no** form of this command to disable DHCPv6 on the interface. Variations of this command include:

ipv6 dhcp server automatic
ipv6 dhcp server automatic allow-hint
ipv6 dhcp server automatic preference <*number*>
ipv6 dhcp server automatic rapid-commit
ipv6 dhcp server <*pool name*>
ipv6 dhcp server <*pool name*> **allow-hint**
ipv6 dhcp server <*pool name*> **preference** <*number*>
ipv6 dhcp server <*pool name*> **rapid-commit**

Syntax Description

automatic	Enables automatic selection of the DHCPv6 server pool based on information extracted from the DHCPv6 client's request. You must specify the pool selection method before configuring other options for this command.
<*pool name*>	Specifies the DHCPv6 server pool that services this interface. All DHCPV^ requests received on this interface are serviced from this pool. If a pool name is not specified, the server pool is selected automatically. You must specify the pool selection method before configuring the other options for this command.
allow-hint	Optional. Specifies that the DHCPv6 server attempts to honor the DHCPv6 client's request for specific values as hinted in the client's request (if they are valid and not already assigned). If this option is not specified, any hints from the DHCPv6 client are ignored.
preference <*number*>	Optional. Specifies the preference value advertised by the server. This option is sent by the server to a DHCPv6 client to influence the selection of a server when there are multiple servers from which to choose. Valid range is **0** to **255**, with a default value of **0**. When the preference value is set to a non-zero value, the server includes a preference option containing the value. If the preference value is not set, or is set to 0, the option is omitted and the client assumes the value is 0.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 server mode is not enabled on the interface.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

Enabling the interface as a DHCPv6 server using this command places the interface into DHCPv6 server mode. DHCPv6 modes (server or relay) are mutually exclusive at the interface. Any existing mode will be removed if a different mode is specified, and a message will be shown indicating the change in DHCPv6 mode.

Usage Examples

The following example enables the interface as a DHCPv6 server, and specifies that the DHCPv6 server pool **POOL1** is associated with the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 address 2001:DB8:1::1/64**
(config-eth 0/1)**#ipv6 dhcp server POOL1**

ipv6 ffe

Use the **ipv6 ffe** command to enable the RapidRoute fast forwarding engine (FFE) on this Internet Protocol version 6 (IPv6) interface with the default number of entries. Use the **no** form of this command to disable this feature. Variations of this command include:

ipv6 ffe
ipv6 ffe max-entries <*value*>

Issuing this command will cause all RapidRoute entries to be cleared from this IPv6 interface.

Syntax Description

max-entries <*value*>	Optional. Specifies the maximum number of entries stored in the flow table. Valid range is from **1** to **500000**.

Default Values

By default, the RapidRoute Engine is enabled on IPv6-enabled interfaces (using the command *ipv6 on page 2231*). The default number of **max-entries** is **4096**.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

RapidRoute can be used to help reduce routing overhead, and thus reduce overall routing times. Routing times are reduced by the creation of a flow table on the ingress interface. The maximum number of entries that can be stored in the flow table at any one time may be specified by using the **max-entries** parameters.

Usage Examples

The following example disables RapidRoute on the IPv6 interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#no ipv6 ffe**

Technology Review

The RapidRoute system goal is to increase IP packet throughput by moving as much of the packet processing into the engine as possible. Packets are classified into flows based upon the IP protocol (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol (ICMP), etc.), the source and destination IP addresses, IP type of service (ToS), and the protocol-specific information, such as the source and destination port numbers. Flows are defined as the unidirectional representation of a conversation between two IP hosts. Each ingress interface keeps its own flow table, a collection of flow entries.

The first packet in a flow that is forwarded through the unit will build a flow entry. When a flow entry is looked up but no entry is found, a RapidRouteBuilder object is allocated and attached to the packet. As the packet passes through the various processing layers, each subsystem will add processing to the RapidRouteBuilder. When packet is about to be forwarded out of the egress interface, the RapidRouteBuilder will be finalized. That is, the flow entry being built will be checked for completeness and committed to the flow table on the ingress interface. Subsequent flow matches can then bypass the normal processing layers.

ipv6 mode host unicast

Use the **ipv6 mode host unicast** command to place the interface in host mode using an Internet Protocol version 6 (IPv6) unicast address. Use the **no** form of this command to disable host mode on the interface.

Syntax Description

No subcommands.

Default Values

By default, host mode is disabled.

Command History

Release R10.9.0	Command was introduced.

Command History

When this command is configured on an interface, the MTU value is learned from received router advertisements. Link MTU value is learned in host mode from the following locations (in decreasing order of priority): the provisioned MTU value in the interface configuration, the router advertisements received on the interface, and the default MTU value (1500).

Usage Examples

The following example places the interface in host mode:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 mode host unicast**

ipv6 mtu *<size>*

Use the **ipv6 mtu** command to specify the maximum transmission unit (MTU) for Internet Protocol version 6 (IPv6) packets on the interface. Use the **no** form of this command to return to the default value.

Syntax Description

<size>	Specifies the MTU value. Valid range is **1280** to **1500** bytes.

Default Values

By default, the MTU of the interface is set to **1280** bytes.

Command History

Release 18.1	Command was introduced.

Functional Notes

In IPv6, the minimum MTU is 1280 octets. Any link that has an MTU less than 1280 octets must use link fragmentation and reassembly that is transparent to IPv6 (for example, the Fragmentation Header). Sources in the IPv6 network are expected to perform path maximum transmission unit (PMTU) discovery to send packets larger than 1280 octets. PMTU works in the following manner: First, the sending node assumes the link MTU of the interface from which the traffic is being forwarded and then sends the IPv6 packet at the link MTU size. If a router on the path is unable to forward the packet, it sends an ICMP *Packet Too Big* message back to the sending node containing the link MTU of the link on which the packet forwarding failed. The sending node then rests the PMTU to the value of the MTU field in the Internet Control Message Protocol version 6 (ICMPv6) *Packet Too Big* message, and the packet is resent.

The MTU for IPv6 packets can be set on a per-interface basis. There are two methods for setting MTUs for interfaces if required: one for Layer 3 interfaces, and one for the underlying Layer 1 and Layer 2 interfaces. For all interface types, use the **ipv6 mtu** *<size>* command to specify the IPv6 MTU in bytes from the interface's configuration mode. The minimum MTU setting for IPv6 is **1280** bytes, and the maximum is **1500** bytes. The IPv6 MTU value is independent of the IPv4 MTU setting (set with the command *ip mtu <size> on page 2211*).

When the interface is forwarding the IPv6 packet as a router, if the packet size exceeds the IPv6 MTU of the egress interface, the packet is dropped and ICMPv6 *Packet Too Big* message is sent to the source. When originating an IPv6 packet from the local IPv6 stack, and the packet is larger than the IPv6 MTU of the egress interface, the packet is fragmented and sent.

Usage Examples

The following example specifies the IPv6 MTU value for the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 mtu 1350**

ipv6 nd advertisement-interval

Use the **ipv6 nd advertisement-interval** command to specify that the Advertisement Interval Option is sent in Internet Protocol version 6 (IPv6) router advertisement (RA) messages from the router. This command is effectual only when the interface is in router mode. Use the **no** form of this command to return to the default interval.

Syntax Description

No subcommands.

Default Values

By default, Advertisement Interval Options are not sent in RA messages.

Command History

Release 18.1	Command was introduced.

Functional Notes

Sending the Advertisement Interval Option should be enabled when the router is functioning in a mobile IP environment to aid movement detection by mobile nodes. This option contains the current value of the maximum router advertisement interval configured using the command *ipv6 nd ra interval on page 2259*.

Usage Examples

The following example specifies that the interface include Advertisement Interval Options in RA messages sent from the router:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 nd advertisement-interval**

ipv6 nd cache max-incomplete <*number*>

Use the **ipv6 nd cache max-incomplete** command to specify the maximum number of incomplete entries the Neighbor Discovery (ND) cache retains. Use the **no** form of this command to return to the default value.

Syntax Description

<*number*>	Specifies the number of incomplete ND entries to retain in the cache. Valid range is **1** to **321**.

Default Values

By default, the incomplete ND entries can take at maximum one-third of the possible ND cache entries (varies by product).

Command History

Release R11.10.0	Command was introduced.

Usage Examples

The following example specifies that the interface stores **150** incomplete entries in the ND cache:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 nd cache max-incomplete 150**

ipv6 nd dad attempts *<number>*

Use the **ipv6 nd dad attempts** command to specify the number of neighbor solicitation (NS) messages sent by the interface when performing Internet Protocol version 6 (IPv6) duplicate address detection (DAD). This command is effectual when the interface is in either host or router mode. Use the **no** form of this command to return to the default value.

Syntax Description

<number>	Specifies the number of NS messages that will be sent. Range is **0** to **10** messages. A value of **0** disables DAD on the interface.

Default Values

By default, the interface sends **1** NS message.

Command History

Release 18.1	Command was introduced.

Functional Notes

DAD is used by devices to determine if IPv6 addresses are unique before they are applied to interfaces. DAD is used in NS messages to detect duplicate unicast addresses. The Target Address fields in the NS messages are set to the IPv6 address for which duplication is being detected. Destination IPv6 addresses for DAD in NS messages are the solicited-node multicast version of the address being tested. Source IPv6 addresses for DAD are set to the IPv6 unspecified address (::). Once the IPv6 address is determined by DAD to be unique, it can be applied to the IPv6 interface on the node.

DAD in AOS is performed when an interface transitions state from DOWN to UP or when manually configuring an address. When performing DAD because of an interface transition, DAD will happen immediately after the interface transition and again 40 seconds later to cooperate with the port being connected to an Ethernet switch.

Usage Examples

The following example specifies that **3** NS messages are sent by the interface when performing DAD:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 nd dad attempts 3**

ipv6 nd managed-config-flag

Use the **ipv6 nd managed-config-flag** command to specify the M flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. The M flag instructs hosts receiving the RA that they can use stateful Dynamic Host Configuration Protocol version 6 (DHCPv6) to configure addresses and other information. Use the **no** form of this command to disable the setting of the M flag.

Syntax Description

No subcommands.

Default Values

By default, the M flag is not set in RAs.

Command History

Release 18.1	Command was introduced.

Functional Notes

If you specify that the M flag is set in RA messages, you do not need to set the 0 flag (it becomes redundant).

Usage Examples

The following example sets the M flag for RA messages sent by the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 nd managed-config-flag**

ipv6 nd ns-interval *<value>*

Use the **ipv6 nd ns-interval** command to specify the interval between transmission of certain Internet Protocol version 6 (IPv6) Neighbor Discovery (ND) messages and to control what ND value is advertised in router advertisement (RA) messages. This command is effectual whether the interface is in host or router mode. Use the **no** form of this command to return the interval to the default value.

Syntax Description

<value>	Specifies the time (in milliseconds) between neighbor message transmissions. Valid range is **1000** to **3600000** ms.

Default Values

By default, the interval is set to **1000** ms for internal use by the router and **0** (unspecified) is sent in RA messages.

Command History

Release 18.1	Command was introduced.

Functional Notes

This command controls the spacing of neighbor solicitation (NS) messages for functions such as address resolution, reachability detection, and duplicate address detection (DAD). For DAD it also serves as the amount of time after the last transmission before the detection phase of autoconfiguration terminates. In addition, the command controls the interval between unsolicited neighbor advertisement (NA) messages.

Usage Examples

The following example changes the interval between RA messages sent from the interface to **2000** ms:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 nd ns-interval 2000**

ipv6 nd other-config-flag

Use the **ipv6 nd other-config-flag** command to specify the O flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the interface is in router mode. When the O flag is set, hosts receiving the RA messages are instructed that they may use stateless Dynamic Host Configuration Protocol version 6 (DHCPv6) to receive information that is not IPv6 addressing information, and to use some other method (whether through manual configuration, stateless address autoconfiguration (SLAAC), etc.) for addressing information. Use the **no** form of this command to disable the O flag setting.

Syntax Description

No subcommands.

Default Values

By default, the O flag is not set in RA messages.

Command History

Release 18.1	Command was introduced.

Functional Notes

If the M flag is set for RA messages, you do not need to set the O flag.

Usage Examples

The following example sets the O flag in RA messages from the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 nd other-config-flag**

ipv6 nd prefix

Use the **ipv6 nd prefix** command to specify the Internet Protocol version 6 (IPv6) address prefixes used in router advertisement (RA) messages sent from the interface. Use the **no** form of this command to remove the specified prefix configuration from the interface. Variations of this command include:

ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise] [**<*valid lifetime*> | **infinite]** <*preferred lifetime* | **infinite**>
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite] [no-advertise] [no-autoconfig] [no-rtr-address] [no-onlink] [off-link]**

Syntax Description

named-prefix <*prefix name*>	Optional. Specifies that a named prefix is used in RA messages. When a named prefix is used, the default prefix cannot be used.
<*ipv6 prefix/prefix-length*>	Specifies the IPv6 prefix and length to be advertised. Pv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
default	Specifies the default values for the IPv6 prefix parameters. Refer to the *Functional Notes* below for more information.
<*valid lifetime*>	Optional. Specifies the valid lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
<*preferred lifetime*>	Optional. Specifies the preferred lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
infinite	Optional. Specifies that the valid and preferred lifetimes of the prefix do not expire.
no-advertise	Optional. Specifies that the prefix is excluded from the RA message.
no-autoconfig	Optional. Sets the A flag in the RA message to **0**, indicating that hosts may not create an address for this prefix using stateless address autoconfiguration (SLAAC). This parameter only affects hosts receiving the RA message, it does not affect the operation of the local router.
no-rtr-address	Optional. Sets the R flag in the RA message to **0** and specifies the full router IPv6 address is not included in the RA message.
no-onlink	Optional. Specifies that the IPv6 prefix in the RA message is not to be used for on-link determination.
off-link	Optional. Sets the L flag value to **0** in RA messages, which indicates the RA makes no statement about the on-link or off-link properties of the IPv6 prefix.

Default Values

By default, all prefixes derived from the interface's configured IPv6 addresses are advertised using the system default values.

By default, the valid lifetime advertised for a prefix is **2592000** seconds and the preferred lifetime advertised is **604800** seconds.

By default, the L flag is set to **1**, the R flag is set to **1**, and the A flag is set to **1**.

Command History

Release 18.1	Command was introduced.
Release R10.9.0	Command was expanded to include the **named-prefix** and *<prefix name>* options.

Functional Notes

This command works for both routers and hosts, but in host implementations it is used to manually add on-link prefixes that do not have an IPv6 address or to make off-link a prefix generated by an IPv6 address command. Hosts do not send RA messages, so the command only adds prefixes to RA messages when the interface is in router mode. This command can also be used to change the defaults used on configured prefixes when all options are not specified.

Changing the prefix defaults will affect prefixes derived from configured IPv6 addresses, as well as prefixes configured using the ***ipv6 nd prefix*** *command.*

Prefixes advertised can be a subset or a superset of the prefixes derived from the IPv6 addresses configured on the interface. Prefixes for IPv6 addresses configured on a router interface are automatically eligible to be advertised on that interface using system or configured default values without having to enter a prefix command. To impose additional controls on those prefixes, an entry must be made using this command with the desired settings.

The **default** parameter is used to change the default settings for the IPv6 prefix parameters. Changing these settings can be useful when multiple prefixes are implemented that will use the same set of parameters. When configuring IPv6 prefixes, the prefix default values are only used if no other parameters are specified after specifying the IPv6 prefix and length (for example, **ipv6 nd prefix 2001:DB8::/64**). If additional parameters are specified, any unspecified parameters use the system default values rather than the configured default values. When the default values are changed, any prefix that uses them will also change. Using this command to change prefix default values also affects prefixes derived from configured IPv6 addresses on the interface.

The optional *<valid lifetime>* parameter specifies the valid lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep this prefix until the valid lifetime expires.

The optional <*preferred lifetime*> parameter specifies the preferred lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep the prefix in the preferred state during this time period. After the preferred time period expires, the prefix transitions to the deprecated state where it remains until the valid lifetime expires and the route is removed. The <*preferred lifetime*> value must be set to be shorter than the <*valid lifetime*> value.

The optional **off-link** parameter sets the L flag (on-link flag) value to **0** in RA messages. When the L flag is set to 0, the advertisement makes no statement about on-link or off-link properties of the prefix. When the L flag is set, the prefix is considered on-link and locally reachable by hosts on the link (meaning a router is not needed). Hosts attached to the link will add on-link prefixes to their prefix list or route table. When off-link is not specified, a connected route is added to the route table of this router for this prefix. When off-link is specified, no route is added to the route table. By default, prefixes are advertised as on-link with the L flag set to 1.

The optional **no-rtr-address** parameter sets the R flag (router flag) of the RA to **0** and does not include the full router address in the advertisement. The router address is typically included in the RA to assist in Mobile IP environments. By default, the R flag is set to 1 and the router address is sent in RA messages.

The optional **no-autoconfig** parameter sets the A flag of the RA to **0**, indicating that hosts may not create an address for this prefix using SLAAC. If the A flag is set to **1** (the default setting), hosts perform SLAAC to generate an address based on the prefix. This parameter only affects hosts receiving the RA, it does not effect the operation of the local router.

The optional **no-advertise** parameter specifies that the prefix is excluded from RA messages. By default, the prefix is included in RA messages. The **no-onlink** parameter informs the router that the prefix is not to be used for on-link determination.

By default, all prefixes derived from the interface's configured IPv6 addresses are advertised using the system default values.

Usage Examples

The following example specifies that the IPv6 prefix **2001:DB8:3F::/48** has an infinite valid and preferred lifetime advertised in RA messages sent from the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 nd prefix 2001:DB8:3F::/48 infinite infinite**

The following example changes the default values and behaviors of prefixes included in RA messages to infinite valid and preferred lifetimes, and specifies that the on- or off-link state of the prefix is not included in the RA and that hosts receiving the RA may not use the prefix for creating an IPv6 address:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 nd prefix default infinite infinite off-link no-autoconfig**

ipv6 nd purge-timer <*value*>

Use the **ipv6 nd purge-timer** command to specify the maximum amount of time an unused Internet Protocol version 6 (IPv6) neighbor entry remains in the neighbor cache. This command applies to interfaces in either host or router mode. Use the **no** form of this command to return the purging interval to the default value.

Syntax Description

<*value*>	Specifies the neighbor cache entry storage time in minutes. Valid range is **10** to **1440** minutes.

Default Values

By default, idle (STALE) neighbor cache entries are cleared after **1440** minutes (24 hours).

Command History

Release 18.1	Command was introduced.

Functional Notes

This command applies to interfaces in either router or host mode. A neighbor entry is typically purged when neighbor unreachability detection (NUD) is invoked and the neighbor is determined to no longer be reachable. However, NUD is not performed on idle (STALE) neighbor entries, so this command provides a method for purging unused entries after a specified amount of time.

Usage Examples

The following example specifies that idle neighbor entries in the neighbor cache are removed after **800** minutes:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 nd purge-timer 800**

ipv6 nd ra interval

Use the **ipv6 nd ra interval** command to specify the interval between transmission of Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the interface is in router mode. Use the **no** form of this command to return to the default value. Variations of this command include:

ipv6 nd ra interval *<max time>*
ipv6 nd ra interval *<max time> <min time>*
ipv6 nd ra interval msec *<max time>*
ipv6 nd ra interval msec *<max time> <min time>*

Syntax Description

<max time>	Specifies the maximum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **4** to **1800** seconds and **70** to **1800000** ms.
<min time>	Optional. Specifies the minimum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **3** seconds to 75 percent of the configured maximum time value in seconds, or **30** ms to 75 percent of the configured maximum time value in ms.
msec	Optional. Specifies that the time values are in milliseconds.

Default Values

By default, the interval is set in seconds and has a maximum interval time of **200** seconds and a minimum interval time of 75 percent of the maximum seconds value, but not less than **3** seconds.

Command History

Release 18.1	Command was introduced.

Functional Notes

If this router is used as a default router, the interval between RA messages should not be set to a larger value than the RA lifetime set by the command *ipv6 nd ra lifetime <value> on page 2260*, which has a default value of **1800** seconds.

Usage Examples

The following example specifies that the maximum interval in seconds between RA message transmissions is **300**:

(config)**#interface eth 0/1**
(config-eth 0/1)**#ipv6 nd ra interval 300**

ipv6 nd ra lifetime <*value*>

Use the **ipv6 nd ra lifetime** command to specify the router lifetime advertised in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is effectual when the interface is in router mode. Use the **no** form of this command to return to the default setting. Variations of this command include:

ipv6 nd ra lifetime <*value*>
ipv6 nd ra lifetime default-route

Syntax Description

<*value*>	Specifies the router lifetime in seconds. Range is **0** to **9000** seconds. A value of **0** indicates this is not a default router. A value other than 0 indicates to other nodes that this router can be used as a default router.
default-route	Specifies that the RA lifetime is **0** if no default route exists on any IPv6 interface.

Default Values

By default, the router lifetime is set to **1800** seconds.

Command History

Release 18.1	Command was introduced.
Release R11.5.0	Command was expanded to include the **default-route** parameter.

Functional Notes

A value other than **0** for a router lifetime should be larger than the router advertisement interval specified in the command *ipv6 nd ra interval on page 2259*.

Usage Examples

In the following example, the router lifetime advertised in RA messages is **3000** seconds:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 nd ra lifetime 3000**

ipv6 nd ra reachable-time <*value*>

Use the **ipv6 nd ra reachable-time** command to specify the value advertised for reachable time in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command also specifies the internal base reachable time used by the router. This command is effectual for interfaces in either host or router mode. Use the **no** form of this command to return the reachability value to the default setting.

Syntax Description

<*value*>	Specifies the reachability time in milliseconds. Range is **0** to **3600000** ms. A value of **0** indicates the reachable time is unspecified.

Default Values

By default, the router advertises a reachability time of **0** ms and uses an internal value of **30000** ms.

Command History

Release 18.1	Command was introduced.

Functional Notes

This command is effectual for interfaces in either router or host mode. For hosts, this value sets the internal reachable time used by the host if no RAs are received specifying a different value. For routers, the value indicates the amount of time a device is considered reachable after having received a reachability confirmation in neighbor unreachabililty detection (NUD).

Usage Examples

The following example specifies that a reachability time of **50000** ms is advertised in RA messages:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 nd ra reachable-time 50000**

ipv6 nd ra suppress

Use the **ipv6 nd ra suppress** command to specify whether Internet Protocol version 6 (IPv6) router advertisement (RA) messages will be suppressed. This command only applies to interfaces in router mode. Use the **no** form of this command to begin sending RA messages.

Syntax Description

No subcommands.

Default Values

By default, RA messages are not suppressed. When IPv6 routing is not enabled on the router, or when implemented in a host-only mode, the default setting is to suppress advertisements on all interface types.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example suppresses RA messages on the interface:

(config)**#interface eth 0/1**
(config-eth 0/1)**#ipv6 nd ra suppress**

ipv6 nd router-preference

Use the **ipv6 nd router-preference** command to specify the default router preference value set in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. Setting this preference helps the receivers of RA messages to determine the preference of one router over another as a default router in environments with multiple routers. Use the **no** form of this command to return the preference to the default setting. Variations of this command include:

ipv6 nd router-preference high
ipv6 nd router-preference low
ipv6 nd router-preference medium

Syntax Description

high	Specifies the preference value is high.
low	Specifies the preference value is low.
medium	Specifies the preference value is medium.

Default Values

By default, the router preference is set to medium.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example specifies that the advertised default router preference is high:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 nd router-preference high**

ipv6 route-cache

Use the **ipv6 route-cache** command to enable Internet Protocol version 6 (IPv6) fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 18.2	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.

Functional Notes

Fast switching allows an IPv6 interface to provide optimum performance when processing IPv6 traffic.

Usage Examples

The following example enables IPv6 fast switching on the Ethernet interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 route-cache**

lldp receive

Use the **lldp receive** command to allow Link Layer Discovery Protocol (LLDP) packets to be received on this interface. Use the **no** form of this command to prevent LLDP packets from being received on the interface.

Syntax Description

No subcommands.

Default Values

By default, all interfaces are configured to send and receive LLDP packets.

Command History

Release 8.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Usage Examples

The following example configures Ethernet interface 0/1 to receive LLDP packets:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#lldp receive**

lldp send

Use the **lldp send** command to configure this interface to transmit Link Layer Discovery Protocol (LLDP) packets or to control the types of information contained in the LLDP packets transmitted by this interface. Use the **no** form of this command to prevent certain information from being transmitted by the interface. Variations of this command include:

lldp send 802.3-info mac-phy-config
lldp send management-address
lldp send med-info network-policy
lldp send port-description
lldp send system-capabilities
lldp send system-description
lldp send system-name
lldp send-and-receive

Syntax Description

802.3-info mac-phy-config	Enables transmission of the capability and settings of the duplex and speed on this interface.
management-address	Enables transmission of management address information on this interface.
med-info network-policy	Enables transmission of LLDP-Media Endpoint Discovery (LLDP-MED) network policy information on the interface.
port-description	Enables transmission of port description information on this interface.
system-capabilities	Enables transmission of this device's system capabilities on this interface.
system-description	Enables transmission of this device's system description on this interface.
system-name	Enables transmission of this device's system name on this interface.
and-receive	Configures this interface to both transmit and receive LLDP packets. This is the default setting.

Default Values

By default, all interfaces that support LLDP except routed Ethernet are configured to transmit and receive LLDP packets. LLDP is disabled by default on routed Ethernet interfaces.

The 802.3 MAC/PHY status configuration and LLDP-MED network policy time length values (TLVs) are only supported on switchport interfaces and NetVanta 1524ST Gigabit Ethernet interfaces.

Command History

Release 8.1	Command was introduced.
Release 17.2	Command was expanded to include the 802.3 and LLDP-MED information.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Individual LLDP information can be enabled or disabled using the various forms of the **lldp send** command. For example, use the **lldp send-and-receive** command to enable transmit and receive of all LLDP information. Then use the **no lldp send port-description** command to prevent LLDP from transmitting port description information.

Usage Examples

The following example configures Ethernet interface 0/1 to transmit LLDP packets containing all enabled information types:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#lldp send**

The following example configures Ethernet interface 0/1 to transmit and receive LLDP packets containing all enabled information types:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#lldp send-and-receive**

mac access-group *<mac acl name>*

Use the **mac access-group** command to associate a media access control (MAC) access control list (ACL) with the interface. When applied, these ACLs provide source MAC address filtering on the interface. Use the **no** form of this command to remove the ACL from the interface.

Syntax Description

<mac acl name>	Specifies the name of the previously created MAC ACL to associate with the interface.

Default Values

By default, no MAC ACLs are configured.

Command History

Release R11.5.0	Command was introduced.

Usage Examples

The following example associates the MAC ACL **MACACL1** with the Gigabit Ethernet interface:

(config)**#interface gigabit-ethernet 0/2**
(config-giga-eth 0/2)**#mac access-group MACACL1**

mac-address *<mac address>*

Use the **mac-address** command to specify the medium access control (MAC) address of the unit. Only the last three values of the MAC address can be modified. The first three values contain the Adtran reserved number (00:0A:C8) by default. Use the **no** form of this command to return to the default MAC address programmed by Adtran.

Syntax Description

<mac address>	Specifies a valid 48-bit MAC address. MAC addresses should be expressed in the following format xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).

Default Values

A unique default MAC address is programmed in each unit shipped by Adtran.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Gigabit Ethernet interfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Usage Examples

The following example configures a MAC address of **00:0A:C8:5F:00:D2**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#mac-address 00:0A:C8:5F:00:D2**

mac aging-time *<value>*

Use the **mac aging-time** command to specify the time that a media access control (MAC) address is considered valid on the interface. Use the **no** form of this command to return the aging time to the default value.

Syntax Description

<value>	Specifies the time, in seconds, that a MAC address is considered valid. Valid range is **0** to **3600** seconds. A value of **0** forces learn and lock behavior.

Default Values

By default, a MAC address is considered valid for **300** seconds.

Command History

Release R11.5.0	Command was introduced.

Usage Examples

The following example sets the MAC address aging time to **1000** seconds:

(config)**#interface gigabit-ethernet 0/2**
(config-giga-eth 0/2)**#mac aging-time 1000**

mac limit *<value>*

Use the **mac limit** command to specify the maximum number of media access control (MAC) addresses to be learned on the interface. This limit pulls from a global pool of 1024 learnable MAC addresses. In addition, when MAC limits are enabled on an interface with a MAC access control list (ACL) applied, addresses are learned that match the ACL up to the specified limit. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the number of MAC addresses to be learned on the interface. Valid range is **1** to **1024**.

Default Values

By default, no MAC address limits are enforced on the interface.

Command History

Release R11.5.0	Command was introduced.

Usage Examples

The following example specifies a limit of **500** MAC addresses can be learned on the interface:

(config)**#interface gigabit-ethernet 0/2**
(config-giga-eth 0/2)**#mac limit 500**

max-reserved-bandwidth *<value>*

Use the **max-reserved-bandwidth** command to specify the percentage of interface bandwidth reserved for use in user-defined (priority or class-based) queues. The remainder of the interface bandwidth is reserved for system-critical traffic and is not available to user-defined queues. Use the **no** form of this command to restore the default value.

Reserving a portion of the interface bandwidth for system-critical traffic is necessary for proper operation. Specifying the entire interface bandwidth for use in user-defined queues can cause undesirable operation.

Syntax Description

<value>	Specifies the maximum percentage of bandwidth to reserve for quality of service (QoS). This setting is configured as a percentage of the total interface speed. Range is **1** to **100** percent.

Default Values

By default, **max-reserved-bandwidth** is set to **75** percent, which reserves 25 percent of the interface bandwidth for system-critical traffic.

Command History

Release 11.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet subinterface.

Usage Examples

The following example specifies **85** percent of the bandwidth on the Ethernet interface 0/1 be available for use in user-defined queues:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#max-reserved-bandwidth 85**

media-gateway ip

Use the **media-gateway ip** command to associate an Internet Protocol version 4 (IPv4) address source to use for Realtime Transport Protocol (RTP) traffic. When configuring Voice over Internet Protocol (VoIP), RTP traffic must have an IPv4 address associated with it. However, some interfaces allow dynamic configuration of IPv4 addresses, causing this value to change periodically. Use the **no** form of this command to disable this function. Variations of this command include:

media-gateway ip loopback <*interface id*>
media-gateway ip primary
media-gateway ip primary vrrp <*number*>
media-gateway ip primary vrrpv3 <*number*>
media-gateway ip secondary <*ipv4 address*>
media-gateway ip secondary vrrp <*number*>
media-gateway ip secondary vrrp <*number*> <*ipv4 address*>
media-gateway ip secondary vrrpv3 <*number*>
media-gateway ip secondary vrrpv3 <*number*> <*ipv4 address*>

Syntax Description

loopback <*interface id*>	Specifies an IPv4 address statically defined to a loopback interface for RTP traffic. This is helpful when using a single IPv4 address across multiple wide area network (WAN) interfaces for RTP traffic. The valid range for loopback interface identifiers is **1** to **1024**. The interface ID is used to uniquely identify a loopback interface. The entered value cannot be in use by another loopback interface.
primary	Specifies using this interface's configured primary IPv4 address for RTP traffic. Applies to static, Dynamic Host Configuration Protocol (DHCP), or negotiated addresses.
secondary <*ipv4 address*>	Specifies using this interface's statically defined secondary IPv4 address for RTP traffic. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
vrrp <*number*>	Specifies that the IPv4 address of the Virtual Router Redundancy Protocol version 2 (VRRP) router group's virtual router ID (VRID) is used as the media gateway address on the interface. Valid VRID range is **1** to **255**.
vrrpv3 <*number*>	Specifies that the IPv4 address of the VRRP version 3 (VRRPv3) VRID is used as the media gateway address on the interface. Valid VRID range is **1** to **255**.
<*ipv4 address*>	Optional. Specifies a secondary IPv4 address of the VRRP or VRRPv3 VRID is used as the media gateway address on the interface. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, **media-gateway ip** is disabled.

Command History

Release 10.1	Command was introduced.
Release 17.3	Command was updated with the loopback interface identification option.
Release A4.01	Command was expanded to include the Metro Ethernet forum (MEF) Ethernet interface.
Release R12.2.0	Command was expanded to include the **vrrp** and **vrrpv3** parameters.

Functional Notes

To use VRRP or VRRPv3 addresses as the media gateway on the interface, you must first have configured VRRP or VRRPv3.

Usage Examples

The following example configures the unit to use the primary IPv4 address for RTP traffic:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#media-gateway ip primary**

media-gateway ipv6

Use the **media-gateway ipv6** command to associate an Internet Protocol version 6 (IPv6) address source to use for Realtime Transport Protocol (RTP) traffic. When configuring Voice over Internet Protocol (VoIP), RTP traffic must have an IPv6 address associated with it. However, some interfaces allow dynamic configuration of IPv6 addresses, causing this value to change periodically. Use the **no** form of this command to disable this function. Variations of this command include:

media-gateway ipv6
media-gateway ipv6 <*ipv6 address*>
media-gateway ipv6 loopback <*interface id*>
media-gateway ipv6 vrrpv3 <*number*>
media-gateway ipv6 vrrpv3 <*number*> <*ipv6 address*>

Syntax Description

<*ipv6 address*>	Specifies an IPv6 address to use for the media gateway. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
loopback <*interface id*>	Specifies an IPv6 address statically defined to a loopback interface for RTP traffic. This is helpful when using a single IPv6 address across multiple wide area network (WAN) interfaces for RTP traffic. The valid range for loopback interface identifiers is **1** to **1024**. The interface ID is used to uniquely identify a loopback interface. The entered value cannot be in use by another loopback interface.
vrrpv3 <*number*>	Specifies that all the secondary IPv6 addresses of the Virtual Routing Redundancy Protocol version 3 (VRRPv3) virtual router ID (VRID) are used as media gateway addresses on the interface. Valid VRID range is **1** to **255**.
<*ipv6 address*>	Optional. Specifies a single IPv6 address of the VRRPv3 VRID is used as the media gateway address on the interface. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.

Default Values

By default, **media-gateway ipv6** is disabled.

Command History

Release R10.8.0	Command was introduced.
Release R12.2.0	Command was expanded to include the **vrrpv3** parameters.

Functional Notes

To use VRRPv3 addresses as the media gateway on the interface, you must first have configured VRRPv3.

Usage Examples

The following example configures the unit to use the IPv6 address for RTP traffic:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#media-gateway ipv6**

men-c-tag <*value*>

Use the **men-c-tag** command to specify the C-tag used to identify traffic on the Layer 3 subinterface within an Ethernet virtual connection (EVC). Use the **no** form of this command to remove the C-tag value.

Syntax Description

<*value*>	Specifies the value for the C-tag. Valid range is **1** to **4094**.

Default Values

By default, the C-tag is not specified.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies a C-tag value of **100** for the traffic associated with the Layer 3 Gigabit Ethernet subinterface 1/1.1:

(config)**#interface gigabit-ethernet 1/1.1**
(config-giga-eth-1/1.1)**#men-c-tag 100**

men-c-tag-pri

Use the **men-c-tag-pri** command to specify the default priority used by the C-tag. The C-tag is used to identify traffic on the Layer 3 subinterface within an Ethernet virtual connection (EVC). Use the **no** form of this command to return to the default value. Variations of this command include:

men-c-tag-pri inherit
men-c-tag-pri <*value*>

Syntax Description

inherit	Specifies that the C-tag inherits the priority of the S-tag.
<*value*>	Specifies the C-tag default priority. Valid range is **0** to **7**.

Default Values

By default, the C-tag priority is set to **inherit**.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies the C-tag priority as **6** on the Layer 3 Gigabit Ethernet subinterface 1/1.1:

(config)**#interface gigabit-ethernet 1/1.1**
(config-giga-eth-1/1.1)**#men-c-tag-pri 6**

men-pri

Use the **men-pri** command to specify the default value of the S-tag used in Ethernet virtual connection (EVC) communication. Use the **no** form of this command to return to the default setting. Variations of this command include:

men-pri inherit
men-pri <*value*>

Syntax Description

inherit	Specifies that the S-tag priority value is inherited from the customer equipment (CE) virtual local area network (VLAN).
<*value*>	Specifies a priority value for the S-tag. Valid range is **0** to **7**.

Default Values

By default, the S-tag is set to **inherit**.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies that the S-tag has a priority of **5** on the Layer 3 Gigabit Ethernet subinterface 1/1.1:

(config)**#interface gigabit-ethernet 1/1.1**
(config-giga-eth-1/1.1)**#men-pri 5**

men-queue

Use the **men-queue** command to specify the output queue used by the Ethernet virtual connection (EVC) for traffic egressing this Layer 3 subinterface. Use the **no** form of this command to return to the default setting. Variations of this command include:

men-queue inherit
men-queue <*value*>

Syntax Description

inherit	Specifies that traffic egressing the subinterface is mapped to the Metro Ethernet network (MEN) queue based on the packet's outer tag value.
<*value*>	Specifies the queue to which the traffic is mapped. Valid range is **0** to **7**.

Default Values

By default, egressing traffic inherits the queue information.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies that egress traffic from the Layer 3 Gigabit Ethernet subinterface 1/1.1 inherits the queue mapping information:

(config)**#interface gigabit-ethernet 1/1.1**
(config-giga-eth-1/1.1)**#men-queue inherit**

mtu <*size*> include-l2-header

Use the **mtu** <*size*> **include-l2-header** command to specify the maximum transmission unit (MTU) for the Layer 2 user network interface (UNI). Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Specifies the MTU size in bytes. Valid range is **60** to **9242** bytes.
include-l2-header	Specifies that the Layer 2 header, any tags, and the Layer 2 payload are included in the MTU size.

Default Values

By default, the MTU on Layer 2 interfaces is set to **9242** bytes.

Command History

Release R11.7.0	Command was introduced.

Functional Notes

This command specifies the MTU for Layer 2 interfaces only. This MTU size includes the Layer 2 header, any associated tags, and the Layer 2 payload, but not the frame check sequence (FCS). If the Layer 2 MTU is configured to be below the MTU for the Layer 3 interface, a misconfiguration occurs and as a result, traffic can be lost. To avoid a misconfiguration, a warning is displayed whenever the Layer 2 MTU is configured below 1526 bytes.

Usage Examples

The following example configures the MTU for the Layer 2 Gigabit Ethernet interface:

(config)**#interface gigabit-ethernet 0/1**
(config-giga-eth 0/1)**#mtu 4400 include-l2-header**

no shutdown track *<name>*

Use the **no shutdown track** command to restore the gigabit switchport interface when the specified track passes. For more information about tracks, refer to *track <name> on page 1886* and the *Network Monitor Track Command Set on page 4098*.

Syntax Description

<name>	Specifies the name of the track to associate with the activation of the interface.

Default Values

By default, this command is not configured.

Command History

Release 17.5	Command was introduced.

Usage Examples

The following example enables the interface based on the specified track:

(config)**#interface gigabit-switchport 0/1**
(config-giga-swx 0/1)**#no shutdown track work-hours**

ospfv3 <*process id*> **area** <*area id*>

Use the **ospfv3 area** command to add an interface to an Open Shortest Path First version 3 (OSPFv3) process, and to configure the OSPFv3 process on the interface. This command places the interface in the specified area for the specified Internet Protocol version 6 (IPv6) OSPFv3 address family, and optionally defines the instance ID that is used to represent this OSPFv3 process in messages on the interface's link. Use the **no** form of this command to remove the OSPFv3 process from the interface. Variations of this command include:

ospfv3 <*process id*> **area** <*area id*> **ipv6**
ospfv3 <*process id*> **area** <*area id*> **ipv6 instance** <*instance id*>

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join, for the specified address family. The process ID is locally significant to the device, and must be unique among all OSPFv3 processes on the device. Valid range is **1** to **65535**.
<*area id*>	Specifies the ID of the area to which this interface is assigned for the given OSPFv3 process. Valid range is **0** to **4294967295**.
ipv6	Identifies the OSPFv3 address family as IPv6.
instance <*instance id*>	Optional. Specifies the value to use in the instance ID field of messages sent or received by this OSPFv3 process on the interface's link. Valid range is **0** to **31**.

Default Values

By default, an OSPFv3 process is not configured on an interface. By default, process IDs, area IDs, and instance IDs are not defined.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

When using this command to enable an OSPFv3 process on an interface, keep the following rules in mind:

- The interface must have the address family enabled on the interface. If the address family is not enabled on the interface, the command is rejected and an error is displayed.
- Only interfaces on the default virtual routing and forwarding (VRF) instance support this command. Interfaces on a nondefault VRF will display an error when you attempt to configure OSPFv3 settings.
- The interface and the specified OSPFv3 process (if defined in the global configuration) must be in the same VRF or the command will fail.
- The address family must match that specified for the OSPFv3 process if the process has been defined in the global configuration or the command will fail.
- If the OSPFv3 process identified by the process ID does not exist in the global configuration, it is automatically created, along with the specified address family, and it is assigned to the VRF of which the interface is a member.

- If the specified OSPFv3 process is already at its maximum limit of processes or address families, the command fails.
- If the specified OSPFv3 process already exists in the global configuration, but its configuration does not include an address family, the specified address family is added to the OSPFv3 router configuration.
- A given OSPFv3 process can only have one address family.
- Multiple OSPFv3 instances per address family, per VRF, can be created and can be assigned to a given interface.
- If the interface's VRF changes, all OSPFv3 assignments are removed.
- To change an OSPFv3 process's VRF, the process must first be removed and then recreated. Removing the process removes all OSPFv3 assignments for that process form all interfaces.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

To add an interface to the OSPFv3 process **5**, in area **10**, with an instance ID of **10**, enter the command as follows:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ospfv3 5 area 10 ipv6 instance 10**

ospfv3 authentication

Use the **ospfv3 authentication** command to authenticate an interface that is performing Internet Protocol version 6 (IPv6) Open Shortest Path First version 3 (OSPFv3) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ospfv3 authentication ipsec spi <*spi*> **md5** <*key*>
ospfv3 authentication ipsec spi <*spi*> **sha1** <*key*>
ospfv3 authentication null

Syntax Description

ipsec	Specifies that IP security (IPsec) authentication is used.
spi <*spi*>	Specifies the security parameter index (SPI). Valid range is **256** to **4294967295**.
md5 <*key*>	Specifies that MD5 authentication is used. Keys are specified in 32 hexadecimal characters.
sha1 <*key*>	Specifies that SHA-1 authentication is used. Keys are specified in 40 hexadecimal characters.
null	Specifies that no OSPFv3 authentication is used.

Default Values

By default, this is set to **null** (meaning no authentication is used).

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example specifies that no OSPFv3 authentication will be used on the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ospfv3 authentication null**

ospfv3 <*process id*> cost <*cost*>

Use the **ospfv3 cost** command to specify a value that represents the cost of sending an Open Shortest Path First version 3 (OSPFv3) packet over the interface. Use the **no** form of this command to return the cost to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2283*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
cost <*cost*>	Specifies the OSPFv3 cost of the interface. This value overrides any automatically computed cost value (default value). Valid range is **1** to **65535**.

Default Values

By default, the OSPFv3 cost of the interface is automatically computed. The automatic cost computation is the reference bandwidth divided by the interface bandwidth. The reference bandwidth is set by the command *auto-cost reference-bandwidth <value> on page 4150*, and defaults to **100** Mbps.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the OSPFv3 cost of the interface as **10**:

```
(config)#interface ethernet 0/1
(config-eth 0/1)#ospfv3 5 cost 10
```

ospfv3 <*process id*> dead-interval <*value*>

Use the **ospfv3 dead-interval** command to specify the maximum interval allowed between Open Shortest Path First version 3 (OSPFv3) Hello packets on the interface. If the maximum interval is exceeded, neighboring devices will assume that the device is down. This value must be the same across all interfaces on a link. Use the **no** form of this command to return the dead interval to the default value.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2283*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
dead-interval <*value*>	Specifies the maximum number of seconds allowed between OSPFv3 Hello packets. It is recommended that this value be **4** times the Hello packet interval (set with the command *ospfv3 <process id> hello-interval <value> on page 2290*). Valid range is **1** to **65535** seconds.

Default Values

By default, the maximum interval allowed between OSPFv3 Hello packets is set to **40** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

To specify the dead interval between OSPFv3 Hello packets on the interface, enter the command as follows:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ospfv3 5 dead-interval 100**

ospfv3 encryption

Use the **ospfv3 encryption** command to specify a symmetrical, bidirectional Open Shortest Path First version 3 (OSPFv3) security association (SA) that uses encapsulating security payload (ESP) for encryption and authentication of all OSPFv3 messages that are sent or received on the interface. This command allows you to specify OSPFv3 security at the interface level. Use the **no** form of this command to remove IP security (IPsec) protection of OSPFv3 messages on the interface. Variations of this command include:

ospfv3 encryption ipsec spi <*spi*> **esp** <*encryption type*> <*encryption key*> <*authentication type*> <*authentication key*>
ospfv3 encryption ipsec spi <*spi*> **esp null** <*authentication type*> <*authentication key*>
ospfv3 encryption null

Syntax Description

ipsec	Specifies that IPsec encryption is used on the interface for OSPFv3 SAs.
spi <*spi*>	Specifies the security parameter index (SPI) for the SA. The value specified must not be in used by any other IPsec function on the system, or an error message is generated. If the same SPI is already in use in the same OSPFv3 area, entering this command with the same value will overwrite the current configuration. Valid SPI range is **256** to **4294967295**.
esp	Specifies that ESP is used.
null	Specifies that OSPFv3 messages on this interface are not encrypted when used in the **ospfv3 encryption null** format (even when encryption is specified by the OSPFv3 area configuration). When used in the **ospfv3 encryption ipsec spi** <*spi*> **esp null** format, **null** indicates that messages on the interface will not be encrypted, but will be authenticated.
<*encryption type*>	Specifies the type of algorithm used to encrypt OSPFv3 messages. Valid values for encryption are: **3des** uses triple data encryption standard (DES). **aes-cbc** uses advanced encryption standard (AES) with cipher block chaining (CBC). Select from **aes-cbc 128**, **aes-cbc 192**, or **aes-cbc 256**. **des** uses DES.
<*encryption key*>	Specifies the hexadecimal encryption key. The size of the encryption key is determined by the respective encryption algorithm, as follows: **3des** uses a **48** character key size. **aes-cbc 128** uses a **32** character key size. **aes-cbc 192** uses a **48** character key size. **aes-cbc 256** uses a **64** character key size. **des** uses a **16** character key size.
<*authentication type*>	Specifies the algorithm used for authenticating OSPFv3 messages. Valid authentication methods are Message-Digest 5 (**md5**) and Secure-Hash 1 (**sha1**) algorithms.

<authentication key>	Specifies the hexadecimal authentication key. The size of the authentication key is determined by the respective authentication algorithm, as follows: **md5** uses a **32** character key size. **sha1** uses a **40** character key size.

Default Values

By default, there is no security for OSPFv3 messages on an interface.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

This commands specifies OSPFv3 security at the interface level. Protection specified with this command overrides any area-level OSPFv3 protection that might apply to the interface.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures OSPFv3 messages with an SPI of **120**, no encryption, and **md5** as the authentication method:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ospfv3 encryption ipsec spi 120 esp null md5 NeWtStpsswdLoonGpsswDhtThmnWoKEY**

ospfv3 <*process id*> **hello-interval** <*value*>

Use the **ospfv3 hello-interval** command to specify the interval between Open Shortest Path First version 3 (OSPFv3) Hello packets sent on the interface. This value must be the same across all interfaces on the link. Use the **no** form of this command to return the Hello packet interval to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2283*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
hello-interval <*value*>	Specifies the number of seconds allowed between OSPFv3 Hello packets. Valid range is **1** to **65535** seconds.

Default Values

By default, the Hello packet interval for OSPFv3 is **10** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the interval between OSPFv3 Hello packets on the interface is **20** seconds:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ospfv3 5 hello-interval 20**

ospfv3 <*process id*> network

Use the **ospfv3 network** command to specify the network type for Open Shortest Path First version 3 (OSPFv3) enabled interfaces. Use the **no** form of this command to return the interface's network type to the default value. Variations of this command include:

ospfv3 <*process id*> **network broadcast**
ospfv3 <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2283*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
broadcast	Specifies that the OSPFv3 network type for the interface is set to broadcast.
point-to-point	Specifies that the OSPFv3 network type for the interface is set to point-to-point.

Default Values

By default, Ethernet interfaces are set to network type broadcast, and point-to-point (PPP), Frame Relay, and loopback interfaces are set to network type point-to-point.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the network interface as point-to-point:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ospfv3 5 network point-to-point**

ospfv3 *<process id>* **priority** *<value>*

Use the **ospfv3 priority** command to specify the Open Shortest Path First version 3 (OSPFv3) priority for the interface. Use the **no** form of this command to return the interface's priority to the default value.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2283*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
priority *<value>*	Specifies the OSPFv3 priority for the interface. Valid range is **0** to **255**.

Default Values

By default, the OSPFv3 priority of an interface is set to **1**.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

Priority is used in the election of the designated router and backup designated router on multi-access networks. Interfaces connected to multi-access networks (such as Ethernet interfaces) perform an election for a designated and backup designated router. The router interface with the highest OSPFv3 priority on the link becomes the designated router for that link. The interface with the next highest priority becomes the designated backup router. In the event there is a tie, the router interface with the highest router ID takes precedence. A priority value of **0** indicates the router is ineligible to become either the designated or backup designated router.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example changes the interface's OSPFv3 priority value to **6**:

```
(config)#interface ethernet 0/1
(config-eth 0/1)#ospfv3 5 priority 6
```

ospfv3 <*process id*> retransmit-interval <*value*>

Use the **ospfv3 retransmit-interval** command to specify the interval between Open Shortest Path First version 3 (OSPFv3) link-state advertisements (LSAs) sent on the interface. Use the **no** form of this command to return the OSPFv3 LSA interval to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2283*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
retransmit-interval <*value*>	Specifies the number of seconds between OSPFv3 LSAs sent on the interface. Valid range is **1** to **65535** seconds.

Default Values

By default, the LSA retransmit interval is set to **5** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the LSA retransmit interval is **10** seconds:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ospfv3 5 retransmit-interval 10**

ospfv3 <*process id*> shutdown

Use the **ospfv3 shutdown** command to disable an Open Shortest Path First version 3 (OSPFv3) process on the interface. When this command is used, the OSPFv3 commands remain in place, but logically it appears to the interface as though the OSPFv3 process has been removed from the configuration. This command can be useful in troubleshooting. Use the **no** form of this command to reinstate the OSPFv3 process.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2283*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.

Default Values

No default values are necessary for this command.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example disables OSPFv3 process **5** on the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ospfv3 5 shutdown**

ospfv3 <*process id*> transmit-delay <*value*>

Use the **ospfv3 transmit-delay** command to specify the estimated time that is required to propagate an Open Shortest Path First version 3 (OSPFv3) link-state advertisement (LSA) on the interface. Use the **no** form of this command to return the transmit delay to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2283*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
transmit-delay <*value*>	Specifies the number of seconds required to send LSAs from the interface. Valid range is **1** to **65535** seconds.

Default Values

By default, the LSA transmit delay is set to **1** second.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example changes the interface's LSA transmit delay to **2** seconds:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ospfv3 5 transmit-delay 2**

packet-capture <*name*>

Use the **packet-capture** command to apply a previously configured packet capture instance to the interface. Use the **no** form of this command to remove the packet capture instance.

Syntax Description

<*name*>	Specifies the name of the packet capture instance to apply to the interface.

Default Values

By default, no packet capture instances are configured or applied to the interface.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

The AOS packet capture feature is used with network monitoring to effectively capture data packets as they traverse the network. For more information about packet capturing, its uses, and its implementation in AOS, refer to the configuration guide *Configuring Packet Capture in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example applies the previously configured packet capture **1CAPTURE** to the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#packet-capture 1CAPTURE**

performance-statistics

Use the **performance-statistics** command to enable gathering performance monitoring statistics on the subinterface. Use the **no** form of this command to disable the performance monitoring feature.

Syntax Description

No subcommands.

Default Values

By default, performance monitoring is enabled.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example enables performance monitoring on the Ethernet subinterface **eth 0/1.1**:

(config)**#interface eth 0/1.1**
(config-eth 0/1.1)**#performance-statistics**

port-auth auth-mode

Use the **port-auth auth-mode** command to configure the authentication mode. Use the **no** form of this command to return to the default setting. Variations of this command include:

port-auth auth-mode mac-based
port-auth auth-mode port-based
port-auth auth-mode port-based mac-auth-bypass
port-auth auth-mode voice-based
port-auth auth-mode voice-based mac-auth-bypass

Syntax Description

mac-based	Specifies a medium access control (MAC)-based authentication mode. Each host must authenticate separately.
port-based	Specifies a port-based authentication mode. Only a single host can participate in the authentication process.
voice-based	Specifies a voice-based authentication mode. Two hosts can participate in the authentication process: one in a voice virtual local area network (VLAN), and one in a data VLAN. A voice VLAN must be configured on the port for voice-based port authentication.
mac-auth-bypass	Optional. Specifies that if 802.1x authentication times out, the port will authenticate with a RADIUS server using the source MAC address. If the device connected to the port responds to 802.1x, MAC bypass will not be attempted.

Default Values

By default, the authentication mode is port based.

Command History

Release 10.1	Command was introduced.
Release 11.5.0	Command was expanded to include the **mac-auth-bypass** parameter.
Release R11.13.0	Command was expanded to include the **voice-based** parameter.

Usage Examples

The following example configures the unit for MAC-based authentication mode:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#port-auth auth-mode mac-based**

The following example configures the unit for voice-based authentication mode:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#port-auth auth-mode voice-based**

port-auth control-direction

Use the **port-auth control-direction** command to configure the direction in which traffic is blocked. This command is only applicable when authentication is port based. Use the **no** form of this command to return to the default setting. Variations of this command include:

port-auth control-direction both
port-auth control-direction in

Syntax Description

both	Blocks traffic in both directions when the port becomes unauthorized.
in	Blocks only incoming traffic when the port becomes unauthorized.

Default Values

By default, traffic is blocked in both directions.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example causes traffic to be blocked in both directions when the port becomes unauthorized:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#port-auth control-direction both**

port-auth guest-vlan <*vlan id*>

Use the **port-auth guest-vlan** command to configure guest virtual local area network (VLAN) for an interface. Use the **no** form of this command to return to the default setting.

Syntax Description

<*vlan id*>	Specifies a valid VLAN interface ID. Range is **1** to **4094**. If the specified VLAN does not exist, this command will create the VLAN.

Default Values

By default, no guest VLAN is configured.

Command History

Release 11.6.0	Command was introduced.

Functional Notes

Guest VLAN allows devices that fail authentication to be assigned to a predefined guest VLAN. For example, if a printer is plugged into a port and there is no RADIUS server to authenticate the new device or if RADIUS is not responding, the printer will be assigned to the guest VLAN and have network access granted to that VLAN.

Usage Examples

The following example configures the Ethernet interface 0/1 for guest VLAN **20**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#port-auth guest-vlan 20**

port-auth multiple-hosts

Use the **port-auth multiple-hosts** command to allow multiple hosts to access an authorized port without going through the authentication process. This command is only applicable when authentication is port based. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example enables multiple hosts to access an authorized port:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#port-auth multiple-hosts**

port-auth port-control

Use the **port-auth port-control** command to configure the port-authorization state. Use the **no** form of this command to return to the default setting. Variations of this command include:

port-auth port-control auto
port-auth port-control force-authorized
port-auth port-control force-unauthorized

Syntax Description

auto	Enables the port-authentication process.
force-authorized	Forces the port into an authorized state.
force-unauthorized	Forces the port into an unauthorized state.

Default Values

By default, all ports are forced to an authorized state.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example forces Ethernet port 0/1 into an unauthorized state:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#port-auth port-control force-unauthorized**

power inline

Use the **power inline** command to detect attached powered devices (PDs) and deliver 48 VDC, compliant with the IEEE 802.3af Power over Ethernet (PoE) standard, to the PD via existing CAT 5 cabling. To disable power detection and supply, use the **power inline never** command. Variations of this command include:

power inline auto
power inline legacy
power inline limit <*value*>
power inline never
power inline 2-point
power inline 4-point

Syntax Description

auto	Enables power detection and supply to PDs.
legacy	Enables power detection and supply of legacy non-IEEE 802.3af-compliant PDs.
limit <*value*>	Specifies the maximum amount of power that can be allocated to a PD connected to a specific port interface.
never	Disables power detection and supply to PDs.
2-point	Enables power detection and supply using the 2-point detection method necessary for some PDs.
4-point	Enables power detection and supply using the 4-point detection method necessary for some PDs. This method works consistently with LinkRunner 1000/200 devices when other detection methods fail.

Default Values

By default, PWR switches discover and provide power to IEEE-compliant PDs.

Command History

Release 9.1	Command was introduced.
Release A4.01	Command was expanded to include the **2-point** parameter.
Release R11.2.0	Command was expanded to include the **limit** parameter.
Release R12.2.0	Command was expanded to include the **4-point** parameter.

Functional Notes

The **power inline limit** <*value*> command specifies the maximum amount of power available for allocation on a particular port. When you set the limit using this command, the switch will use this value instead of the PD Classification to determine the amount of power that must be available before delivering power to a newly connected PD. If the total power available is greater than this setting, power will be delivered to the PD. In addition, if the PD ever tries to draw more power than this setting, power to the PD will be shut off.

The **power inline limit** <*value*> command is available only in AOS firmware version R11.2.0 and later, but the command is hidden and therefore does not provide any help text.

Usage Examples

The following example configures the Ethernet interface to detect and supply power to PDs:

(config)**#interface ethernet 0/3**
(config-eth 0/3)**#power inline auto**

The following example sets the maximum amount of power allocated to a PD on a Gigabit switchport interface to 12:

(config)**#interface gigabit-switchport 0/1**
(config-giga-swx 0/1)**#power inline limit 12**

qos

Use the **qos** (quality of service) command to set the interface to the trusted state and to set the default cost of service (CoS) value. To return to defaults, use the **no** form of this command. Variations of this command include:

qos default-cos <*value*>
qos trust cos

Syntax Description

default-cos <*value*>	Sets the default CoS value for untrusted ports and all untagged packets. Range is **0** through **7**.
trust cos	Sets the interface to the trusted state.

Default Values

By default, the interface is untrusted with a default CoS of **0**.

Command History

Release 5.1	Command was introduced.

Functional Notes

Set the interface to **trust cos** if received 802.1P. CoS values are considered valid (i.e., no need to reclassify) and do not need to be tagged with the default value. When set to untrusted, the **default-cos** value for the interface is used.

Usage Examples

The following example sets Ethernet interface 0/1 as a trusted interface and assigns untagged packets a CoS value of **1**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#qos trust cos**
(config-eth 0/1)**#qos default-cos 1**

qos-policy

Use the **qos-policy** command to apply a previously configured quality of service (QoS) map to incoming or outgoing packets on an interface. Use the **no** form of this command to remove the map from the interface. Variations of this command include:

qos-policy in *<name>*
qos-policy out *<name>*

Syntax Description

<name>	Specifies the name of a previously created QoS map (refer to *qos map <name> <number> on page 1673* for more information).
in	Assigns a QoS map to this interface's input.
out	Assigns a QoS map to this interface's output.

Default Values

No default values are necessary for this command.

Command History

Release 9.1	Command was introduced.
Release 15.1	Command was expanded to include the **in** parameter.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

When a QoS policy is applied to an interface, it may be disabled if the interface bandwidth is not adequate to support the requested bandwidth on the map set. Once the bandwidth problem is resolved, the map will work again. The bandwidth will be rechecked on any of the following changes:

1. A priority or class-based entry is added to, deleted from, or changed in a QoS map set.
2. The interface bandwidth is changed by the **bandwidth** command on the interface.
3. A QoS policy is applied to an interface.
4. A cross connect is created that includes an interface with a QoS policy.
5. The interface queuing method is changed to fair queue to use weighted fair queuing.
6. The interface operational status changes.
7. The interface bandwidth changes for other reasons (e.g., when asymmetric digital subscriber line (ADSL) finishes training).

In order to prevent the map from being disabled in cases of temporary inadequate bandwidth (e.g., a single link goes down in a dual T1 multilink configuration where the map requests more than one T1's worth of bandwidth), the QoS map uses the maximum theoretical bandwidth on an interface, not the actual bandwidth at that time. This actually helps QoS keep higher priority class-based traffic working better than best-effort traffic when the bandwidth drops.

Usage Examples

The following example applies the QoS map **VOICEMAP** to the Ethernet interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#qos-policy out VOICEMAP**

rtp quality-monitoring

Use the **rtp quality-monitoring** command to enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets on this interface. If the global command (**ip rtp quality-monitoring**) is disabled when this command is issued, the system will return the following warning: "Applied but not used, you must globally enable **ip rtp quality-monitoring** to use VQM." Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, VQM is enabled on all wide area network (WAN) and local area network (LAN) interfaces.

Command History

Release 17.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Usage Examples

The following example enables RTP quality monitoring on the Ethernet 0/2 interface:

(config)**#interface eth 0/2**
(config-eth 0/2)**#rtp quality-monitoring**

s-tag-dei

Use the **s-tag-dei** command to configure traffic egressing the interface to reflect the packet color, either green or yellow. Packets are colored by setting the Canonical Format Indicator/Discard Eligibility Indicator (CFI/DEI) bit in the S-TAG VLAN header. Green packets are set to 0, while yellow packets are set to 1. Use the **no** form of the command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example configures the egressing traffic on the Ethernet 0/2 interface to reflect the packet color in the S-TAG VLAN header:

```
(config)#interface eth 0/2
(config-eth 0/2)#s-tag-dei
```

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Us the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Usage Examples

The following example enables SNMP capability on the Ethernet interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#no snmp trap link-status**

spanning-tree bpdufilter

Use the **spanning-tree bpdufilter** command to enable or disable the bridge protocol data unit (BPDU) filter on a specific interface. This setting overrides the related global setting (refer to *spanning-tree edgeport bpdufilter default on page 1835*). Use the **no** form of this command to return to the default setting. Variations of this command include:

spanning-tree bpdufilter disable
spanning-tree bpdufilter enable

Syntax Description

disable	Disables BPDU filter for this interface.
enable	Enables BPDU filter for this interface.

Default Values

By default, this setting is disabled.

Command History

Release 5.1	Command was introduced.

Functional Notes

The bpdufilter blocks any BPDUs from being transmitted and received on an interface.

Usage Examples

The following example enables the BPDU filter on the Ethernet interface 0/3:

(config)**#interface ethernet 0/3**
(config-eth 0/3)**#spanning-tree bpdufilter enable**

The BPDU filter can be disabled on the Ethernet interface 0/3 by issuing the following commands:

(config)**#interface ethernet 0/3**
(config-eth 0/3)**#spanning-tree bpdufilter disable**

spanning-tree bpduguard

Use the **spanning-tree bpduguard** command to enable or disable the bridge protocol data unit (BPDU) guard on a specific interface. This setting overrides the related global setting (refer to *spanning-tree forward-time <value> on page 1839*). Use the **no** form of this command to return to the default setting. Variations of this command include:

spanning-tree bpduguard disable
spanning-tree bpduguard enable

Syntax Description

disable	Disables BPDU guard for this interface.
enable	Enables BPDU guard for this interface.

Default Values

By default, this setting is disabled.

Command History

Release 5.1	Command was introduced.

Functional Notes

The bpduguard blocks any BPDUs from being received on an interface.

Usage Examples

The following example enables the BPDU guard on the interface Ethernet interface 0/3:

(config)**#interface ethernet 0/3**
(config-eth 0/3)**#spanning-tree bpduguard enable**

The BPDU guard can be disabled on the Ethernet interface 0/3 by issuing the following commands:

(config)**#interface ethernet 0/3**
(config-eth 0/3)**#spanning-tree bpduguard disable**

spanning-tree cost <*value*>

Use the **spanning-tree cost** command to assign a cost to the interface. The cost value is used when computing the spanning-tree root path. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies a cost value of **1** to **200000000**.

Default Values

By default, the cost value is set to **1000** Mbps.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example sets the interface to a path cost of **1200**:

(config)**#interface ethernet 0/3**
(config-eth 0/3)**#spanning-tree cost 1200**

spanning-tree edgeport

Use the **spanning-tree edgeport** command to enable or disable the interface as an edgeport. This command overrides the related global setting (refer to *spanning-tree edgeport default on page 1837*). Variations of this command include:

spanning-tree edgeport disable
spanning-tree edgeport enable

Syntax Description

disable	Specifies that the interface is not an edgeport.
enable	Specifies that the interface is an edgeport.

Default Values

By default, this setting is disabled.

Command History

Release 5.1	Command was introduced.
Release 8.1	Command was added to the ATM subinterface command set.
Release R10.1.0	Command was expanded to include the **disable** and **enable** keywords.

Functional Notes

When an interface is designated as an edgeport, the interface will immediately go into a forwarding state when the link becomes active. When an interface is not designated as an edgeport, the interface must progress through the listening and learning states before going to the forwarding state.

Usage Examples

The following example specifies that the interface is an edgeport:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#spanning-tree edgeport enable**

The following example disables the interface as an edgeport:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#spanning-tree edgeport disable**

spanning-tree link-type

Use the **spanning-tree link-type** command to configure the spanning tree protocol link type for each interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

spanning-tree link-type auto
spanning-tree link-type point-to-point
spanning-tree link-type shared

Syntax Description

auto	Determines link type by the port's duplex settings.
point-to-point	Manually sets link type to **point-to-point** regardless of duplex settings.
shared	Manually sets link type to **shared** regardless of duplex settings.

Default Values

By default, the interface is set to auto.

Command History

Release 5.1	Command was introduced.

Functional Notes

This command overrides the default link type setting determined by the duplex of the individual port. By default, a port configured for half-duplex is set to **shared** link type, and a port configured for full-duplex is set to **point-to-point** link type. Setting the link type manually overrides the default and forces the port to use the specified link type. Use the **link-type auto** command to restore the convention of determining link type based on duplex settings.

Usage Examples

The following example forces the link type to **point-to-point**, even if the port is configured to be half-duplex:

(config)**#interface ethernet 0/3**
(config-eth 0/3)**#spanning-tree link-type point-to-point**

Technology Review

Rapid transitions are possible in Rapid Spanning Tree Protocol (RSTP) by taking advantage of point-to-point links (a port is connected to exactly one other bridge) and edge-port connections (a port is not connected to any additional bridges). Setting the link type to **auto** allows the spanning tree to automatically configure the link type based on the duplex of the link. Setting the link type to **point-to-point** allows a half-duplex link to act as if it were a point-to-point link.

spanning-tree path-cost *<value>*

Use the **spanning-tree path-cost** command to assign a cost to a bridge group that is used when computing the spanning-tree root path. To return to the default path-cost value, use the **no** form of this command.

Syntax Description

<value>	Assigns a number to the bridge interface to be used as the path cost in spanning calculations. Valid range is **0** to **65535**.

Default Values

By default, the path-cost value is set to **19**.

Command History

Release 1.1	Command was introduced.
Release 8.1	Command was added to the ATM subinterface command set.
Release R10.1.0	Command was added to the Ethernet interface command set.

Functional Notes

The specified value is inversely proportional to the likelihood the bridge interface will be chosen as the root path. Set the path-cost value lower to increase the chance the interface will be the root. To obtain the most accurate spanning-tree calculations, develop a system for determining path costs for links and apply it to all bridged interfaces.

Usage Examples

The following example assigns a path cost of 100 on an Ethernet interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#spanning-tree path-cost 100**

Technology Review

Spanning-tree protocol provides a way to prevent loopback or parallel paths in bridged networks. Using the priority values and path costs assigned to each bridging interface, the spanning-tree protocol determines the root path and identifies whether to block or allow other paths.

spanning-tree pathcost method

Use the **spanning-tree pathcost method** command to select a short or long method used by the spanning-tree protocol. Variations of this command include:

spanning-tree pathcost method long
spanning-tree pathcost method short

Syntax Description

long	Specifies 32-bit values when calculating pathcosts.
short	Specifies 16-bit values when calculating pathcosts.

Default Values

By default, **spanning-tree pathcost method** is set to **short**.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example specifies that the spanning tree protocol use a long pathcost method:

(config)**#interface ethernet 0/3**
(config-eth 0/3)**#spanning-tree pathcost method long**

spanning-tree port-priority <*value*>

Use the **spanning-tree port-priority** command to select the priority level of this interface. To return to the default setting, use the **no** form of this command.

Syntax Description

<*value*>	Specifies a priority-level value from **0** to **240** (this value must be in increments of 16).

Default Values

By default, this set to **128**.

Command History

Release 5.1	Command was introduced.

Functional Notes

The only time that this priority level is used is when two interfaces with a path to the root have equal cost. At that point, the level set in this command will determine which port the spanning tree will use. Set the priority value lower to increase the chance the interface will be used.

Usage Examples

The following example sets the interface to a priority of **100**:

(config)**#interface ethernet 0/3**
(config-eth 0/3)**#spanning-tree port-priority 100**

spanning-tree rootguard

Use the **spanning-tree rootguard** command to enable or disable the root guard on a specific interface. This setting overrides the related global setting (refer to *spanning-tree edgeport rootguard default on page 1838*). Use the **no** form of this command to return to the default setting. Variations of this command include:

spanning-tree rootguard disable
spanning-tree rootguard enable

Syntax Description

disable	Disables root guard for this interface.
enable	Enables root guard for this interface.

Default Values

By default, this setting is disabled.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

Root guard blocks an interface from being elected to the root port role. If information about a superior root bridge is received, the interface will no longer forward traffic until superior root bridge proposals stop. If an interface has bridge protocol data unit (BPDU) filter or BPDU guard configured, configuring root guard will have no effect on the operation of the interface. The root guard setting can be overridden on an individual port basis.

Usage Examples

The following example enables the root guard on the gigabit switchport interface 0/3:

(config)**#interface gigabit-switchport 0/3**
(config-giga-swx 0/3)**#spanning-tree rootguard enable**

The following example disables the root guard on the gigabit switchport interface 0/3:

(config)**#interface gigabit-switchport 0/3**
(config-giga-swx 0/3)**#spanning-tree rootguard disable**

speed

Use the **speed** command to configure the speed of an Ethernet interface. Use the **no** form of this command to return to the default value. Variations of this command include:

speed 10
speed 100
speed 1000
speed 1000 nonegotiate
speed 2500
speed 10000
speed auto

Syntax Description

10	Specifies 10 Mbps Ethernet.
100	Specifies 100 Mbps Ethernet.
1000	Specifies 1 Gbps Ethernet. This only applies to Gigabit Ethernet interfaces.
2500	Specifies 2.5 Gbps Ethernet. This only applies to Gigabit Ethernet interfaces.
10000	Specifies 10 Gbps Ethernet. This only applies to 10 Gigabit Ethernet interfaces.
nonegotiate	Optional. Specifies that auto-negotiation is disabled on Gigabit Ethernet interfaces that use a fiber medium.
auto	Automatically detects 10 or 100 Mbps Ethernet and negotiates the duplex setting.

Some Ethernet equipment (though rare) is unable to negotiate duplex if speed is manually determined. To avoid incompatibilities, manually set the duplex if the speed is manually set. Refer to ethernet-cfm mep on page 2175 and half-duplex on page 2185.

Default Values

By default, speed is set to **auto**.

Command History

Release 1.1	Command was introduced.
Release 17.5	Command was expanded to include the **2500** Mbps parameter.
Release R10.10.0	Command was expanded to include the **10000** Mbps parameter.
Release R12.1.0	Command was made unavailable for Ethernet interfaces on virtual AOS (vAOS) instances.

Functional Notes

This command is not available for Ethernet interfaces on vAOS instances.

Usage Examples

The following example configures the Ethernet port for **100** Mbps operation:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#speed 100**

storm-control action shutdown

Use the **storm-control action shutdown** command to shut down the interface when a storm occurs. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled; the interface will only filter traffic.

Command History

Release 5.1	Command was introduced.

Functional Notes

Enabling this option shuts down the interface if a multicast, unicast, or broadcast storm occurs.

Usage Examples

The following example shuts down Ethernet interface 0/1 if a storm is detected:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#storm-control action shutdown**

storm-control level

Use the **storm-control level** command to configure limits on the rates of broadcast, multicast, and unicast traffic on a port. Use the **no** form of this command to disable this feature. Variations of this command include:

storm-control broadcast level *<rising level>*
storm-control broadcast level *<rising level> <falling level>*
storm-control multicast level *<rising level>*
storm-control multicast level *<rising level> <falling level>*
storm-control multicast-broadcast level ***<rising level>***
storm-control unicast level *<rising level>*
storm-control unicast level *<rising level> <falling level>*

Syntax Description

broadcast level	Sets levels for broadcast traffic.
multicast level	Sets levels for multicast traffic.
multicast-broadcast level	Sets levels for multicast and broadcast traffic.
unicast level	Sets levels for unicast traffic.
<rising level>	Specifies a rising level, which determines the percentage of total bandwidth the port accepts before it begins blocking packets. Range is **1** to **100** percent.
<falling level>	Optional. Specifies a falling level, which determines when the storm is considered over, causing AOS to no longer block packets. This level must be less than the rising level. Range is **1** to **100** percent.

Default Values

By default, **storm-control** is disabled.

Command History

Release 5.1	Command was introduced.

Functional Notes

This setting configures the rising and falling suppression values. When the selected rising level (which is a percentage of total bandwidth) is reached, the port begins blocking packets of the specified type (i.e., broadcast, multicast, or unicast). AOS uses the rising level as its falling level if no falling level is specified.

Availability of this command and its variations will differ across AOS platforms.

Usage Examples

The following example sets the rising suppression level to **85** percent for multicast packets:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#storm-control multicast level 85**

The following example sets the rising suppression level to **80** percent for broadcast packets, with a falling level of **50** percent:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#storm-control broadcast level 80 50**

storm-control rate

Use the **storm-control rate** command to configure maximum ingress data rates for broadcast, unknown multicast, and unknown unicast traffic on a switch port. Use the **no** form of this command to disable the feature. Variations of this command include:

storm-control broadcast rate <*rate*>
storm-control broadcast rate <*rate*> **burst** <*size*>
storm-control multicast-unknown rate <*rate*>
storm-control multicast-unknown rate <*rate*> **burst** <*size*>
storm-control unicast-unknown rate <*rate*>
storm-control unicast-unknown rate <*rate*> **burst** <*size*>

Syntax Description

broadcast	Specifies the maximum data rate for all ingress broadcast traffic.
multicast-unknown	Specifies the maximum data rate for ingress unknown multicast traffic.
unicast-unknown	Specifies the maximum data rate for ingress unknown unicast traffic.
rate <*rate*>	Specifies the maximum ingress data rate in Kilobytes per second. Valid range is **64** to **33554368** Kbps.
burst <*size*>	Optional. Specifies the maximum traffic burst (in bytes) of the specified traffic type that can ingress the port. Valid selections are **4K**, **16K**, **64K**, **256K**, **1M**, **4M**, **8M**, and **16M** bytes.

Default Values

By default, storm control is disabled. When enabled, the burst size is set to **64K** bytes by default.

Command History

Release R11.8.0	Command was introduced.

Functional Notes

Storm control is used to lessen the impacts of traffic flooding on certain ports.

Address Resolution Protocol (ARP), Dynamic Host Control Protocol (DHCP), and other protocols commonly use broadcasts, so setting the broadcast storm control rate too low can adversely impact these protocols in an otherwise healthy network.

The configured multicast storm control rate applies only to multicast traffic with addresses not learned by Internet Group Management Protocol (IGMP) snooping.

Unknown unicast traffic usually exist only for initial traffic to a client or traffic sent to a client that was unlearned or that timed out. Setting the unicast storm control rate too low can impact traffic to clients that actually exist but are temporarily unknown to the switch. Spanning tree topology change notifications (TCNs) clear the known unicast addresses on some ports of the switch and cause all unicast traffic from these clients to be unknown until the addresses are relearned. This behavior can cause the temporary rate of unknown unicast frames to spike. Switching networks that have relatively static topologies should use the spanning tree edge-port setting to limit spanning tree TCNs so that a lower storm control unicast rate can be set. If the network topology changes frequently, a larger unicast storm control rate should be set so that traffic is not adversely impacted after a spanning tree TCN.

All traffic is received on switchports at full line rate, meaning that the momentary rate of received traffic will almost always exceed any storm control rate configured lower than the port's linked rate. The configured burst size determines how many bytes can burst over the configured rate before storm control makes a decision to begin dropping traffic for a configured traffic type. A smaller storm control burst size causes the rate to be imposed on received frames earlier in the storm of undesired frames. Setting a higher burst rate is less likely to drop frames in case of many back-to-back frames, but also exposes the network to more of the initial frames of a storm of undesired frames. Once a burst is exhausted, it takes an interval of time to refill completely. This interval, in seconds, is defined as the (burst rate * 8)/rate.

When a switchport is part of a port channel, storm control settings are not allowed on the switchport. Rather, storm control rate and burst settings are only allowed on the port channel of which the switchport is a member.

Usage Examples

The following example configures broadcast traffic storm control with a rate of **1000** Kbps and the default burst size:

(config)**#interface xgigabit-switchport 1/1**
(config-xgiga-swx 1/1)**#storm-control broadcast rate 1000**

subtended-host mode

Use the **subtended-host mode** command to enable or disable subtended host listening on the interface. This command allows the interface to receive pre-provisioning information from another AOS unit. Variations of this command include:

subtended-host mode listener
subtended-host mode disabled

Syntax Description

listener	Enables the interface to receive pre-provisioning information from another unit.
disabled	Disables the interface from receiving any pre-provisioning information from another unit.

Default Values

By default, the first configured MEF Ethernet interface has pre-provisioning listening enabled. In addition, the Gigabit Ethernet interface **0/1** and EFM group **1/1** interfaces have pre-provisioning listening enabled by default. Any additional interfaces have pre-provisioning listening disabled.

Command History

Release A4.05	Command was introduced.
Release R11.1.0	Command was expanded to include the Gigabit Ethernet and EFM group interfaces.

Functional Notes

Only one interface at a time can have the subtended-host mode set to **listener**. If all interfaces have a subtended-host mode of **disabled**, then all pre-provisioning information is discarded.

Usage Examples

The following example enables the Ethernet interface 0/1 to receive subtended-host provisioning:

(config)**#interface ethernet 0/1**
(config-ethernet 0/1)**#subtended-host mode listener**

switchport access vlan <*vlan id*>

Use the **switchport access vlan** command to set the port to be a member of the virtual local area network (VLAN) when in access mode. To reset the port to be a member of the default VLAN, use the **no** form of this command.

Syntax Description

<*vlan id*>	Specifies a valid VLAN interface ID. Range is **1** to **4094**.

Default Values

By default, this is set to VLAN **1** (the default VLAN).

Command History

Release 5.1	Command was introduced.

Functional Notes

If the port is in the trunk mode, this command will not alter the switchport mode to access. Instead it will save the value to be applied when the port does switch to access mode. Refer to *switchport mode on page 2331* for more information.

Usage Examples

The following example sets the switchport mode to static access and makes the Ethernet interface 0/1 port a member of VLAN **2**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#switchport mode access**
(config-eth 0/1)**#switchport access vlan 2**

switchport gvrp

Use the **switchport gvrp** command to enable or disable GARP VLAN Registration Protocol (GVRP) on an interface. Use the **no** form of this command to return to the default value.

Syntax Description

No subcommands.

Default Values

By default, GVRP is disabled on all ports.

Command History

Release 8.1	Command was introduced.

Functional Notes

Enabling GVRP on any interface enables GVRP globally.

Usage Examples

The following example enables GVRP on Ethernet interface 0/24:

(config)**#interface ethernet 0/24**
(config-eth 0/24)**#switchport gvrp**

switchport mode

Use the **switchport mode** command to configure the virtual local area network (VLAN) membership mode. Use the **no** form of this command to reset membership mode to the default value. Variations of this command include:

switchport mode access
switchport mode activchassis
switchport mode stack
switchport mode trunk

Syntax Description

access	Sets port to be a single (nontrunked) port that transmits and receives no tagged packets.
activchassis	Sets the port to allow it to communicate with other ActivChassis devices.
stack	Sets the port to allow it to communicate with a switch stack.
trunk	Sets port to transmit and receive packets on all VLANs included in its VLAN allowed list.

Default Values

By default, on non-ActivChassis devices, the **switchport mode** is set to **access**. By default, on ActivChassis-enabled devices, the **switchport mode** is set to **activchassis**.

Command History

Release 5.1	Command was introduced.
Release AC1.0	Command was expanded to include the **activchassis** parameter.

Functional Notes

Configuring the interface for stack mode (using the **switchport mode stack** command) enables the switch to communicate with other switches that are capable of stacking.

- If the switch is configured as the stack master (using the (config)**#stack master** command), it will begin advertising itself as a stack master.
- If the switch is configured as the stack member (using the (config)**#stack member** command), it will begin advertising other stack masters that it knows about.

Stack mode also allows the port to transmit and receive packets on all VLANs that are included in the VLAN allowed list.

In ActivChassis mode, the switchport becomes part of the ActivChassis backplane, and it is not available to connect to devices outside of the ActivChassis. The port must be directly connected to other devices with the same capability and settings. In addition, if the port is part of the ActivChassis backplane, and it currently has an active link, the port mode cannot be changed from **activchassis** mode. For more information about configuring ActivChassis, refer to the configuration guide *Configuring ActivChassis in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example sets the port to be a **trunk** port:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#switchport mode trunk**

The following example changes the port function on a device with ActivChassis enabled:

(config)**#interface xgigabit-switchport 1/1**
(config-xgiga-swx 1/1)**#switchport mode activchassis**

switchport port-security

Use the **switchport port-security** command to enable port security functionality on the interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

This command is disabled by default.

Command History

Release 8.1	Command was introduced.

Functional Notes

You cannot enable port security on a port that is already configured as the following:

- Monitor session destination
- Member of a port channel interface
- Dynamic or trunk port (i.e., the port must be configured as static access)

Usage Examples

The following example enables port security on the Ethernet interface 0/1 interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#switchport port-security**

switchport port-security aging

Use the **switchport port-security aging** command to enable and configure secure medium access control (MAC) address aging on a particular interface. Use the **no** form of this command to disable this feature. Variations of this command include:

switchport port-security aging static
switchport port-security aging time <*value*>
switchport port-security aging type absolute

Syntax Description

static	Configures the interface to age static, as well as dynamic entries in the secure MAC address table.
time <*value*>	Enables port security aging for dynamic entries in the secure MAC address table by configuring a time (in minutes). Disable aging by setting the time to 0.
type absolute	Configures the address to be removed after the specified time regardless of activity.

Default Values

By default, dynamic and static aging are disabled.

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example sets the aging time of secure MAC addresses to **10** minutes:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#switchport port-security aging time 10**

switchport port-security expire

Use the **switchport port-security expire** command to disable an interface after a specified amount of time. Use the **no** form of this command to return to the default setting. Variations of this command include:

switchport port-security expire time <*value*>
switchport port-security expire type absolute

Syntax Description

time <*value*>	Enables port expiration by configuring a time (in minutes). Disable by setting time to 0.
type absolute	Configures the interface to shut down after the specified time regardless of activity.

Default Values

By default, this command is disabled and set to **type absolute**.

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example disables Ethernet interface 0/1 after **10** minutes:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#switchport port-security expire time 10**

switchport port-security mac-address

Use the **switchport port-security mac-address** command to add a static secure medium access control (MAC) address or sticky secure MAC address associated with the interface and to enable sticky address learning. Use the **no** form of this command to remove a MAC address associated with this port. Variations of this command include the following:

switchport port-security mac-address <*mac address*>
switchport port-security mac-address <*mac address*> **vlan** <*vlan id*>
switchport port-security mac-address sticky
switchport port-security mac-address sticky-volatile
switchport port-security mac-address sticky <*mac address*>
switchport port-security mac-address sticky <*mac address*> **vlan** <*vlan id*>

Syntax Description

sticky	Optional. Enables sticky address learning if no MAC address is specified. The learned addresses persist across a reboot.
sticky-volatile	Optional. Enables sticky address learning for the immediate session only. The learned addresses do not appear in the configuration and do not persist across a reboot.
<*mac address*>	Optional. Adds a MAC address associated with this interface. MAC addresses should be expressed in the following format xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).
vlan <*vlan id*>	Optional. Associates the MAC address with the specified VLAN. VLAN ID range is **1** to **4094**.

Default Values

By default, sticky learning is disabled and there are no configured MAC addresses.

Command History

Release 8.1	Command was introduced.
Release 17.4	Command was expanded to include the **sticky-volatile** parameter.
Release 17.9	Command was expanded to include the **vlan** parameter.

Functional Notes

For more information about port security configuration, refer to the configuration guide *Configuring Port Access Control in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example adds a single static address and enables sticky address learning on interface Ethernet interface 0/1:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#switchport port-security mac-address 00:A0:C8:02:D0:30**
(config-eth 0/1)**#switchport port-security mac-address sticky**

switchport port-security maximum <*value*>

Use the **switchport port-security maximum** command to configure the maximum number of secure medium access control (MAC) addresses associated with the interface. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the maximum number of secure MAC addresses to be associated with the interface. Range is **1** to **132**.

Default Values

The default value for this command is **1**.

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example sets the maximum supported MAC addresses for Ethernet interface 0/1 to **2**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#switchport port-security maximum 2**

switchport port-security violation

Use the **switchport port-security violation** command to configure the action to be taken once a security violation is encountered. Use the **no** form of this command to return to the default setting. Variations of this command include:

switchport port-security violation protect
switchport port-security violation restrict
switchport port-security violation shutdown

Syntax Description

protect	Determines that the unit will not learn any new secure addresses (nor allow these new sources to pass traffic) until the number of currently active secure addresses drops below the maximum setting.
restrict	Determines that the security violation counter increments and an Simple Network Management Protocol (SNMP) trap is sent once a violation is detected. The new address is not learned and data from that address is not allowed to pass.
shutdown	Determines that the interface is disabled once a violation is detected. A **no shutdown** command is required to re-enable the interface.

Default Values

The default for this command is shutdown.

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example configures the interface to react to security violations by not learning the addresses and not accepting data from the violation source:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#switchport port-security violation restrict**

switchport protected

Use the **switchport protected** command to prevent the port from transmitting traffic to all other protected ports. A protected port can only send traffic to unprotected ports. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

This command is disabled by default.

Command History

Release 10.1	Command was introduced.

Usage Examples

In the example below, all three of the ports are on virtual local area network (VLAN) 3, and Ethernet 0/1 and Ethernet 0/2 are designated as protected ports. Ethernet 0/3 is unprotected. Ethernet 0/1 and Ethernet 0/2 will be allowed to send traffic to Ethernet 0/3, but traffic traveling between Ethernet 0/1 and Ethernet 0/2 will be blocked.

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#switchport access vlan 3**
(config-eth 0/1)**#switchport protected**
(config-eth 0/1)**#exit**

(config)**#interface ethernet 0/2**
(config-eth 0/2)**#switchport access vlan 3**
(config-eth 0/2)**#switchport protected**
(config-eth 0/2)**#exit**

(config)**#interface ethernet 0/3**
(config-eth 0/3)**#switchport access vlan 3**

switchport trunk allowed vlan

Use the **switchport trunk allowed vlan** command to allow certain virtual local area networks (VLANs) to transmit and receive traffic on this port when the interface is in trunking mode. To return to defaults, use the **no** form of this command. Variations of this command include:

switchport trunk allowed vlan <*list*>
switchport trunk allowed vlan add <*list*>
switchport trunk allowed vlan all
switchport trunk allowed vlan except <*list*>
switchport trunk allowed vlan none
switchport trunk allowed vlan remove <*list*>

Syntax Description

<*list*>	Specifies a list of valid VLAN interface IDs. Refer to *Functional Notes* below.
add	Adds the specified VLAN IDs to the VLAN trunking allowed list.
all	Adds all configured VLAN IDs to the VLAN trunking allowed list.
except	Adds all configured VLAN IDs to the VLAN trunking allowed list except those specified in the <*vlan id list*>.
none	Adds no VLAN IDs to the VLAN trunking allowed list.
remove	Removes VLAN IDs from the VLAN trunking allowed list.

Default Values

By default, all valid VLANs are allowed.

Command History

Release 5.1	Command was introduced.

Functional Notes

A VLAN list is a set of VLAN IDs delimited by commas. A valid VLAN ID value must be from **1** through **4094**. A range of IDs may be expressed as a single element by using a hyphen between endpoints. For example, the VLAN ID range **1,2,3,4,6,7,8,9,500** may be more easily expressed as **1-4,6-9,500**. No spaces are allowed in a valid ID range.

Usage Examples

The following example adds VLANs to the previously existing list of VLANs allowed to transmit and receive on this port:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#switchport trunk allowed vlan add 1-4,6-9,500**

switchport trunk fixed vlan

Use the **switchport trunk fixed vlan** command to change the configured list of virtual local area networks (VLANs) that remain fixed in use only when GARP VLAN Registration Protocol (GVRP) is enabled on the interface. Of these VLANs, VLANs statically created will be available for use on the interface. Use the **no** form of this command to disable this feature. Variations of this command include:

switchport trunk fixed vlan add <*list*>
switchport trunk fixed vlan all
switchport trunk fixed vlan except <*list*>
switchport trunk fixed vlan none
switchport trunk fixed vlan remove <*list*>

Syntax Description

<*list*>	Specifies a list of valid VLAN interface IDs. Refer to *Functional Notes* below.
add	Adds VLANs to the VLAN GVRP trunking fixed list.
all	Adds all VLANs to the VLAN GVRP trunking fixed list.
except	Adds all VLAN IDs to the VLAN trunking fixed list except those in the command line VLAN ID list.
none	Removes all VLANs from the VLAN GVRP trunking fixed list.
remove	Removes VLAN from the VLAN trunking fixed list.

Default Values

By default, no VLANs are in the VLAN GVRP trunking fixed list (**switchport trunk fixed vlan none**).

A VLAN list is a set of VLAN IDs delimited by commas. A valid VLAN ID value must be from **1** through **4094**. A range of IDs may be expressed as a single element by using a hyphen between endpoints. For example, the VLAN ID range **1,2,3,4,6,7,8,9,500** may be more easily expressed as **1-4,6-9,500**. No spaces are allowed in a valid ID range.

Command History

Release 8.1	Command was introduced.

Functional Notes

This command has no effect on VLAN membership configuration unless GVRP is enabled on the interface.

Usage Examples

The following example changes the configured list of fixed VLANs by adding VLAN **50** to the list.

(config-eth 0/20)**#switchport trunk fixed vlan add 1-15,25-30,40**
(config-eth 0/20)**#switchport trunk fixed vlan add 50**

The following example changes the configured list of fixed VLANs by removing VLANs 10 to 100 from the list:

(config-eth 0/20)**#switchport trunk fixed vlan remove 10-100**

The following example changes the configured list of fixed VLANs to include only VLANs 1 to 1000:

(config-eth 0/20)**#switchport trunk fixed vlan 1-1000**

The following example changes the configured list of fixed VLANs to include no VLANs (except those VLANs that are native):

(config-eth 0/20)**#switchport trunk fixed vlan none**

switchport trunk native vlan <*vlan id*>

Use the **switchport trunk native vlan** command to set the virtual local area network (VLAN) native to the interface when the interface is in trunking mode. To return to defaults, use the **no** form of this command.

Syntax Description

<*vlan id*>	Specifies a valid VLAN interface ID. Range is **1** to **4094**.

Default Values

By default, this is set to VLAN **1**.

Command History

Release 5.1	Command was introduced.

Functional Notes

Configure which VLAN the interface uses as its native VLAN during trunking. Packets from this VLAN leaving the interface will not be tagged with the VLAN number. Any untagged packets received by the interface are considered a part of the native VLAN ID.

Usage Examples

The following example sets the native VLAN on Ethernet interface 0/1 to VLAN **2**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#switchport trunk native vlan 2**

switchport vlan

Use the **switchport vlan** command to create a Link Layer Discovery Protocol-Media Endpoint Discovery (LLDP-MED) network policy that specifies a virtual local area network (VLAN) for **voice**, **guest-voice**, **softphone**, or **voice-signalling** applications. Use the optional **cos** and **dscp** keywords to define class of service (CoS) and differentiated services code point (DSCP) values associated with the application. Use the **no** form of this command to remove an existing network policy. Variations of this command include:

switchport guest-voice vlan <*vlan id*>
switchport guest-voice vlan <*vlan id*> **[cos** <*value*> **| dscp** <*value*> **| cos** <*value*> **dscp** <*value*>**]**
switchport softphone vlan <*vlan id*>
switchport softphone vlan <*vlan id*> **[cos** <*value*> **| dscp** <*value*> **| cos** <*value*> **dscp** <*value*>**]**
switchport voice vlan <*vlan id*>
switchport voice vlan <*vlan id*> **[cos** <*value*> **| dscp** <*value*> **| cos** <*value*> **dscp** <*value*>**]**
switchport voice-signalling vlan <*vlan id*>
switchport voice-signalling vlan <*vlan id*> **[cos** <*value*> **| dscp** <*value*> **| cos** <*value*> **dscp** <*value*>**]**

Syntax Description

guest-voice	Specifies a guest voice application, which is used to define a policy for guest users with a limited feature set voice service.
softphone	Specifies a softphone application, which is used to define a policy for softphone applications that operate on devices, such as PCs or laptop computers.
voice	Specifies a voice application, which is used to define a policy for dedicated IP phone handsets and other similar devices supporting interactive voice services.
voice-signalling	Specifies a voice signaling application, which is used to define a policy for the command and control signaling that supports voice and guest voice applications.
<*vlan id*>	Specifies the voice VLAN ID. Range is **1** to **4094**.
cos <*value*>	Optional. Specifies the CoS value assigned to the application. Range is **0** to **7**.
dscp <*value*>	Optional. Specifies the DSCP value assigned to the application. Range is **0** to **63**.

Default Values

By default, no LLDP-MED network policies are configured.

If an application and VLAN are specified without the optional CoS or DSCP parameters, then default CoS and DSCP values are assigned.

Default CoS values are: **voice** (5); **voice-signalling** (3); **guest-voice** (0); **softphone** (0).

Default DSCP values are: **voice** (46); **voice-signalling** (26); **guest-voice** (0); **softphone** (0).

Command History

Release 16.1	The command **switchport voice vlan** <*vlan id*> was introduced.
Release 17.2	Command was expanded to include the additional applications: **guest-voice**, **softphone**, and **voice-signalling**. The optional **cos** and **dscp** parameters were added.

Functional Notes

The switchport command allows a configured interface to function as an access point (AP) for a VLAN while adding the specified VLAN to the port's allowed VLAN list. This command automatically sets the port to spanning tree edgeport mode, but this mode is not automatically reset when the voice, guest voice, softphone, or signaling VLAN is removed.

If the VLAN specified in this command does not yet exist, it will be created in Adtran Operating System (AOS) when the command is issued.

A network policy is typically configured on switchport interfaces in AOS devices that support LLDP-MED. An exception is the NetVanta 1524ST, where network policies are configured on Gigabit Ethernet interfaces.

At least one network policy should be configured on a switchport interface that is connected to an LLDP-MED capable endpoint. Depending on the type and use of Voice over Internet Protocol (VoIP) equipment attached to the switchport interface, multiple network policies may need to be configured on the same interface.

Some endpoints prefer to use untagged VLANs for their application. To achieve this in AOS, configure the application to be on the same VLAN of which the port is a member. By default, this is VLAN 1.

For more information about allowed VLAN lists, refer to switchport trunk allowed vlan on page 2341. For more information about spanning-tree edgeport mode, refer to spanning-tree edgeport on page 2315. For more information about switchport mode, refer to switchport mode on page 2331.

Usage Examples

The following example establishes a voice network policy that uses VLAN **200**.

(config)**#interface switchport 0/1**
(config-swx 0/1)**#switchport voice vlan 200**

Since CoS and DSCP values are not specified in the above network policy, the default values for voice applications will be used: CoS (5); DSCP (46).

The following example establishes a voice network policy that uses VLAN 200 with CoS priority set to **4** and DSCP priority set to **36**.

(config)**#interface switchport 0/1**
(config-swx 0/1)**#switchport voice vlan 200 cos 4 dscp 36**

traffic-shape rate <*value*>

Use the **traffic-shape rate** command to specify and enforce an output bandwidth for Ethernet and virtual local area network (VLAN) interfaces. Variations of this command include:

traffic-shape rate <*value*>
traffic-shape rate <*value*> **count-eth-overhead**
traffic-shape rate <*value*> <*burst*>
traffic-shape rate <*value*> <*burst*> **count-eth-overhead**

Syntax Description

<*value*>	Specifies the rate (in bits per second) at which the interface should be shaped.
<*burst*>	Optional. Specifies the allowed burst in bytes. By default, the burst is specified as the rate divided by 5 and represents the number of bytes that would flow within 200 ms.
count-eth-overhead	Optional. Indicates to include the Ethernet header overhead bytes when determining packet size.

Default Values

By default, traffic-shaping rate is disabled.

Command History

Release 10.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the **count-eth-overhead** parameter, system management Ethernet virtual connection (EVC) and the system control EVC.

Functional Notes

Traffic shaping can be used to limit an Ethernet segment to a particular rate or to specify use of quality of service (QoS) on Ethernet or VLAN interfaces.

Usage Examples

The following example sets the outbound rate of Ethernet interface 0/1 to 128 kbps and applies a QoS policy that gives all Realtime Transport Protocol (RTP) traffic priority over all other traffic:

(config)**#qos map voip 1**
(config-qos-map)**#match ip rtp 10000 10500 all**
(config-qos-map)**#priority unlimited**
(config-qos-map)**#interface ethernet 0/1**
(config-eth 0/1)**#traffic-shape rate 128000**
(config-eth 0/1)**#qos-policy out voip**

vlan-id <*vlan id*>

Use the **vlan-id** command to set a virtual local area network (VLAN) ID for the Ethernet interface. Use the **no** form of this command to remove an entry. Variations of this command include:

vlan-id <*vlan id*>
vlan-id <*vlan id*> **native**

Syntax Description

<*vlan id*>	Specifies a valid VLAN interface ID number. Range is **1** to **4095**.
native	Optional. Specifies that data for that VLAN ID goes out untagged. If **native** is not specified, data for that VLAN ID goes out tagged.

Default Values

By default, no VLAN ID is set.

Command History

Release 6.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet subinterface.

Usage Examples

The following example configures a native VLAN of 5 for the Ethernet interface 0/1:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#vlan-id 5 native**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an interface to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the interface from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an interface's VRF association will clear all IP-related settings on that interface.

Syntax Description

<name>	Specifies the name of the VRF to which to assign the interface.

Default Values

By default, interfaces are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release 17.8	The keyword **ip** was removed from this command.

Functional Notes

VRF instances must be created first before an interface can be assigned. An interface can only be assigned to one VRF, but multiple interfaces can be assigned to the same VRF.

An interface will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the Ethernet interface 0/1 to the VRF instance named **RED**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#vrf forwarding RED**

vrrp <*number*>

Use the **vrrp** command to configure Internet Protocol version 4 (IPv4) Virtual Router Redundancy Protocol version 2 (VRRPv2) routers within a router group. Use the **no** form of this command to remove the VRRP router's configurations. Variations of this command include:

vrrp <*number*> **description** <*text*>
vrrp <*number*> **ip** <*ipv4 address*>
vrrp <*number*> **ip** <*ipv4 address*> **secondary**
vrrp <*number*> **preempt**
vrrp <*number*> **preempt delay minimum** <*time*>
vrrp <*number*> **priority** <*level*>
vrrp <*number*> **shutdown**
vrrp <*number*> **startup-delay** <*delay*>
vrrp <*number*> **timers advertise** <*interval*>
vrrp <*number*> **timers learn**
vrrp <*number*> **track** <*name*>
vrrp <*number*> **track** <*name*> **decrement** <*value*>

Syntax Description

<*number*>	Specifies the VRRP router group's virtual router ID (VRID) number. Range is **1** to **255**.
description <*text*>	Specifies the textual description of the VRRP router within the group.
ip <*ipv4 address*>	Specifies the IPv4 address to be used by the VRRP router. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
secondary	Optional. Specifies the entry of an additional VRRP router supported IPv4 address.
preempt	Allows a VRRP router to preempt the current master router if its priority level is higher than the current master's.
delay minimum <*time*>	Optional. Specifies a delay (in seconds) before the specified router will attempt to preempt the current master router. Range is **0** to **255** seconds.
priority <*level*>	Specifies the configured priority level of the VRRP router. Range is **1** to **254**.
shutdown	Disables the VRRP router.
startup-delay <*delay*>	Specifies a time delay (in seconds) before a VRRP router becomes active. Range is **0** to **255** seconds.
timers	Specifies the configuration of the VRRP timers.
advertise <*interval*>	Specifies the time (in seconds) between advertisements sent by the master router. Range is **1** to **255** seconds.
learn	Specifies that the backup VRRP router learns the advertisement interval of the master router.
track <*name*>	Specifies a change in priority level of the VRRP router based upon the specified track.
decrement <*value*>	Optional. Specifies the numerical amount to decrement the VRRP's priority level if the track transitions to a FAIL state. Range is **1** to **254**.

Default Values

By default, VRRP is enabled.

By default, a VRRP router will preempt with no additional delay.

The default configured priority for a VRRP router that is either a backup router or not the IP address owner is **100**. The default actual priority of a VRRP router that is the IP address owner is **255**.

By default, startup-delay is enabled with a default value of **35** seconds.

By default, the advertisement interval is **1** second.

By default, the default decrement value is **10**.

Command History

Release 16.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet subinterface.

Functional Notes

A VRRP router may be part of more than one virtual router group. Although VRRP group VRIDs can be numbered between 1 and 255, only two VRRP routers per interface are supported.

Adtran recommends that the **timers advertise** setting is kept at the default value. If it is necessary to change this setting, ensure that all VRRP routers are configured with the new value, as all VRRP routers in the virtual group must have the same advertisement interval value. It is also recommended that if the **timers learn** function is enabled on one router in a virtual router group, then the **timers learn** function should be enabled on all routers in the group.

When the virtual router's specified IPv4 address is independent of the IPv4 addresses assigned to real interfaces on the VRRP routers, there is no IPv4 address owner. This addressing method is preferred if object tracking will be used to monitor the network connection. The IPv4 address used for the virtual router must be on the same subnet as either the primary or secondary IPv4 addresses assigned to the VRRP router's real interface.

A track must be created before the **vrrp track** command can be issued. Refer to the *Network Monitor Track Command Set on page 4098* for more information on creating tracks. If a VRRP router owns the virtual router IP address, then the VRRP router's priority level cannot be decremented as a result of the track command. If object tracking will be used, it is important that no VRRP router own the virtual router IP address.

Usage Examples

The following example describes a VRRP router within virtual router group **1** as the **Default Master Router**:

(config)**#interface eth 0/1**
(config-eth 0/1)**#vrrp 1 description Default Master Router**

The following example specifies an IPv4 address of **10.0.0.1** for a VRRP router within virtual router group **1**:

(config)**#interface eth 0/1**
(config-eth 0/1)**#vrrp 1 ip 10.0.0.1**

The following example specifies that the VRRP router within virtual router group **1** preempts the current master router after a **30** second delay:

(config)**#interface eth 0/1**
(config-eth 0/1)**#vrrp 1 preempt delay minimum 30**

The following example specifies the configured priority for the VRRP router within virtual router group **1** is **254**:

(config)**#interface eth 0/1**
(config-eth 0/1)**#vrrp 1 priority 254**

The following example disables the VRRP router within virtual router group **1**:

(config)**#interface eth 0/1**
(config-eth 0/1)**#vrrp 1 shutdown**

The following example configures a VRRP router on group **1** to delay **45** seconds before becoming active:

(config)**#interface eth 0/1**
(config-eth 0/1)**#vrrp 1 startup-delay 45**

vrrpv3 <*vrid*> address-family

Use the **vrrpv3 address-family** command to configure Virtual Router Redundancy Protocol version 3 (VRRPv3) routers on the interface. This command enables VRRPv3, creates a virtual router ID (VRID), and specifies whether you are using Internet Protocol version 4 (IPv4) or IP version 6 (IPv6) VRRPv3. Use the **no** form of this command to remove the VRRPv3 router configuration. Variations of this command include:

vrrpv3 <*vrid*> **address-family ipv4**
vrrpv3 <*vrid*> **address-family ipv6**

Syntax Description

<*vrid*>	Specifies the VRID for the virtual router instance. This value is advertised by VRRPv3 and is used to generate the virtual router medium access control (MAC) address. Valid range is **1** to **255**.
ipv4	Specifies that IPv4 is used with VRRPv3, and enters the virtual router instance's configuration mode.
ipv6	Specifies that IPv6 is used with VRRPv3, and enters the virtual router instance's configuration mode.

Default Values

By default, VRRPv3 is not configured.

Command History

Release R10.11.0	Command was introduced. This command replaces **vrrpv3** <*vrid*> on the interface.

Functional Notes

VRID values must be the same on all routers that are part of the virtual router group. VRID numbering is independent between VRRPv3 IPv4 and IPv6 address families. Once the VRRPv3 VRID is created and the address family is specified, the virtual router instance's configuration mode is entered. Only two VRIDs per interface per IP version are supported. For more information about configuring the VRRPv3 instance, refer to *VRRPv3 Command Set on page 4221*.

Usage Examples

The following example enables IPv4 VRRPv3, creates a VRID of **15** for the instance, and enters the virtual router instance's configuration mode:

```
(config)#interface ethernet 0/1
(config-eth 0/1)#vrrpv3 15 address-family ipv4
(config-if-vrrpv3 15)#
```

The following example enables IPv6 VRRPv3, creates a VRID of **6** for the instance, and enters the virtual router instance's configuration mode:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#vrrpv3 6 address-family ipv6**
(config-if-vrrpv3 6)#

vxlan tunnel <*interface id*> vni <*number*>

Use the **vxlan tunnel** <*interface id*> **vni** <*number*> command to associate the interface with a virtual extensible local area network (VxLAN) tunnel interface and VxLAN network ID (VNI). Use the **no** form of this command to return to the default setting.

Syntax Description

<interface id>	Specifies the VxLAN interface ID number. Valid range is **1** to **1024**.
<number>	Specifies the VNI number to which this interface is mapped. Valid range is **1** to **677215**.

Default Values

By default, an Ethernet interface is not associated with a VxLAN tunnel interface or a VNI.

Command History

Release R13.1.0	Command was introduced.

Functional Notes

Two Ethernet interfaces cannot be associated with the same VxLAN tunnel interface or VNI. If the VxLAN tunnel needs to be protected with virtual private network (VPN), an IP security (IPSec) profile must be applied to the tunnel using the command *tunnel protection ipsec profile <name> on page 3349***.** When 802.1q encapsulation is enabled, VxLAN can only be configured on Ethernet subinterfaces.

Usage Examples

The following example associates Ethernet interface 0/1 with VxLAN tunnel interface **3** and VNI **2**:

(config)**#interface ethernet 0/1**
(config-eth-0/1)**#vxlan tunnel 3 vni 2**

FDL INTERFACE COMMAND SET

FDL Interface Configuration mode is used for establishing a Telnet session over the FDL (facility data link). To activate, enter the **interface fdl** command and specify the associated slot/port number (of the T1 interface used) at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface fdl 1/1
(config-fdl 1/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

ip address <ipv4 address> <subnet mask> on page 2358
ip address range <start ipv4 address> <end ipv4 address> <subnet mask> secondary on page 2359
ip learn-address on page 2360
ip mtu <size> on page 2361
peer default ip address <ipv4 address> on page 2363

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the specified interface. Use the **no** form of this command to remove a configured IPv4 address. Variations of this command include:

ip address <*ipv4 address*> <*subnet mask*>
ip address <*ipv4 address*> <*subnet mask*> **secondary**

Syntax Description

<*ipv4 address*>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*subnet mask*>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the specified interface.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 7.1	Command was introduced for the facility data link (FDL) interface.
Release R10.1.0	Command was expanded to include the **secondary** keyword.

Usage Examples

The following example configures an IPv4 address of **192.22.72.101 /30**:

(config)**#interface fdl 1/1**
(config-fdl 1/1)**#ip address 192.22.72.101 /30**

ip address range *<start ipv4 address> <end ipv4 address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the specified interface. Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#interface fdl 1/1**
(config-fdl 1/1)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip learn-address

Use the **ip learn-address** command to automatically learn the IP address of the remote unit. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example enables the facility data link (FDL) to automatically learn the remote unit's IP address:

(config)**#interface fdl 1/1**
(config-fdl 1/1)**#ip learn-address**

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces	(all types)1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

Open shortest path first (OSPF) will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the interface:

(config)**#interface fdl 1/1**
(config-fdl 1/1)**#ip mtu 1200**

peer default ip address *<ipv4 address>*

Use the **peer default ip address** command to specify the default Internet Protocol version 4 (IPv4) address of the remote end of this interface. Use the **no** form of this command to remove a default IP address.

Syntax Description

<ipv4 address>	Specifies the default IPv4 address for the remote end. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, there is no assigned peer default IPv4 address.

Command History

Release 3.1	Command was introduced.
Release 7.1	Command was expanded to include the facility data link (FDL).

Functional Notes

This command is useful if the peer's FDL interface is on a different subnet than the local unit's FDL interface IPv4 address. This is common if the FDL interface is unnumbered to another interface's IPv4 address.

Usage Examples

The following example sets the default peer IPv4 address to **192.22.71.50**:

(config)**#interface fdl 1/1**
(config-fdl 1/1)**#peer default ip address 192.22.71.50**

FXO INTERFACE COMMAND SET

To activate the Foreign Exchange Office (FXO) Interface Configuration mode, enter the **interface fxo** command and specify the FXO port at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface fxo 0/1
(config-fxo 0/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

impedance on page 2365
loopback on page 2366
rx-gain <value> on page 2367
test erl on page 2368
test loop on page 2370
test ring-ground on page 2371
test tip-ground on page 2372
test tone on page 2373
tx-gain <value> on page 2374

impedance

Use the **impedance** command to configure the alternating current (AC) impedance of the 2-wire interface. Use the **no** form of this command to return to the default value. Variations of this command include:

impedance [600c | 900r]
impedance [900c | 600r]
impedance bt3
impedance [z1| z2 | z3 | z4 | z5 | z6 | z7]

Syntax Description

600c	Specifies an impedance of 600 Ω **+** 2.16 µF.
600r	Specifies an impedance of 600 Ω real.
900c	Specifies an impedance of 900 Ω + 2.16 µF.
900r	Specifies an impedance of 900 Ω real.
bt3	Specifies an impedance of Rs 370 ohms, Rp 620 ohms, Cp 310nF
z1	Specifies an impedance of Rs 220 W, Rp 820 W, Cp 115 nF.
z2	Specifies an impedance of Rs 270 W, Rp 750 W, Cp 150 nF.
z3	Specifies an impedance of Rs 270 W, Rp 750 W, Cp 150 nF, Zin 600r.
z4	Specifies an impedance of Rs 320 W, Rp 1050 W, Cp 230 nF.
z5	Specifies an impedance of Rs 350 W, Rp 1000 W, Cp 210 nF, Zin 600r.
z6	Specifies an impedance of Rs 370 W, Rp 620 W, Cp 310 nF.
z7	Specifies an impedance of Rp 800 W, Rs 100 W, Cs 50 nF.

Default Values

By default, the impedance is set to **600c**.

Command History

Release 7.1	Command was introduced.
Release A1	Command was expanded to include the settings **z1** through **z7**.
Release 14.2.0	Command was expanded to include the setting bt3

Usage Examples

The following example sets the impedance to 600 Ω + 2.16 µF:

(config)**#interface fxo 0/1**
(config-fxo 0/1)**#impedance 600c**

loopback

Use the **loopback** command to activate a loopback on the foreign exchange office (FXO) module. Use the **no** form of this command to deactivate the loopback. Variations of this command include:

loopback analog
loopback digital

Syntax Description

analog	Initiates a loopback toward the T1 network side of the connection after passing through analog filters in the voice CODEC.
digital	Initiates the same loopback before passing through analog filters in the voice coder-decoder (CODEC).

Default Values

No default values are necessary for this command.

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example activates a loopback toward the T1 network side of the connection after passing through analog filters in the voice CODEC:

(config)**#interface fxo 0/1**
(config-fxo 0/1)**#loopback analog**

rx-gain <*value*>

Use the **rx-gain** command to define the receive gain characteristics on the foreign exchange office (FXO) interface. Receive gain determines the amplification of the received signal before transmitting it out the FXO interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Defines the receive gain characteristics for the interface in 0.1 decibel increments. Range is **-6.0** to **10.0** dB.

Default Values

By default, this command is set to **0** dB.

Command History

Release 7.1	Command was introduced.

Functional Notes

When increasing this value, the signal being received on this port sounds louder. When decreasing this value, the signal being received on this port sounds softer.

Usage Examples

The following example defines the receive gain as **-5.4** dB:

(config)**#interface fxo 0/1**
(config-fxo 0/1)**#rx-gain -5.4**

test erl

Use the **test erl** command to automatically determine the correct impedance value for analog lines connected to the foreign exchange office (FXO) port. This is helpful when troubleshooting problems with FXO equipment and assists in adjusting the correct audio levels. Use the **no** form of the **test erl all** and **test erl current** command to disable these features. Variations of this command include:

test erl all
test erl all auto-set
test erl clear-results
test erl current
test erl display-results

*This feature is available only on units with digital signal processor (DSP) hardware version Freescale MSC7119, and AOS version A2.02 or above. To determine the DSP hardware version, issue the **show version** command and look for the DSP hardware version.*

Syntax Description

all	Specifies running the test repeatedly, testing all available impedance settings for the interface.
auto-set	Optional. Sets automatically the best measured impedance for the interface.
clear-results	Clears the results from the echo return loss (erl) test.
current	Specifies running the test once, using the current impedance setting.
display-results	Displays a snapshot of the current test status.

Default Values

By default, this command is disabled.

Command History

Release A2.04	Command was introduced.

Functional Notes

Before using this feature, an analog line from the service provider must be connected to the FXO interface and the line must be idle (no call in progress). The FXO interface must be connected to a voice trunk in order to make the tool available for use.

During the test, the tool sets the FXO transmit gain and receive gain levels to 0 dB to make the proper measurements. These settings are returned to the configured values when the test is complete. The rx-gain value adjusts the level being transmitted from the FXO to the line. The tx-gain value adjusts the level being transmitted from the FXO to the dsp.

Common low ERL values are between 5 and 8 dB. Acceptable ERL values begin around 12 dB. The higher the ERL value, the more gain adjustment can be made without introducing echo. The commonly recommended configuration is a receive gain of 0 dB and a transmit gain of +6 dB.

The following is an error that could result by attempting to measure ERL when a measurement sequence is already active:

```
% could not run erl test
```

During test execution, a warning is issued when a test sequence terminates abnormally. Reasons for early termination include:

- Was not able to seize the line
- Line disconnected during test
- DSP timeout (i.e., when the DSP hardware version does not support this feature)
- Test runs for more than 20 seconds per impedance value (for example, 80 seconds with a 4 impedance setting)

Usage Examples

The following example tests the FXO interface 0/1 to automatically find the best measured impedance settings:

(config)**#interface fxo 0/1**
(config-fxo 0/1)**#test erl all auto-set**

The following example displays the ERL test status (the output is shown after the command):

(config)**#interface fxo 0/1**
(config-fxo 0/1)**#test erl display-results**

Port	Impedance	Status	Measured ERL
fxo 0/1	600 c		10 dB
fxo 0/1	900 r		8 dB
fxo 0/1	900 c		9 dB
fxo 0/1	z1		13 dB
fxo 0/1	z2		11 dB
fxo 0/1	z3		14 dB
fxo 0/1	z4		12 dB
fxo 0/1	z5	test calling	

test loop

Use the **test loop** command to manually control the foreign exchange office (FXO) interface's hook switch. This is helpful when troubleshooting problems with the FXO equipment. Use the **no** form of this command to disable this feature. Variations of this command include:

test loop closed
test loop open

Syntax Description

closed	Closes the hook switch, allowing DC current to flow through the interface.
open	Opens the hook switch, preventing DC current from flowing through the interface.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example opens the interface's hook switch:

(config)**#interface fxo 02/1**
(config-fxo 0/1)**#test loop open**

test ring-ground

Use the **test ring-ground** command to force the ring conductor to ground potential and provides battery on tip for detection of tip ground. This is helpful when troubleshooting problems with ground start (GS) circuits. Use the **no** form of this command to return to the default value.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example forces a ring-ground test of the foreign exchange office (FXO) interface:

```
(config)#interface fxo 0/1
(config-fxo 0/1)#test ring-ground
```

test tip-ground

Use the **test tip-ground** command to detect the removal of the ring ground and check for the loop condition on an active foreign exchange office (FXO) interface. This is helpful when troubleshooting problems with ground start (GS) circuits. Use the **no** form of this command to return to the default value.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example forces a tip-ground test of the FXO interface:

(config)**#interface fxo 0/1**
(config-fxo 0/1)**#test tip-ground**

test tone

Use the **test tone** command to activate the 1 kHz test tone. Use the **no** form of this command to deactivate the test tone. Variations of this command include:

test tone far
test tone near

Syntax Description

far	Sends the test tone out the T1 network interface to the remote end.
near	Sends the test tone toward the foreign exchange office (FXO) interface.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example sends the test tone toward the FXO interface:

(config)**#interface fxo 0/1**
(config-fxo 0/1)**#test tone near**

tx-gain <*value*>

Use the **tx-gain** command to define the transmit gain characteristics on the foreign exchange office (FXO) interface. Transmit gain determines the amplification of the transmitted signal before transmitting from the FXO interface toward the network. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Defines the transmit gain characteristics in 0.1 decibel increments. Range is **-6.0** to **10.0** dB.

Default Values

By default, transmit gain is set to **0** dB.

Command History

Release 7.1	Command was introduced.

Functional Notes

When increasing this value, the signal being transmitted to the far end sounds louder. When decreasing this value, the signal being transmitted to the far end sounds softer.

Usage Examples

The following example defines the transmit gain as **-5.4** dB on the FXO interface:

(config)**#interface fxo 0/1**
(config-fxo 0/1)**#tx-gain -5.4**

FXS INTERFACE COMMAND SET

To activate the Foreign Exchange Station (FXS) Interface Configuration mode, enter the **interface fxs** command and specify the FXS port at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface fxs 2/1
(config-fxs 2/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

battery-mode on page 2376
caller-id on page 2377
holdover <value> on page 2378
impedance on page 2379
loopback on page 2381
onhook-transmission on page 2382
ring-frequency <value> on page 2383
ring-voltage <value> on page 2384
rx-gain <value> on page 2385
signal on page 2386
test commands begin on page 2387
tx-gain <value> on page 2393

battery-mode

Use the **battery-mode** command to configure the battery that feeds the foreign exchange station (FXS) loop. Use the **no** form of this command to return to the default setting. Variations of this command include:

battery-mode auto
battery-mode high
battery-mode low

Syntax Description

auto	Configures the interface to automatically switch between high and low battery.
high	Configures the interface to only use the high battery.
low	Configures the interface to only use the low battery.

Default Values

By default, the battery mode is set to **auto**.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example configures the battery mode for **high**:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#battery-mode high**

caller-id

Use the **caller-id** command to configure caller identification (ID). Use the **no** form of this command to cancel the setting. Variations of this command include:

caller-id delay <*value*>
caller-id format mdmf
caller-id format sdmf

Syntax Description

delay <*value*>	Specifies the delay between ring-off and caller ID frequency-shift keying (FSK). Valid range is **500** to **2000** ms. Common values are 500, 750, and 1000.
format	Specifies the format for caller ID as **mdmf** or **sdmf**.
mdmf	Indicates the caller ID format as multiple data message format (mdmf).
sdmf	Indicates the caller ID format as single data message format (sdmf).

Default Values

By default, caller ID is disabled.

Command History

Release A2	Command was introduced.

Usage Examples

The following example configures the caller ID delay to **500** ms:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#caller-id delay 500**

holdover *<value>*

Use the **holdover** command to configure the amount of time (in seconds) to sustain battery power at the foreign exchange station (FXS) port even if a call could not be connected. Once the holdover period has expired, the power is removed from the FXS port. A value of **0** will result in the battery being maintained at the FXS indefinitely. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the time (in seconds) to apply power from the battery to the FXS port. Valid range is **0** to **65535** seconds.

Default Values

The default value for this command is **60** seconds.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example configures the holdover to **25** seconds:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#holdover 25**

impedance

Use the **impedance** command to configure the alternating current (AC) impedance of the 2-wire interface. Use the **no** form of this command to return to the default value. Variations of this command include:

impedance 600c
impedance 600r
impedance 900b
impedance 900c
impedance 900r
impedance z1
impedance z2
impedance z3
impedance z4
impedance z5
impedance z6
impedance z7

Syntax Description

600c	Specifies an impedance of 600 Ω **+** 2.16 µF.
600r	Specifies an impedance of 600 Ω real.
900b	Use only when directed by Adtran and only with part number 1203602L1.
900c	Specifies an impedance of 900 Ω + 2.16 µF.
900r	Specifies an impedance of 900 Ω real.
z1	Specifies an impedance of Rs 220 W, Rp 820 W, Cp 115 nF.
z2	Specifies an impedance of Rs 270 W, Rp 750 W, Cp 150 nF.
z3	Specifies an impedance of Rs 270 W, Rp 750 W, Cp 150 nF, Zin 600r.
z4	Specifies an impedance of Rs 320 W, Rp 1050 W, Cp 230 nF.
z5	Specifies an impedance of Rs 350 W, Rp 1000 W, Cp 210 nF, Zin 600r.
z6	Specifies an impedance of Rs 370 W, Rp 620 W, Cp 310 nF.
z7	Specifies an impedance of Rp 800 W, Rs 100 W, Cs 50 nF.

Default Values

The default value for this command is **600r**.

Command History

Release 6.1	Command was introduced.
Release A1	Command was expanded to include the **900b** impedance setting.
Release A2	Command was expanded to include the **z1** impedance setting.
Release A4.03	Command was expanded to include the **z2**, **z3**, **z4**, **z5**, **z6**, and **z7** impedance settings.

Usage Examples

The following example sets the impedance to 600 Ω + 2.16 μF:

>**enable**
#**configure terminal**
(config)#**interface fxo 0/1**
(config-fxo 0/1)#**impedance 600c**

loopback

Use the **loopback** command to activate a loopback toward the T1 network side on the foreign exchange station (FXS) module. Use the **no** form of this command to deactivate the loopback. Variations of this command include:

loopback analog
loopback digital

Syntax Description

analog	Initiates a loopback toward the T1 network side of the connection after passing through analog filters in the voice coder-decoder (CODEC).
digital	Initiates the same loopback before passing through analog filters in the voice CODEC.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.

Usage Examples

The following example activates a loopback toward the T1 network side of the connection after passing through analog filters in the voice CODEC:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#loopback analog**

onhook-transmission

Use the **onhook-transmission** command to configure the on-hook transmission of voice band audio on the foreign exchange station (FXS) interface. Use the **no** form of this command to return to the default value. Variations of this command include:

onhook-transmission always
onhook-transmission auto

Syntax Description

always	Enables on-hook transmission of voice band audio.
auto	Enables on-hook transmission of voice band audio when it is possible. This option lowers the power consumption of the unit; however, it should not be used if voice message waiting indication is enabled on the port.

Default Values

By default, on-hook transmission is set to **always**.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example sets the on-hook transmission to **auto**:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#onhook-transmission auto**

ring-frequency *<value>*

Use the **ring-frequency** command to change the ring frequency of a single foreign exchange service (FXS) port from the default system country value. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the FXS port ring frequency. Valid values are **20**, **25**, and **50** Hz.

Default Values

By default, the command *voice system-country <name> on page 1970* automatically configures the appropriate FXS port ring frequency for the specified country. Below is a list of the default ring frequencies (in Hertz) for fully-supported countries:

Australia	25 Hz	Mexico	25 Hz
Belgium	25 Hz	Puerto Rico	20 Hz
Canada	20 Hz	United Arab Emirates	25 Hz
ETSI	25 Hz	United Kingdom	25 Hz
Ireland	25 Hz	United States	20 Hz

Command History

Release A5.01	Command was introduced.

Usage Examples

The following example configures the ring frequency for FXS port **2/1** as **25** Hz**.**

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#ring-frequency 25**

ring-voltage <*value*>

The **ring-voltage** command sets the ring voltage for the foreign exchange station (FXS) interface. Increasing the ring voltage, sends a stronger ring signal to the phones connected to this interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies a ring voltage. Select from **50**, **60** or **70** Vrms.

Default Values

By default, ring voltage is set to **50** Vrms.

Command History

Release 6.1	Command was introduced.

Usage Examples

The following example sets the ring voltage to **60** Vrms:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#ring-voltage 60**

rx-gain <*value*>

Use the **rx-gain** command to define the receive gain characteristics on the foreign exchange station (FXS) interface. Receive gain determines the amplification of the received signal before transmitting out the FXS interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Defines the receive gain characteristics for the interface in 0.1 decibel increments. Range is **-12.0** to **6.0** dB.

Default Values

By default, this command is set to **-3.0** dB.

Command History

Release 6.1	Command was introduced.

Functional Notes

When increasing this value, the signal being received on this port sounds louder. When decreasing this value, the signal being received on this port sounds softer.

Usage Examples

The following example defines the receive gain as **-6.4** dB:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#rx-gain -6.4**

signal

The **signal** command configures the signaling mode for the foreign exchange station (FXS) interface. Use the **no** form of this command to return to the default value. Variations of this command include:

signal ground-start
signal loop-start

Syntax Description

ground-start	Applies resistance to the tip conductor of the circuit to indicate an off-hook condition.
loop-start	Bridges the tip and ring to indicate an off-hook (seizing the line) condition.

Default Values

By default, this command is set to **loop-start**.

Command History

Release 6.1	Command was introduced.

Functional Notes

This signaling mode must match the configuration of the network.

Usage Examples

The following example sets the signaling mode to **loop-start**:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#signal loop-start**

test battery

Use the **test battery** command to provide battery on the 2-wire foreign exchange station (FXS) interface. This is helpful when troubleshooting wiring problems with the FXS equipment. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 6.1	Command was introduced.

Usage Examples

The following example provides battery on the 2-wire FXS interface:

```
(config)#interface fxs 2/1
(config-fxs 2/1)#test battery
```

test line

The **test line** command performs GR-909 line tests including the Hazardous Potential Test, the Foreign ElectroMotive Force Test, the Resistive Faults Test, the Receiver-Off-Hook Test, and the Ringers Test on the foreign exchange station (FXS) interface.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example runs GR-909 line tests on the FXS interface:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#test line**

test reverse-battery

Use the **test reverse-battery** command to provide reverse battery polarity on the foreign exchange station (FXS) interface. This is helpful when troubleshooting wiring problems with the FXS equipment. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 6.1	Command was introduced.

Usage Examples

The following example provides reverse battery polarity on the FXS interface:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#test reverse-battery**

test ringing

Use the **test ringing** command to activate ringing voltage on the 2-wire foreign exchange station (FXS) interface (using a 2-seconds-on/4-seconds-off cadence). The **no** form of this command removes the ringing voltage from the interface.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 6.1	Command was introduced.

Usage Examples

The following example activates ringing voltage on the 2-wire FXS interface:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#test ringing**

test tip-open

Use the **test tip-open** command to provide battery on ring and a high impedance on tip. This is helpful when troubleshooting problems with ground start (GS) interfaces. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 6.1	Command was introduced.

Usage Examples

The following example provides battery on ring and a high impedance on tip on the foreign exchange station (FXS) interface:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#test tip-open**

test tone

Use the **test tone** command to activate the 1 kHz test tone. Use the **no** form of this command to deactivate the test tone. Variations of this command include:

test tone near
test tone far

Syntax Description

near	Sends the test tone toward the foreign exchange station (FXS) interface.
far	Sends the test tone out the T1 network interface to the remote end.

Default Values

By default, this command is disabled.

Command History

Release 6.1	Command was introduced.

Usage Examples

The following example sends the test tone toward the FXS interface:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#test tone near**

tx-gain <*value*>

Use the **tx-gain** command to define the transmit gain characteristics (configured in 0.1 dB increments) on the foreign exchange station (FXS) interface. Transmit gain determines the amplification of the received signal before transmitting from the FXS interface toward the network. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Defines the transmit gain characteristics for the interface in 0.1 decibel increments. Range is **-12.0** to **6.0** dB.

Default Values

By default, this command is set to **-6.0** dB.

Command History

Release 6.1	Command was introduced.

Functional Notes

When increasing this value, the signal being transmitted to the far end will sound louder. When decreasing this value, the signal being transmitted to the far end sounds softer.

Usage Examples

The following example defines the transmit gain as **-6.4** dB on the FXS interface:

(config)**#interface fxs 2/1**
(config-fxs 2/1)**#tx-gain -6.4**

G.703 INTERFACE COMMAND SET

To activate the G.703 Interface Configuration mode, enter the **interface e1** command (and specify the G.703 port) at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface e1 1/2
(config-e1 1/2)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

coding on page 2395
framing crc4 on page 2396
loopback network on page 2397
snmp trap link-status on page 2398
test-pattern on page 2399
ts16 on page 2400

coding

Use the **coding** command to configure the line coding for the G.703 physical interface. This setting must match the line coding supplied on the circuit by the private branch exchange (PBX). Use the **no** form of this command to return to the default setting. Variations of this command include:

coding ami
coding hdb3

Syntax Description

ami	Configures the line coding for alternate mark inversion (AMI).
hdb3	Configures the line coding for high-density bipolar 3 (HDB3).

Default Values

By default, all E1 interfaces are configured with HDB3 line coding.

Command History

Release 5.1	Command was introduced.

Functional Notes

The line coding configured in the unit must match the line coding of the E1 circuit. A mismatch will result in line errors (e.g., bipolar violations (BPVs)).

Usage Examples

The following example configures the G.703 interface for AMI line coding:

(config)**#interface e1 1/2**
(config-e1 1/2)**#coding ami**

framing crc4

Use the **framing crc4** command to configure the framing format for the G.703 interface. This parameter should match the framing format set on the external device. Use the **no** form of this command to return to the default value.

Syntax Description

crc4	Enables CRC4 bits to be transmitted in the outgoing data stream. Also, the received signal is checked for CRC4 errors.

Default Values

By default, CRC4 is enabled.

Command History

Release 5.1	Command was introduced.

Functional Notes

The framing value must match the configuration of the E1 circuit. A mismatch will result in a loss of frame alarm.

Usage Examples

The following example configures the G.703 interface for CRC4 framing:

(config)**#interface e1 1/2**
(config-e1 1/2)**#framing crc4**

loopback network

Use the **loopback network** command to initiate a loopback on the interface toward the network. Use the **no** form of this command to deactivate the loopback. Variations of this command include:

loopback network line
loopback network payload

Syntax Description

line	Initiates a metallic loopback of the physical E1 network interface.
payload	Initiates a loopback of the E1 framer (CSU portion) of the E1 network interface.

Default Values

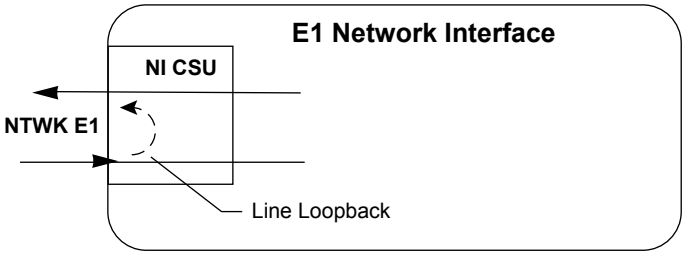
No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.

Functional Notes

The following diagram depicts a line loopback.



Usage Examples

The following example initiates a line loopback of the G.703 interface:

(config)**#interface e1 1/2**
(config-e1 1/2)**#loopback network line**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the G.703 interface:

(config)**#interface e1 1/2**
(config-e1 1/2)**#no snmp trap link-status**

test-pattern

Use the **test-pattern** command to activate the built-in pattern generator and begin sending the specified test pattern. This pattern generation can be used to verify a data path when used in conjunction with an active loopback. Use the **no** form of this command to cease pattern generation. Variations of this command include:

test-pattern ones
test-pattern zeros

Syntax Description

ones	Generates a test pattern of continuous ones.
zeros	Generates a test pattern of continuous zeros.

Default Values

No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.
Release 6.1	Command was expanded to include the E1 and G.703 interfaces.

Usage Examples

The following example activates the pattern generator for a stream of continuous **ones**:

(config)**#interface e1 1/2**
(config-e1 1/2)**#test-pattern ones**

ts16

Use the **ts16** command to enable timeslot 16 multiframe to be checked on the receive signal. Use the **no** form of this command to disable timeslot 16.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example enables timeslot **16** multiframing:

```
(config)#interface e1 1/2
(config-e1 1/2)#ts16
```

HSSI INTERFACE COMMAND SET

To activate the High Speed Serial Interface (HSSI) Interface Configuration mode, enter the **interface hssi** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface hssi 1/1
(config-hssi 1/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

external-loopback-request on page 2402
loopback on page 2403
snmp trap link-status on page 2404

external-loopback-request

Use the **external-loopback-request** command to enable LC (loopback circuit C) input to control loopbacks toward the network. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example enables the unit to accept external loopback requests:

(config)**#interface hssi 1/1**
(config-hssi 1/1)**#external-loopback-request**

loopback

Use the **loopback** command to initiate or remove a loopback. Use the **no loopback** command to disable all loopbacks. Variations of this command include:

loopback dce
loopback dte
loopback line
loopback remote
loopback none

Syntax Description

dce	Initiates a loopback on the data communication equipment (DCE).
dte	Initiates a loopback on the data terminal equipment (DTE).
line	Initiates a local line loopback.
remote	Initiates a remote line loopback.
none	Removes an active loopback.

Default Values

By default, no loopbacks are active.

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example initiates a local **line** loopback on the high speed serial interface (HSSI):

(config)**#interface hssi 1/1**
(config-hssi 1/1)**#loopback line**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the interface:

(config)**#interface hssi 1/1**
(config-hssi 1/1)**#no snmp trap link-status**

MODEM INTERFACE COMMAND SET

To activate the Modem Interface Configuration mode, enter the **interface modem** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface modem 1/2
(config-modem 1/2)#
```

> *The modem interface number in the example above is shown as **modem 1/2**. This number is based on the interface's location (slot/port) and could vary depending on the unit's configuration. Use the **do show interfaces** command to determine the appropriate interface number.*

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

caller-id override on page 2406
dialin on page 2407
ignore-ring on page 2408
init-string <string> on page 2409
resource pool-member on page 2410

caller-id override

Use the **caller-id override** command to configure the unit to replace caller ID information with a user-specified number. Use the **no** form of this command to disable any caller ID overrides. Variations of this command include:

caller-id override always <*number*>
caller-id override if-no-cid <*number*>

Syntax Description

always <*number*>	Always forces replacement of the incoming caller ID number with the number given.
if-no-cid <*number*>	Replaces the incoming caller ID number with the number given only if there is no caller ID information available for the incoming call.

Default Values

By default, this command is disabled.

Command History

Release 6.1	Command was introduced.

Functional Notes

This command forces a replacement of the incoming caller ID number with the number given. The received caller ID, if any, is discarded, and the given override number is used to connect the incoming call to a circuit of the same number.

Usage Examples

The following example configures the unit to always provide the given number as the caller ID number:

(config)**#interface modem 1/2**
(config-modem 1/2)**#caller-id override always 5555555**

dialin

Use the **dialin** command to enable the modem for remote console dial in, disabling the use of the modem for dial backup. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, **dialin** is disabled.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example enables remote console dial in:

(config)**#interface modem 1/2**
(config-modem 1/2)**#dialin**

ignore-ring

Use the **ignore-ring** command to ignore incoming call ring events for the modem. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, **ignore-ring** is disabled.

Command History

Release R14.3	Command was introduced.

Usage Examples

The following example configures the modem to ignore incoming call ring events:

(config)**#interface modem 1/2**
(config-modem 1/2)**#ignore-ring**

init-string *<string>*

Use the **init-string** command to specify an initialization string for the modem using standard AT commands. Use the **no** form of this command to return to the default initialization string.

Syntax Description

<string>	Specifies an initialization string using standard AT commands. This string must start with AT and cannot contain spaces.

Default Values

<string>	**ate0q0v1x4\n0**	
	at	All initialization strings must begin with AT.
	e0	Disables command echo.
	q0	Response messages on.
	v1	Formats result codes in long word form.
	x4	Specifies extended response set, dial tone, and busy signal detection for result codes following modem operations.
	\n0	Selects standard buffered connection only.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example configures the modem to perform a hang-up at each initialization (to verify that the line is free) and maintains the default initialization:

(config)**#interface modem 1/2**
(config-modem 1/2)**#init-string ate0q0v1x4\n0**

resource pool-member

Use the **resource pool-member** command to assign the interface to a resource pool, making it a demand routing resource. Use the **no** form of this command to return to the default value. Variations of this command include:

resource pool-member <*name*>
resource pool-member <*name*> <*cost*>

Syntax Description

<*name*>	Specifies the name of the resource pool to which this interface is assigned.
<*cost*>	Optional. Specifies the cost of using this resource interface within the specified pool. In the event of a tie, a resource with a lower cost will be selected first. Interfaces with the same cost will be selected in alphabetical order by interface name.

Default Values

By default, the interface is not assigned to any resource pool.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures a basic rate interface (BRI) as a member of resource pool **MyPool**:

(config)**#interface modem 1/2**
(config-modem 1/2)**#resource pool-member MyPool**

PRI INTERFACE COMMAND SET

To activate the PRI Interface Configuration mode, enter the **interface pri** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface pri 2
(config-pri 2)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
description <text> on page 80
do on page 81
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

calling-party on page 2412
calling-party name-facility-timeout <value> on page 2414
connect e1<slot/port> tdm-group <number> on page 2415
connect t1 <slot/port> tdm-group <number> on page 2416
digits-transferred <value> on page 2417
isdn alert disable pi-8 on page 2418
isdn connect enable pi-2 on page 2419
isdn disconnect progress-tone on page 2420
isdn name-delivery on page 2421
isdn overlap-receive on page 2422
isdn pi-location on page 2423
isdn setup enable on page 2424
isdn supplementary-service on page 2425
isdn switch-type on page 2427
redirecting-number on page 2428
role on page 2429
snmp trap on page 2430
snmp trap link-status on page 2431

calling-party

Use the **calling-party** command to configure and control the primary rate interface (PRI) outgoing caller ID information. Use the **no** form of this command to disable this feature. Variations of this command include:

calling-party name <*name*>
calling-party number <*number*>
calling-party override always
calling-party override if-no-CID
calling-party presentation allowed
calling-party presentation not-available
calling-party presentation restricted
calling-party screening auto
calling-party screening network-provided

Syntax Description

name <*name*>	Configure the calling party name for the PRI.
number <*number*>	Configure the calling party number for the PRI.
override always	Enables the calling party to be replaced with the override number.
override if-no-CID	Enables the calling party to be replaced if caller ID no number is received.
presentation allowed	Enables the presentation of caller ID to always be allowed.
presentation not-available	Sets the calling party number to not available.
presentation restricted	Restricts the delivery on the caller ID information.
screening auto	Specifies that the calling party screening indicator is automatically determined.
screening network-provided	Specifies that the calling party screening indicator is provided by the network.

Default Values

By default, the command is disabled and the calling party screening indicator is set to **auto**.

Command History

Release 11.1	Command was introduced.
Release R10.5.0	Command was expanded to include the basic rate interface (PRI) and the **screening** parameters.

Usage Examples

The following example configures calling party outgoing information:

(config)**#interface pri 2**
(config-pri 2)**#calling-party override always**
(config-pri 2)**#calling-party presentation 555-8000**
(config-pri 2)**#calling-party name Company, Inc.**

calling-party name-facility-timeout <*value*>

Use the **calling-party name-facility-timeout** command to set the name facility timeout. This value determines the number of seconds to wait for the calling-party name delivery after the initial SETUP message is received. Once the name delivery is received or the timeout has passed, the corresponding INVITE is sent using the Session Initiation Protocol (SIP) trunk. Set the value to **0** to eliminate the delay. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Sets the number of seconds to wait for the calling-party name delivery. Valid range is **0** to **5**.

Default Values

By default, the timeout is **2** seconds.

Command History

Release A2.03	Command was introduced.

Usage Examples

The following example sets the **calling-party name-facility-timeout** to **5** seconds:

(config)**#interface pri 2**
(config-pri 2)**#calling-party name-facility-timeout 5**

connect e1<*slot/port*> tdm-group <*number*>

Use the **connect e1 tdm-group** command to configure the time division multiplexing (TDM) group connection used for the primary rate integrated services digital network (ISDN) primary rate interface (PRI) interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*slot/port*>	Specifies the E1 interface identifier.
<*number*>	Specifies the TDM group number. Valid range is **1** to **255**.

Default Values

By default, the command is disabled.

Command History

Release A2	Command was introduced.

Usage Examples

The following example configures the unit to connect **tdm-group 1** of the E1 to the PRI interface **2**:

(config)**#interface pri 2**
(config-pri 2)**#connect e1 0/1 tdm-group 1**

connect t1 <*slot/port*> tdm-group <*number*>

Use the **connect t1 tdm-group** command to configure the time division multiplexing (TDM) group connection used for the primary rate interface (PRI). Use the **no** form of this command to return to the default value.

Syntax Description

<*slot/port*>	Configure the T1 interface identifier.
<*number*>	Configure the TDM group number. Valid range is **1** to **255**.

Default Values

By default, the command is disabled.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures the unit to connect tdm-group 1 of the T1 to the PRI:

(config)**#interface pri 2**
(config-pri 2)**#connect t1 1/1 tdm-group 1**

digits-transferred <*value*>

Use the **digits-transferred** command to define how many of the received digits should be sent to the internal switchboard from an incoming call on a trunk. The number of digits transferred are the least digits received. Direct inward dialing (DID) should be used if a Telco provider is providing digits to the unit on inbound calls or if the unit needs to provide DID information to a piece of customer premises equipment (CPE). Use the **no** form of this command to disable this feature. Variations of this command include:

digits-transferred <*value*>
digits-transferred <*value*> **no-prefix**
digits-transferred <*value*> **prefix** <*number*>

Syntax Description

<*value*>	Specifies the number of digits to be transferred. The valid number of digits are **0**, **3**, **4**, **7** or **all**.
no-prefix	Optional. Specifies transferring the DID digits without appending a prefix.
prefix <*number*>	Optional. Specifies a sequence of digits to be appended to the digits that will be transmitted. For example, if seven digits will be transferred via DID, then prefix the seven digits with 256. Thus, **555-8000** would be prefixed with **256**, and **256-555-8000** would not.

Default Values

No default values are necessary for this command.

Command History

Release 14.1	Command was introduced.

Usage Examples

The following example transfers the digits **555-8000** and adds the prefix **256**:

(config)**#interface pri 2**
(config-pri 2)**#digits-transferred 5558000 prefix 256**

isdn alert disable pi-8

Use the **isdn alert disable pi-8** command to disable progress indicator 8 in integrated services digital network (ISDN) alert messages on the primary rate interface (PRI). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, progress indicator 8 is enabled.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example disables progress indicator 8 in the alert message:

(config)**#interface pri 2**
(config-pri 2)**#isdn alert disable pi-8**

isdn connect enable pi-2

Use the **isdn connect enable pi-2** command to enable progress indicator 2 in integrated services digital network (ISDN) connect messages on the primary rate interface (PRI). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, progress indicator 2 is disabled.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example enables progress indicator 2 in the connect message:

(config)**#interface pri 2**
(config-pri 2)**#isdn connect enable pi-2**

isdn disconnect progress-tone

Use the **isdn disconnect progress-tone** command to specify that calls use a progress tone to indicate the call should be disconnected. Use the **no** form of this command to disable the feature.

Syntax Description

No subcommands.

Default Values

By default, call progress tones are not used.

Command History

Release R10.5.0	Command was introduced.

Usage Example

The following example enables the use of progress tones when calls are disconnected:

(config)**#interface pri 2**
(config-pri 2)**#isdn disconnect progress-tone**

isdn name-delivery

Use the **isdn name-delivery** command to control the delivery of the name associated with the primary rate interface (PRI). This command can be used to block the caller ID name on the PRI. Use the **no** form of this command to return to the default setting. Variations of this command include:

isdn name-delivery display
isdn name-delivery proceeding
isdn name-delivery setup

Syntax Description

display	Delivers the calling party's name in a display information element (IE) in the SETUP message.
proceeding	Delivers the calling party's name in a facility IE after the PROCEEDING message.
setup	Delivers the calling party's name in a facility IE in the SETUP message.

Default Values

By default, **isdn name-delivery** is disabled.

Command History

Release 11.1	Command was introduced.
Release 14.1	Command was updated.

Usage Examples

The following example configures the calling party information to be delivered in the setup message:

(config)**#interface pri 2**
(config-pri 2)**#isdn name-delivery setup**

isdn overlap-receive

Use the **isdn overlap-receive** command to enable overlap receiving mode on the primary rate interface (PRI). Use the **no** form of this command to return to the default setting. Variations of this command include:

isdn overlap-receive timeout <*value*>
isdn overlap-receive digits-transferred <*value*>

Syntax Description

timeout <*value*>	Specifies how long the interface will attempt to match direct inward dialing (DID) digits received in INFO messages to entries in the voice dial-plan. If no matching entry is found, the interface will deliver the message when the timeout period expires. Valid range is **1** to **15** seconds.
digits-transferred <*value*>	Specifies how many DID digits the interface will collect before delivering the call. Valid range is **1** to **64** digits

Default Values

By default, **isdn overlap-receive** is disabled.

Command History

Release R10.7.0	Command was introduced.

Functional Notes

When **isdn overlap-receive** is enabled, the interface will accept a SETUP message where the Called Party Number (CPN) information element is either missing or does not have enough DID digits. When more digits are received in subsequent INFO messages, the number is matched against entries in the voice dial-plan to determine when there are enough digits to deliver the call.

If no matching voice dial-plan entry is found, the interface will deliver the call when configuration the **isdn overlap-receive timeout** expires.

When **isdn overlap-receive did-length** is configured, no voice dial-plan look-up occurs. The interface will deliver the call as soon as the specified number of DID digits has been collected.

If at any time an INFO message is received with CPN information element containing **#** or a Sending Complete information element is received, the interface will deliver the call immediately.

Usage Examples

The following example enables overlap receiving with a timeout value of **7** seconds on the PRI:

(config)**#interface PRI 2**
(config-pri 2)**#isdn overlap-receiving timeout 7**

isdn pi-location

Use the **isdn pi-location** command to configure the location of the progress indicator in integrated services digital network (ISDN) messages on the primary rate interface (PRI). The location is a progress indicator information element that indicates from where the message comes. Use the **no** form of this command to return to the default setting. Variations of this command include:

isdn pi-location private
isdn pi-location public

Syntax Description

private	Sets the location of the progress indicator to private network serving the local user.
public	Sets the location of the progress indicator to public network serving the local user.

Default Values

By default, the progress indicator location is public.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example set the progress indicator location to private:

(config)**#interface pri 2**
(config-pri 2)**#isdn pi-location private**

isdn setup enable

Use the **isdn setup enable** command to enable progress indicators in the integrated services digital network (ISDN) setup message and redirecting numbers for ISDN calls on the primary rate interface (PRI). The redirecting number is used to insert the caller's number when a call is diverted by a blind transfer or forward that both occurs on an ISDN trunk in local mode and proceeds out of an ISDN trunk. Use the **no** form of this command to disable this feature. Variations of this command include:

isdn setup enable called
isdn setup enable calling
isdn setup enable pi-1
isdn setup enable pi-3
isdn setup enable redirecting-number

Syntax Description

called	Enables the called number in ISDN setup messages.
calling	Enables the calling number in ISDN setup messages.
pi-1	Enables progress indicator 1 for ISDN setup messages. Progress indicator 1 indicates that the call is not end-to-end ISDN and further call progress information may be available in-band.
pi-3	Enables progress indicator 3 for ISDN setup messages. Progress indicator 3 indicates that the origination address is non-ISDN.
redirecting-number	Enables redirecting numbers for ISDN calls.

Default Values

By default, the called and calling numbers are included in ISDN setup messages.

Command History

Release A4.01	Command was introduced.
Release A4.03	Command was expanded to include the **redirecting-number** parameter.
Release R10.5.0	Command was expanded to include the **called** and **calling** parameters.

Usage Examples

The following example enables redirecting numbers for ISDN calls:

(config)**#interface pri 2**
(config-pri 2)**#isdn setup enable redirecting-number**

isdn supplementary-service

Use the **isdn supplementary-service** command to enable integrated services digital network (ISDN) supplementary services on a primary rate interface (PRI). Use the **no** form of this command to disable this feature. Variations of this command include:

isdn supplementary-service ect
isdn supplementary-service rlt
isdn supplementary-service tbct
isdn supplementary-service tbct active-transfers <*value*>
isdn supplementary-service tbct d-channel-id <*id number*>
isdn supplementary-service tbct d-channel-id auto
isdn supplementary-service tbct notify-controller
isdn supplementary-service tbct transfer-counters
isdn supplementary-service tbct transfer-rate <*value*>

Syntax Description

ect	Enables European Telecommunications Standards Institute (ETSI) explicit call transfer (ECT).
rlt	Enables Digital Multiplex System (DMS) release link trunk (RLT).
tbct	Enables National ISDN II two B-channel transfer (TBCT).
active-transfers <*value*>	Optional. Sets the number of simultaneous TBCT transfers. Valid range is **0** to **60000**.
d-channel-id <*id number*>	Optional. Sets the D-channel ID for TBCT on the interface.
d-channel-id auto	Optional. Sets the D-channel ID for TBCT to be automatically configured.
notify-controller	Optional. Enables TBCT notification to the controller.
transfer-counters	Optional. Enables transfer counters during TBCT.
transfer-rate <*value*>	Optional. Sets the number of transfers allowed within a 10-second interval. Valid range is **0** to **500**.

Default Values

By default, ECT, RLT, and TBCT are disabled.

By default, the **tbct active-transfers** value is set to **100**, the **tbct d-channel-id** is set to **auto**, the **tbct notify-controller** is disabled, the **tbct transfer-counters** are enabled, and the **tbct transfer-rate** is set to **10**.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example enables TBCT on PRI interface 2 and sets the number of simultaneous TBCT transfers to **5000**:

(config)**#interface pri 2**
(config-pri 2)**#isdn supplementary-service tbct**
(config-pri 2)**#isdn supplementary-service tbct active-transfers 5000**

isdn switch-type

Use the **isdn switch-type** command to configure the switch type assigned on the primary rate integrated services digital network (ISDN) primary rate interface (PRI) circuit. Telephone companies use various types of ISDN switches and this setting must match the switch type used by your provider. Use the **no** form of this command to return to the default setting. Variations of this command include:

isdn switch-type 4ess
isdn switch-type 5ess
isdn switch-type dms100
isdn switch-type etsi
isdn switch-type etsi legacy
isdn switch-type ni2

Syntax Description

4ess	Sets the ISDN switch type to ATT 4ESS.
5ess	Sets the ISDN switch type to Lucent 5ESS.
dms100	Sets the ISDN switch type to Northern ISDN II.
etsi	Sets the ISDN switch type to European Telecommunications Standards Institute (ETSI) (ETS 300 403).
etsi legacy	Sets the ISDN switch type to legacy ETSI (ETS 300 102).
ni2	Sets the ISDN switch type to National ISDN II.

Default Values

By default, the command is set to **ni2**.

Command History

Release 11.1	Command was introduced.
Release A2	Command was expanded to include the ETSI switch types.

Usage Examples

The following example configures the PRI switch type National ISDN II:

(config)**#interface pri 2**
(config-pri 2)**#isdn switch-type ni2**

redirecting-number

Use the **redirecting-number** command to configure the format in which redirecting numbers are sent on the primary rate interface (PRI). Use the **no** form of this command to return to the default setting. Variations of this command include:

redirecting-number as-received
redirecting-number prefer-national

Syntax Description

as-received	Configures the redirecting number to be sent exactly as it is received.
prefer-national	Configures the redirecting number to be sent in E.164 format, if possible.

Default Values

No default values are necessary for this command.

Command History

Release A4.01	Command was introduced.

Usage Examples

The following example configures the redirecting number to be sent in E.164 format:

(config)**#interface pri 2**
(config-pri 2)**#redirecting-number prefer-national**

role

Use the **role** command to configure the interface protocol to use on the primary rate interface (PRI). This setting controls the functional mode of the interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

role network
role network b-channel-restarts disable
role network b-channel-restarts enable
role user

Syntax Description

network	Sets the port to operate in network termination (NT) mode.
b-channel-restarts disable	Optional. Disables B-channel restarts.
b-channel-restarts enable	Optional. Enables B-channel restarts.
user	Sets the port to operate in terminal equipment (TE) mode.

Default Values

By default, the role is set to **network b-channel-restarts disable**.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures the interface protocol as **user** on the PRI:

(config)**#interface pri 2**
(config-pri 2)**#role user**

snmp trap

Use the snmp trap command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Use the no form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release A5.01	Command was introduced.

Usage Examples

The following example enables SNMP on the primary rate interface (PRI) 2:

(config)**#interface pri 2**
(config-pri 2)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release A5.01	Command was introduced.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the primary rate interface (PRI) 2:

(config)**#interface pri 2**
(config-pri 2)**#no snmp trap link-status**

SERIAL INTERFACE COMMAND SET

To activate the Serial Interface Configuration mode, enter the **interface serial** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface serial 1/1
(config-ser 1/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

et-clock-source on page 2433
ignore dcd on page 2434
invert etclock on page 2435
invert rxclock on page 2436
invert txclock on page 2437
serial-mode on page 2438
snmp trap on page 2439
snmp trap link-status on page 2440

et-clock-source

Use the **et-clock-source** command to configure the clock source used when creating the external transmit reference clock (et-clock). Use the **no** form of this command to return to the default value. Variations of this command include:

et-clock-source rxclock
et-clock-source txclock

Syntax Description

rxclock	Uses the clock recovered from the receive signal to generate et-clock.
txclock	Uses the clock recovered from the transmit signal to generate et-clock.

Default Values

By default, the clock recovered from the transmit signal is used to generate the et-clock.

Command History

Release 1.1	Command was introduced.

Functional Notes

The external transmit clock (et-clock) is an interface timing signal (provided by the data terminal equipment (DTE) device) used to synchronize the transfer of transmit data.

Usage Examples

The following example configures the serial interface to recover the clock signal from the received signal and use it to generate et-clock:

(config)**#interface serial 1/1**
(config-ser 1/1)**#et-clock-source rxclock**

ignore dcd

Use the **ignore dcd** command to specify the behavior of the serial interface when the data carrier detect (DCD) signal is lost. Use the **no** form of this command to return to the default value.

Syntax Description

No subcommands.

Default Values

By default, the serial interface does not ignore a change in status of the DCD signal.

Command History

Release 1.1	Command was introduced.

Functional Notes

When configured to follow DCD (default condition), the serial interface will not attempt to establish a connection when DCD is not present. When configured to ignore DCD, the serial interface will continue to attempt to establish a connection even when DCD is not present.

Usage Examples

The following example configures the serial interface to ignore a loss of the DCD signal:

(config)**#interface serial 1/1**
(config-ser 1/1)**#ignore dcd**

invert etclock

Use the **invert etclock** command to configure the serial interface to invert the external transmit reference clock (et-clock) in the data stream before transmitting. Use the **no** form of this command to return to the default value.

Syntax Description

No subcommands.

Default Values

By default, the serial interface does not invert et-clock.

Command History

Release 1.1	Command was introduced.

Functional Notes

If the serial interface cable is long, causing a phase shift in the data, the et-clock can be inverted using the **invert etclock** command. This switches the phase of the clock, which compensates for a long cable.

Usage Examples

The following example configures the serial interface to invert et-clock:

(config)**#interface serial 1/1**
(config-ser 1/1)**#invert etclock**

invert rxclock

Use the **invert rxclock** command to configure the serial interface to expect an inverted receive clock (found in the received data stream). Use the **no** form of this command to return to the default value.

Syntax Description

No subcommands.

Default Values

By default, the serial interface does not expect an inverted receive clock (**rxclock**).

Command History

Release 1.1	Command was introduced.

Functional Notes

If the serial interface cable is long, causing a phase shift in the data, the transmit clock can be inverted using the **invert txclock** command (refer to *invert txclock on page 2437*). This switches the phase of the clock, which compensates for a long cable. If the transmit clock of the connected device is inverted, use the **invert rxclock** command to configure the receiving interface appropriately.

Usage Examples

The following example configures the serial interface to invert receive clock:

(config)**#interface serial 1/1**
(config-ser 1/1)**#invert rxclock**

invert txclock

Use the **invert txclock** command to configure the serial interface to invert the transmit clock (found in the transmitted data stream) before sending the signal. Use the **no** form of this command to return to the default value.

Syntax Description

No subcommands.

Default Values

By default, the serial interface does not invert transmit clock (**txclock)**.

Command History

Release 1.1	Command was introduced.

Functional Notes

If the serial interface cable is long, causing a phase shift in the data, the transmit clock can be inverted (using the **invert txclock** command). This switches the phase of the clock, which compensates for a long cable. If the transmit clock of the connected device is inverted, use the **invert rxclock** command to configure the receiving interface appropriately.

Usage Examples

The following example configures the serial interface to invert the transmit clock:

(config)**#interface serial 1/1**
(config-ser 1/1)**#invert txclock**

serial-mode

Use the **serial-mode** command to specify the electrical mode for the interface. Use the **no** form of this command to return to the default value. Variations of this command include:

serial-mode eia530
serial-mode v35
serial-mode x21

Syntax Description

eia530	Configures the interface for use with the EIA 530 adapter cable (P/N 1200883L1).
v35	Configures the interface for use with the V.35 adapter cable (P/N 1200873L1).
x21	Configures the interface for use with the X.21 adapter cable (P/N 1200874L1).

Default Values

By default, the serial interface is configured for a **V.35** adapter cable.

Command History

Release 1.1	Command was introduced.

Functional Notes

The pinouts for each of the available interfaces can be found in the *Hardware configuration guide* located online at http://supportforums.adtran.com.

Usage Examples

The following example configures the serial interface to work with the **X.21** adapter cable:

(config)**#interface serial 1/1**
(config-ser 1/1)**#serial-mode x21**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.

Usage Examples

The following example enables SNMP on the serial interface:

(config)**#interface serial 1/1**
(config-ser 1/1)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the serial interface:

(config)**#interface serial 1/1**
(config-ser 1/1)**#no snmp trap link-status**

SHDSL INTERFACE COMMAND SET

To activate the Single-Pair High-Speed Digital Subscriber Line (SHDSL) Interface Configuration mode, enter the **interface shdsl** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface shdsl 1/1
(config-shdsl 1/1)#
```

*Not all SHDSL commands apply to all SHDSL interfaces. Type **interface shdsl <slot/port>** to display a list of valid commands.*

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

alarm-threshold on page 2443
annex on page 2444
boot alternate-image on page 2445
equipment-type on page 2446
ignore-error-duration <time> on page 2447
inband-detection on page 2448
inband-protocol on page 2449
line-mode on page 2450
linerate <value> on page 2451
linerate adaptive <min DS0s-max DS0s> <target dBs> on page 2452
linerate fixed <min DS0s-max DS0s> on page 2453
loopback on page 2454
loopback remote inband on page 2455
outage-retrain on page 2456

alarm-threshold

Use the **alarm-threshold** command to set thresholds for specific alarm conditions. Use the **no** form of this command to disable threshold settings. Variations of this command include:

alarm-threshold loop-attenuation <*value*>
alarm-threshold snr-margin <*value*>

Syntax Description

loop-attenuation <*value*>	Specifies a loop-attenuation threshold value from 1 to 127 dB. If signal energy loss on the loop exceeds the configured value, the router issues an alarm.
snr-margin <*value*>	Specifies a value for signal-to-noise ratio (SNR) margin from 1 to 15 dB. If the difference in amplitude between the baseband signal and the noise exceeds the configured value, the router issues an alarm.

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example sets the loop attenuation threshold at **45** dB:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#alarm-threshold loop-attenuation 45**

annex

Use the **annex** command to select the single-pair, high-speed digital subscriber line (SHDSL) operating mode supported on this interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

annex a
annex a-efm
annex a-or-b
annex a-or-b-efm
annex b
annex b-efm
annex b
annex efm

Syntax Description

a	Specifies Annex A (North American operating parameters).
a-efm	Specifies Annex A and IEEE 802.3ah handshake parameters.
a-or-b	Specifies Annex A or Annex B. This parameter enables the detection and selection of the annex type depending on the connected terminating unit.
a-or-b-efm	Specifies Annex A or Annex B and IEEE 802.3ah handshake parameters. This parameter enables the detection and selection of the annex type depending on the connected terminating unit.
b	Specifies Annex B (European operating parameters).
b-efm	Specifies Annex B and IEEE 802.3ah handshake parameters.
efm	Specifies IEEE 802.3ah handshake parameters.

Default Values

By default, the SHDSL operating mode is set to **a-or-b**.

Command History

Release 15.1	Command was introduced.
Release R10.6.0	Command was expanded to include the **a-efm**, **a-or-b-efm**, **b-efm**, and **efm** parameters.

Usage Examples

The following example sets the operating mode to **annex a**:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#annex a**

boot alternate-image

Use the **boot alternate-image** command to execute new code after a firmware upgrade.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.

Functional Notes

The current single-pair high-speed digital subscriber line (SHDSL) network interface module (NIM) card (P/N 1200867L1) supports two code images commonly referred to as the active image and the inactive image. When a firmware upgrade is performed on the card (through the **copy** <*filename*> **interface shdsl x/y** Enable mode command), the new firmware is placed in the inactive image space. This new code will not be executed until the **boot alternate-image** command is issued. When the user does this, the NIM will reboot (taking the current line down) with the new code. At this point, the old code becomes the inactive image and the new recently updated code becomes the active image.

Usage Examples

The following example causes the firmware upgrade to take effect:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#boot alternate-image**

equipment-type

Use the **equipment-type** command to determine the operating mode for the single-pair high-speed digital subscriber line (SHDSL) interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

equipment-type co
equipment-type cpe

Syntax Description

co	Use this option only in a campus environment when operating two SHDSL network interface modules (NIMs) back-to-back. In this setup, configure the master NIM to CO and the slave NIM to customer premises equipment (CPE).
cpe	Use this option when interfacing directly with your service provider or when acting as the slave NIM in a campus environment.

Default Values

The default for this command is **cpe**.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example changes the operating mode of the SHDSL interface to CO:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#equipment-type co**

ignore-error-duration <*time*>

Use the **ignore-error-duration** command to specify the amount of time that errors are ignored during line training. Use the **no** form of this command to return to the default setting.

Syntax Description

<*time*>	Specifies time in seconds. Valid range is **15** to **30** seconds.

Default Values

By default, **ignore-error-duration** is set to **15** seconds.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example sets the amount of time errors are ignored during line training to **25** seconds:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#ignore-error-duration 25**

inband-detection

Use the **inband-detection** command to enable inband loopback pattern detection on the single-pair high-speed digital subscriber line (SHDSL) interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is enabled.

Command History

Release 4.1	Command was introduced.

Usage Examples

The following example disables inband loopback pattern detection:

```
(config)#interface shdsl 1/1
(config-shdsl 1/1)#no inband-detection
```

inband-protocol

Use the **inband-protocol** command to designate the inband loopback pattern to send/detect on the single-pair high-speed digital subscriber line (SHDSL) interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

inband-protocol pn127
inband-protocol v54

Syntax Description

pn127	Selects PN127 as the inband loopback pattern to send/detect.
v54	Selects V.54 as the inband loopback pattern to send/detect.

Default Values

By default, the inband loopback pattern is set to **v54**.

Command History

Release 4.1	Command was introduced.

Functional Notes

Inband loopbacks are specific patterns that are sent in place of user data to trigger a loopback. Both PN127 and V.54 are industry standard loopback patterns used to allow remote loopbacks.

Usage Examples

The following example sets the inband loopback pattern for **pn127**:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#inband-protocol pn127**

line-mode

Use the **line-mode** command to select the controller line mode. Use the **no** form of this command to return to the default setting. Variations of this command include:

line-mode 2-wire
line-mode 4-wire

Syntax Description

2-wire	Specifies two-wire mode.
4-wire	Specifies four-wire mode for extended operation.

Default Values

By default, the digital subscriber line (DSL) operating mode is set to **2-wire**.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example sets the line mode to **4-wire**:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#line-mode 4-wire**

linerate *<value>*

Use the **linerate** command to define the line rate for the single-pair high-speed digital subscriber line (SHDSL) interface (the value includes 8 kbps of framing overhead). This command is functional only in CO operating mode (refer to *equipment-type on page 2446*). The first two selections listed in the command line interface (CLI) (72 and 136 kbps) are not supported by the SHDSL network interface module (NIM) (P/N 1200867L1). Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the line rate in kbps. Range is **200** to **2312** kbps in 64k increments.

Default Values

By default, the line rate is set to **2056** kbps.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example changes the line rate of the SHDSL interface to **264** kbps:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#linerate 264**

linerate adaptive *<min DS0s-max DS0s> <target dBs>*

Use the **linerate adaptive** command to configure the single-pair, high-speed digital subscriber line (SHDSL) interface for adaptive line rate training according to the signal quality conditions on the line. Variations of this command include:

linerate adaptive <*min DS0s-max DS0s*> <*target dBs*> **current-condition**
linerate adaptive <*min DS0s-max DS0s*> <*target dBs*> **worstcase-condition**

Syntax Description

<min DS0s-max DS0s>	Specifies a range of DS0s for the minimum and maximum possible values for the linerate in the format <minimum number of DS0s-maximum number of DS0s>. The line rate is determined by multiplying the DS0 number by 64 kbps. The default range is **3-89** DS0s.
<target dBs>	Specifies the target signal quality margin desired for the interface. Valid range is **-10** to **20** dBs. The default value is **3** dBs.
current-condition	Configures the SHDSL interface for adaptive line rate training according to current signal quality conditions on the line. This mode is not recommended per ITU-T G991.2 Section 6.3.6.
worstcase-condition	Configures the SHDSL interface for adaptive line rate training according to worst-case signal quality conditions on the line.

Default Values

The default value for this command is **linerate adaptive 3-89 3 worstcase-condition**.

Command History

Release R10.6.0	Command was introduced.

Usage Examples

The following example configures the SHDSL interface for adaptive line rate training according to worst-case signal quality conditions on the line.

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#linerate adaptive 3-64 5 worstcase-condition**

linerate fixed *<min DS0s-max DS0s>*

Use the **linerate fixed** command to configure the single-pair, high-speed digital subscriber line (SHDSL) interface for fixed adaptive line rate training. When in this mode, no line probing is performed by the interface. The line rate is determined by comparing the range of level zero digital signals (DS0s) specified with what is allowed by the other end point during the SHDSL handshake process.

Syntax Description

<min DS0s-max DS0s>	Specifies a range of DS0s for the minimum and maximum possible values for the linerate in the format <minimum number of DS0s-maximum number of DS0s>. The line rate is determined by multiplying the DS0 number by 64 kbps. The default range is **3-89** DS0s.

Default Values

No default values are necessary for this command.

Command History

Release R10.6.0	Command was introduced.

Usage Examples

The following example configures the SHDSL interface for fixed line rate training:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#linerate fixed 3-64**

loopback

Use the **loopback** command to initiate a loopback test on the single-pair high-speed digital subscriber line (SHDSL) interface. Use the **no** form of this command to deactivate the loopback. Variations of this command include:

loopback analog
loopback digital
loopback network
loopback remote

Syntax Description

analog	Loops the circuit at the analog hybrid.
digital	Loops the circuit at the framer.
network	Loops data back towards the network.
remote	Transmits a network loopback request. This command is functional only in CO operating mode (refer to *equipment-type on page 2446*).

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.
Release 15.1	Command was expanded to include the analog and digital loopbacks.

Usage Examples

The following example initiates a loopback test on the SHDSL interface that will loop the data back toward the network:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#loopback network**

loopback remote inband

Use the **loopback remote inband** command to inject the selected inband loop-up pattern into the data stream to cause a loopback at the far end. Use the **no** form of this command to inject a loop-down pattern into the data stream to cause an existing inband loopback at the far end to cease.

Syntax Description

No subcommands.

Default Values

By default, this command is enabled.

Command History

Release 4.1	Command was introduced.

Usage Examples

The following example injects a loop-down pattern into the data stream, causing existing loopbacks at the far end to stop:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#no loopback remote inband**

outage-retrain

Use the **outage-retrain** command to cause the single-pair high-speed digital subscriber line (SHDSL) interface to force the SHDSL retrain sequence (which takes the line down temporarily) if the interface detects more than ten consecutive errored seconds. A retrain is forced in hopes that the newly retrained line will achieve better performance than the previous training state. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example forces a retrain sequence on the SHDSL interface:

```
(config)#interface shdsl 1/1
(config-shdsl 1/1)#outage-retrain
```

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Us the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the single-pair high-speed digital subscriber line (SHDSL) interface, Ethernet in the first mile (EFM) group, system management Ethernet virtual connection (EVC) and the system control EVC.

Usage Examples

The following example enables SNMP capability on the SHDSL interface:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the single-pair high-speed digital subscriber line (SHDSL) interface, Ethernet in the first mile (EFM) group, system management Ethernet virtual connection (EVC) and the system control EVC.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the SHDSL interface:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#no snmp trap link-status**

test-pattern

Use the **test-pattern** command to activate the built-in pattern generator and begin sending the selected test pattern toward the network. This pattern generation can be used to verify a data path when used in conjunction with an active loopback. Use the **no** form of this command to cease pattern generation. Variations of this command include:

test-pattern clear
test-pattern errors
test-pattern insert
test-pattern p215

Syntax Description

clear	Clears the test pattern error count.
errors	Displays the test pattern error count.
insert	Inserts an error into the currently active test pattern.
p215	Generates a pseudorandom test pattern sequence based on a 15-bit shift register.

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example sends a **p215** test pattern:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#test-pattern p215**

test splice-detect distance-type

Use the **test splice-detect distance-type** command to specify the unit of measurement used in the bad splice detection test. Use the **no** form of this command to return to the default unit of measurement. Variations of this command include:

test splice-detect distance-type feet
test splice-detect distance-type meters

Syntax Description

feet	Specifies the distance to the detected bad splice is measured in feet.
meters	Specifies the distance to the detected bad splice is measured in meters.

Default Values

By default, distances in the bad splice detection test are measured in feet.

Command History

Release A4.05	Command was introduced.

Functional Notes

The bad splice detection test is a line testing feature that allows users to locate intermittent faults in lines by estimating the distance to the fault. Splice detection is always enabled on the SHDSL EFM NIM2 module and it continually monitors the signal-to-noise ratio (SNR) of the connection. When a negative change in the SNR is detected, a measurement is taken to determine the distance to where the issue is possibly occurring on the line. Bad splice detection test results can be viewed using the command *show interfaces shdsl <slot/port> splice-detect on page 691*.

Usage Examples

In the following example, the unit of measurement used by the bad splice detection test is changed from feet to meters:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#test splice-detect distance-type meters**

test tscan

Use the **test tscan** command to initiate a Tscan test, as well as configure and display Tscan test parameters for the interface. Variations of this command include:

test tscan
test tscan clear-results
test tscan display-results

Syntax Description

clear-results	Clears the Tscan test results from previously completed Tscan tests.
display-results	Displays the results of the most recently completed Tscan test.

Default Values

By default, Tscan tests are not run on the interface.

Command History

Release A4.05	Command was introduced.

Functional Notes

The Tscan line test is a testing feature that allows users to isolate faults in lines by estimating the distance to the fault and determining the type of fault, whether a short or an open connection. Tscan is an intrusive test, which causes trained SHDSL loops to go down, but it is useful as a method for finding faults in loops that will not train, rather than as a performance metric for operational loops.

Tscan tests can be started on any port that is enabled. Tscan tests typically take from 20 seconds to one minute to complete, and timeout after 90 seconds to restore control to the command line interface (CLI). When the test is complete, results are displayed in the CLI or can be viewed at a later time using the command **test tscan display-results**. Displayed results include the date and time of the test, the status of the test, the line rate used while Tscan operates (typically 16 or 32 DSOs), the distance to the fault if one is detected (displayed in feet), and the fault type that is found. The minimum distance for the Tscan test is **0** feet and the maximum Tscan test distance is **1200** feet.

Usage Examples

The following example initiates a Tscan test on SHDSL interface **1/1**:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#test tscan**

The following example displays results from a recently completed Tscan test:

(config)**#interface shdsl 1/1**
(config-shdsl 1/1)**#test tscan display-results**
shdsl 1/1 TSCAN Results
Date/Time: Thu, October 28, 2010 04:30:59 PM, CDT
Status: Done
Rate: 32 DSOs
Distance: 1100 ft
Fault: Open

T1 INTERFACE COMMAND SET

To activate the T1 Interface Configuration mode, enter the **interface t1** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface t1 1/1
(config-t1 1/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

All other commands for this command set are described in this section in alphabetical order.

clock source

Use the **clock source** command to configure the source timing used for the interface. Use the **no** form of this command to return to the default value. Variations of this command include:

clock source internal
clock source line
clock source system
clock source through
clock source through t1 *<interface id>*

Syntax Description

internal	Configures the unit to provide clocking using the internal oscillator.
line	Configures the unit to recover clocking from the T1 circuit.
system	Configures the unit to provide clocking using the system clock.
through	Configures the unit to recover clocking from the circuit connected to the DSX-1 interface.
through t1 *<interface id>*	Configures the unit to recover clocking from the alternate interface. Only valid on T1 systems with multiple T1 interfaces and a single clock source.

Default Values

By default, the **clock source** is set to **line**.

Command History

Release 1.1	Command was introduced.
Release 13.1	Command was expanded to include the system as a clocking source.

Functional Notes

When operating on a circuit that is providing timing, setting the **clock source** to **line** can avoid errors, such as clock slip seconds (CSS).

Usage Examples

The following example configures the unit to recover clocking from the primary circuit:

(config)**#interface t1 1/1**
(config-t1 1/1)**#clock source line**

coding

Use the **coding** command to configure the line coding for a T1 physical interface. This setting must match the line coding supplied on the circuit by the service provider. Use the **no** form of this command to return to the default setting. Variations of this command include:

coding ami
coding b8zs

Syntax Description

ami	Configures the line coding for alternate mark inversion (AMI).
b8zs	Configures the line coding for bipolar eight zero substitution (B8ZS).

Default Values

By default, all T1 interfaces are configured with **b8zs** line coding.

Command History

Release 1.1	Command was introduced.

Functional Notes

The line coding configured in the unit must match the line coding of the T1 circuit. A mismatch will result in line errors (e.g., bipolar violations (BPVs)).

Usage Examples

The following example configures the T1 interface for **ami** line coding:

(config)**#interface t1 1/1**
(config-t1 1/1)**#coding ami**

fdl

Use the **fdl** command to configure the format for the facility data link (FDL) channel on the T1 circuit. FDL channels are only available on point-to-point circuits. Use the **no** form of this command to return to the default value. Variations of this command include:

fdl ansi
fdl att
fdl none

Syntax Description

ansi	Configures the FDL for ANSI T1.403 standard.
att	Configures the FDL for AT&T TR 54016 standard.
none	Disables FDL on this circuit.

Default Values

By default, the FDL is configured for **ansi**.

Command History

Release 1.1	Command was introduced.

Functional Notes

T1 circuits using extended superframe (ESF) framing format (specified using the **framing** command) reserve 12 bits as a data link communication channel, referred to as the FDL, between the equipment on either end of the circuit. The FDL allows the transmission of trouble flags, such as the Yellow Alarm signal. Refer to *framing on page 2467* for related information.

Usage Examples

The following example disables the FDL channel for the T1 circuit:

(config)**#interface t1 1/1**
(config-t1 1/1)**#fdl none**

framing

Use the **framing** command to configure the framing format for the T1 interface. This parameter should match the framing format supplied by your network provider. Use the **no** form of this command to return to the default value. Variations of this command include:

framing d4
framing esf

Syntax Description

d4	Specifies D4 superframe (SF) format.
esf	Specifies extended superframe (ESF) format.

Default Values

By default, the framing format is set to **esf**.

Command History

Release 1.1	Command was introduced.

Functional Notes

A frame is comprised of a single byte from each of the T1's timeslots; there are 24 timeslots on a single T1 circuit. Framing bits are used to separate the frames and indicate the order of information arriving at the receiving equipment. D4 and ESF are two methods of collecting and organizing frames over the circuit.

Usage Examples

The following example configures the T1 interface for D4 framing:

(config)**#interface t1 1/1**
(config-t1 1/1)**#framing d4**

lbo

Use the **lbo** command to configure the line build out (LBO) for the T1 interface. Use the **no** form of this command to return to the default value. Variations of this command include:

lbo short <*value*>
lbo long <*value*>

Syntax Description

long <*value*>	Configures the LBO (in dB) for T1 interfaces with cable lengths greater than 655 feet. Choose from **-22.5**, **-15**, **-7.5**, and **0** dB.
short <*value*>	Configures the LBO (in feet) for T1 interfaces with cable lengths less than 655 feet. Range is **0** to **655** feet.

Default Values

By default, the build out is set to **0** dB.

Command History

Release 1.1	Command was introduced.

Functional Notes

LBO is artificial attenuation of a T1 output signal to simulate a degraded signal. This is useful to avoid overdriving a receiver's circuits. The shorter the distance between T1 equipment (measured in cable length), the greater the attenuation value. For example, two units in close proximity should be configured for the maximum attenuation (-22.5 dB).

Usage Examples

The following example configures the T1 interface LBO for **-22.5** dB:

(config)**#interface t1 1/1**
(config-t1 1/1)**#lbo -22.5**

loopback network

Use the **loopback network** command to initiate a loopback on the interface toward the network. Use the **no** form of this command to deactivate the loopback. Variations of this command include:

loopback network line
loopback network payload

Syntax Description

line	Initiates a metallic loopback of the physical T1 network interface.
payload	Initiates a loopback of the T1 framer (CSU portion) of the T1 network interface.

Default Values

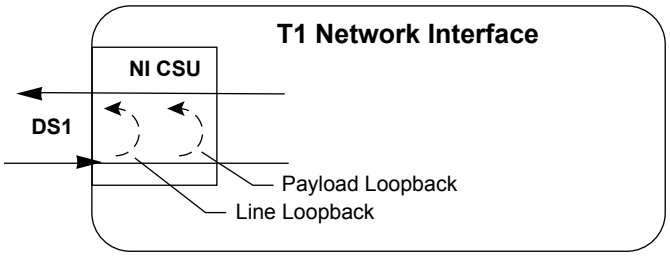
No default values are necessary for this command.

Command History

Release 1.1	Command was introduced.

Functional Notes

The following diagram depicts the difference between a line and payload loopback.



Usage Examples

The following example initiates a payload loopback of the T1 interface:

(config)**#interface t1 1/1**
(config-t1 1/1)**#loopback network payload**

loopback remote line

Use the **loopback remote line** command to send a loopback code to the remote unit to initiate a line loopback. Use the **no** form of this command to send a loopdown code to the remote unit to deactivate the loopback. Variations of this command include:

loopback remote line fdl
loopback remote line inband

Syntax Description

fdl	Uses the facility data link (FDL) to initiate a full 1.544 Mbps physical (metallic) loopback of the signal received by the remote unit from the network.
inband	Uses the inband channel to initiate a full 1.544 Mbps physical (metallic) loopback of the signal received by the remote unit from the network.

Default Values

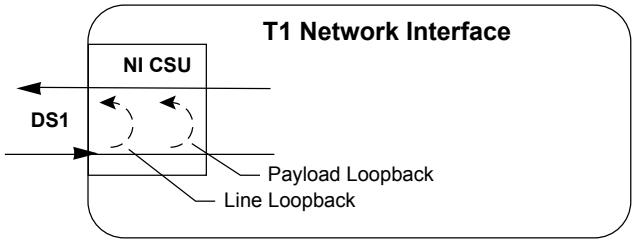
No default values are necessary for this command.

Command History

Release 1.1	Command was introduced.

Functional Notes

The following diagram depicts the difference between a line and payload loopback.



Usage Examples

The following example initiates a remote line loopback using the FDL:

(config)**#interface t1 1/1**
(config-t1 1/1)**#loopback remote line fdl**

loopback remote payload

Use the **loopback remote payload** command to send a loopback code to the remote unit to initiate a payload loopback. A payload loopback is a 1.536 Mbps loopback of the payload data received from the network maintaining bit-sequence integrity for the information bits by synchronizing (regenerating) the timing. Use the **no** form of this command to send a loopdown code to the remote unit to deactivate the loopback.

Syntax Description

No subcommands.

Default Values

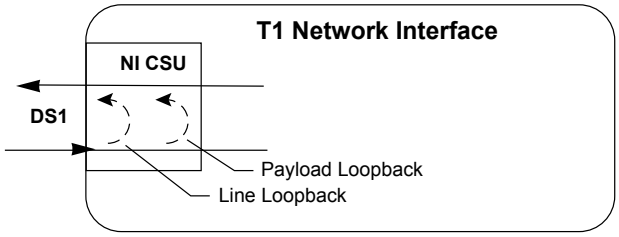
No default values are necessary for this command.

Command History

Release 1.1	Command was introduced.

Functional Notes

The following diagram depicts the difference between a line and payload loopback.



Usage Examples

The following example initiates a remote payload loopback:

(config)**#interface t1 1/1**
(config-t1 1/1)**#loopback remote payload**

remote-alarm rai

The **remote-alarm rai** command selects the alarm signaling type to be sent when a loss of frame is detected on the T1 receive signal. Use the **no** form of this command to disable all transmitted alarms.

Syntax Description

rai	Specifies sending a remote alarm indication (RAI) in response to a loss of frame. Also, prevents a received RAI from causing a change in interface operational status.

Default Values

The default for this command is **rai**.

Command History

Release 7.1	Command was expanded to include the T1 interface.

Usage Examples

The following example enables transmission of RAI in response to a loss of frame:

(config)**#interface t1 1/1**
(config-t1 1/1)**#remote-alarm rai**

remote-loopback

Use the **remote-loopback** command to configure the interface to respond to loopbacks initiated by a remote unit (or the service provider). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, all interfaces respond to remote loopbacks.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example enables remote loopbacks on the T1 interface:

(config)**#interface t1 1/1**
(config-t1 1/1)**#remote-loopback**

snmp trap line-status

Use the **snmp trap line-status** command to control the Simple Network Management Protocol (SNMP) variable dsx1LineStatusChangeTrapEnable (RFC 2495) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the dsx1LineStatusChangeTrapEnable object identifier (OID) is set to enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 11.1	Command was introduced.

Functional Notes

The **snmp trap line-status** command is used to control the RFC 2495 dsx1LineStatusChangeTrapEnable OID (OID number 1.3.6.1.2.1.10.18.6.1.17.0).

Usage Examples

The following example disables the line-status trap on the T1 interface:

(config)**#interface t1 1/1**
(config-t1 1/1)**#no snmp trap line-status**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the T1 interface:

(config)**#interface t1 1/1**
(config-t1 1/1)**#no snmp trap link-status**

snmp trap threshold-reached

Use the **snmp trap threshold-reached** command to control the Simple Network Management Protocol (SNMP) variable adGenAOSDs1ThresholdReached (adGenAOSDs1-Ext MIB) to enable the interface to send SNMP traps when a DS1 performance counter threshold is reached. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the adGenAOSDs1ThresholdReached object identifier (OID) is disabled for all interfaces.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example disables SNMP threshold reached trap on the T1 interface:

(config)**#interface t1 1/1**
(config-t1 1/1)**#no snmp trap threshold-reached**

system-timing

Use the **system-timing** command to configure the Rx clock as the primary or secondary timing source for the system. Use the **no** form of this command to disable this feature.Variations of this command include:

system-timing primary
system-timing secondary

Syntax Description

primary	Specifies the Rx clock as the primary timing source.
secondary	Specifies the Rx clock as the secondary timing source.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example configures the T1 interface to provide its Rx clock as the primary timing source for the system:

(config)**#interface t1 1/1**
(config-t1 1/1)**#system timing primary**

tdm-group <*number*>

Use the **tdm-group** command to create a group of contiguous level zero digital signals (DS0s) on this interface to be used during the **cross-connect** process. Refer to *cross-connect on page 76* for related information. Use the **no** form of this command to remove configured time division multiplexing (TDM) groups. Variations of this command include:

tdm-group <*number*> **timeslots** <*value*>
tdm-group <*number*> **timeslots** <*value*> **speed [56 | 64]**

*Changing **tdm-group** settings could result in service interruption.*

Syntax Description

<*number*>	Identifies the created TDM group. Valid range is **1** to **255**.
timeslots <*value*>	Specifies the channels to be used in the TDM group. Valid range is **1** to **31**. The timeslot value can be entered as a single number representing one of the 31 E1 channel timeslots or as a contiguous group of channels. (For example, **1-10** specifies the first 10 channels of the E1.)
speed [56 | 64]	Optional. Specifies the individual DS0 rate on the T1 interface to be 64 kbps. Only the T1 + DSX-1 network interface module (NIM) supports the 56 kbps DS0 rate. The default speed is 64 kbps.

Default Values

By default, there are no configured TDM groups.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example creates a TDM group (labeled **5**) of 10 DS0s at 64 kbps each:

(config)**#interface t1 1/1**
(config-t1 1/1)**#tdm-group 5 timeslots 1-10 speed 64**

test-pattern

Use the **test-pattern** command to activate the built-in pattern generator and begin sending the specified test pattern. This pattern generation can be used to verify a data path when used in conjunction with an active loopback. Use the **no** form of this command to cease pattern generation. Variations of this command include:

test-pattern clear
test-pattern errors
test-pattern insert
test-pattern ones
test-pattern p215
test-pattern p220
test-pattern p511
test-pattern qrss
test-pattern zeros

Syntax Description

clear	Clears the test pattern error count.
errors	Displays the test pattern errored seconds.
insert	Inserts an error into the currently active test pattern.
ones	Generates a test pattern of continuous ones.
p215	Generates a pseudorandom test pattern sequence based on a 15-bit shift register.
p220	Generates a pseudorandom test pattern sequence based on a 20-bit shift register.
p511	Generates a test pattern of repeating ones and zeros.
qrss	Generates a test pattern of random ones and zeros.
zeros	Generates a test pattern of continuous zeros.

Default Values

No default values are necessary for this command.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example activates the pattern generator for a stream of continuous **ones**:

(config)**#interface t1 1/1**
(config-t1 1/1)**#test-pattern ones**

timing-domain <*domain*>

Use the **timing-domain** command to assign the interface to a system-wide voice timing domain. Use the **no** form of this command to return to the default.

Syntax Description

<*domain*>	Assigns the interface to a system-wide timing domain. Valid domains are **1** and **2**.

Default Values

By default, interfaces are assigned to timing domain **1**.

Command History

Release A5.01	Command was introduced.

Usage Examples

The following example assigns the interface to timing domain **2**:

(config)**#interface t1 1/1**
(config-t1 1/1)**#timing-domain 2**

T3 INTERFACE COMMAND SET

To activate the T3 Interface Configuration mode, enter the **interface t3** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface t3 1/1
(config-t3 1/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

All other commands for this command set are described in this section in alphabetical order.

clock source

Use the **clock source** command to configure the source timing used for the interface. The clock specified using the **clock source** command is also the system master clock. Use the **no** form of this command to return to the default value. Variations of this command include:

clock source local
clock source loop

Syntax Description

local	Configures the unit to provide clocking using the internal oscillator.
loop	Configures the unit to recover clocking from the T3 circuit.

Default Values

By default, all T3 interfaces are configured with **loop** as the clock source.

Command History

Release 6.1	Command was introduced.

Usage Examples

The following example configures the unit to recover clocking from the circuit:

(config)**#interface t3 1/1**
(config-t3 1/1)**#clock source loop**

coding b3zs

Use the **coding b3zs** command to configure the line coding for a T3 physical interface. This setting must match the line coding supplied on the circuit by the service provider.

Syntax Description

b3zs	Configures the line coding for bipolar three zero substitution (B3ZS).

Default Values

By default, all T3 interfaces are configured with **b3zs** line coding.

Command History

Release 6.1	Command was introduced.

Functional Notes

The line coding configured in the unit must match the line coding of the T3 circuit. A mismatch will result in line errors (e.g., bipolar violations (BPVs)).

Usage Examples

The following example configures the T1 interface for **b3zs** line coding:

(config)**#interface t3 1/1**
(config-t3 1/1)**#coding b3zs**

framing

Use the **framing** command to configure the network framing format for a T3 physical interface. Use the **no** form of this command to return to the default value. Variations of this command include:

framing cbit
framing m13

Syntax Description

cbit	Configures the interface for C-bit parity framing.
m13	Configures the interface for M13 framing.

Default Values

By default, all T3 interfaces are configured for **cbit** parity framing.

Command History

Release 6.1	Command was introduced.

Functional Notes

M13 is an asynchronous framing format that uses all 21 DS3 M-Frame C-bits for bit stuffing indicators. End-to-end path parity and datalink capabilities are not provided by the standard M13 format. C-bit parity framing differs from M13 by allowing monitoring of the data path (end-to-end) and supporting out-of-band (OOB) data links.

Usage Examples

The following example configures the T3 interface for **m13** framing:

(config)**#interface t3 1/1**
(config-t3 1/1)**#framing m13**

line-length

Use the **line-length** command to configure the line length for a T3 physical interface. Use the **no** form of this command to return to the default value. Variations of this command include:

line-length long
line-length short

Syntax Description

long	Configures the line length for a distance of 225 to 450 feet of cable.
short	Configures the line length for a distance of 0 to 225 feet of cable.

Default Values

By default, all T3 interfaces are configured for a **short** line length.

Command History

Release 6.1	Command was introduced.

Usage Examples

The following example configures the T3 interface for **long** line length:

(config)**#interface t3 1/1**
(config-t3 1/1)**#line-length long**

loopback network

Use the **loopback network** command to initiate a local T3 loopback on the interface toward the network. Use the **no** form of this command to deactivate the loopback. Variations of this command include:

loopback network line
loopback network payload

Syntax Description

line	Initiates a loopback of the physical T3 network interface; that is, data received on the T3 is transmitted back out on the T3.
payload	Initiates a loopback of the T3 framer (TSU portion) of the T3 network interface.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.

Usage Examples

The following example initiates a payload loopback of the T3 interface:

(config)**#interface t3 1/1**
(config-t3 1/1)**#loopback network payload**

loopback remote

Use the **loopback remote** command to initiate a loopback test on the T3 interface that sends a remote loopback code out the T3 circuit to loop up the far end. This command only applies when C-bit framing is used on the circuit. Use the **no** form of this command to deactivate the loopback. Variations of this command include:

loopback remote line
loopback remote payload

Syntax Description

line	Initiates a line loopback.
payload	Initiates a payload loopback.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.

Usage Examples

This example initiates a remote loopback on the T3 interface:

(config)**#interface t3 1/1**
(config-t3 1/1)**#loopback remote**

remote-loopback

Use the **remote-loopback** command to configure the T3 interface to be looped *from* the far end (remote device, Telco, etc.). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, all interfaces respond to remote loopbacks.

Command History

Release 6.1	Command was introduced.

Usage Examples

This example enables remote loopbacks on the T3 interface:

(config)**#interface t3 1/1**
(config-t3 1/1)**#remote-loopback**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high link data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.

Usage Examples

The following example disables the link-status trap on the T3 interface:

(config)**#interface t3 1/1**
(config-t3 1/1)**#no snmp trap link-status**

test-pattern

Use the **test-pattern** command to activate the built-in pattern generator and begin sending the selected test pattern toward the network. This pattern generation can verify a data path when used in conjunction with an active loopback. Use the **no** form of this command to cease pattern generation. Variations of this command include:

test-pattern clear
test-pattern errors
test-pattern insert
test-pattern ones
test-pattern p215
test-pattern p223
test-pattern zeros

Syntax Description

clear	Clears the test pattern error count.
errors	Displays the test pattern error count.
insert	Inserts an error into the currently active test pattern.
ones	Generates a test pattern of continuous ones.
p215	Generates a pseudorandom test pattern sequence based on a 15-bit shift register.
p223	Generates a pseudorandom test pattern sequence based on a 23-bit shift register.
zeros	Generates a test pattern of continuous zeros.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.

Usage Examples

The following example enables a **p215** test pattern:

(config)**#interface t3 1/1**
(config-t3 1/1)**#test-pattern p215**

T4 INTERFACE COMMAND SET

The T4 interface is used to supply configurable synchronous clock output for network synchronization (Network Sync). You can configure the output format and output squelch threshold for the interface. Enter the T4 interface configuration mode by entering the **interface** <*interface*> command from the Global Configuration mode as follows:

```
(config)#interface t4 0/1
(config-t4 0/1)#
```

The following command is common to multiple command sets and is covered in a centralized section of this guide. For more information, refer to the section listed below:

alias "<text>" on page 75
do on page 81
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

format on page 2492
minimum-ssm-ql <value> on page 2493

format

Use the **format** command to specify the output format for the clock. Use the **no** form of this command to return to the default output format. Variations of this command include:

format ds1 d4
format ds1 esf
format e12 cas
format e12 ccs
format t12

Syntax Description

ds1 ds4	Specifies a 1544 kbps synchronization interface (DS1-D4/DS1-SF).
ds1 esf	Specifies a 1544 kbps synchronization interface with extended superframing (DS1-ESF).
e12 cas	Specifies a 2048 kbps synchronization interface (E12) with channel associated signaling pulse code modulation 30 (CAS PCM30) framing.
e12 ccs	Specifies a 2048 kbps synchronization interface (E12) with common channel signaling pulse code modulation 31 (CCS PCM31) framing.
t12	Specifies a 2048 kHz synchronization interface (T12).

Default Values

By default, the format is set to **t12**.

Command History

Release R10.11.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **e12 cas** and **e12 ccs** parameters, and the hyphen was removed from the **ds1** parameters.

Usage Examples

The following example changes the clock output format to **e12**:

(config)**#interface t4 0/1**
(config-t4 0/1)**#format e12**

minimum-ssm-ql <*value*>

Use the **minimum-ssm-ql** command to specify a squelch level for the T4 interface output. When the quality level (QL) of the synchronization status message (SSM) received by the Network Ethernet synchronization message channel (ESMC) process is below this level, the output is squelched. Use the **no** form of this command to disable this feature, which results in the output never being squelched.

Syntax Description

<*value*>	Specifies the minimum level of the synchronization status message (SSM) for the output to be active. Refer to the **Functional Notes** of this command for specific details.

Default Values

By default, squelch is disabled. The output is always active.

Command History

Release R10.11.0	Command was introduced.
Release R11.7.0	Command was altered to remove the following parameters: **ql-dnu** for EEC Option 1 and **ql-dus**, **ql-prov**, and **ql-smc** for EEC Option 2.

Functional Notes

The various <*value*> parameters available for SSM override vary according to the Ethernet equipment clock (EEC) option selected in the network synchronization (Network Sync) configuration (refer to the command *eec-option on page 4437*). If you have not specified an EEC option, Option 2 is used by default. The following lists outline the <*value*> parameters for the **minimum-ssm-ql** command.

SSM Override Parameters for EEC Option 1

ql-eec1	Synchronous digital hierarchy (SDH) Equipment Clock (0xB)
ql-prc	Primary Reference Clock (0x2)
ql-ssu-a	First Level Synchronization Supply Unit (0x4)
ql-ssu-b	Second Level Synchronization Supply Unit (0x8)
<*input*>	Enter SSM as a decimal or hexadecimal value

SSM Override Parameters for EEC Option 2

ql-eec2	Stratum 3 Traceable (0xA)
ql-prs	Stratum 1 Traceable (0x1)
ql-st2	Stratum 2 Traceable (0x7)
ql-st3e	Stratum 3E Traceable (0xD)
ql-stu	Synchronized Traceability Unknown (0x0)

ql-tnc	Transit Node Clock Traceable (0x4)
<input>	Enter SSM as a decimal or hexadecimal value

The Network Sync command set and **esmc-process** must be active for squelch to operate. Refer to the Network Sync command set on *page 4434* and the **esmc-process** command on *page 4438* for more information.

When squelch is active, the output depends on the selected format, as follows:

Format:	**Output:**
format ds1 d4	T1 AIS (unframed, all ones)
format ds1 esf	T1 AIS (unframed, all ones)
format e12 cas	E1 AIS (unframed, all ones)
format e12 ccs	E1 AIS (unframed, all ones)
format t12	none

Usage Examples

The following example enables and configures the squelch threshold as EEC option 2 **ql-tnc**:

(config)**#interface t4 0/1**
(config-t4 0/1)**#minimum-ssm-ql ql-tnc**

VDSL INTERFACE COMMAND SET

To activate the Very High-Speed Digital Subscriber Line (VDSL) Interface Configuration mode, enter the **interface vdsl** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface vdsl 1/1
(config-vdsl 1/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

performance-statistics on page 2496

performance-statistics

Use the **performance-statistics** command to enable gathering performance monitoring statistics on the interface. Use the **no** form of this command to disable the performance monitoring feature.

Syntax Description

No subcommands.

Default Values

By default, performance monitoring is enabled.

Command History

Release 10.10.0	Command was introduced.
Release R11.2.0	Command expanded to include the very high-speed digital subscriber line (VDSL) interfaces.

Usage Examples

The following example enables performance monitoring on the vdsl interface **vdsl 1/1**:

(config)**#interface vdsl 1/1**
(config-vdsl 1/1)**#performance-statistics**

VIRTUAL INTERFACE COMMAND SETS

This section includes the following command sets:

ATM INTERFACE COMMAND SET

To create a virtual asynchronous transfer mode (ATM) interface and/or activate the ATM Interface Configuration mode, enter the **interface atm** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface atm 1
(config-atm 1)#
```

By default, ATM interfaces are created as point-to-point links. This default setting cannot be altered. The following command creates the exact same interface as that mentioned above:

```
>enable
#configure terminal
(config)#interface atm 1 point-to-point
(config-atm 1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

rtp quality-monitoring on page 2499
snmp trap on page 2500
snmp trap link-status on page 2501

rtp quality-monitoring

Use the **rtp quality-monitoring** command to enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets on this interface. If the global command (**ip rtp quality-monitoring**) is disabled when this command is issued, the system will return the following warning: "Applied but not used, you must globally enable **ip rtp quality-monitoring** to use VQM." Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, VQM is enabled on all wide area network (WAN) and local area network (LAN) interfaces.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables RTP quality monitoring on the asynchronous transfer mode (ATM) interface:

(config)**#interface atm 1**
(config-atm 1)**#rtp quality-monitoring**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.

Usage Examples

The following example enables SNMP on the ATM interface:

(config)**#interface atm 1**
(config-atm 1)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the ATM interface:

(config)**#interface atm 1**
(config-atm 1)**#no snmp trap link-status**

ATM SUBINTERFACE COMMAND SET

To create a virtual asynchronous transfer mode (ATM) subinterface and/or activate the ATM Subinterface Configuration mode, enter the **interface atm** command (and specify a subinterface) at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface atm 1.1
(config-atm 1.1)#
```

By default, ATM subinterfaces are created as point-to-point links. This default setting cannot be altered. The following command creates the exact same interface as that mentioned above:

```
>enable
#configure terminal
(config)#interface atm 1.1 point-to-point
(config-atm 1.1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

atm routed-bridged ip on page 2504
bandwidth <value> on page 2505
bridge-group <value> on page 2506
cos on page 2507
dial-backup commands begin on page 2508
dynamic-dns on page 2525
encapsulation on page 2527
fair-queue on page 2528
hold-queue <value> out on page 2529
ip commands begin on page 2530
ipv6 dhcp relay destination <ipv6 address> on page 2575

atm routed-bridged ip

Use the **atm routed-bridged ip** command to enable IP routed bridge encapsulation (RBE) on an interface. Use the **no** form of this command to disable RBE operation.

Syntax Description

No subcommands.

Default Values

By default, RBE is disabled.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example enables RBE:

(config)**#interface atm 1.1**
(config-atm 1.1)**#atm routed-bridged ip**

bandwidth *<value>*

Use the **bandwidth** command to provide the bandwidth value of an interface to the higher level protocols. This value is used in cost calculations. Use the **no** form of this command to restore the default value.

Syntax Description

<value>	Specifies bandwidth in kbps. Range is **1** to **4294967295** kbps.

Default Values

To view the default values, use the **show interfaces** command.

Command History

Release 3.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

The **bandwidth** command is an informational value that is communicated to the higher level protocols to be used in cost calculations. While this is a routing parameter that does not affect the physical interface, it does affect the amount of bandwidth available for use in Quality of Service (QoS) configurations.

It is important to note that there is an order of precedence in determining the interface bandwidth reported by the router for QoS. Under normal circumstances, the Layer 1 bandwidth is reported based on the interface type. For example, a T1 interface will report the available bandwidth as 1.536 Mbps. This can be misleading in QoS configurations if the **bandwidth** command has been applied to the IP interface for routing purposes because the command overrides the reported available bandwidth that can be utilized for QoS. Using the **bandwidth** command can severely disrupt the configuration of QoS on the interface, therefore, use the **max-reserved-bandwidth** command (*page 2576*) to adjust the bandwidth appropriately for QoS configurations.

Usage Examples

The following example sets bandwidth of the ATM subinterface to 10 Mbps:

(config)**#interface atm 1.1**
(config-atm 1.1)**#bandwidth 10000**

bridge-group *<value>*

Use the **bridge-group** command to assign an interface to the specified bridge group. Use the **no** form of this command to remove the interface from the bridge group.

Syntax Description

<value>	Specifies the bridge group (by number) to which to assign this interface. Range is **1** to **255**.

Default Values

By default, there are no configured bridge groups.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

A bridged network can provide excellent traffic management to reduce collisions and limit the amount of bandwidth wasted with unnecessary transmissions when routing is not necessary. Any two interfaces can be bridged (Ethernet to T1, Ethernet to Frame Relay subinterface).

Usage Examples

The following example assigns the ATM subinterface labeled **1.1** to bridge group **1**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#bridge-group 1**

cos

Use the **cos** command to define class of service (CoS) settings on an asynchronous transfer mode (ATM) subinterface. Use the **no** form of this command to remove the parameters. Variations of this command include:

cos ubr
cos vbr-nrt <*pcr*> <*scr*> <*mbs*>
cos vbr-rt <*pcr*> <*scr*> <*mbs*>

Syntax Description

ubr	Indicates unspecified bit rate (UBR) for the CoS.
vbr-nrt	Specifies the variable bit rate (VBR) nonreal time (NRT) peak cell rate (PCR), sustained cell rate (SCR), and maximum burst size (MBS).
vbr-rt	Specifies the variable bit rate real time (RT) peak cell rate, sustained cell rate, and maximum burst size.
<*pcr*>	Indicates the peak cell rate or maximum number of cells per second the connection can transfer into the network. Valid range is **32** to **50000** kbps.
<*scr*>	Indicates the sustained cell rate or average number of cells per second that the connection can transfer into the network. Valid range is **32** to **50000** kbps.
<*mbs*>	Indicates the maximum burst size of cells allowed on the connection. Valid range is **3** to **65535**.

Default Values

The default setting for this feature is **cos ubr**.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example defines variable bit rate real time on the ATM subinterface 1.2:

(config)**#interface atm 1.2 point-to-point**
(config-atm 1.2)**#no shutdown**
(config-atm 1.2)**#pvc 1/101**
(config-atm 1.2)**#ip address 10.23.107.35 255.255.255.240**
(config-atm 1.2)**#COS VBR-rt 2304 1024 3**
(config-atm 1.2)**#bandwidth 2304**

dial-backup auto-backup

Use the **dial-backup auto-backup** command to configure the subinterface to automatically attempt a dial backup upon failure. Use the **no** form of this command to disable this feature. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2511*.

Syntax Description

No subcommands.

Default Values

By default, all backup endpoints will automatically attempt dial backup upon a failure.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example enables automatic dial backup on the endpoint:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup auto-backup**

dial-backup auto-restore

Use the **dial-backup auto-restore** command to configure the subinterface to automatically discontinue dial backup when all network conditions are operational. Use the **no** form of this command to disable the auto-restore feature. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2511*.

Syntax Description

No subcommands.

Default Values

By default, all backup endpoints will automatically restore the primary connection when the failure condition clears.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example configures AOS to automatically restore the primary connection when the failure condition clears:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup auto-restore**

dial-backup backup-delay *<value>*

Use the **dial-backup backup-delay** command to configure the amount of time the router will wait after the failure condition is recognized before attempting to backup the link. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2511*.

Syntax Description

<value>	Specifies the delay period (in seconds) a failure must be active before AOS will enter backup operation on the interface. Valid range is **10** to **86400** seconds.

Default Values

By default, the **dial-backup backup-delay** period is set to **10** seconds.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example configures AOS to wait **60** seconds (on an endpoint with an active alarm condition) before attempting dial-backup operation:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup backup-delay 60**

dial-backup call-mode

Use the **dial-backup call-mode** command to specify whether the configured backup interface answers or originates (or a combination of both) backup calls. Use the **no** form of this command to return to the default value. Variations of this command include:

dial-backup call-mode answer
dial-backup call-mode answer-always
dial-backup call-mode originate
dial-backup call-mode originate-answer
dial-backup call-mode originate-answer-always

Syntax Description

answer	Answers and backs up primary link on failure.
answer-always	Answers and backs up regardless of primary link state.
originate	Originates backup call on primary link failure.
originate-answer	Originates or answers call on primary link failure.
originate-answer-always	Originates on failure; answers and backs up always.

Default Values

By default, the **dial-backup call-mode** is set to **originate-answer**.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

The majority of the configuration for AOS dial-backup implementation is configured via the dial-backup Point-to-Point Protocol (PPP) interface configuration commands. However, the numbers dialed are configured in the primary interface. Full sample configurations follow:

Sample configuration for remote router (dialing out)

```
hostname “Remote3200”
enable password adtran
!
interface eth 0/1
 ip address 192.168.1.254 255.255.255.0
 no shutdown
!
interface modem 1/3
 no shutdown
!
interface t1 1/1
```

```
 coding b8zs
 framing esf
 clock source line
 tdm-group 1 timeslots 1-24
 no shutdown
!
interface fr 1 point-to-point
 frame-relay lmi-type ansi
 no shutdown
 cross-connect 1 t1 1/1 1 fr 1
!
interface fr 1.16 point-to-point
 frame-relay interface-dlci 16
 ip address 10.1.1.2 255.255.255.252
 dial-backup call-mode originate
 dial-backup number 5551111 analog ppp1
 dial-backup number 5552222 analog ppp1
no shutdown
!
interface ppp 1
 ip address 172.22.56.1 255.255.255.252
 ppp authentication chap
 username remoter outer password remoteness
 ppp chap hostname local router
 ppp chap password adtran
 no shutdown
!
ip route 192.168.2.0 255.255.255.0 172.22.56.2 255.255.255.252
!
line telnet 0 4
 password password
```

Sample configuration for central router (dialing in)

```
hostname “Central3200”
enable password adtran
!
interface eth 0/1
 ip address 192.168.100.254 255.255.255.0
 no shutdown
!
interface modem 1/3
 no shutdown
!
interface t1 1/1
 coding b8zs
 framing esf
 clock source line
```

```
 tdm-group 1 timeslots 1-24
 no shutdown
!
interface fr 1 point-to-point
 frame-relay lmi-type ansi
 no shutdown
 cross-connect 1 t1 1/1 1 fr 1
!
interface fr 1.100 point-to-point
 frame-relay interface-dlci 100
 ip address 10.1.1.1 255.255.255.252
 dial-backup call-mode answer
 dial-backup number 555-8888 analog ppp 1
!
interface ppp 1
 ip address 172.22.56.2 255.255.255.252
 ppp authentication chap
 username local router password adtran
 ppp chap hostname remote router
 ppp chap password remoteness
 no shutdown
!
ip route 192.168.1.0 255.255.255.0 172.22.56.1 255.255.255.252

line telnet 0 4
 password password
```

Usage Examples

The following example configures AOS to generate backup calls for this endpoint using an analog modem interface (to phone number 555 1111), but never answer calls and specifies **ppp 2** as the backup interface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup call-mode originate**
(config-atm 1.1)**#dial-backup number 555 1111 analog ppp 2**

Technology Review

This technology review provides information regarding specific dial-backup router behavior (i.e., when the router will perform dial backup, where in the configuration AOS accesses specific routing information, etc.):

Dialing Out

1. AOS determines to place an outbound call when either the Layer 1 or Layer 2 has a failure.
2. When placing outbound calls, AOS matches the number dialed to a PPP interface. This is accomplished with an addition to the **dial-backup number** command (refer to *dial-backup number on page 2518*).
3. When placing the call, AOS uses the configuration of the related PPP interface for authentication and IP negotiation.
4. If the call fails to connect on the first number dialed, AOS places a call to the second number (if a second number is configured). The second number to be dialed references a separate PPP interface.

Dialing In

1. AOS receives an inbound call on a physical interface.
2. Caller ID is used to match the **dial-backup number** command to the configured PPP interface.
3. If a match is found, the call connects and AOS pulls down the primary connection if it is not already in a down state.
4. If no match is found from caller ID, the call is terminated.

dial-backup connect-timeout <*value*>

Use the **dial-backup connect-timeout** command to specify the number of seconds to wait for a connection after a call is attempted before trying to call again or dialing a different number. It is recommended this number be greater than 60. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2511*.

Syntax Description

<*value*>	Specifies the amount of time (in seconds) that the router will wait for a connection before attempting another call. Valid range is **10** to **300** seconds.

Default Values

By default, the **dial-backup connect-timeout** period is set to **60** seconds.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example configures AOS to wait **120** seconds before retrying a failed dial-backup call:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup connect-timeout 120**

dial-backup force

Use the **dial-backup force** command to manually override the automatic dial-backup feature. This can be used to force a link into backup to allow maintenance to be performed on the primary link without disrupting data. Use the **no** form of this command to return to the normal dial-backup operation state. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2511*. Variations of this command include:

dial-backup force backup
dial-backup force primary

Syntax Description

backup	Forces backup regardless of primary link state.
primary	Forces primary link regardless of its state.

Default Values

By default, this feature is disabled.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example configures AOS to force this endpoint into dial backup:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup force backup**

dial-backup maximum-retry <*value*>

Use the **dial-backup maximum-retry** command to select the number of calls the router will make when attempting to backup a link. Use the **no** form of this command to return to the default state. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2511*.

Syntax Description

<*value*>	Selects the number of call retry attempts that will be made after a link failure. Valid range is **0** to **15** attempts. Setting this value to 0 will allow unlimited retries during the time the network is failed.

Default Values

By default, the **dial-backup maximum-retry** period is set to **0** attempts.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example configures AOS to retry a dial-backup call **4** times before considering backup operation not available:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup maximum-retry 4**

dial-backup number

Use the **dial-backup number** command to configure the phone number and the call type the router will dial upon network failure. Multiple entries can be made for an interface to allow alternate sites to be dialed. Use the **no** form of this command to disable this feature. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2511*. Variations of this command include:

dial-backup number <*number*> **analog ppp** <*interface*>
dial-backup number <*number*> **digital-56k** <*isdn min chan*> <*isdn max chan*> **ppp** <*interface*>
dial-backup number <*number*> **digital-64k** <*isdn min chan*> <*isdn max chan*> **ppp** <*interface*>

Syntax Description

<*number*>	Specifies the phone numbers to call when the backup is initiated.
analog	Indicates the number connects to an analog modem.
digital-56k	Indicates the number belongs to a digital 56 kbps per DS0 connection.
digital-64k	Indicates the number belongs to a digital 64 kbps per DS0 connection.
<*isdn min chan*>	Specifies the minimum number of DS0s required for a digital 56 or 64 kbps connection. Range is **1** to **24** DS0s.
<*isdn max chan*>	Specifies the maximum number of DS0s desired for a digital 56 or 64 kbps connection. Range is **1** to **24** DS0s.
ppp <*interface*>	Specifies the Point-to-Point Protocol (PPP) interface to use as the backup for this interface (for example, **ppp 1**).

Default Values

By default, there are no configured dial-backup numbers.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.
Release 17.2	Command was expanded to include the cellular connections.
Release 17.3	Cellular connections were removed from this command.

Usage Examples

The following example configures AOS to dial **704-555-1212** (digital 64 kbps connection) to initiate dial-backup operation for this endpoint using the configured **ppp 1** backup interface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup number 7045551212 digital-64k 1 1 ppp 1**

dial-backup priority <*value*>

Use the **dial-backup priority** command to select the backup priority for this interface. This allows the user to establish the highest priority backup link and ensure that link will override backups attempted by lower priority links. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2511*.

Syntax Description

<*value*>	Sets the relative priority to this link. Valid range is **0** to **100**. A value of **100** designates the highest priority.

Default Values

By default, the **dial-backup priority** is set to **50**.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example assigns the highest priority to this endpoint:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup priority 100**

dial-backup randomize-timers

Use the **dial-backup randomize-timers** command to randomize the call timers to minimize potential contention for resources. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2511*.

Syntax Description

No subcommands.

Default Values

By default, AOS does not randomize the dial-backup call timers.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example configures AOS to randomize the dial-backup timers associated with this endpoint:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup randomize-timers**

dial-backup redial-delay <*value*>

Use the **dial-backup redial-delay** command to configure the delay after an unsuccessful call until the call will be re-tried. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2511*.

Syntax Description

<*value*>	Specifies the delay (in seconds) between attempting to redial a failed backup attempt. Valid range is **10** to **3600** seconds.

Default Values

By default, the **dial-backup redial-delay** period is set to **10** seconds.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example configures a redial delay of **25** seconds on this endpoint:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup redial-delay 25**

dial-backup restore-delay *<value>*

Use the **dial-backup restore-delay** command to configure the amount of time the router will wait after the network is restored before disconnecting the backup link and reverting to the primary. This setting is used to prevent disconnecting the backup link if the primary link is bouncing in and out of alarm. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2511*.

Syntax Description

<value>	Specifies the number of seconds AOS will wait (after a primary link is restored) before disconnecting dial-backup operation. Range is **10** to **86400** seconds.

Default Values

By default, the **dial-backup restore-delay** period is set to **10** seconds.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example configures AOS to wait **30** seconds before disconnecting dial-backup operation and restoring the primary connection for this endpoint:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup restore-delay 30**

dial-backup schedule

Use the **dial-backup schedule** command to set the time of day that backup will be enabled. Use this command if backup is desired only during normal business hours and on specific days of the week. Use the **no** form of this command to disable dial backup (as specified). For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2511*. Variations of this command include:

dial-backup schedule day <*name*>
dial-backup schedule enable-time <*value*>
dial-backup schedule disable-time <*value*>

Syntax Description

day <*name*>	Sets the days to allow backup. Valid range is Monday through Sunday.
enable-time <*value*>	Sets the time of day to enable backup. Time is entered in a 24-hour format (00:00).
disable-time <*value*>	Sets the time of day to disable backup. Time is entered in a 24-hour format (00:00).

Default Values

By default, dial backup is enabled for all days and times if the **dial-backup auto-backup** command has been issued and the dial-backup schedule has not been entered.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example enables dial backup Monday through Friday 8:00 a.m. to 7:00 p.m.:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup schedule enable-time 08:00**
(config-atm 1.1)**#dial-backup schedule disable-time 19:00**
(config-atm 1.1)**#no dial-backup schedule day Saturday**
(config-atm 1.1)**#no dial-backup schedule day Sunday**

dial-backup shutdown

Use the **dial-backup shutdown** command to deactivate all dial-backup functionality in the unit. Dial-backup configuration parameters are kept intact, but the unit will not initiate (or respond) to dial-backup sequences in the event of a network outage. Use the **no** form of this command to reactivate the dial-backup interface. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2511*.

Syntax Description

No subcommands.

Default Values

By default, all AOS interfaces are disabled.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example deactivates the configured dial-backup interface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dial-backup shutdown**

dynamic-dns

Use the **dynamic-dns** command to configure Dynamic DNS service provided by Dynamic Network Services, Inc. (www.dyndns.org). Use the **no** form of this command to disable this feature. Variations of this command include:

dynamic-dns custom <*hostname*> <*minutes*>
dynamic-dns dyndns <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-custom <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-static <*hostname*> <*username*> <*password*>

Syntax Description

<*hostname*>	Specifies the host name for the server that updates the dynamic domain naming system (DNS).
<*minutes*>	Specifies the intervals in minutes to update the server with information (updates also occur when the interface's IP address changes regardless of the update intervals).
<*username*>	Specifies the user name.
<*password*>	Specifies the password.
	Refer to *Functional Notes* below for additional argument descriptions.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.
Release 12.1	Command was expanded.

Functional Notes

custom - Constanttime.com's Custom Dynamic DNS^{SM} service allows you complete access and management control over your domain name regardless of where you purchased/registered it. This allows you to manage IP address mappings (A records), domain aliases (CNAME records), and mail servers (mail exchange (MX) records).

dyndns - The Dynamic DNS^{SM} offered by Dynamic Network Services, Inc. (DynDNS.org) allows you to alias a dynamic IP address to a static host name in various domains. This allows your unit to be more easily accessed from various locations on the Internet. This service is provided for up to five host names.

dyndns-custom - DynDNS.org's Custom DNS^{SM} service provides a full DNS solution, giving you complete control over an entire domain name. A Web-based interface provides two levels of control over your domain, catering to average or advanced users. Five globally redundant DNS servers ensure that your domain will always resolve.

A choice of two interfaces is available. The basic interface is designed for most users. It comes preconfigured for most common configurations and allows for easy creation of most common record types. The advanced interface is designed for system administrators with a solid DNS background, and provides layout and functionality similar to a BIND zone file allowing for the creation of nearly any record type.

Custom DNS^{SM} can be used with both static and dynamic IPs, and has the same automatic update capability through Custom DNS-aware clients as Dynamic DNS.

dyndns-static - The Static DNS service is similar to DynDNS.org's Dynamic DNS^{SM} service in that it allows a host name, such as yourname.dyndns.org, to point to your IP address. Unlike a Dynamic DNS host, a Static DNS host does not expire after 35 days without updates, but updates take longer to propagate through the DNS system. This service is provided for up to five host names.

If your IP address does not change often or at all, but you still want an easy name to remember it by (without having to purchase your own domain name), Static DNS service is ideal for you.

If you would like to use your own domain name (such as yourname.com), you need Custom DNS service that also provides full dynamic and static IP address support.

Usage Examples

The following example sets the Dynamic DNS to **dyndns-custom** with host name **host**, user name **user**, and password **pass**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#dynamic-dns dyndns-custom host user pass**

encapsulation

Use the **encapsulation** command to configure the encapsulation type for the ATM Adaptation Layer (AAL) of the Asynchronous Transfer Mode (ATM) Protocol Reference Model. Use the **no** form of this command to return to the default setting. Variations of this command include:

encapsulation aal5mux ip
encapsulation aal5mux ppp
encapsulation aal5snap

Syntax Description

aal5mux ip	Specifies encapsulation type for multiplexed virtual circuits using the IP protocol.
aal5mux ppp	Specifies encapsulation type for multiplexed virtual circuits using the Point-to-Point Protocol (PPP).
aal5snap	Specifies encapsulation type that supports LLC/SNAP protocols.

Default Values

By default, the encapsulation type is **aal5snap**.

Command History

Release 8.1	Command was introduced.

Functional Notes

For PPP and Point-to-Point Protocol over Ethernet (PPoE), the encapsulation type can be **aal5snap** or **aal5mux ppp**. For IP with no bridging, the encapsulation type can be **aal5snap** or **aal5mux ip**. For IP with bridging, the encapsulation type can only be **aal5snap**. For bridging, the encapsulation type can only be **aal5snap**.

Usage Examples

The following example sets the encapsulation type to **aal5snap**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#encapsulation aal5snap**

fair-queue

Use the **fair-queue** command to enable weighted fair queuing (WFQ) on an interface. Use the **no** form of this command to disable WFQ and enable first in, first out (FIFO) queueing for an interface. Variations of this command include:

fair-queue
fair-queue <*value*>

WFQ must be enabled on an interface to use priority queuing. By default, WFQ is enabled for all interfaces with maximum bandwidth speeds equivalent to T1/E1 and below.

Syntax Description

<*value*>	Optional. Value that specifies the maximum number of packets that can be present in each conversation subqueue. Packets received for a conversation after this limit is reached are discarded. Range is **16** to **512** packets.

Default Values

By default, **fair-queue** is enabled with a threshold of **64** packets.

Command History

Release 5.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example enables WFQ on the interface with a threshold set at **100** packets:

(config)**#interface atm 1.1**
(config-atm 1.1)**#fair-queue 100**

hold-queue <*value*> out

Use the **hold-queue out** command to change the overall size of an interface's wide area network (WAN) output queue. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	The total number of packets the output queue can contain before packets are dropped. Range is **16** to **1000** packets.

Default Values

The default queue size for weighted fair queuing (WFQ) is **400**. The default queue size for Point-to-Point Protocol (PPP) first in, first out (FIFO) and Frame Relay round-robin is **200**.

Command History

Release 5.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example sets the overall output queue size to **700**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#hold-queue 700 out**

ip access-group *<ipv4 acl name>*

Use the **ip access-group** command to create an Internet Protocol version 4 (IPv4) access control list (ACL) to be used for packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ip access-group *<ipv4 acl name>* **in**
ip access-group *<ipv4 acl name>* **out**

Syntax Description

<ipv4 acl name>	Specifies the assigned IPv4 ACL name.
in	Enables access control on packets received on the specified interface.
out	Enables access control on packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 3.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

When this command is enabled, the IPv4 destination address of each packet must be validated before being passed through. If the packet is not acceptable per these settings, it is dropped.

Usage Examples

The following example sets up the router to only allow Telnet traffic into the ATM subinterface:

(config)**#ip access-list extended TelnetOnly**
(config-ext-nacl)**#permit tcp any any eq telnet**
(config-ext-nacl)**#interface atm 1.1**
(config-atm 1.1)**#ip access-group TelnetOnly in**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to an interface. IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

> NOTE *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an interface.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the Ethernet interface 0/1:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the ATM interface 1.1:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip access-policy PRIVATE**

ip address dhcp

Use the **ip address dhcp** command to use Dynamic Host Configuration Protocol (DHCP) to obtain an address on the interface. Use the **no** form of this command to remove a configured IP address (using DHCP) and disable DHCP operation on the interface. Variables that may be used with this command to further define the DHCP configuration include:

ip address dhcp class-id [ascii <*string*> **| hex** <*value*>**] [client-id [**<*interface*> **|** <*identifier*>**]] [hostname** <*"string"*>**] [track** <*name*>**] [**<*administrative distance*>**]**
ip address dhcp client-id [<*interface*> **|** <*identifier*>**] [hostname** <*"string"*>**] [track** <*name*>**] [**<*administrative distance*>**]**
ip address dhcp hostname *"*<*string*>*"* **[no-default-route | no-domain-name | no-nameservers] [track** <*name*>**] [**<*administrative distance*>**]**
ip address dhcp [no-default-route | no-domain-name | no-nameservers] [track <*name*>**] [**<*administrative distance*>**]**
ip address dhcp track <*name*> **[**<*administrative distance*>**]**

Syntax Description

<*administrative distance*>	Optional. Specifies the administrative distance to use when adding the DHCP gateway into the route table. It is used to determine the best route when multiple routes to the same destination exist. The lower the administrative distance, the more reliable the route. Range is **1** to **255**.
class-id	Optional. Specifies the vendor class identifier for the interface.
ascii <*string*>	Specifies the vendor class identifier in an ASCII string of up to **255** bytes.
hex <*value*>	Specfies the vendor class identifier in hexadecimal format. Valid range is up to **510** hexadecimal numbers. An even number of digits is required.
client-id	Optional. Specifies the client identifier used when obtaining an IP address from a DHCP server.
<*interface*>	Specifies an interface, thus defining the client identifier as the hexadecimal medium access control (MAC) address of the specified interface (including a hexadecimal number added to the front of the MAC address to identify the media type). For example, specifying the **client-id ethernet 0/1** (where the Ethernet interface has a MAC address of d217.0491.1150) defines the client identifier as **01:d2:17:04:91:11:50** (where 01 defines the media type as Ethernet). Refer to *hardware-address on page 4344* for a detailed listing of media types.
<*identifier*>	Specifies a custom client-identifier using a text string (that is converted to a hexadecimal equivalent) or 7 to 28 hexadecimal numbers (with colon delimiters). For example, a custom client identifier of **0f:ff:ff:ff:ff:51:04:99:a1** may be entered using the <*identifier*> option.
hostname <*"string"*>	Optional. Specifies a text string (to override the global router name) to use as the name in the DHCP option 12 field. The string is enclosed in quotation marks and can consist of up to 35 characters.

no-default-route Optional. Specifies that no default route is obtained via DHCP.

no-domain-name Optional. Specifies that no domain name is obtained via DHCP.

no-nameservers Optional. Specifies that no domain naming system (DNS) servers are obtained via DHCP.

track *<name>* Optional. Attaches a network monitoring track to the DHCP client. The DHCP gateway route for this client will only reside in the route table while the track is in the pass state. For more information on configuring track objects, refer to *track <name> on page 1886*.

Default Values

<administrative distance> By default, the administrative distance value is 1.

class-id Optional. By default, no vendor class identifier is configured.

client-id Optional. By default, the client identifier is populated using the following formula:

TYPE: INTERFACE SPECIFIC INFO : MAC ADDRESS

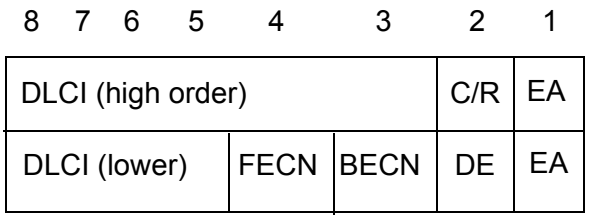
Where TYPE specifies the media type in the form of one hexadecimal byte (refer to *hardware-address on page 4344* for a detailed listing of media types), and the MAC ADDRESS is the medium access control (MAC) address assigned to the first Ethernet interface in the unit in the form of six hexadecimal bytes. (For units with a single Ethernet interface, the MAC ADDRESS assigned to Ethernet 0/1 is used in this field.)

INTERFACE SPECIFIC INFO is only used for Frame Relay interfaces and can be determined using the following:

FR_PORT#: Q.922 ADDRESS

Where the FR_PORT# specifies the label assigned to the virtual Frame Relay interface using four hexadecimal bytes. For example, a virtual Frame Relay interface labeled 1 would have a FR_PORT# of 00:00:00:01.

The Q.922 ADDRESS field is populated using the following:



Where the FECN, BECN, C/R, DE, and high order extended address (EA) bits are assumed to be 0 and the lower order EA bit is set to 1.

The following list provides a few example DLCIs and associated Q.922 address:

DLCI (decimal) / Q.922 address (hex)

16 / 0x0401
50 / 0x0C21
60 / 0x0CC1
70 / 0x1061
80 / 0x1401

hostname *“<string>”* By default, the host name is the name configured using the Global Configuration **hostname** command.

Command History

Release 2.1	Command was introduced.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 13.1	Command was expanded to include the track and administrative distance.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.10.0	Command was expanded to include the **class-id** parameter in support of DHCP Option 60.

Functional Notes

DHCP allows interfaces to acquire a dynamically assigned IP address from a configured DHCP server on the network. Many service providers require the use of DHCP when connecting to their services. Using DHCP reduces the number of dedicated IP addresses the ISP must obtain. Consult your ISP to determine the proper values for the **client-id** and **hostname** fields.

The vendor class identifier is sent to the DHCP server in DHCP discover and request messages via DHCP Option 60. This option gives the DHCP server details regarding DHCP client configuration and also allows the server to send any vendor-specific information to the client in DHCP offer messages via Option 43.

Usage Examples

The following example enables DHCP operation on the interface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip address dhcp**

The following example enables DHCP operation on the interface utilizing host name **adtran** and does not allow obtaining a default route, domain name, or name servers. It also sets the administrative distance as **5**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip address dhcp hostname “adtran” no-default-route no-domain-name no-nameservers 5**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the specified interface. Use the optional **secondary** keyword to define a secondary IPv4 address. Use the **no** form of this command to remove a configured IPv4 address. Variations of this command include:

ip address <*ipv4 address*> <*subnet mask*>
ip address <*ipv4 address*> <*subnet mask*> **secondary**

Syntax Description

<ipv4 address>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the specified interface.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a secondary IPv4 address of **192.22.72.101 255.255.255.252**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip address 192.22.72.101 255.255.255.252 secondary**

ip address range *<start ip address> <end ip address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the specified interface. Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip crypto map *<name>*

Use the **ip crypto map** command to associate Internet Protocol version 4 (IPv4) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

When you apply a map to an interface, you are applying all crypto maps with the given map name. This allows you to apply multiple crypto maps if you have created maps that share the same name, but have different map index numbers.

Syntax Description

<name>	Specifies the IPv4 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

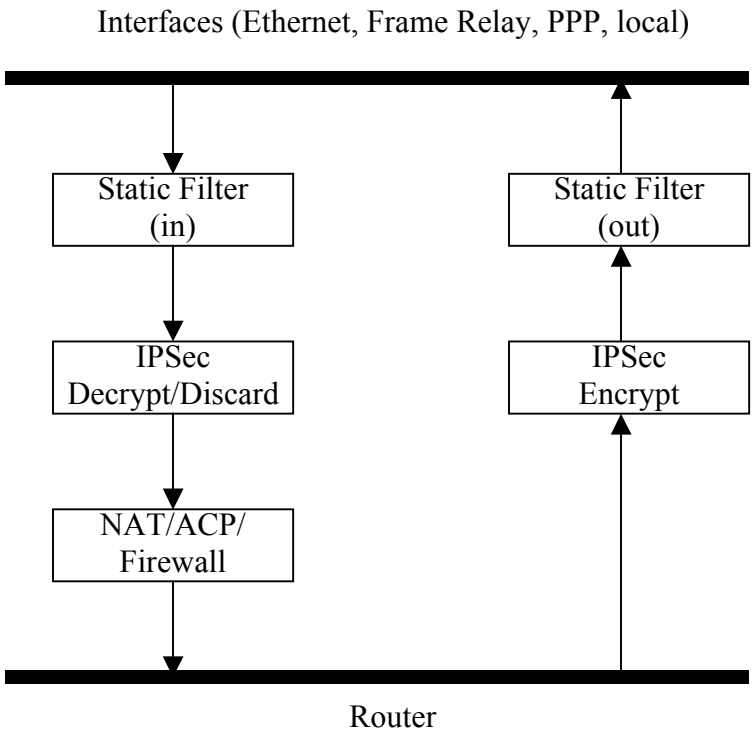
Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 9.1	Command was expanded to include the High-Levell Data Link Control (HDLC) interface.
Release 11.1	Command was expanded to include the demand interface.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.7.0	Command syntax was changed to require the **ip** keyword.

Functional Notes

When configuring a system to use both the stateful inspection firewall and Internet key exchange (IKE) negotiation for VPN, keep the following notes in mind.

When defining the IPv4 policy class and associated access control lists (ACLs) that describe the behavior of the IPv4 firewall, do not forget to include the traffic coming into the system over a VPN tunnel terminated by the system. The firewall should be set up with respect to the unencrypted traffic that is destined to be sent or received over the VPN tunnel. The following diagram represents typical AOS data-flow logic.



As shown in the diagram above, data coming into the product is first processed by the static filter associated with the interface on which the data is received. This access group is a true static filter and is available for use regardless of whether the IPv4 firewall is enabled or disabled. Next (if the data is encrypted), it is sent to the IPSec engine for decryption. The decrypted data is then processed by the stateful inspection firewall. Therefore, given a terminating VPN tunnel, only unencrypted data is processed by the firewall.

The IPv4 ACLs for a crypto map on an interface work in reverse logic to the ACLs for a policy class on an interface. When specifying the ACLs for a crypto map, the source information is the private local side, unencrypted source of the data. The destination information will be the far-end, unencrypted destination of the data. However, ACLs for a policy class work in reverse. The source information for the ACL in a policy class is the far end. The destination information is the local side.

Usage Examples

The following example applies all IPv4 crypto maps with the name **MyMap** to the interface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip crypto map MyMap**

ip dhcp

Use the **ip dhcp** command to release or renew the Dynamic Host Configuration Protocol (DHCP) Internet Protocol version 4 (IPv4) address. This command is only applicable when using DHCP for IP address assignment. Variations of this command include:

ip dhcp release
ip dhcp renew

Syntax Description

release	Releases the DHCP IPv4 address.
renew	Renews the DHCP IPv4 address.

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.
Release 8.1	Command was added to the asynchronous transfer mode (ATM) subinterface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release R10.1.0	Command was added to the bridged virtual interface (BVI).

Usage Examples

The following example releases the IPv4 DHCP address for the ATM subinterface 1.1:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip dhcp release**

ip dhcp relay destination *<ipv4 address>*

Use the **ip dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 4 (IPv4) and to specify the IPv4 address for the DHCPv4 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv4 relay functionality is disabled on the interface.

Syntax Description

<ipv4 address>	Specifies the IPv4 address for the DHCPv4 messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.

Usage Examples

The following example enables DHCPv4 relay agent functionality and specifies the destination address as **192.33.4.251**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip dhcp relay destination 192.33.4.251**

ip directed-broadcast

Use the **ip directed-broadcast** command to allow reception/forwarding of directed broadcasts. Use the **no** form of this command to disable this feature. Variations of this command include:

ip directed-broadcast
ip directed-broadcast *<name>*

Syntax Description

<name>	Specifies IP access control list (ACL) name.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.

Functional Notes

A directed broadcast is a packet intended for all nodes on a nonlocal network. For example, the broadcast address 255.255.255.255 reaches all nodes on a network; the directed broadcast address 128.1.255.255 is intended for all nodes whose network address is 128.1.0.0. A router not directly attached to 128.1.0.0 simply forwards the directed broadcast packet to the next hop. A router on network 128.1.0.0 that has **ip directed-broadcast** enabled, accepts and forwards the packet to all nodes whose network address is 128.1.0.0. Routers connecting subnets of 128.1.0.0 also accept and forward the packet to the nodes on their respective subnets. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is distributed as a broadcast on the destination subnet. The packet is then sent as a link-layer broadcast.

The **ip directed-broadcast** command controls the distribution of directed broadcasts when they reach their target subnets. Only the final transmission of the directed broadcast on its ultimate destination subnet is affected. It does not affect the transit unicast routing of IP directed broadcasts.

If **ip directed-broadcast** is enabled for this interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which this interface is attached will be forwarded as broadcasts on that subnet. Forwarding of the packets can be limited by specifying an ACL with this command. In this case, only directed broadcasts that are permitted by the specified ACL will be forwarded, and all other directed broadcasts directed to this interface subnet will be dropped.

Disabling the **ip directed-broadcast** command will cause directed broadcasts destined for the subnet to which this interface is attached to be dropped.

This option is a requirement for routers as described in RFC 1812, section 4.2.2.11. Furthermore, it is disabled by default (RFC 2644), with the intended goal of reducing the efficacy of certain types of denial of service (DoS) attacks.

Usage Examples

The following example enables forwarding of directed broadcasts on the interface **atm 1.1**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip directed-broadcast**

ip ffe

Use the **ip ffe** command to enable the RapidRoute Engine on this interface with the default number of entries. Use the **no** form of this command to disable this feature. Variations of this command include:

ip ffe
ip ffe max-entries <*value*>

Issuing this command will cause all RapidRoute entries on this interface to be cleared.

Syntax Description

max-entries <*value*>	Optional. Specifies the maximum number of entries stored in the flow table. Valid range is from **1** to **8192**.

Default Values

By default, the RapidRoute Engine is disabled. The default number of **max-entries** is **4096**.

Command History

Release 13.1	Command was introduced.
Release 17.6	Command was expanded to include the high level data link control (HDLC) and tunnel interfaces.

Functional Notes

RapidRoute can be used to help reduce routing overhead, and thus reduce overall routing times. Routing times are reduced by the creation of a flow table on the ingress interface. The maximum number of entries that can be stored in the flow table at any one time may be specified by using the **max-entries** parameters.

Usage Examples

The following example enables RapidRoute and sets the maximum number of entries in the flow table to **50**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip ffe max-entries 50**

Technology Review

The RapidRoute system goal is to increase IP packet throughput by moving as much of the packet processing into the engine as possible. Packets are classified into flows based upon the IP protocol (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol (ICMP), etc.), the source and destination IP addresses, IP type of service (ToS), and the protocol-specific information, such as the source and destination port numbers. Flows are defined as the unidirectional representation of a conversation between two IP hosts. Each ingress interface keeps its own flow table, a collection of flow entries.

The first packet in a flow that is forwarded through the unit will build a flow entry. When a flow entry is looked up but no entry is found, a RapidRouteBuilder object is allocated and attached to the packet. As the packet passes through the various processing layers, each subsystem will add processing to the RapidRouteBuilder. When packet is about to be forwarded out of the egress interface, the RapidRouteBuilder will be finalized. That is, the flow entry being built will be checked for completeness and committed to the flow table on the ingress interface. Subsequent flow matches can then bypass the normal processing layers.

ip flow

Use the **ip flow** command to enable integrated traffic monitoring (ITM) for all traffic received or forwarded on an interface. Use the **no** form of this command to disable traffic monitoring. Variations of this command include:

ip flow egress
ip flow egress <*name*>
ip flow ingress
ip flow ingress <*name*>

Syntax Description

egress	Specifies that all outgoing traffic be monitored.
ingress	Specifies that all incoming traffic be monitored.
<*name*>	Optional. Specifies the name of an access control list (ACL) to use for filtering traffic.

Default Values

By default, no traffic monitoring is enabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables traffic monitoring on an **atm** subinterface to monitor **incoming** traffic through an ACL called **myacl**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip flow ingress myacl**

ip helper-address *<ip address>*

Use the **ip helper-address** command to configure AOS to forward User Datagram Protocol (UDP) broadcast packets received on the interface. Use the **no** form of this command to disable forwarding packets.

> NOTE *The **ip helper** command must be used in conjunction with the **ip forward-protocol** command to configure AOS to forward UDP broadcast packets. Refer to ip forward-protocol udp <value> on page 1398 for more information.*

Syntax Description

<ip address>	Specifies the destination IP address for the forwarded UDP packets. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, broadcast UDP packets are not forwarded.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

When used in conjunction with the **ip forward-protocol** command, the **ip helper-address** feature allows you to customize which broadcast packets are forwarded.

To implement the helper address feature, assign an address(es) (specifying the device that needs to receive the broadcast traffic) to the interface closest to the host that transmits the broadcast packets. When broadcast packets (of the specified type forwarded using the **ip forward-protocol** command) are received on the interface, they will be forwarded to the device that needs the information.

Only packets meeting the following criteria are considered eligible by the **ip helper-address** feature:

1. The packet IP protocol is UDP.
2. Any UDP port specified using the **ip forward-protocol** command.
3. The medium access control (MAC) address of the frame is an all-ones broadcast address (ffff.ffff.ffff).
4. The destination IP address is broadcast defined by all ones (**255.255.255.255**) or a subnet broadcast (for example, **192.33.4.251** for the **192.33.4.248 /30** subnet).

Usage Examples

The following example forwards all domain naming system (DNS) broadcast traffic to the DNS server with IP address **192.33.5.99**:

(config)**#ip forward-protocol udp domain**
(config)**#interface atm 1.1**
(config-atm 1.1)**#ip helper-address 192.33.5.99**

ip igmp

Use the **ip igmp** command to configure multicasting related functions for the interface. Variations of this command include:

ip igmp immediate-leave
ip igmp last-member-query-interval <*milliseconds*>
ip igmp querier-timeout <*seconds*>
ip igmp query-interval <*seconds*>
ip igmp query-max-response-time <*seconds*>
ip igmp static-group <*address*>
ip igmp version [1 | 2]

Syntax Description

immediate-leave	Specifies that if only one host (or Internet Group Management Protocol (IGMP) snooping switch) is connected to the interface, when a leave is received, multicast of that group is immediately terminated as opposed to sending a group query and timing out the group if no device responds. Works in conjunction with **ip igmp last-member-query-interval**. Applies to all groups when configured. Use the **no** form of this command to disable the **immediate-leave** feature.
last-member-query-interval <*milliseconds*>	Controls the timeout (in milliseconds) used to detect whether any group receivers remain on an interface after a receiver leaves a group. If a receiver sends a leave-group message (IGMP Version 2), the router sends a group-specific query on that interface. After twice the time specified by this command plus as much as one second longer, if no receiver responds, the router removes that interface from the group and stops sending that group's multicast packets to the interface. Range is **100** to **65535** ms. Use the **no** form of this command to return to the default setting.
querier-timeout <*seconds*>	Specifies the interval (in seconds) that the router waits after the current querier's last query before it takes over as querier (IGMP Version 2). Range is **60** to **300** seconds. Use the **no** form of this command to return to the default setting.
query-interval <*seconds*>	Specifies the interval (in seconds) at which IGMP queries are sent on an interface. Host query messages are addressed to the all-hosts multicast group with an IP time to live (TTL) of 1. The router uses queries to detect whether multicast group members are on the interface and to select an IGMP designated router (DR) for the attached segment (if more than one multicast router exists). Only the DR for the segment sends queries. For IGMP Version 2, the DR is the router with the lowest IP address on the segment. Range is **0** to **65535** seconds. Use the **no** form of this command to return to the default setting.
query-max-response-time <*seconds*>	Specifies the maximum response time (in seconds) advertised by this interface in queries when using IGMP Version 2. Hosts are allowed a random time within this period to respond, reducing response bursts. Use the **no** form of this command to return to the default setting.

Syntax Description

static-group <*address*>	Configures the router's interface to be a statically connected member of the specified group. Packets received on the correct reverse path forwarding (RPF) interface are forwarded to this interface regardless of whether any receivers have joined the specified group using IGMP. Use the **no** form of this command to remove a configured static group.
version [1 | 2]	Sets the interface's IGMP version. Use the **no** form of this command to return to the default setting.

Default Values

ip igmp immediate-leave	No default
ip igmp last-member-query-interval	**1000** milliseconds
ip igmp querier-timeout	2x the **query-interval** value
ip igmp query-interval	**60** seconds
ip igmp query-max-response-time	**10** seconds
ip igmp static-group	No default
ip igmp version	Version **1**

Command History

Release 7.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example sets the query message interval on the interface to **200** milliseconds:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip igmp last-member-query-interval 200**

ip mcast-stub downstream

Use the **ip mcast-stub downstream** command to enable multicast forwarding and Internet Group Management Protocol (IGMP) (router mode) on an interface and place it in multicast stub downstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub upstream** commands. Downstream interfaces connect to segments with multicast hosts. Multiple interfaces may be configured in downstream mode; however, interfaces connecting to the multicast network (upstream) should not be configured in downstream mode. Interfaces configured as downstream should have the lowest IP address of all IGMP-capable routers on the connected segment in order to be selected as the designated router (DR) and ensure proper forwarding. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub upstream on page 2554* for more information.

Usage Examples

The following example enables multicast forwarding and IGMP on the interface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip mcast-stub downstream**

ip mcast-stub fixed

Use the **ip mcast-stub fixed** command to allow forwarding of multicast traffic on a selected interface after enabling multicast routing. Use the **no** form of this command to disable this mode.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 12.1	Command was introduced.

Functional Notes

Multicast routing must be enabled prior to setting **ip mcast-stub fixed** on the selected interface. Also, use the **ip igmp static-group** <*address*> command to receive multicast traffic without host-initiated Internet Group Management Protocol (IGMP) activity on the selected interface. Otherwise, all host-initiated IGMP transactions will enter multicast routes on the router's interface involved with IGMP activities.

Usage Examples

The following example enables multicast traffic forwarding and IGMP on the interface:

(config)**#interface atm1.1**
(config-atm 1.1)**#ip mcast-stub fixed**

ip mcast-stub helper-enable

Use the **ip mcast-stub helper-enable** command to assign the **ip mcast-stub helper-address** as the Internet Group Management Protocol (IGMP) proxy. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 8.1	Command was introduced.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address, ip mcast-stub upstream**, and **ip mcast-stub downstream** commands. When enabled, the interface becomes a helper forwarding interface. The IGMP host function is dynamically enabled and the interface becomes the active upstream interface, enabling the router to perform as an IGMP proxy. Refer to *ip mcast-stub helper-address <ip address> on page 1418*, *ip mcast-stub downstream on page 2551*, and *ip mcast-stub upstream on page 2554* for more information.

Usage Examples

The following example sets the helper address as the IGMP proxy:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip mcast-stub helper-enable**

ip mcast-stub upstream

Use the **ip mcast-stub upstream** command to enable multicast forwarding on an interface and place it in multicast stub upstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub downstream** commands. When enabled, the interface becomes a candidate to be a helper forwarding interface. If chosen as the best path toward the helper address by the router's unicast route table, the Internet Group Management Protocol (IGMP) host function is dynamically enabled and the interface becomes the active upstream interface, enabling the router to perform as an IGMP proxy. Though multiple interfaces may be candidates, no more than one interface will actively serve as the helper forwarding interface. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub downstream on page 2551* for more information.

Usage Examples

The following example enables multicast forwarding on the interface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip mcast-stub upstream**

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces	(all types)1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

Open shortest path first (OSPF) will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the interface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip mtu 1200**

ip ospf

Use the **ip ospf** command to customize Open Shortest Path First version 2 (OSPFv2) settings (if needed). Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **area** <*area id*>
ip ospf <*process id*> **authentication-key** <*password*>
ip ospf <*process id*> **cost** <*value*>
ip ospf <*process id*> **dead-interval** <*seconds*>
ip ospf <*process id*> **hello-interval** <*seconds*>
ip ospf <*process id*> **message-digest-key [1 | 2] md5** <*key*>
ip ospf <*process id*> **priority** <*value*>
ip ospf <*process id*> **retransmit-interval** <*seconds*>
ip ospf <*process id*> **shutdown**
ip ospf <*process id*> **transmit-delay** <*seconds*>

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
area <*area id*>	Specifies the ID of the area to which this interface is assigned for the specified OSPFv2 process. Valid range is **0** to **4294967295**.
authentication-key <*password*>	Assigns a simple-text authentication password to be used by other routers using the OSPF simple password authentication.
cost <*value*>	Specifies the OSPF cost of sending a packet on the interface. This value overrides any computed cost value. Range is **1** to **65535**.
dead-interval <*seconds*>	Sets the maximum interval (in seconds) allowed between hello packets. If the maximum is exceeded, neighboring devices will determine that the device is down. Range is **0** to **32767** seconds.
hello-interval <*seconds*>	Specifies the interval (in seconds) between hello packets sent on the interface. Range is **0** to **32767** seconds.
message-digest-key [1 | 2] md5 <*key*>	Configures OSPF message digest 5 (MD5) authentication (16 byte maximum) keys.
priority <*value*>	Sets the OSPF priority. The value set in this field helps determine the designated router (DR) for this network. Range is **0** to **255**.
retransmit-interval <*seconds*>	Specifies the interval (in seconds) between link state advertisements (LSAs). Range is **0** to **32767** seconds.

shutdown	Disables the OSPFv2 process on the interface. When this keyword is used, the OSPFv2 settings remain in place, but logically it appears to the interface as though the process has been removed from the configuration. This parameter can be useful in troubleshooting.
transmit-delay <*seconds*>	Sets the estimated time (in seconds) required to send a link state advertisement (LSA) on the interface. Range is **0** to **32767** seconds.

Default Values

The defaults for this command are:

dead-interval <*seconds*>	40 seconds
hello-interval <*seconds*>	10 seconds: Ethernet, Frame Relay, and Point-to-Point Protocol (PPP)
priority <*value*>	1
retransmit-interval <*seconds*>	5 seconds
transmit-delay <*seconds*>	1 second

Command History

Release 3.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.
Release R11.3.0	Command was expanded to include the <*process id*>, **area** <*area id*>, and **shutdown** parameters.

Usage Examples

The following example sets the maximum number of seconds allowed between hello packets to **25000**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip ospf 1 dead-interval 25000**

ip ospf <*process id*> authentication

Use the **ip ospf authentication** command to authenticate an interface that is performing open shortest path first (OSPF) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **authentication**
ip ospf <*process id*> **authentication message-digest**
ip ospf <*process id*> **authentication null**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
message-digest	Optional. Selects message digest authentication type.
null	Optional. Specifies that no authentication be used.

Default Values

By default, **ip ospf authentication** is set to **null** (meaning no authentication is used).

Command History

Release 3.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Usage Examples

The following example specifies that no authentication will be used on the ATM subinterface 1.1:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip ospf 1 authentication null**

ip ospf <*process id*> network

Use the **ip ospf network** command to specify the type of network on this interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **network broadcast**
ip ospf <*process id*> **network point-to-point**

Syntax Description

<process id>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
broadcast	Sets the network type for broadcast.
point-to-point	Sets the network type for point-to-point.

Default Values

By default, Ethernet defaults to **broadcast**. Point-to-Point Protocol (PPP) and Frame Relay default to **point-to-point**.

Command History

Release 3.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Functional Notes

A point-to-point network will not elect designated routers.

Usage Examples

The following example designates a broadcast network type:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip ospf network broadcast**

ip pim sparse-mode

Use the **ip pim sparse-mode** command to enable protocol-independent multicast (PIM) sparse mode for this interface. Use the **no** form of this command to disable PIM sparse mode.

Syntax Description

No subcommands.

Default Values

By default, PIM sparse mode for this interface is disabled.

Command History

Release 11.1	Command was introduced.

Functional Notes

PIM sparse mode is a multicast routing protocol that makes use of the unicast forwarding table. It builds unidirectional shared trees rooted at a rendezvous point (RP) for a multicast group or a shortest-path tree rooted at a specific source for a multicast group.

Usage Examples

The following example enables PIM sparse mode on the interface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip pim sparse-mode**

ip pim-sparse dr-priority <*value*>

Use the **ip pim-sparse dr-priority** command to specify the priority for the designated router (DR). This command modifies the router's priority in the DR election process. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the priority of this interface (to be used when determining the DR). Valid range is **1** to **4294967295**.

Default Values

By default, the priority of all protocol-independent multicast (PIM) interfaces is 1.

Command History

Release 11.1	Command was introduced.

Functional Notes

Interfaces advertise their configured priority values in the hello messages transmitted on the interface. Routers use the priority values to determine the appropriate DR. The router on the network segment with the highest priority is selected as the DR. If a hello message is received on the interface from a router on the network segment and it does not contain a priority, the entire network segment defaults to DR selection based on IP addresses instead of priority. In this instance, the DR is selected as the router on the network segment that has the highest IP address. AOS will always include a priority in all transmitted hello messages. If no priority is specifically designated by the user, the priority is set as the default of 1.

Usage Examples

The following example specifies a priority of **100** on the asynchronous transfer mode (ATM) subinterface 1.1:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip pim-sparse dr-priority 100**

ip pim-sparse hello-timer <*value*>

Use the **ip pim-sparse hello-timer** command to specify protocol-independent multicast (PIM) sparse hello timer period. This is the time interval at which periodic hellos are sent out on all interfaces of a PIM-capable router. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the interval (in seconds) at which periodic hellos are sent out of the interface. Valid range is **10** to **3600** seconds.

Default Values

By default, the hellos are transmitted on PIM interfaces every 60 seconds.

Command History

Release 11.1	Command was introduced.

Functional Notes

Hello messages are used to inform neighbors of a router's presence. Hello messages normally generate a small amount of traffic on an interface. Setting the **hello-timer** to a small interval increases the number of hellos sent (thus increasing the amount of traffic). Set the **hello-timer** to a reasonable value, taking into consideration the bandwidth available on the interface.

Usage Examples

The following example specifies hellos be sent on the asynchronous transfer mode (ATM) subinterface 1.1 every **3600** seconds:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip pim-sparse hello-timer 3600**

ip pim-sparse nbr-timeout <*value*>

Use the **ip pim-sparse nbr-timeout** command to specify protocol-independent multicast (PIM) sparse neighbor timeout. This is the time interval after which a PIM-capable router will consider a neighbor not present. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the time interval in seconds after which a neighbor is considered not present. Valid range is **30** to **10800** seconds.

Default Values

By default, the nbr-timeout is set to **105** seconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the nbr-timeout to **300** seconds:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip pim-sparse nbr-timeout 300**

ip pim-sparse override-interval <*value*>

Use the **ip pim-sparse override-interval** command to specify the protocol-independent multicast (PIM) sparse join/prune override interval. This delay interval is the period after a join/prune that another router on the local area network (LAN) may override a join/prune. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the delay time in milliseconds. Valid range is **0** to **65535** milliseconds.

Default Values

By default, the override interval is set to **2500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the override interval to **3000** milliseconds:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip pim-sparse override-interval 3000**

ip pim-sparse propagation-delay *<value>*

Use the **ip pim-sparse propagation-delay** command to specify the expected propagation delay for join/prune messages. Set the propagation delay (in milliseconds) to estimate the amount of delay found in the local link. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the expected propagation delay in the local link in milliseconds. Valid range is **0** to **32767** milliseconds.

Default Values

By default, the propagation delay is set to **500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the propagation delay to **300** milliseconds:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip pim-sparse propagation-delay 300**

ip policy route-map *<name>*

Use the **ip policy route-map** command to assign a policy route map to this interface. Use the **no** form of this command to remove the route-map policy.

Syntax Description

<name>	Specifies the name of the policy route map to assign to this interface.

Default Values

By default, no policy route map is assigned to this interface.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example assigns the policy route map **policy1** to the asynchronous transfer mode (ATM) subinterface 1.1:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip policy route-map policy1**

ip proxy-arp

Use the **ip proxy-arp** command to enable proxy Address Resolution Protocol (ARP) on the interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, proxy ARP is enabled.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

In general, the principle of proxy ARP allows a router to insert its IP address in the source IP address field of a packet (if the packet is from a host on one of its subnetworks). This allows hosts to reach devices on other subnetworks without implementing routing or specifying a default gateway.

If proxy ARP is enabled, AOS will respond to all proxy ARP requests with its specified medium access control (MAC) address and forward packets accordingly.

Enabling proxy ARP on an interface may introduce unnecessary ARP traffic on the network.

Usage Examples

The following example enables proxy ARP on the ATM subinterface 1.1:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip proxy-arp**

ip rip receive version

Use the **ip rip receive version** command to configure the Routing Information Protocol (RIP) version the unit accepts in all RIP packets received on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip receive version 1
ip rip receive version 2

Syntax Description

1	Accepts only received RIP version 1 packets on the interface.
2	Accepts only received RIP version 2 packets on the interface.

Default Values

By default, all interfaces implement RIP version 1 (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

Use the **ip rip receive version** to specify a RIP version that will override the **version** (in the Router RIP) configuration.

AOS only accepts one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the ATM subinterface 1.1 to accept only RIP version 2 packets:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip rip receive version 2**

ip rip send version

Use the **ip rip send version** command to configure the Routing Information Protocol (RIP) version the unit sends in all RIP packets transmitted on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip send version 1
ip rip send version 2

Syntax Description

1	Transmits only RIP version 1 packets on the interface.
2	Transmits only RIP version 2 packets on the interface.

Default Values

By default, all interfaces transmit RIP version 1 (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

Use the **ip rip send version** to specify a RIP version that will override the **version** (in the Router RIP) configuration.

AOS only transmits one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the ATM subinterface 1.1 to transmit only RIP version 2 packets:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip rip send version 2**

ip rip summary-address *<ip address> <subnet mask>*

Use the **ip rip summary-address** command to manually summarize the routes Routing Information Protocol (RIP) will advertise and send out a specified interface. Use the **no** form of this command to disable this mode.

Syntax Description

<ip address>	Specifies the summarized network IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.0**).
<subnet mask>	Specifies the subnet mask that corresponds to the range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no manual summarization is applied by RIP.

Command History

Release 12.1	Command was introduced.

Functional Notes

Unlike the automatic summarization on classful network boundaries, only specific network advertisements are made by RIP using the **ip rip summary-address** command. This command is only effective if RIP version 2 is configured.

Usage Examples

The following example enables manual summarization on the specified IP address:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip rip summary-address 10.10.123.0 255.255.255.0**

ip route-cache

Use the **ip route-cache** command to enable fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

*Using network address translation (NAT) or the AOS firewall capabilities on an interface requires process switching mode (using the **no ip route-cache** command).*

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 2.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

Fast switching allows an IP interface to provide optimum performance when processing IP traffic.

Usage Examples

The following example enables fast switching on the ATM subinterface 1.1:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip route-cache**

ip unnumbered *<interface>*

Use the **ip unnumbered** command to use the IP address assigned to the specified interface for all IP processing on the active interface. Use the **no** form of this command to remove the unnumbered configuration.

Syntax Description

<interface>	Specifies the interface that contains the IP address to use as the source address for all packets transmitted on this interface. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip unnumbered ?** for a list of valid interfaces.

Default Values

By default, all interfaces are configured to use a specified IP address (using the command *ip address <ipv4 address> <subnet mask> on page 2536*).

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface.

Functional Notes

If **ip unnumbered** is enabled on an interface, all IP traffic from the interface will use a source IP address taken from the specified interface. For example, specifying **ip unnumbered eth 0/1** while in the Frame Relay Subinterface Configuration mode configures the Frame Relay subinterface to use the IP address assigned to the Ethernet interface for all IP processing. In addition, AOS uses the specified interface information when sending route updates over the unnumbered interface.

Usage Examples

The following example configures the ATM subinterface 1.1 to use the IP address assigned to the Ethernet interface (**eth 0/1**):

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip unnumbered eth 0/1**

ip urlfilter *<name>*

Use the **ip urlfilter** command to apply a universal resource locator (URL) filter to the interface for all inbound or outbound traffic. Use the **no** form of this command to remove the URL filter from an interface. Variations of this command include:

ip urlfilter <*name*> **in**
ip urlfilter <*name*> **out**

Syntax Description

<*name*>	Specifies the URL filter name to use on the interface.
in	Applies the filter to the inbound traffic.
out	Applies the filter to the outbound traffic.

Default Values

By default, there are no URL filters applied to any interfaces.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the virtual local area network (VLAN) interfaces.

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be created by using the **ip urlfilter** <*name*> **http** command before applying it to the interface. Refer to *ip urlfilter allowmode on page 1493* for more information on using this command.

Usage Examples

The following example performs URL filtering on all traffic entering through the asynchronous transfer mode (ATM) subinterface 1.1 and matches the URL filter named **MyFilter**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ip urlfilter MyFilter in**

ipv6 dhcp relay destination <*ipv6 address*>

Use the **ipv6 dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 6 (IPv6) and to specify the IPv6 address for the DHCPv6 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv6 relay functionality is disabled on the interface. Variations of this command include:

ipv6 dhcp relay destination <*ipv6 address*>
ipv6 dhcp relay destination <*ipv6 address*> <*interface*>

Syntax Description

<*ipv6 address*>	Specifies the IPv6 address for the DHCPv6 messages. IPv6 addresses should be specified in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
<*interface*>	Optional. Specifies an output interface to use when sending messages to the DHCPv6 server. If no interface is specified, the interface is selected by the routing table. This parameter is only required when the IPv6 address is a link-scoped address. Interfaces are specified in the <*interface type*> <*slot/port* | *interface id*> format. For example, for an Ethernet interface, use **eth 0/1**. Type **ipv6 dhcp relay destination** <*ipv6 address*> **?** to display a list of valid interfaces.

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.1.0	Command was expanded to include the Tunnel interface.

Functional Notes

To configure an interface to function as a DHCPv6 relay agent, you must first enable IPv6 on the interface using the command **ipv6**.

Usage Examples

The following example enables DHCPv6 relay agent functionality and specifies the destination address as **2001:DB8:2::1**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#ipv6**
(config-atm 1.1)**#ipv6 dhcp relay destination 2001:DB8:2::1**

max-reserved-bandwidth <*value*>

Use the **max-reserved-bandwidth** command to specify the percentage of interface bandwidth reserved for use in user-defined (priority or class-based) queues. The remainder of the interface bandwidth is reserved for system-critical traffic and is not available to user-defined queues. Use the **no** form of this command to restore the default value.

Reserving a portion of the interface bandwidth for system-critical traffic is necessary for proper operation. Specifying the entire interface bandwidth for use in user-defined queues can cause undesirable operation.

Syntax Description

<*value*>	Specifies the maximum percentage of bandwidth to reserve for quality of service (QoS). This setting is configured as a percentage of the total interface speed. Range is **1** to **100** percent.

Default Values

By default, **max-reserved-bandwidth** is set to 75 percent, which reserves 25 percent of the interface bandwidth for system-critical traffic.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example specifies **85** percent bandwidth on the asynchronous transfer mode (ATM) subinterface to be available for use in user-defined queues:

(config)**#interface atm 1.1**
(config-atm 1.1)**#max-reserved-bandwidth 85**

media-gateway ip

Use the **media-gateway ip** command to associate an Internet Protocol version 4 (IPv4) address source to use for Realtime Transport Protocol (RTP) traffic. When configuring Voice over Internet Protocol (VoIP), RTP traffic must have an IPv4 address associated with it. However, some interfaces allow dynamic configuration of IPv4 addresses, causing this value to change periodically. Use the **no** form of this command to disable this function. Variations of this command include:

media-gateway ip loopback <*interface id*>
media-gateway ip primary
media-gateway ip secondary <*ipv4 address*>

Syntax Description

loopback <*interface id*>	Specifies an IPv4 address statically defined to a loopback interface for RTP traffic. This is helpful when using a single IPv4 address across multiple wide area network (WAN) interfaces for RTP traffic. The valid range for loopback interface identifiers is **1** to **1024**. The interface ID is used to uniquely identify a loopback interface. The entered value cannot be in use by another loopback interface.
primary	Specifies using this interface's configured primary IPv4 address for RTP traffic. Applies to static, Dynamic Host Configuration Protocol (DHCP), or negotiated addresses.
secondary <*ipv4 address*>	Specifies using this interface's statically defined secondary IPv4 address for RTP traffic. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, **media-gateway ip** is disabled.

Command History

Release 10.1	Command was introduced.
Release 17.3	Command was updated with the loopback interface identification option.
Release A4.01	Command was expanded to include the Metro Ethernet forum (MEF) Ethernet interface.

Usage Examples

The following example configures the unit to use the primary IPv4 address for RTP traffic:

(config)**#interface atm 1.1**
(config-atm 1.1)**#media-gateway ip primary**

oam retry

Use the **oam retry** command to configure parameters related to operations, administration, and maintenance (OAM) management for an asynchronous transfer mode (ATM) interface. Use the **no** form of this command to disable OAM management parameters. Variations of this command include:

oam retry
oam retry *<up value>*
oam retry *<up value> <down value>*
oam retry *<up value> <down value> <value>*

Syntax Description

<up value>	Optional. Specifies the number of consecutive end-to-end F5 OAM loopback cell responses that must be received in order to change a permanent virtual circuit (PVC) connection state to up. Range is **1** to **255**.
<down value>	Optional. Specifies the number of consecutive end-to-end F5 OAM loopback cell responses that are not received in order to change a PVC state to down. Range is **1** to **255**.
<value>	Optional. Specifies the frequency (in seconds) that end-to-end F5 OAM loopback cells are transmitted when a change in the up/down state of a PVC is being verified. Range is **1** to **600** seconds.

Default Values

By default, the up-count is set to 3, the down-count is set to 5, and the retry frequency is 1.

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example configures the OAM parameters with an up-count of **2**, down-count of **2**, and retry frequency of **10**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#oam retry 2 2 10**

oam-pvc managed

Use the **oam-pvc managed** command to enable end-to-end F5 operations, administration, and maintenance (OAM) loopback cell generation and OAM management for an asynchronous transfer mode (ATM) interface. Use the **no** form of this command to disable generation of OAM loopback cells. Variations of this command include:

oam-pvc managed
oam-pvc managed <*value*>

Syntax Description

<*value*>	Optional. Specifies the time delay between transmitting OAM loopback cells. Range is **0** to **600** seconds.

Default Values

By default, the frequency is 1 second.

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example enables OAM loopback cell generation with a frequency of **5** seconds:

(config)**#interface atm 1.1**
(config-atm 1.1)**#oam-pvc managed 5**

packet-capture <*name*>

Use the **packet-capture** command to apply a previously configured packet capture instance to the interface. Use the **no** form of this command to remove the packet capture instance.

Syntax Description

<*name*>	Specifies the name of the packet capture instance to apply to the interface.

Default Values

By default, no packet capture instances are configured or applied to the interface.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

The AOS packet capture feature is used with network monitoring to effectively capture data packets as they traverse the network. For more information about packet capturing, its uses, and its implementation in AOS, refer to the configuration guide *Configuring Packet Capture in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example applies the previously configured packet capture **1CAPTURE** to the interface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#packet-capture 1CAPTURE**

pvc <*VPI/VCI*>

Use the **pvc** command to select the asynchronous transfer mode (ATM) virtual link for this subinterface. Use the **no** form of this command to remove the link.

Syntax Description

<*VPI/VCI*>	Specifies the ATM network virtual path identifier (VPI) for this permanent virtual circuit (PVC). The VPI value range is **0** to **255**, and the virtual channel identifier (VCI) value range is **32** to **65535**.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.

Usage Examples

The following example sets the VPI to **8** and the VCI to **35**:

(config)**#interface atm 1.1**
(config-atm 1.1)**#pvc 8/35**

qos-policy

Use the **qos-policy** command to apply a previously configured quality of service (QoS) map to incoming or outgoing packets on an interface. Use the **no** form of this command to remove the map from the interface. Variations of this command include:

qos-policy in *<name>*
qos-policy out *<name>*

Syntax Description

<name>	Specifies the name of a previously created QoS map (refer to *qos map <name> <number> on page 1673* for more information).
in	Assigns a QoS map to this interface's input.
out	Assigns a QoS map to this interface's output.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.
Release 15.1	Command was expanded to include the **in** parameter.

Functional Notes

When a QoS policy is applied to an interface, it may be disabled if the interface bandwidth is not adequate to support the requested bandwidth on the map set. Once the bandwidth problem is resolved, the map will work again. The bandwidth will be rechecked on any of the following changes:

1. A priority or class-based entry is added to, deleted from, or changed in a QoS map set.
2. The interface bandwidth is changed by the **bandwidth** command on the interface.
3. A QoS policy is applied to an interface.
4. A cross connect is created that includes an interface with a QoS policy.
5. The interface queuing method is changed to fair-queue to use weighted fair queuing (WFQ).
6. The interface operational status changes.
7. The interface bandwidth changes for other reasons (e.g., when asymmetric digital subscriber line (ADSL) finishes training).

In order to prevent the map from being disabled in cases of temporary inadequate bandwidth (e.g., a single link goes down in a dual T1 multilink configuration where the map requests more than one T1's worth of bandwidth), the QoS map uses the maximum theoretical bandwidth on an interface, not the actual bandwidth at that time. This actually helps QoS keep higher priority class-based traffic working better than best-effort traffic when the bandwidth drops.

Usage Examples

The following example applies the QoS map **VOICEMAP** to the ATM subinterface 1.1:

(config)**#interface atm 1.1**
(config-atm 1.1)**#qos-policy out VOICEMAP**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.
Release 17.9	Command was expanded to the Frame Relay and the ATM subinterfaces.

Usage Examples

The following example enables SNMP on the virtual ATM subinterface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release 17.9	Command was explanded to the Frame Relay and the ATM subinterfaces.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on th ATM subinterface:

(config)**#interface atm 1.1**
(confi-atm 1.1)**#no snmp trap link-status**

spanning-tree bpdufilter

Use the **spanning-tree bpdufilter** command to block bridge protocol data units (BPDUs) from being transmitted and received on this interface. To return to the default value, use the **no** form of this command. Variations of this command include:

spanning-tree bpdufilter disable
spanning-tree bpdufilter enable

Syntax Description

disable	Disables the BPDU filter.
enable	Enables the BPDU filter.

Default Values

By default, this command is set to **disable**.

Command History

Release 5.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

The purpose of this command is to remove a port from participation in the spanning tree. This might be beneficial while debugging a network setup. It normally should not be used in a live network.

Usage Examples

The following example enables the BPDU filter on the interface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#spanning-tree bpdufilter enable**

spanning-tree bpduguard

Use the **spanning-tree bpduguard** command to block bridge protocol data units (BPDUs) from being received on this interface. To return to the default value, use the **no** form of this command. Variations of this command include:

spanning-tree bpduguard disable
spanning-tree bpduguard enable

Syntax Description

disable	Disables the BPDU block.
enable	Enables the BPDU block.

Default Values

By default, this command is set to **disable**.

Command History

Release 5.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Usage Examples

The following example enables the bpduguard on the interface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#spanning-tree bpduguard enable**

spanning-tree edgeport

Use the **spanning-tree edgeport** command to set this interface to be an edgeport. This command overrides the global setting (refer to *spanning-tree edgeport default on page 1837*). Use the **no** form of this command to return to the default value.

Syntax Description

No subcommands.

Default Values

By default, this command is set to disable.

Command History

Release 5.1	Command was introduced.
Release 8.1	Command was added to the ATM Subinterface command set.

Functional Notes

When an interface is designated as an edgeport, the interface will immediately go to a forwarding state when the link becomes active. When an interface is not designated as an edgeport, the interface must go through the listening and learning states before going to the forwarding state.

Usage Examples

The following example configures the interface to be an edgeport:

(config)**#interface atm 1.1**
(config-atm 1.1)**#spanning-tree edgeport**

An individual interface can be configured to not be considered an edgeport. For example:

(config)**#interface atm 1.1**
(config-atm 1.1)**#spanning-tree edgeport disable**

or

(config)**#interface atm 1.1**
(config-atm 1.1)**#no spanning-tree edgeport**

spanning-tree link-type

Use the **spanning-tree link-type** command to configure the spanning-tree protocol link type for an interface. To return to the default value, use the **no** form of this command. Variations of this command include:

spanning-tree link-type auto
spanning-tree link-type point-to-point
spanning-tree link-type shared

Syntax Description

auto	Determines link type by the port's duplex settings.
point-to-point	Sets link type manually to point-to-point regardless of duplex settings.
shared	Sets link type manually to shared regardless of duplex settings.

Default Values

By default, a port is set to auto.

Command History

Release 5.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

This command overrides the default link-type setting determined by the duplex of the individual port. By default, a port configured for half-duplex is set to **shared** link type, and a port configured for full-duplex is set to **point-to-point** link type. Setting the link type manually overrides the default and forces the port to use the specified link type. Using the **link-type auto** command, restores the convention of determining link type based on duplex settings.

Usage Examples

The following example forces the link type to point-to-point, even if the port is configured to be half-duplex:

(config)**#bridge 1 protocol ieee**
(config)**#interface atm 1.1**
(config-atm 1.1)**#spanning-tree link-type point-to-point**

Technology Review

Rapid transitions are possible in Rapid Spanning Tree Protocol (RSTP) by taking advantage of point-to-point links (a port is connected to exactly one other bridge) and edge-port connections (a port is not connected to any additional bridges). Setting the link type to **auto** allows the spanning tree to automatically configure the link type based on the duplex of the link. Setting the link type to **point-to-point** allows a half-duplex link to act as if it were a point-to-point link.

spanning-tree path-cost *<value>*

Use the **spanning-tree path-cost** command to assign a cost to a bridge group that is used when computing the spanning-tree root path. To return to the default path-cost value, use the **no** form of this command.

Syntax Description

<value>	Assigns a number to the bridge interface to be used as the path cost in spanning calculations. Valid range is **0** to **65535**.

Default Values

By default, the path-cost value is set to 19.

Command History

Release 1.1	Command was introduced.
Release 8.1	Command was added to the ATM subinterface command set.
Release R10.1.0	Command was added to the Ethernet interface command set.

Functional Notes

The specified value is inversely proportional to the likelihood the bridge interface will be chosen as the root path. Set the path-cost value lower to increase the chance the interface will be the root. To obtain the most accurate spanning-tree calculations, develop a system for determining path costs for links and apply it to all bridged interfaces.

Usage Examples

The following example assigns a path cost of 100 for bridge group 17 on an ATM subinterface:

(config)**#interface atm 1.1**
(config-atm 1.1)**#spanning-tree path-cost 100**

Technology Review

Spanning-tree protocol provides a way to prevent loopback or parallel paths in bridged networks. Using the priority values and path costs assigned to each bridging interface, the spanning-tree protocol determines the root path and identifies whether to block or allow other paths.

spanning-tree port-priority <*value*>

Use the **spanning-tree port-priority** command to select the priority level of a port associated with a bridge. To return to the default bridge-group priority value, use the **no** form of this command.

Syntax Description

<*value*>	Assigns a priority value for the bridge group; the lower the value, the higher the priority. Valid range is **0** to **255**.

Default Values

By default, the bridge-group priority value is set to 128.

Command History

Release 1.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.

Functional Notes

The only time that this priority level is used is when two interfaces with a path to the root have equal cost. At that point, the level set in this command will determine which port the bridge will use. Set the priority value lower to increase the chance the interface will be used.

Usage Examples

The following example sets the maximum priority on the ATM subinterface labeled 1.1 in bridge group 17:

(config)**#interface atm 1.1**
(config-atm 1.1)**#spanning-tree port-priority 0**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an interface to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the interface from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an interface's VRF association will clear all IP-related settings on that interface.

Syntax Description

<name>	Specifies the name of the VRF to which to assign the interface.

Default Values

By default, interfaces are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release 17.8	The keyword **ip** was removed from this command.

Functional Notes

VRF instances must be created first before an interface can be assigned. An interface can only be assigned to one VRF, but multiple interfaces can be assigned to the same VRF.

An interface will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the ATM subinterface labeled 1.1 to the VRF instance named **RED**:

(config)**#interface atm 1.1**
(config-fr 1.16)**#vrf forwarding RED**

BVI INTERFACE COMMAND SET

To activate the Bridged Virtual Interface Configuration mode, first enable integrated routing and bridging (IRB) via the **bridge irb** command (refer to *bridge irb on page 1229*) at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#bridge irb
```

Next, enter the **interface bvi** command and a specific interface number that corresponds to an existing bridge group at the Global Configuration mode prompt. For example:

```
(config)#bridge irb
(config)#interface bvi 1
(config-bvi 1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81M
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

bandwidth <value> on page 2594
dynamic-dns on page 2595
ip commands begin on page 2597
ipv6 dhcp relay destination <ipv6 address> on page 2628
mac-address <mac address> on page 2629
max-reserved-bandwidth <value> on page 2630
packet-capture <name> on page 2631
qos-policy out <name> on page 2632
rtp quality-monitoring on page 2633
traffic-shape rate <value> on page 2634
vrf forwarding <name> on page 2635

bandwidth *<value>*

Use the **bandwidth** command to provide the bandwidth value of an interface to the higher level protocols. This value is used in cost calculations. Use the **no** form of this command to restore the default value.

Syntax Description

<value>	Specifies bandwidth in kbps. Range is **1** to **4294967295** kbps.

Default Values

To view default values, use the **show interfaces** command.

Command History

Release 3.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

The **bandwidth** command is an informational value that is communicated to the higher level protocols to be used in cost calculations. While this is a routing parameter that does not affect the physical interface, it does affect the amount of bandwidth available for use in Quality of Service (QoS) configurations.

It is important to note that there is an order of precedence in determining the interface bandwidth reported by the router for QoS. Under normal circumstances, the Layer 1 bandwidth is reported based on the interface type. For example, a T1 interface will report the available bandwidth as 1.536 Mbps. This can be misleading in QoS configurations if the **bandwidth** command has been applied to the IP interface for routing purposes because the command overrides the reported available bandwidth that can be utilized for QoS. Using the **bandwidth** command can severely disrupt the configuration of QoS on the interface, therefore, use the **max-reserved-bandwidth** command (*page 2630*) to adjust the bandwidth appropriately for QoS configurations.

Usage Examples

The following example sets bandwidth of BVI 1 to 10 Mbps:

(config)**#interface bvi 1**
(config-bvi 1)**#bandwidth 10000**

dynamic-dns

Use the **dynamic-dns** command to configure Dynamic DNS service provided by Dynamic Network Services, Inc. (www.dyndns.org). Use the **no** form of this command to disable this feature. Variations of this command include:

dynamic-dns custom <*hostname*> <*minutes*>
dynamic-dns dyndns <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-custom <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-static <*hostname*> <*username*> <*password*>

Syntax Description

<*hostname*>	Specifies the host name for the server that updates the dynamic domain naming system (DNS).
<*minutes*>	Specifies the intervals in minutes to update the server with information (updates also occur when the interface's IP address changes regardless of the update intervals).
<*username*>	Specifies a user name using an alphanumerical string up to 30 characters in length (the user name is case sensitive).
<*password*>	Specifies a password using an alphanumerical string up to 30 characters in length (the password is case sensitive). Refer to *Functional Notes* below for additional argument descriptions.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.
Release 12.1	Command was expanded.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

custom - Constanttime.com's Custom Dynamic DNS^{SM} service allows you complete access and management control over your domain name regardless of where you purchased/registered it. This allows you to manage IP address mappings (A records), domain aliases (CNAME records), and mail servers (mail exchange (MX) records).

dyndns - The Dynamic DNS^{SM} offered by Dynamic Network Services, Inc. (DynDNS.org) allows you to alias a dynamic IP address to a static host name in various domains. This allows your unit to be more easily accessed from various locations on the Internet. This service is provided for up to five host names.

dyndns-custom - DynDNS.org's Custom DNS^{SM} service provides a full DNS solution, giving you complete control over an entire domain name. A Web-based interface provides two levels of control over your domain, catering to average or advanced users. Five globally redundant DNS servers ensure that your domain will always resolve.

A choice of two interfaces is available. The basic interface is designed for most users. It comes preconfigured for most common configurations and allows for easy creation of most common record types. The advanced interface is designed for system administrators with a solid DNS background, and provides layout and functionality similar to a BIND zone file allowing for the creation of nearly any record type.

Custom DNS^{SM} can be used with both static and dynamic IPs, and has the same automatic update capability through Custom DNS-aware clients as Dynamic DNS.

dyndns-static - The Static DNS service is similar to DynDNS.org's Dynamic DNS^{SM} service in that it allows a host name, such as yourname.dyndns.org, to point to your IP address. Unlike a Dynamic DNS host, a Static DNS host does not expire after 35 days without updates, but updates take longer to propagate through the DNS system. This service is provided for up to five host names.

If your IP address does not change often or at all, but you still want an easy name to remember it by (without having to purchase your own domain name), Static DNS service is ideal for you.

If you would like to use your own domain name (such as yourname.com), you need Custom DNS service that also provides full dynamic and static IP address support.

Usage Examples

The following example sets the Dynamic DNS to **dyndns-custom** with host name **host**, user name **user**, and password **pass**:

(config)**#interface bvi 1**
(config-bvi 1)**#dynamic-dns dyndns-custom host user pass**

ip access-group *<ipv4 acl name>*

Use the **ip access-group** command to create an Internet Protocol version 4 (IPv4) access control list (ACL) to be used for packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ip access-group *<ipv4 acl name>* **in**
ip access-group *<ipv4 acl name>* **out**

Syntax Description

<ipv4 acl name>	Specifies the IPv4 ACL name.
in	Enables access control on packets received on the specified interface.
out	Enables access control on packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 3.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

When this command is enabled, the IPv4 destination address of each packet must be validated before being passed through. If the packet is not acceptable per these settings, it is dropped.

Usage Examples

The following example sets up the router to only allow Telnet traffic into BVI 1:

(config)**#interface bvi 1**
(config)**#ip access-list extended TelnetOnly**
(config-ext-nacl)**#permit tcp any any eq telnet**
(config)**#interface bvi 1**
(config-bvi 1)**#ip access-group TelnetOnly in**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to an interface. IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

> NOTE *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an interface.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the Ethernet interface 0/1:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the BVI interface 1:

(config)**#interface bvi 1**
(config-bvi 1)**#ip access-policy PRIVATE**

ip crypto map *<name>*

Use the **ip crypto map** command to associate Internet Protocol version 4 (IPv4) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

When you apply a map to an interface, you are applying all crypto maps with the given map name. This allows you to apply multiple crypto maps if you have created maps that share the same name, but have different map index numbers.

Syntax Description

<name>	Specifies the IPv4 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

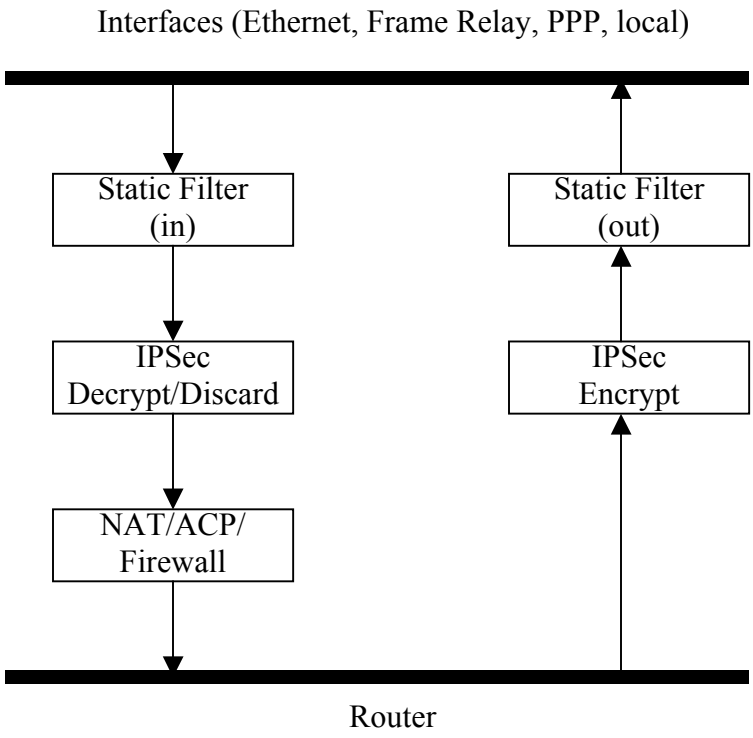
Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 9.1	Command was expanded to include the High-Levell Data Link Control (HDLC) interface.
Release 11.1	Command was expanded to include the demand interface.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.7.0	Command syntax was changed to require the **ip** keyword.

Functional Notes

When configuring a system to use both the stateful inspection firewall and Internet key exchange (IKE) negotiation for VPN, keep the following notes in mind.

When defining the IPv4 policy class and associated access control lists (ACLs) that describe the behavior of the IPv4 firewall, do not forget to include the traffic coming into the system over a VPN tunnel terminated by the system. The firewall should be set up with respect to the unencrypted traffic that is destined to be sent or received over the VPN tunnel. The following diagram represents typical AOS data-flow logic.



As shown in the diagram above, data coming into the product is first processed by the static filter associated with the interface on which the data is received. This access group is a true static filter and is available for use regardless of whether the IPv4 firewall is enabled or disabled. Next (if the data is encrypted), it is sent to the IPSec engine for decryption. The decrypted data is then processed by the stateful inspection firewall. Therefore, given a terminating VPN tunnel, only unencrypted data is processed by the firewall.

The IPv4 ACLs for a crypto map on an interface work in reverse logic to the ACLs for a policy class on an interface. When specifying the ACLs for a crypto map, the source information is the private local side, unencrypted source of the data. The destination information will be the far-end, unencrypted destination of the data. However, ACLs for a policy class work in reverse. The source information for the ACL in a policy class is the far end. The destination information is the local side.

Usage Examples

The following example applies all IPv4 crypto maps with the name **MyMap** to the interface:

(config)**#interface bvi 1**
(config-bvi 1)**#ip crypto map MyMap**

ip address dhcp

Use the **ip address dhcp** command to use Dynamic Host Configuration Protocol (DHCP) to obtain an address on the interface. Use the **no** form of this command to remove a configured IP address (using DHCP) and disable DHCP operation on the interface. Variables that may be used with this command to further define the DHCP configuration include:

ip address dhcp class-id [ascii *<string>* **| hex** *<value>***] [client-id [***<interface>* **|** *<identifier>***]] [hostname** *<"string">***] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp client-id [*<interface>* **|** *<identifier>***] [hostname** *<"string">***] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp hostname *"<string>"* **[no-default-route | no-domain-name | no-nameservers] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp [no-default-route | no-domain-name | no-nameservers] [track *<name>***] [***<administrative distance>***]**
ip address dhcp track *<name>* **[***<administrative distance>***]**

Syntax Description

<administrative distance>	Optional. Specifies the administrative distance to use when adding the DHCP gateway into the route table. It is used to determine the best route when multiple routes to the same destination exist. The lower the administrative distance, the more reliable the route. Range is **1** to **255**.
class-id	Optional. Specifies the vendor class identifier for the interface.
ascii *<string>*	Specifies the vendor class identifier in an ASCII string of up to **255** bytes.
hex *<value>*	Specfies the vendor class identifier in hexadecimal format. Valid range is up to **510** hexadecimal numbers. An even number of digits is required.
client-id	Optional. Specifies the client identifier used when obtaining an IP address from a DHCP server.
<interface>	Specifies an interface, thus defining the client identifier as the hexadecimal medium access control (MAC) address of the specified interface (including a hexadecimal number added to the front of the MAC address to identify the media type). For example, specifying the **client-id ethernet 0/1** (where the Ethernet interface has a MAC address of d217.0491.1150) defines the client identifier as **01:d2:17:04:91:11:50** (where 01 defines the media type as Ethernet). Refer to *hardware-address on page 4344* for a detailed listing of media types.
<identifier>	Specifies a custom client-identifier using a text string (that is converted to a hexadecimal equivalent) or 7 to 28 hexadecimal numbers (with colon delimiters). For example, a custom client identifier of **0f:ff:ff:ff:ff:51:04:99:a1** may be entered using the *<identifier>* option.
hostname *<"string">*	Optional. Specifies a text string (to override the global router name) to use as the name in the DHCP option 12 field. The string is enclosed in quotation marks and can consist of up to 35 characters.

no-default-route Optional. Specifies that no default route is obtained via DHCP.

no-domain-name Optional. Specifies that no domain name is obtained via DHCP.

no-nameservers Optional. Specifies that no domain naming system (DNS) servers are obtained via DHCP.

track *<name>* Optional. Attaches a network monitoring track to the DHCP client. The DHCP gateway route for this client will only reside in the route table while the track is in the pass state. For more information on configuring track objects, refer to *track <name> on page 1886*.

Default Values

<administrative distance> By default, the administrative distance value is 1.

class-id Optional. By default, no vendor class identifier is configured.

client-id Optional. By default, the client identifier is populated using the following formula:

TYPE: INTERFACE SPECIFIC INFO : MAC ADDRESS

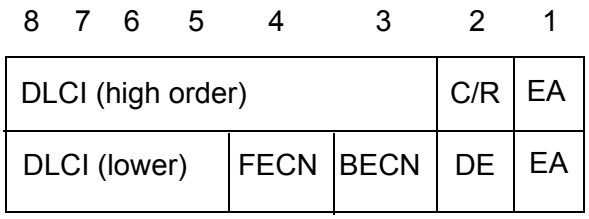
Where TYPE specifies the media type in the form of one hexadecimal byte (refer to *hardware-address on page 4344* for a detailed listing of media types), and the MAC ADDRESS is the medium access control (MAC) address assigned to the first Ethernet interface in the unit in the form of six hexadecimal bytes. (For units with a single Ethernet interface, the MAC ADDRESS assigned to Ethernet 0/1 is used in this field.)

INTERFACE SPECIFIC INFO is only used for Frame Relay interfaces and can be determined using the following:

FR_PORT#: Q.922 ADDRESS

Where the FR_PORT# specifies the label assigned to the virtual Frame Relay interface using four hexadecimal bytes. For example, a virtual Frame Relay interface labeled 1 would have a FR_PORT# of 00:00:00:01.

The Q.922 ADDRESS field is populated using the following:



Where the FECN, BECN, C/R, DE, and high order extended address (EA) bits are assumed to be 0 and the lower order EA bit is set to 1.

The following list provides a few example DLCIs and associated Q.922 address:

DLCI (decimal) / Q.922 address (hex)

16 / 0x0401
50 / 0x0C21
60 / 0x0CC1
70 / 0x1061
80 / 0x1401

hostname *“<string>”* By default, the host name is the name configured using the Global Configuration **hostname** command.

Command History

Release 2.1	Command was introduced.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 13.1	Command was expanded to include the track and administrative distance.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.10.0	Command was expanded to include the **class-id** parameter in support of DHCP Option 60.

Functional Notes

DHCP allows interfaces to acquire a dynamically assigned IP address from a configured DHCP server on the network. Many service providers require the use of DHCP when connecting to their services. Using DHCP reduces the number of dedicated IP addresses the ISP must obtain. Consult your ISP to determine the proper values for the **client-id** and **hostname** fields.

The vendor class identifier is sent to the DHCP server in DHCP discover and request messages via DHCP Option 60. This option gives the DHCP server details regarding DHCP client configuration and also allows the server to send any vendor-specific information to the client in DHCP offer messages via Option 43.

Usage Examples

The following example enables DHCP operation on the interface:

(config)**#interface bvi 1**
(config-bvi 1)**#ip address dhcp**

The following example enables DHCP operation on the interface utilizing host name **adtran** and does not allow obtaining a default route, domain name, or name servers. It also sets the administrative distance as **5**:

(config)**#interface bvi 1**
(config-bvi 1)**#ip address dhcp hostname “adtran” no-default-route no-domain-name no-nameservers 5**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the specified interface. Use the optional **secondary** keyword to define a secondary IPv4 address. Use the **no** form of this command to remove a configured IPv4 address. Variations of this command include:

ip address <*ipv4 address*> <*subnet mask*>
ip address <*ipv4 address*> <*subnet mask*> **secondary**

Syntax Description

<ipv4 address>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the specified interface.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 1.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a secondary IPv4 address of **192.22.72.101 255.255.255.252**:

(config)**#interface bvi 1**
(config-bvi 1)**#ip address 192.22.72.101 255.255.255.252 secondary**

ip address range *<start ip address> <end ip address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the specified interface. Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#interface bvi 1**
(config-bvi 1)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip dhcp

Use the **ip dhcp** command to release or renew the Dynamic Host Configuration Protocol (DHCP) Internet Protocol version 4 (IPv4) address. This command is only applicable when using DHCP for IP address assignment. Variations of this command include:

ip dhcp release
ip dhcp renew

Syntax Description

release	Releases the DHCP IPv4 address.
renew	Renews the DHCP IPv4 address.

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.
Release 8.1	Command was added to the asynchronous transfer mode (ATM) subinterface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release R10.1.0	Command was added to the bridged virtual interface (BVI).

Usage Examples

The following example releases the DHCP IPv4 address for the virtual interface:

(config)**#interface bvi 1**
(config-bvi 1)**#ip dhcp release**

ip dhcp relay destination *<ipv4 address>*

Use the **ip dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 4 (IPv4) and to specify the IPv4 address for the DHCPv4 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv4 relay functionality is disabled on the interface.

Syntax Description

<ipv4 address>	Specifies the IPv4 address for the DHCPv4 messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.

Usage Examples

The following example enables DHCPv4 relay agent functionality and specifies the destination address as **192.33.4.251**:

(config)**#interface bvi 1**
(config-bvi 1)**#ip dhcp relay destination 192.33.4.251**

ip directed-broadcast

Use the **ip directed-broadcast** command to allow reception/forwarding of directed broadcasts. Use the **no** form of this command to disable this feature. Variations of this command include:

ip directed-broadcast
ip directed-broadcast <*name*>

Syntax Description

<*name*>	Specifies IP access control list (ACL) name.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

A directed broadcast is a packet intended for all nodes on a nonlocal network. For example, the broadcast address 255.255.255.255 reaches all nodes on a network; the directed broadcast address 128.1.255.255 is intended for all nodes whose network address is 128.1.0.0. A router not directly attached to 128.1.0.0 simply forwards the directed broadcast packet to the next hop. A router on network 128.1.0.0 that has **ip directed-broadcast** enabled, accepts and forwards the packet to all nodes whose network address is 128.1.0.0. Routers connecting subnets of 128.1.0.0 also accept and forward the packet to the nodes on their respective subnets. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is distributed as a broadcast on the destination subnet. The packet is then sent as a link-layer broadcast.

The **ip directed-broadcast** command controls the distribution of directed broadcasts when they reach their target subnets. Only the final transmission of the directed broadcast on its ultimate destination subnet is affected. It does not affect the transit unicast routing of IP directed broadcasts.

If **ip directed-broadcast** is enabled for this interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which this interface is attached will be forwarded as broadcasts on that subnet. Forwarding of the packets can be limited by specifying an ACL with this command. In this case, only directed broadcasts that are permitted by the specified ACL will be forwarded, and all other directed broadcasts directed to this interface subnet will be dropped.

Disabling the **ip directed-broadcast** command will cause directed broadcasts destined for the subnet to which this interface is attached to be dropped.

This option is a requirement for routers as described in RFC 1812, section 4.2.2.11. Furthermore, it is disabled by default (RFC 2644), with the intended goal of reducing the efficacy of certain types of denial of service (DoS) attacks.

Usage Examples

The following example enables forwarding of directed broadcasts on BVI 1:

(config)**#interface bvi 1**
(config-bvi 1)**#ip directed-broadcast**

ip flow

Use the **ip flow** command to enable integrated traffic monitoring (ITM) for all traffic received or forwarded on an interface. Use the **no** form of this command to disable traffic monitoring. Variations of this command include:

ip flow egress
ip flow egress <*name*>
ip flow ingress
ip flow ingress <*name*>

Syntax Description

egress	Specifies that all outgoing traffic be monitored.
ingress	Specifies that all incoming traffic be monitored.
<*name*>	Optional. Specifies the name of an access control list (ACL) to use for filtering traffic.

Default Values

By default, no traffic monitoring is enabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables traffic monitoring on a bridged virtual interface (BVI) to monitor incoming traffic through an ACL called **myacl**:

(config)**#interface bvi 1**
(config-bvi 1)**#ip flow ingress myacl**

ip helper-address *<ip address>*

Use the **ip helper-address** command to configure AOS to forward User Datagram Protocol (UDP) broadcast packets received on the interface. Use the **no** form of this command to disable forwarding packets.

> NOTE *The **ip helper** command must be used in conjunction with the **ip forward-protocol** command to configure AOS to forward UDP broadcast packets. Refer to ip forward-protocol udp <value> on page 1398 for more information.*

Syntax Description

<ip address>	Specifies the destination IP address for the forwarded UDP packets. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, broadcast UDP packets are not forwarded.

Command History

Release 1.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

When used in conjunction with the **ip forward-protocol** command, the **ip helper-address** feature allows you to customize which broadcast packets are forwarded.

To implement the helper address feature, assign a helper-address(es) (specifying the device that needs to receive the broadcast traffic) to the interface closest to the host that transmits the broadcast packets. When broadcast packets (of the specified type forwarded using the **ip forward-protocol** command) are received on the interface, they will be forwarded to the device that needs the information.

Only packets meeting the following criteria are considered eligible by the **ip helper-address** feature:

1. The packet IP protocol is UDP.
2. Any UDP port specified using the **ip forward-protocol** command.
3. The medium access control (MAC) address of the frame is an all-ones broadcast address (ffff.ffff.ffff).
4. The destination IP address is broadcast defined by all ones (255.255.255.255) or a subnet broadcast (for example, 192.33.4.251 for the 192.33.4.248 /30 subnet).

Usage Examples

The following example forwards all DNS broadcast traffic to the DNS server with IP address **192.33.5.99**:

(config)**#ip forward-protocol udp domain**
(config)**#interface bvi 1**
(config-bvi 1)**#ip helper-address 192.33.5.99**

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces	(all types)1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

Open shortest path first (OSPF) will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the interface:

(config)**#interface bvi 1**
(config-bvi 1)**#ip mtu 1200**

ip ospf

Use the **ip ospf** command to customize Open Shortest Path First version 2 (OSPFv2) settings (if needed). Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **area** <*area id*>
ip ospf <*process id*> **authentication-key** <*password*>
ip ospf <*process id*> **cost** <*value*>
ip ospf <*process id*> **dead-interval** <*seconds*>
ip ospf <*process id*> **hello-interval** <*seconds*>
ip ospf <*process id*> **message-digest-key [1 | 2] md5** <*key*>
ip ospf <*process id*> **priority** <*value*>
ip ospf <*process id*> **retransmit-interval** <*seconds*>
ip ospf <*process id*> **shutdown**
ip ospf <*process id*> **transmit-delay** <*seconds*>

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
area <*area id*>	Specifies the ID of the area to which this interface is assigned for the specified OSPFv2 process. Valid range is **0** to **4294967295**.
authentication-key <*password*>	Assigns a simple-text authentication password to be used by other routers using the OSPF simple password authentication.
cost <*value*>	Specifies the OSPF cost of sending a packet on the interface. This value overrides any computed cost value. Range is **1** to **65535**.
dead-interval <*seconds*>	Sets the maximum interval (in seconds) allowed between hello packets. If the maximum is exceeded, neighboring devices will determine that the device is down. Range is **0** to **32767** seconds.
hello-interval <*seconds*>	Specifies the interval (in seconds) between hello packets sent on the interface. Range is **0** to **32767** seconds.
message-digest-key [1 | 2] md5 <*key*>	Configures OSPF message digest 5 (MD5) authentication (16 byte maximum) keys.
priority <*value*>	Sets the OSPF priority. The value set in this field helps determine the designated router (DR) for this network. Range is **0** to **255**.
retransmit-interval <*seconds*>	Specifies the interval (in seconds) between link state advertisements (LSAs). Range is **0** to **32767** seconds.

shutdown	Disables the OSPFv2 process on the interface. When this keyword is used, the OSPFv2 settings remain in place, but logically it appears to the interface as though the process has been removed from the configuration. This parameter can be useful in troubleshooting.
transmit-delay <*seconds*>	Sets the estimated time (in seconds) required to send a link state advertisement (LSA) on the interface. Range is **0** to **32767** seconds.

Default Values

The defaults for this command are:

dead-interval <*seconds*>	40 seconds
hello-interval <*seconds*>	10 seconds: Ethernet, Frame Relay, and Point-to-Point Protocol (PPP)
priority <*value*>	1
retransmit-interval <*seconds*>	5 seconds
transmit-delay <*seconds*>	1 second

Command History

Release 3.1	Command was introduced.
Release 15.1	Command was expanded to include the BVIs.
Release R11.3.0	Command was expanded to include the <*process id*>, **area** <*area id*>, and **shutdown** parameters.

Usage Examples

The following example sets the maximum number of seconds allowed between hello packets to **25000**:

(config)**#interface bvi 1**
(config-bvi 1)**#ip ospf 1 dead-interval 25000**

ip ospf <*process id*> authentication

Use the **ip ospf authentication** command to authenticate an interface that is performing open shortest path first (OSPF) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **authentication**
ip ospf <*process id*> **authentication message-digest**
ip ospf <*process id*> **authentication null**

Syntax Description

<process id>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
message-digest	Optional. Selects message digest authentication type.
null	Optional. Specifies that no authentication be used.

Default Values

By default, **ip ospf authentication** is set to **null** (meaning no authentication is used).

Command History

Release 3.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Usage Examples

The following example specifies that no authentication will be used on BVI 1:

(config)**#interface bvi 1**
(config-bvi 1)**#ip ospf 1 authentication null**

ip ospf <*process id*> network

Use the **ip ospf network** command to specify the type of network on this interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **network broadcast**
ip ospf <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
broadcast	Sets the network type for broadcast.
point-to-point	Sets the network type for point-to-point.

Default Values

By default, Ethernet defaults to **broadcast**. Point-to-Point Protocol (PPP) and Frame Relay default to **point-to-point**.

Command History

Release 3.1	Command was introduced.
Release 15.1	Command was expanded to include the BVIs.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Functional Notes

A point-to-point network will not elect designated routers.

Usage Examples

The following example designates a broadcast network type:

(config)**#interface bvi 1**
(config-bvi 1)**#ip ospf 1 network broadcast**

ip policy route-map *<name>*

Use the **ip policy route-map** command to assign a policy route map to this interface. Use the **no** form of this command to remove the route-map policy.

Syntax Description

<name>	Specifies the name of the policy route map to assign to this interface.

Default Values

By default, no policy route map is assigned to this interface.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Usage Examples

The following example assigns the policy route map **policy1** to the interface:

(config)**#interface bvi 1**
(config-bvi 1)**#ip policy route-map policy1**

ip proxy-arp

Use the **ip proxy-arp** command to enable proxy Address Resolution Protocol (ARP) on the interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, proxy ARP is enabled.

Command History

Release 1.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

In general, the principle of proxy ARP allows a router to insert its IP address in the source IP address field of a packet (if the packet is from a host on one of its subnetworks). This allows hosts to reach devices on other subnetworks without implementing routing or specifying a default gateway.

If proxy ARP is enabled, AOS will respond to all proxy ARP requests with its specified medium access control (MAC) address and forward packets accordingly.

Enabling proxy ARP on an interface may introduce unnecessary ARP traffic on the network.

Usage Examples

The following example enables proxy ARP on BVI 1:

(config)**#interface bvi 1**
(config-bvi 1)**#ip proxy-arp**

ip rip receive version

Use the **ip rip receive version** command to configure the Routing Information Protocol (RIP) version the unit accepts in all RIP packets received on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip receive version 1
ip rip receive version 2

Syntax Description

1	Accepts only received RIP version 1 packets on the interface.
2	Accepts only received RIP version 2 packets on the interface.

Default Values

By default, all interfaces implement RIP version 1 (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

Use the **ip rip receive version** command to specify a RIP version that will override the **version** (in the Router RIP) configuration.

AOS only accepts one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures a BVI to accept only RIP version 2 packets:

(config)**#interface bvi 1**
(config-bvi 1)**#ip rip receive version 2**

ip rip send version

Use the **ip rip send version** command to configure the Routing Information Protocol (RIP) version the unit sends in all RIP packets transmitted on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip send version 1
ip rip send version 2

Syntax Description

1	Transmits only RIP version 1 packets on the interface.
2	Transmits only RIP version 2 packets on the interface.

Default Values

By default, all interfaces transmit RIP version 1 (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

Use the **ip rip send version** to specify a RIP version that will override the **version** (in the Router RIP) configuration.

AOS only transmits one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures a BVI to transmit only RIP version 2 packets:

(config)**#interface bvi 1**
(config-bvi 1)**#ip rip send version 2**

ip rip summary-address *<ip address> <subnet mask>*

Use the **ip rip summary-address** command to manually summarize the routes Routing Information Protocol (RIP) will advertise and send out a specified interface. Use the **no** form of this command to disable this mode.

Syntax Description

<ip address>	Specifies the summarized network IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.0**).
<subnet mask>	Specifies the subnet mask that corresponds to the range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no manual summarization is applied by RIP.

Command History

Release 12.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

Unlike the automatic summarization on classful network boundaries, only specific network advertisements are made by RIP using the **ip rip summary-address** command. This command is only effective if RIP version 2 is configured.

Usage Examples

The following example enables manual summarization on the specified IP address:

(config)**#interface bvi 1**
(config-bvi 1)**#ip rip summary-address 10.10.123.0 255.255.255.0**

ip route-cache

Use the **ip route-cache** command to enable fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

*Using network address translation (NAT) or the AOS firewall capabilities on an interface requires process switching mode (using the **no ip route-cache** command).*

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual bridged virtual interfaces (BVIs). IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 2.1	Command was introduced.
Release 15.1	Command was expanded to include the BVIs.

Functional Notes

Fast switching allows an IP interface to provide optimum performance when processing IP traffic.

Usage Examples

The following example enables fast-cache switching on a BVI:

(config)**#interface bvi 1**
(config-bvi 1)**#ip route-cache**

ip unnumbered *<interface>*

Use the **ip unnumbered** command to use the IP address assigned to the specified interface for all IP processing on the active interface. Use the **no** form of this command to remove the unnumbered configuration.

Syntax Description

<interface>	Specifies the interface that contains the IP address to use as the source address for all packets transmitted on this interface. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; and for an ATM subinterface, use **atm 1.1**. Type **ip unnumbered ?** for a list of valid interfaces.

Default Values

By default, all interfaces are configured to use a specified IP address (using the **ip address** command).

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

If **ip unnumbered** is enabled on an interface, all IP traffic from the interface will use a source IP address taken from the specified interface. For example, specifying **ip unnumbered eth 0/1** while in the BVI Configuration mode configures the BVI to use the IP address assigned to the Ethernet interface for all IP processing. In addition, AOS uses the specified interface information when sending route updates over the unnumbered interface.

Usage Examples

The following example configures BVI 1 to use the IP address assigned to the Ethernet interface (**eth 0/1**):

(config)**#interface bvi 1**
(config-bvi 1)**#ip unnumbered eth 0/1**

ip urlfilter <*name*>

Use the **ip urlfilter** command to apply a universal resource locator (URL) filter to the interface for all inbound or outbound traffic. Use the **no** form of this command to remove the URL filter from an interface. Variations of this command include:

ip urlfilter <*name*> **in**
ip urlfilter <*name*> **out**

Syntax Description

<*name*>	Specifies the URL filter name to use on the interface.
in	Applies the filter to the inbound traffic.
out	Applies the filter to the outbound traffic.

Default Values

By default, there are no URL filters applied to any interfaces.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be created by using the **ip urlfilter** <*name*> **http** command before applying it to the interface. Refer to *ip urlfilter allowmode on page 1493* for more information on using this command.

Usage Examples

The following example performs URL filtering on all traffic entering through BVI 1 and matches the URL filter named **MyFilter**:

(config)**#interface bvi 1**
(config-bvi 1)**#ip urlfilter MyFilter in**

ipv6 dhcp relay destination *<ipv6 address>*

Use the **ipv6 dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 6 (IPv6) and to specify the IPv6 address for the DHCPv6 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv6 relay functionality is disabled on the interface. Variations of this command include:

ipv6 dhcp relay destination *<ipv6 address>*
ipv6 dhcp relay destination *<ipv6 address> <interface>*

Syntax Description

<ipv6 address>	Specifies the IPv6 address for the DHCPv6 messages. IPv6 addresses should be specified in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
<interface>	Optional. Specifies an output interface to use when sending messages to the DHCPv6 server. If no interface is specified, the interface is selected by the routing table. This parameter is only required when the IPv6 address is a link-scoped address. Interfaces are specified in the *<interface type> <slot/port | interface id>* format. For example, for an Ethernet interface, use **eth 0/1**. Type **ipv6 dhcp relay destination** *<ipv6 address>* **?** to display a list of valid interfaces.

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.1.0	Command was expanded to include the Tunnel interface.

Functional Notes

To configure an interface to function as a DHCPv6 relay agent, you must first enable IPv6 on the interface using the command **ipv6**.

Usage Examples

The following example enables DHCPv6 relay agent functionality and specifies the destination address as **2001:DB8:2::1**:

(config)**#interface bvi 1**
(config-bvi 1)**#ipv6**
(config-bvi 1)**#ipv6 dhcp relay destination 2001:DB8:2::1**

mac-address *<mac address>*

Use the **mac-address** command to specify the medium access control (MAC) address of the virtual local area network (VLAN) interface. Only the last three values of the MAC address can be modified. The first three values contain the Adtran reserved number (00:0A:C8) by default. Use the **no** form of this command to return to the default MAC address programmed by Adtran.

Syntax Description

<mac address>	Specifies a valid 48-bit MAC address. MAC addresses should be expressed in the following format xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).

Default Values

A unique default MAC address is programmed in each unit shipped by Adtran.

Command History

Release 5.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Usage Examples

The following example configures a MAC address of **00:0A:C8:5F:00:D2** for BVI 1:

(config)**#interface bvi 1**
(config-bvi 1)**#mac-address 00:0A:C8:5F:00:D2**

max-reserved-bandwidth *<value>*

Use the **max-reserved-bandwidth** command to specify the percentage of interface bandwidth reserved for use in user-defined (priority or class-based) queues. The remainder of the interface bandwidth is reserved for system-critical traffic and is not available to user-defined queues. Use the **no** form of this command to restore the default value.

Reserving a portion of the interface bandwidth for system-critical traffic is necessary for proper operation. Specifying the entire interface bandwidth for use in user-defined queues can cause undesirable operation.

Syntax Description

<value>	Specifies the maximum percentage of bandwidth to reserve for quality of service (QoS). This setting is configured as a percentage of the total interface speed. Range is **1** to **100** percent.

Default Values

By default, **max-reserved-bandwidth** is set to 75 percent, which reserves 25 percent of the interface bandwidth for system-critical traffic.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Usage Examples

The following example specifies **85** percent of the bandwidth on BVI 1 be available for use in user-defined queues:

(config)**#interface bvi 1**
(config-bvi 1)**#max-reserved-bandwidth 85**

packet-capture <*name*>

Use the **packet-capture** command to apply a previously configured packet capture instance to the interface. Use the **no** form of this command to remove the packet capture instance.

Syntax Description

<*name*>	Specifies the name of the packet capture instance to apply to the interface.

Default Values

By default, no packet capture instances are configured or applied to the interface.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

The AOS packet capture feature is used with network monitoring to effectively capture data packets as they traverse the network. For more information about packet capturing, its uses, and its implementation in AOS, refer to the configuration guide *Configuring Packet Capture in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example applies the previously configured packet capture **1CAPTURE** to the interface:

(config)**#interface bvi 1**
(config-bvi 1)**#packet-capture 1CAPTURE**

qos-policy out *<name>*

Use the **qos-policy out** command to apply a previously configured quality of service (QoS) map to outgoing packets on an interface. Use the **no** form of this command to remove the map from the interface.

Syntax Description

<name>	Specifies the name of a previously created QoS map (refer to *qos map <name> <number> on page 1673* for more information).

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

When a QoS policy is applied to an interface, it may be disabled if the interface bandwidth is not adequate to support the requested bandwidth on the map set. Once the bandwidth problem is resolved, the map will work again. The bandwidth will be rechecked on any of the following changes:

1. A priority or class-based entry is added to, deleted from, or changed in a QoS map set.
2. The interface bandwidth is changed by the **bandwidth** command on the interface.
3. A QoS policy is applied to an interface.
4. A cross connect is created that includes an interface with a QoS policy.
5. The interface queuing method is changed to fair-queue to use weighted fair queuing (WFQ).
6. The interface operational status changes.
7. The interface bandwidth changes for other reasons (e.g., when asymmetric digital subscriber line (ADSL) finishes training).

In order to prevent the map from being disabled in cases of temporary inadequate bandwidth (e.g., a single link goes down in a dual T1 multilink configuration where the map requests more than one T1's worth of bandwidth), the QoS map uses the maximum theoretical bandwidth on an interface, not the actual bandwidth at that time. This actually helps QoS keep higher priority class-based traffic working better than best-effort traffic when the bandwidth drops.

Usage Examples

The following example applies the QoS map **VOICEMAP** to BVI 1:

(config)**#interface bvi 1**
(config-bvi 1)**#qos-policy out VOICEMAP**

rtp quality-monitoring

Use the **rtp quality-monitoring** command to enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets on this interface. If the global command (**ip rtp quality-monitoring**) is disabled when this command is issued, the system will return the following warning: "Applied but not used, you must globally enable **ip rtp quality-monitoring** to use VQM." Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, VQM is enabled on all wide area network (WAN) and local area network (LAN) interfaces.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables RTP quality monitoring on the bridged virtual interface (BVI) 1:

```
(config)#interface bvi 1
(config-bvi 1)#rtp quality-monitoring
```

traffic-shape rate <*value*>

Use the **traffic-shape rate** command to specify and enforce an output bandwidth for the bridged virtual interface (BVI). Use the **no** form of this command to disable this feature. Variations of this command include:

traffic-shape rate <*value*>
traffic-shape rate <*value*> **count-eth-overhead**
traffic-shape rate <*value*> <*burst*>
traffic-shape rate <*value*> <*burst*> **count-eth-overhead**

Syntax Description

<*value*>	Specifies the rate (in bits per second) at which the interface should be shaped.
<*burst*>	Optional. Specifies the allowed burst in bytes. By default, the burst is specified as the rate divided by 5 and represents the number of bytes that would flow within 200 ms.
count-eth-overhead	Optional. Indicates to include the Ethernet header overhead bytes when determining packet size.

Default Values

By default, **traffic-shape rate** is disabled.

Command History

Release 10.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release R11.1.0	Command was expanded to include the **count-eth-overhead** parameter, system management Ethernet virtual connection (EVC) and the system control EVC.

Functional Notes

Traffic shaping can be used to limit the virtual local area network (VLAN) interface to a particular rate or to specify use of quality of service (QoS).

Usage Examples

The following example sets the outbound rate of BVI 1 to 128 kbps and applies a QoS policy that gives all Realtime Transport Protocol (RTP) traffic priority over all other traffic:

(config)**#qos map voip 1**
(config-qos-map)**#match ip rtp 10000 10500 all**
(config-qos-map)**#priority unlimited**
(config-qos-map)**#interface bvi 1**
(config-bvi 1)**#traffic-shape rate 128000**
(config-bvi 1)**#qos-policy out voip**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an interface to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the interface from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an interface's VRF association will clear all IP-related settings on that interface.

Syntax Description

<name>	Specifies the name of the VRF to which to assign the interface.

Default Values

By default, interfaces are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release 17.8	The keyword **ip** was removed from this command.

Functional Notes

VRF instances must be created first before an interface can be assigned. An interface can only be assigned to one VRF, but multiple interfaces can be assigned to the same VRF.

An interface will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the **bvi 1** interface to the VRF instance named **RED**:

(config)**#interface bvi 1**
(config-bvi 1)**#vrf forwarding RED**

DEMAND INTERFACE COMMAND SET

To create a virtual demand interface and/or activate the Demand Interface Configuration mode, enter the **interface demand** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface demand 1
(config-demand 1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

bandwidth <value> on page 2638
called-number <number> on page 2639
caller-number <number> on page 2640
connect-mode on page 2641
connect-order on page 2642
connect-sequence on page 2643
connect-sequence attempts <value> on page 2645
connect-sequence interface-recovery on page 2646
demand-hold-queue <number> timeout <value> on page 2647
dynamic-dns on page 2648
fair-queue on page 2650
fast-idle <value> on page 2651
hold-queue <value> out on page 2652
idle-timeout <value> on page 2653
ip commands begin on page 2654
keepalive <value> on page 2689
lldp receive on page 2690
lldp send on page 2691

bandwidth <*value*>

Use the **bandwidth** command to provide the bandwidth value of an interface to the higher level protocols. This value is used in cost calculations. Use the **no** form of this command to restore the default value.

Syntax Description

<*value*>	Specifies the bandwidth value in kbps.

Default Values

To view default values, use the **show interfaces** command.

Command History

Release 3.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

The **bandwidth** command is an informational value that is communicated to the higher level protocols to be used in cost calculations. While this is a routing parameter that does not affect the physical interface, it does affect the amount of bandwidth available for use in Quality of Service (QoS) configurations.

It is important to note that there is an order of precedence in determining the interface bandwidth reported by the router for QoS. Under normal circumstances, the Layer 1 bandwidth is reported based on the interface type. For example, a T1 interface will report the available bandwidth as 1.536 Mbps. This can be misleading in QoS configurations if the **bandwidth** command has been applied to the IP interface for routing purposes because the command overrides the reported available bandwidth that can be utilized for QoS. Using the **bandwidth** command can severely disrupt the configuration of QoS on the interface, therefore, use the **max-reserved-bandwidth** command (*page 2694*) to adjust the bandwidth appropriately for QoS configurations.

Usage Examples

The following example sets the bandwidth of the demand interface to 10 Mbps:

(config)**#interface demand 1**
(config-demand 1)**#bandwidth 10000**

called-number *<number>*

Use the **called-number** command to link calls to specific interfaces based on their dialed number identification service (DNIS) numbers. Multiple called numbers may be specified for an interface. Use the **no** form of this command to restore the default value.

Syntax Description

<number>	Identifies the called number to be linked to an interface. The DNIS number is limited to 20 digits.

Default Values

By default, no called numbers are defined.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example links calls with a DNIS number of **2565558409** to the demand interface **1**:

(config)**#interface demand 1**
(config-demand 1)**#called-number 2565558409**

caller-number <*number*>

Use the **caller-number** command to link calls to specific interfaces based on its caller ID (CLID) number. Multiple caller ID numbers may be specified, allowing the interface to accept calls from different remote resources. Use the **no** form of this command to restore the default value.

Syntax Description

<*number*>	Identifies the caller's number to be linked to an interface. The CLID number is limited to 20 digits.

Default Values

By default, no caller numbers are defined.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example links calls with a CLID number of **2565559911** to the demand interface **1**:

(config)**#interface demand 1**
(config-demand 1)**#caller-number 2565559911**

connect-mode

Use the **connect-mode** command to configure the interface to only answer calls, only originate calls, or to both answer and originate calls. Use the **no** form of this command to restore the default value. Variations of this command include:

connect-mode answer
connect-mode either
connect-mode originate

Syntax Description

answer	Specifies the interface may be used to answer calls, but not originate calls.
either	Specifies the interface may be used to answer and originate calls.
originate	Specifies the interface may be used to originate calls, but not answer calls.

Default Values

By default, the connect mode is set to both answer and originate calls.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures demand interface **1** to only answer calls:

(config)**#interface demand 1**
(config-demand 1)**#connect-mode answer**

connect-order

Use the **connect-order** command to specify the starting point in the connection sequence for each sequence activation. The connection sequence is a circular list. Use the **no** form of this command to restore the default value. Variations of this command include:

connect-order last-successful
connect-order round-robin
connect-order sequential

Syntax Description

last-successful	Specifies the connect sequence be processed beginning with the last successful entry or the first entry if there are no previous connections.
round-robin	Specifies the connect sequence be processed beginning with the entry that follows the last successful entry or the first entry if there are no previous connections.
sequential	Specifies the connect sequence be processed from the beginning of the list.

Default Values

By default, connect sequences are processed sequentially.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures the connection sequence to begin with the last successful entry:

(config)**#interface demand 1**
(config-demand 1)**#connect-order last-successful**

connect-sequence

Use the **connect-sequence** command to provide instructions to the interface on how to use the resource pool and telephone numbers to connect to demand destinations. Use the **no** form of this command to restore the default value.Variations of this command include the following:

connect-sequence <*value*> **dial-string** <*string*> **forced-analog**
connect-sequence <*value*> **dial-string** <*string*> **forced-analog busyout-threshold** <*value*>
connect-sequence <*value*> **dial-string** <*string*> **forced-cellular**
connect-sequence <*value*> **dial-string** <*string*> **forced-cellular busyout-threshold** <*value*>
connect-sequence <*value*> **dial-string** <*string*> **forced-isdn-56k**
connect-sequence <*value*> **dial-string** <*string*> **forced-isdn-56k busyout-threshold** <*value*>
connect-sequence <*value*> **dial-string** <*string*> **forced-isdn-64k**
connect-sequence <*value*> **dial-string** <*string*> **forced-isdn-64k busyout-threshold** <*value*>
connect-sequence <*value*> **dial-string** <*string*> **isdn-56k**
connect-sequence <*value*> **dial-string** <*string*> **isdn-56k busyout-threshold** <*value*>
connect-sequence <*value*> **dial-string** <*string*> **isdn-64k**
connect-sequence <*value*> **dial-string** <*string*> **isdn-64k busyout-threshold** <*value*>

Syntax Description

<*value*>	Specifies the sequence number for this connection specification entry. Range is **1** to **65535**.
dial-string <*string*>	Specifies the telephone number to dial when using this connection. The dial string is limited to 20 digits.
forced-analog	Specifies that only analog resources may be used.
forced-cellular	Specifies that only cellular resources may be used.
forced-isdn-56k	Specifies that only integrated services digital network (ISDN) resources may be used. Call is placed using ISDN 56k.
forced-isdn-64k	Specifies that only ISDN resources may be used. Call is placed using ISDN 64k.
isdn-56k	Specifies any dial resource may be used if ISDN 56k call type is used.
isdn-64k	Specifies any dial resource may be used if ISDN 64k call type is used.
busyout-threshold <*value*>	Optional. Specifies the maximum number of connect sequence cycles during an activation attempt that must fail before it is skipped until the next activation attempt.

Default Values

By default, any dial resource may be used.

By default, the dial string for cellular connections is **#777**.

Command History

Release 11.1	Command was introduced.
Release 17.2	Command was expanded to include the cellular connections.

Usage Examples

The following example instructs demand interface **1** to place the call using ISDN 64k:

(config)**#interface demand 1**
(config-demand 1)**#connect-sequence 65 dial-string 2565559911 forced-isdn-64k**

The following example instructs demand interface 1 to place the call using a cellular connection:

(config)**#interface demand 1**
(config-demand 1)**#connect-sequence 1 dial-string #777 forced-cellular**

connect-sequence attempts *<value>*

Use the **connect-sequence attempts** command to limit the number of times the connect sequence will cycle when its entries are unable to establish a connection. When the maximum number of attempts are exhausted, the interface will go into recovery mode. Refer to *connect-sequence interface-recovery on page 2646* for more information. Use the **no** form of this command to restore the default value.

Syntax Description

<value>	Specifies the number of times the connect sequence will cycle through its entries if it is unable to make a connection. Range is **0** to **65535**.

Default Values

By default, the **connect-sequence attempts** are unlimited.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example instructs demand interface **1** to attempt its connection sequence **500** times:

(config)**#interface demand 1**
(config-demand 1)**#connect-sequence attempts 500**

connect-sequence interface-recovery

Use the **connect-sequence interface-recovery** command to allow the interface to go down in the event that the **connect-sequence attempts** value is exhausted. Refer to *connect-sequence attempts <value> on page 2645* for more information. Use the **no** form of this command to restore the default value. Variations of this command include:

connect-sequence interface-recovery
connect-sequence interface-recovery retry-interval <*value*>
connect-sequence interface-recovery retry-interval <*value*> **max-retries** <*number*>

Syntax Description

retry-interval <*value*>	Optional. Specifies the number of seconds the interface will wait between connect sequence cycles during recovery attempts.
max-retries <*number*>	Optional. Specifies the maximum number of times the connect sequence will cycle in an attempt to bring the interface back up. When in interface recovery mode, this value overrides the **connect-sequence attempts** value.

Default Values

By default, the **connect-sequence interface-recovery retry-interval** is set to 120 seconds and **max-retries** are unlimited.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures demand interface **1** to wait **60** seconds between retry attempts with a maximum number of **500** retries:

(config)**#interface demand 1**
(config-demand 1)**#connect-sequence interface-recovery retry-interval 60 max-retries 500**

demand-hold-queue <*number*> timeout <*value*>

Use the **demand-hold-queue timeout** command to set the number and length of time interesting packets will be held while a connection is being made. Use the **no** form of this command to restore the default value.

Syntax Description

<*number*>	Specifies the number of packets that may be stored in the hold queue. Range is **0** to **100**.
<*value*>	Specifies the number of seconds a packet may remain in the hold queue. Range is **0** to **255** seconds.

Default Values

By default, the hold queue is disabled.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures demand interface **1** to hold **50** packets in the queue for up to **120** seconds:

(config)**#interface demand 1**
(config-demand 1)**#demand-hold-queue 50 timeout 120**

dynamic-dns

Use the **dynamic-dns** command to configure Dynamic DNS service provided by Dynamic Network Services, Inc. (www.dyndns.org). Use the **no** form of this command to disable this feature. Variations of this command include:

dynamic-dns custom <*hostname*> <*minutes*>
dynamic-dns dyndns <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-custom <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-static <*hostname*> <*username*> <*password*>

Syntax Description

<*hostname*>	Specifies the host name for the server that updates the dynamic domain naming system (DNS).
<*minutes*>	Specifies the intervals in minutes to update the server with information (updates also occur when the interface's IP address changes regardless of the update intervals).
<*username*>	Specifies a user name using an alphanumerical string up to 30 characters in length (the user name is case sensitive).
<*password*>	Specifies a password using an alphanumerical string up to 30 characters in length (the password is case sensitive). Refer to *Functional Notes* below for additional argument descriptions.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.
Release 12.1	Command was expanded.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

custom - Constanttime.com's Custom Dynamic DNS^{SM} service allows you complete access and management control over your domain name regardless of where you purchased/registered it. This allows you to manage IP address mappings (A records), domain aliases (CNAME records), and mail servers (mail exchange (MX) records).

dyndns - The Dynamic DNS^{SM} offered by Dynamic Network Services, Inc. (DynDNS.org) allows you to alias a dynamic IP address to a static host name in various domains. This allows your unit to be more easily accessed from various locations on the Internet. This service is provided for up to five host names.

dyndns-custom - DynDNS.org's Custom DNS^{SM} service provides a full DNS solution, giving you complete control over an entire domain name. A Web-based interface provides two levels of control over your domain, catering to average or advanced users. Five globally redundant DNS servers ensure that your domain will always resolve.

A choice of two interfaces is available. The basic interface is designed for most users. It comes preconfigured for most common configurations and allows for easy creation of most common record types. The advanced interface is designed for system administrators with a solid DNS background, and provides layout and functionality similar to a BIND zone file allowing for the creation of nearly any record type.

Custom DNS^{SM} can be used with both static and dynamic IPs, and has the same automatic update capability through Custom DNS-aware clients as Dynamic DNS.

dyndns-static - The Static DNS service is similar to DynDNS.org's Dynamic DNS^{SM} service in that it allows a host name, such as yourname.dyndns.org, to point to your IP address. Unlike a Dynamic DNS host, a Static DNS host does not expire after 35 days without updates, but updates take longer to propagate through the DNS system. This service is provided for up to five host names.

If your IP address does not change often or at all, but you still want an easy name to remember it by (without having to purchase your own domain name), Static DNS service is ideal for you.

If you would like to use your own domain name (such as yourname.com), you need Custom DNS service that also provides full dynamic and static IP address support.

Usage Examples

The following example sets the Dynamic DNS to **dyndns-custom** with host name **host**, user name **user**, and password **pass**:

(config)**#interface demand 1**
(config-demand 1)**#dynamic-dns dyndns-custom host user pass**

fair-queue

Use the **fair-queue** command to enable weighted fair queuing (WFQ) on an interface. Use the **no** form of this command to disable WFQ and enable first in, first out (FIFO) queueing for an interface. Variations of this command include:

fair-queue
fair-queue <*threshold*>

WFQ must be enabled on an interface to use priority queuing. By default, WFQ is enabled for all interfaces with maximum bandwidth speeds equivalent to T1/E1 and below.

Syntax Description

<*threshold*>	Optional. Specifies the maximum number of packets that can be present in each conversation subqueue. Packets received for a conversation after this limit is reached are discarded. Range: **16** to **512** packets.

Default Values

By default, WFQ is enabled with a threshold of 64 packets.

Command History

Release 5.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Usage Examples

The following example enables WFQ on the interface with a threshold set at 100 packets:

(config)**#interface demand 1**
(config-demand 1)**#fair-queue 100**

fast-idle *<value>*

Use the **fast-idle** command to set the amount of time the demand interface connection will remain active in the absence of interesting traffic when there is contention for the demand resources being used by this interface. Use the **no** form of this command to restore the default value.

Syntax Description

<value>	Specifies the number of seconds the interface will remain up in the absence of interesting traffic. Range is **1** to **2147483** seconds.

Default Values

By default, **fast-idle** is set to 120 seconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets fast idle to **1073752** seconds:

(config)**#interface demand 1**
(config-demand 1)**#fast-idle 1073752**

hold-queue <*value*> out

Use the **hold-queue out** command to change the overall size of an interface's wide area network (WAN) output queue. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the total number of packets the output queue can contain before packets are dropped. Range is **16** to **1000** packets.

Default Values

The default queue size for weighted fair queuing (WFQ) is **400**. The default queue size for Point-to-Point Protocol (PPP) first in, first out (FIFO) and Frame Relay round-robin is **200**.

Command History

Release 5.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Usage Examples

The following example sets the overall output queue size to **700**:

(config)**#interface demand 1**
(config-demand 1)**#hold-queue 700 out**

idle-timeout <*value*>

Use the **idle-timeout** command to set the amount of time the interface link/bundle will remain up in the absence of interesting traffic. Interesting traffic and direction logic are set using the **match-interesting** commands. Refer to *match-interesting ip on page 2693* for more information. Use the **no** form of this command to restore the default value.

Syntax Description

<*value*>	Specifies the number of seconds the interface will remain up in the absence of interesting traffic. Range is **1** to **2147483** seconds.

Default Values

By default, **idle-timeout** is set to **120** seconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example configures demand interface **1** to time out after **360** seconds:

(config)**#interface demand 1**
(config-demand 1)**#idle-timeout 360**

ip access-group *<ipv4 acl name>*

Use the **ip access-group** command to create an Internet Protocol version 4 (IPv4) access control list (ACL) to be used for packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ip access-group *<ipv4 acl name>* **in**
ip access-group *<ipv4 acl name>* **out**

Syntax Description

<ipv4 acl name>	Indicates the assigned IPv4 ACL name.
in	Enables access control on packets received on the specified interface.
out	Enables access control on packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 3.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

When this command is enabled, the IPv4 destination address of each packet must be validated before being passed through. If the packet is not acceptable per these settings, it is dropped.

Usage Examples

The following example sets up the router to only allow Telnet traffic into the demand interface:

(config)**#ip access-list extended TelnetOnly**
(config-ext-nacl)**#permit tcp any any eq telnet**
(config-ext-nacl)**#interface demand 1**
(config-demand 1)**#ip access-group TelnetOnly in**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to an interface. IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

> NOTE *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an interface.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the deman interface 1:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the demand interface 1:

(config)**#interface demand 1**
(config-demand 1)**#ip access-policy PRIVATE**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the specified interface. Use the optional keyword **secondary** to define a secondary IPv4 address. Use the **no** form of this command to remove a configured IPv4 address. Variations of this command include:

ip address <*ipv4 address*> <*subnet mask*>
ip address <*ipv4 address*> <*subnet mask*> **secondary**

Syntax Description

<*ipv4 address*>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*subnet mask*>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the specified interface.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a secondary IPv4 address of **192.22.72.101 255.255.255.252**:

(config)**#interface demand 1**
(config-demand 1)**#ip address 192.22.72.101 255.255.255.252 secondary**

ip address cellular

Use the **ip address cellular** command to allow the interface to be assigned an IP address and name server from a cellular modem. Use the **no** form of this command to disable the feature. Variations of this command include:

ip address cellular
ip address cellular no-nameservers

Syntax Description

no-nameservers	Optional. Specifies that the interface receives an IP address from a cellular modem but does not receive a name server.

Default Values

By default, the interface is assigned an address with the command *ip address <ipv4 address> <subnet mask> on page 2657*.

Command History

Release 11.9.0	Command was introduced.

Functional Notes

In order to configure the demand interface using the **ip address cellular** command, you must also configure the interface to use High Level Data Link Control (HDLC) encapsulation, have a cellular resource configured in the resource pool, and configure the **connect-sequence** to use **forced-cellular**. In addition, for interesting traffic to arrive at the demand interface, a static route must be configured on the AOS device. The following configuration example displays the necessary configurations for this command to be used:

(config)**#interface demand 1 encapsulation hdlc**
(config-demand 1)**#resource pool LTERESOURCE**
(config-demand 1)**#connect-sequence 1 dial-string #777 forced-cellular**
(config-demand 1)**#ip address cellular**
(config-demand 1)**#exit**
(config)**#ip route 0.0.0.0 0.0.0.0 demand 1**

Usage Examples

The following example enables the demand interface to receive an IP address and name server from a cellular modem:

(config)**#interface demand 1**
(config-demand 1)**#ip address cellular**

ip address negotiated

Use the **ip address negotiated** command to allow the interface to negotiate (i.e., be assigned) an IP address from the far-end Point-to-Point Protocol (PPP) connection. Use the **no** form of this command to disable the negotiation for an IP address. Variations of this command include:

ip address negotiated
ip address negotiated dns-sync
ip address negotiated dns-sync no-default
ip address negotiated no-default
ip address negotiated no-default dns-sync

Syntax Description

dns-sync	Optional. Specifies that when the IP address is negotiated, domain naming system (DNS) information is also received.
no-default	Optional. Prevents the insertion of a default route. Some systems already have a default route configured and need a static route to the PPP interface to function correctly.

Default Values

By default, the interface is assigned an address with the **ip address** <*ip address*> <*subnet mask*> command.

Command History

Release 5.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was expanded to include the **dns-sync** parameter.

Usage Examples

The following example enables the demand interface to negotiate an IP address from the far-end connection:

(config)**#interface demand 1**
(config-demand 1)**#ip address negotiated**

The following example enables the demand interface to negotiate an IP address from the far-end connection without inserting a default route:

(config)**#interface demand 1**
(config-demand 1)**#ip address negotiated no-default**

ip address range *<start ip address> <end ip address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the specified interface. Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#interface demand 1**
(config-demand 1)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip crypto map *<name>*

Use the **ip crypto map** command to associate Internet Protocol version 4 (IPv4) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

When you apply a map to an interface, you are applying all crypto maps with the given map name. This allows you to apply multiple crypto maps if you have created maps that share the same name, but have different map index numbers.

Syntax Description

<name>	Specifies the IPv4 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

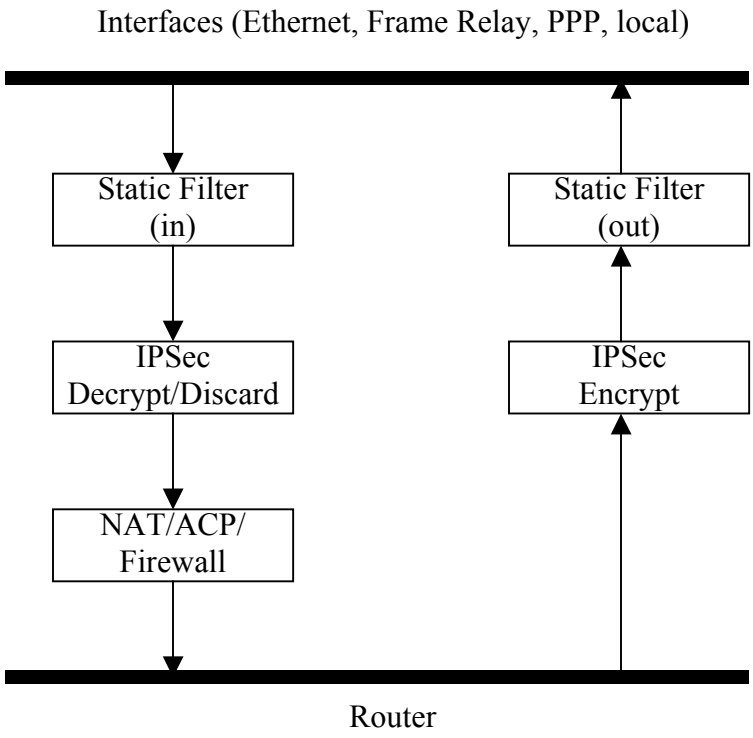
Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 9.1	Command was expanded to include the High-Levell Data Link Control (HDLC) interface.
Release 11.1	Command was expanded to include the demand interface.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.7.0	Command syntax was changed to require the **ip** keyword.

Functional Notes

When configuring a system to use both the stateful inspection firewall and Internet key exchange (IKE) negotiation for VPN, keep the following notes in mind.

When defining the IPv4 policy class and associated access control lists (ACLs) that describe the behavior of the IPv4 firewall, do not forget to include the traffic coming into the system over a VPN tunnel terminated by the system. The firewall should be set up with respect to the unencrypted traffic that is destined to be sent or received over the VPN tunnel. The following diagram represents typical AOS data-flow logic.



As shown in the diagram above, data coming into the product is first processed by the static filter associated with the interface on which the data is received. This access group is a true static filter and is available for use regardless of whether the IPv4 firewall is enabled or disabled. Next (if the data is encrypted), it is sent to the IPSec engine for decryption. The decrypted data is then processed by the stateful inspection firewall. Therefore, given a terminating VPN tunnel, only unencrypted data is processed by the firewall.

The IPv4 ACLs for a crypto map on an interface work in reverse logic to the ACLs for a policy class on an interface. When specifying the ACLs for a crypto map, the source information is the private local side, unencrypted source of the data. The destination information will be the far-end, unencrypted destination of the data. However, ACLs for a policy class work in reverse. The source information for the ACL in a policy class is the far end. The destination information is the local side.

Usage Examples

The following example applies all IPv4 crypto maps with the name **MyMap** to the interface:

(config)**#demand 1**
(config-demand 1)**#ip crypto map MyMap**

ip dhcp relay destination *<ipv4 address>*

Use the **ip dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 4 (IPv4) and to specify the IPv4 address for the DHCPv4 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv4 relay functionality is disabled on the interface.

Syntax Description

<ipv4 address>	Specifies the IPv4 address for the DHCPv4 messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.

Usage Examples

The following example enables DHCPv4 relay agent functionality and specifies the destination address as **192.33.4.251**:

(config)**#interface demand 1**
(config-demand 1)**#ip dhcp relay destination 192.33.4.251**

ip directed-broadcast

Use the **ip directed-broadcast** command to allow reception/forwarding of directed broadcasts. Use the **no** form of this command to disable this feature. Variations of this command include:

ip directed-broadcast
ip directed-broadcast *<name>*

Syntax Description

<name>	Specifies IP access control list (ACL) name.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.

Functional Notes

A directed broadcast is a packet intended for all nodes on a nonlocal network. For example, the broadcast address 255.255.255.255 reaches all nodes on a network; the directed broadcast address 128.1.255.255 is intended for all nodes whose network address is 128.1.0.0. A router not directly attached to 128.1.0.0 simply forwards the directed broadcast packet to the next hop. A router on network 128.1.0.0 that has **ip directed-broadcast** enabled, accepts and forwards the packet to all nodes whose network address is 128.1.0.0. Routers connecting subnets of 128.1.0.0 also accept and forward the packet to the nodes on their respective subnets. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is distributed as a broadcast on the destination subnet. The packet is then sent as a link-layer broadcast.

The **ip directed-broadcast** command controls the distribution of directed broadcasts when they reach their target subnets. Only the final transmission of the directed broadcast on its ultimate destination subnet is affected. It does not affect the transit unicast routing of IP directed broadcasts.

If **ip directed-broadcast** is enabled for this interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which this interface is attached will be forwarded as broadcasts on that subnet. Forwarding of the packets can be limited by specifying an ACL with this command. In this case, only directed broadcasts that are permitted by the specified ACL will be forwarded, and all other directed broadcasts directed to this interface subnet will be dropped.

Disabling the **ip directed-broadcast** command will cause directed broadcasts destined for the subnet to which this interface is attached to be dropped.

This option is a requirement for routers as described in RFC 1812, section 4.2.2.11. Furthermore, it is disabled by default (RFC 2644), with the intended goal of reducing the efficacy of certain types of denial of service (DoS) attacks.

Usage Examples

The following example enables forwarding of directed broadcasts on the interface **demand 1**:

(config)**#interface demand 1**
(config-demand 1)**#ip directed-broadcast**

ip flow

Use the **ip flow** command to enable integrated traffic monitoring (ITM) for all traffic received or forwarded on an interface. Use the **no** form of this command to disable traffic monitoring. Variations of this command include:

ip flow egress
ip flow egress <*name*>
ip flow ingress
ip flow ingress <*name*>

Syntax Description

egress	Specifies that all outgoing traffic be monitored.
ingress	Specifies that all incoming traffic be monitored.
<*name*>	Optional. Specifies the name of an access control list (ACL) to use for filtering traffic.

Default Values

By default, no traffic monitoring is enabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables traffic monitoring on a **demand** interface to monitor **incoming** traffic through an ACL called **myacl**:

(config)**#interface demand 1**
(config-demand 1)**#ip flow ingress myacl**

ip helper-address *<ip address>*

Use the **ip helper-address** command to configure AOS to forward User Datagram Protocol (UDP) broadcast packets received on the interface. Use the **no** form of this command to disable forwarding packets.

> NOTE *The **ip helper** command must be used in conjunction with the **ip forward-protocol** command to configure AOS to forward UDP broadcast packets. Refer to ip forward-protocol udp <value> on page 1398 for more information.*

Syntax Description

<ip address>	Specifies the destination IP address for the forwarded UDP packets. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, broadcast UDP packets are not forwarded.

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

When used in conjunction with the **ip forward-protocol** command, the **ip helper-address** feature allows you to customize which broadcast packets are forwarded.

To implement the helper address feature, assign a helper address(es) (specifying the device that needs to receive the broadcast traffic) to the interface closest to the host that transmits the broadcast packets. When broadcast packets (of the specified type forwarded using the **ip forward-protocol** command) are received on the interface, they will be forwarded to the device that needs the information.

Only packets meeting the following criteria are considered eligible by the **ip helper-address** feature:

1. The packet IP protocol is UDP.
2. Any UDP port specified using the **ip forward-protocol** command.
3. The medium access control (MAC) address of the frame is an all-ones broadcast address (ffff.ffff.ffff).
4. The destination IP address is broadcast defined by all ones (**255.255.255.255**) or a subnet broadcast (for example, **192.33.4.251** for the **192.33.4.248 /30** subnet).

Usage Examples

The following example forwards all domain naming system (DNS) broadcast traffic to the DNS server with IP address **192.33.5.99**:

(config)**#ip forward-protocol udp domain**
(config)**#interface demand 1**
(config-demand 1)**#ip helper-address 192.33.5.99**

ip igmp

Use the **ip igmp** command to configure multicasting related functions for the interface. Variations of this command include:

ip igmp immediate-leave
ip igmp last-member-query-interval <*milliseconds*>
ip igmp querier-timeout <*seconds*>
ip igmp query-interval <*seconds*>
ip igmp query-max-response-time <*seconds*>
ip igmp static-group <*address*>
ip igmp version [1 | 2]

Syntax Description

immediate-leave	Specifies that if only one host (or Internet Group Management Protocol (IGMP) snooping switch) is connected to the interface, when a leave is received, multicast of that group is immediately terminated as opposed to sending a group query and timing out the group if no device responds. Works in conjunction with **ip igmp last-member-query-interval**. Applies to all groups when configured. Use the **no** form of this command to disable the **immediate-leave** feature.
last-member-query-interval <*milliseconds*>	Controls the timeout (in milliseconds) used to detect whether any group receivers remain on an interface after a receiver leaves a group. If a receiver sends a leave-group message (IGMP Version 2), the router sends a group-specific query on that interface. After twice the time specified by this command plus as much as one second longer, if no receiver responds, the router removes that interface from the group and stops sending that group's multicast packets to the interface. Range is **100** to **65535** ms. Use the **no** form of this command to return to the default setting.
querier-timeout <*seconds*>	Specifies the interval (in seconds) that the router waits after the current querier's last query before it takes over as querier (IGMP V2). Range is **60** to **300** seconds. Use the **no** form of this command to return to the default setting.
query-interval <*seconds*>	Specifies the interval (in seconds) at which IGMP queries are sent on an interface. Host query messages are addressed to the all-hosts multicast group with an IP time to live (TTL) of 1. The router uses queries to detect whether multicast group members are on the interface and to select an IGMP designated router (DR) for the attached segment (if more than one multicast router exists). Only the DR for the segment sends queries. For IGMP V2, the DR is the router with the lowest IP address on the segment. Range is **0** to **65535** seconds. Use the **no** form of this command to return to the default setting.
query-max-response-time <*seconds*>	Specifies the maximum response time (in seconds) advertised by this interface in queries when using IGMP V2. Hosts are allowed a random time within this period to respond, reducing response bursts. Use the **no** form of this command to return to the default setting.

Syntax Description (Continued)

static-group <*address*>	Configures the router's interface to be a statically connected member of the specified group. Packets received on the correct reverse path forwarding (RPF) interface are forwarded to this interface regardless of whether any receivers have joined the specified group using IGMP. Use the **no** form of this command to remove a configured static group.
version [1 | 2]	Sets the interface's IGMP version. Use the **no** form of this command to return to the default setting.

Default Values

ip igmp immediate-leave	No default
ip igmp last-member-query-interval	**1000** milliseconds
ip igmp querier-timeout	2x the **query-interval** value
ip igmp query-interval	**60** seconds
ip igmp query-max-response-time	**10** seconds
ip igmp static-group	No default
ip igmp version	Version **1**

Command History

Release 7.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Usage Examples

The following example sets the query message interval on the interface to **200** milliseconds:

(config)**#interface demand 1**
(config-demand 1)**#ip igmp last-member-query-interval 200**

ip mcast-stub downstream

Use the **ip mcast-stub downstream** command to enable multicast forwarding and Internet Group Management Protocol (IGMP) (router mode) on an interface and place it in multicast stub downstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub upstream** commands. Downstream interfaces connect to segments with multicast hosts. Multiple interfaces may be configured in downstream mode; however, interfaces connecting to the multicast network (upstream) should not be configured in downstream mode. Interfaces configured as downstream should have the lowest IP address of all IGMP-capable routers on the connected segment in order to be selected as the designated router (DR) and ensure proper forwarding. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub upstream on page 2674* for more information.

Usage Examples

The following example enables multicast forwarding and IGMP on the interface:

(config)**#interface demand 1**
(config-demand 1)**#ip mcast-stub downstream**

ip mcast-stub fixed

Use the **ip mcast-stub fixed** command to allow forwarding of multicast traffic on a selected interface after enabling multicast routing. Use the **no** form of this command to disable this mode.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 12.1	Command was introduced.

Functional Notes

Multicast routing must be enabled prior to setting **ip mcast-stub fixed** on the selected interface. Also, use the command *ip igmp on page 2669* to receive multicast traffic without host-initiated Internet Group Management Protocol (IGMP) activity on the selected interface. Otherwise, all host-initiated IGMP transactions will enter multicast routes on the router's interface involved with IGMP activities.

Usage Examples

The following example enables multicast traffic forwarding and IGMP on the interface:

(config)**#interface demand 1**
(config-demand 1)**#ip mcast-stub fixed**

ip mcast-stub helper-enable

Use the **ip mcast-stub helper-enable** command to assign the **ip mcast-stub helper-address** as the Internet Group Management Protocol (IGMP) proxy. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 8.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address**, **ip mcast-stub upstream**, and **ip mcast-stub downstream** commands. When enabled, the interface becomes a helper forwarding interface. The IGMP host function is dynamically enabled and the interface becomes the active upstream interface, enabling the unit to perform as an IGMP proxy. Refer to *ip mcast-stub helper-address <ip address> on page 1418*, *ip mcast-stub downstream on page 2671*, and *ip mcast-stub upstream on page 2674* for more information.

Usage Examples

The following example sets the helper address as the IGMP proxy:

(config)**#interface demand 1**
(config-demand 1)**#ip mcast-stub helper-enable**

ip mcast-stub upstream

Use the **ip mcast-stub upstream** command to enable multicast forwarding on an interface and place it in multicast stub upstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub downstream** commands. When enabled, the interface becomes a candidate to be a helper forwarding interface. If chosen as the best path toward the helper address by the router's unicast route table, the IGMP host function is dynamically enabled and the interface becomes the active upstream interface, enabling the router to perform as an IGMP proxy. Though multiple interfaces may be candidates, no more than one interface will actively serve as the helper forwarding interface. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub downstream on page 2671* for more information.

Usage Examples

The following example enables multicast forwarding on the interface:

(config)**#interface demand 1**
(config-demand 1)**#ip mcast-stub upstream**

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces	(all types)1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

Open shortest path first (OSPF) will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the interface:

(config)**#interface demand 1**
(config-demand 1)**#ip mtu 1200**

ip ospf

Use the **ip ospf** command to customize Open Shortest Path First version 2 (OSPFv2) settings (if needed). Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **area** <*area id*>
ip ospf <*process id*> **authentication-key** <*password*>
ip ospf <*process id*> **cost** <*value*>
ip ospf <*process id*> **dead-interval** <*seconds*>
ip ospf <*process id*> **hello-interval** <*seconds*>
ip ospf <*process id*> **message-digest-key [1 | 2] md5** <*key*>
ip ospf <*process id*> **priority** <*value*>
ip ospf <*process id*> **retransmit-interval** <*seconds*>
ip ospf <*process id*> **shutdown**
ip ospf <*process id*> **transmit-delay** <*seconds*>

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
area <*area id*>	Specifies the ID of the area to which this interface is assigned for the specified OSPFv2 process. Valid range is **0** to **4294967295**.
authentication-key <*password*>	Assigns a simple-text authentication password to be used by other routers using the OSPF simple password authentication.
cost <*value*>	Specifies the OSPF cost of sending a packet on the interface. This value overrides any computed cost value. Range is **1** to **65535**.
dead-interval <*seconds*>	Sets the maximum interval (in seconds) allowed between hello packets. If the maximum is exceeded, neighboring devices will determine that the device is down. Range is **0** to **32767** seconds.
hello-interval <*seconds*>	Specifies the interval (in seconds) between hello packets sent on the interface. Range is **0** to **32767** seconds.
message-digest-key [1 | 2] md5 <*key*>	Configures OSPF message digest 5 (MD5) authentication (16 byte maximum) keys.
priority <*value*>	Sets the OSPF priority. The value set in this field helps determine the designated router (DR) for this network. Range is **0** to **255**.
retransmit-interval <*seconds*>	Specifies the interval (in seconds) between link state advertisements (LSAs). Range is **0** to **32767** seconds.

shutdown	Disables the OSPFv2 process on the interface. When this keyword is used, the OSPFv2 settings remain in place, but logically it appears to the interface as though the process has been removed from the configuration. This parameter can be useful in troubleshooting.
transmit-delay <*seconds*>	Sets the estimated time (in seconds) required to send a link state advertisement (LSA) on the interface. Range is **0** to **32767** seconds.

Default Values

The defaults for this command are:

dead-interval <*seconds*>	40 seconds
hello-interval <*seconds*>	10 seconds: Ethernet, Frame Relay, and Point-to-Point Protocol (PPP)
priority <*value*>	1
retransmit-interval <*seconds*>	5 seconds
transmit-delay <*seconds*>	1 second

Command History

Release 3.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release R11.3.0	Command was expanded to include the <*process id*>, **area** <*area id*>, and **shutdown** parameters.

Usage Examples

The following example sets the maximum number of seconds allowed between hello packets to **25000**:

(config)**#interface demand 1**
(config-demand 1)**#ip ospf 1 dead-interval 25000**

ip ospf <*process id*> authentication

Use the **ip ospf authentication** command to authenticate an interface that is performing open shortest path first (OSPF) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **authentication**
ip ospf <*process id*> **authentication message-digest**
ip ospf <*process id*> **authentication null**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
message-digest	Optional. Selects message digest authentication type.
null	Optional. Specifies that no authentication be used.

Default Values

By default, **ip ospf authentication** is set to **null** (meaning no authentication is used).

Command History

Release 3.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Usage Examples

The following example specifies that no authentication will be used on the demand interface:

(config)**#interface demand 1**
(config-demand 1)**#ip ospf 1 authentication null**

ip ospf <*process id*> network

Use the **ip ospf network** command to specify the type of network on this interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **network broadcast**
ip ospf <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
broadcast	Sets the network type for broadcast.
point-to-point	Sets the network type for point-to-point.

Default Values

By default, Ethernet defaults to **broadcast**. Point-to-Point Protocol (PPP) and Frame Relay default to **point-to-point**.

Command History

Release 3.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Functional Notes

A point-to-point network will not elect designated routers.

Usage Examples

The following example designates a broadcast network type:

(config)**#interface demand 1**
(config-demand 1)**#ip ospf 1 network broadcast**

ip policy route-map *<name>*

Use the **ip policy route-map** command to associate a route map with a network interface source. Use the **no** form of this command to disable this feature.

Syntax Description

<name>	Specifies the route map to associate with this interface.

Default Values

By default, policy-based routing is disabled for all interfaces.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example associates the route map named **MyMap** with demand interface **1**:

(config)**#interface demand 1**
(config-demand 1)**#ip policy route-map MyMap**

ip proxy-arp

Use the **ip proxy-arp** command to enable proxy Address Resolution Protocol (ARP) on the interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, proxy ARP is enabled.

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

In general, the principle of proxy ARP allows a router to insert its IP address in the source IP address field of a packet (if the packet is from a host on one of its subnetworks). This allows hosts to reach devices on other subnetworks without implementing routing or specifying a default gateway.

If proxy ARP is enabled, AOS will respond to all proxy ARP requests with its specified medium access control (MAC) address and forward packets accordingly.

Enabling proxy ARP on an interface may introduce unnecessary ARP traffic on the network.

Usage Examples

The following example enables proxy ARP on the virtual demand interface:

(config)**#interface demand 1**
(config-demand 1)**#ip proxy-arp**

ip rip receive version

Use the **ip rip receive version** command to configure the Routing Information Protocol (RIP) version the unit accepts in all RIP packets received on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip receive version 1
ip rip receive version 2

Syntax Description

1	Accepts only received RIP version 1 packets on the interface.
2	Accepts only received RIP version 2 packets on the interface.

Default Values

By default, all interfaces implement RIP version 1 (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

Use the **ip rip receive version** to specify a RIP version that overrides the **version** (in the Router RIP) configuration.

AOS only accepts one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the virtual demand interface to accept only RIP version 2 packets:

(config)**#interface demand 1**
(config-demand 1)**#ip rip receive version 2**

ip rip send version

Use the **ip rip send version** command to configure the Routing Information Protocol (RIP) version the unit sends in all RIP packets transmitted on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip send version 1
ip rip send version 2

Syntax Description

1	Transmits only RIP version 1 packets on the interface.
2	Transmits only RIP version 2 packets on the interface.

Default Values

By default, all interfaces transmit RIP version 1 (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

Use the **ip rip send version** to specify a RIP version that overrides the **version** (in the Router RIP) configuration.

AOS only transmits one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the virtual demand interface to transmit only RIP version 2 packets:

(config)**#interface demand 1**
(config-demand 1)**#ip rip send version 2**

ip rip summary-address *<ip address> <subnet mask>*

Use the **ip rip summary-address** command to manually summarize the routes Routing Information Protocol (RIP) will advertise and send out a specified interface. Use the **no** form of this command to disable this mode.

Syntax Description

<ip address>	Specifies the summarized network IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.0**).
<subnet mask>	Specifies the subnet mask that corresponds to the range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no manual summarization is applied by RIP.

Command History

Release 12.1	Command was introduced.

Functional Notes

Unlike the automatic summarization on classful network boundaries, only specific network advertisements are made by RIP using the **ip rip summary-address** command. This command is only effective if RIP version 2 is configured.

Usage Examples

The following example enables manual summarization on the specified IP address:

(config)**#interface demand 1**
(config-demand 1)**#ip rip summary-address 10.10.123.0 255.255.255.0**

ip route-cache

Use the **ip route-cache** command to enable fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

*Using network address translation (NAT) or the AOS firewall capabilities on an interface requires process switching mode (using the **no ip route-cache** command).*

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual demand interfaces.

Command History

Release 2.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

Fast-cache switching allows an IP interface to provide optimum performance when processing IP traffic.

Usage Examples

The following example enables fast-cache switching on the virtual demand interface:

(config)**#interface demand 1**
(config-demand 1)**#ip route-cache**

ip unnumbered *<interface>*

Use the **ip unnumbered** command to use the IP address assigned to the specified interface for all IP processing on the active interface. Use the **no** form of this command to remove the unnumbered configuration.

Syntax Description

<interface>	Specifies the interface that contains the IP address to use as the source address for all packets transmitted on this interface. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip unnumbered ?** for a list of valid interfaces.

Default Values

By default, all interfaces are configured to use a specified IP address (using the **ip address** command).

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

If **ip unnumbered** is enabled on an interface, all IP traffic from the interface will use a source IP address taken from the specified interface. For example, specifying **ip unnumbered eth 0/1** while in the Demand Interface Configuration mode configures the demand interface to use the IP address assigned to the Ethernet interface for all IP processing. In addition, AOS uses the specified interface information when sending route updates over the unnumbered interface. Static routes may either use the interface name (ppp 1) or the far-end address (if it will be discovered).

Usage Examples

The following example configures the demand interface (labeled **demand 1**) to use the IP address assigned to the Ethernet interface (**eth 0/1**):

(config)**#interface demand 1**
(config-demand 1)**#ip unnumbered eth 0/1**

ip urlfilter <*name*>

Use the **ip urlfilter** command to apply a universal resource locator (URL) filter to the interface for all inbound or outbound traffic. Use the **no** form of this command to remove the URL filter from an interface. Variations of this command include:

ip urlfilter <*name*> **in**
ip urlfilter <*name*> **out**

Syntax Description

<*name*>	Specifies the URL filter name to use on the interface.
in	Applies the filter to the inbound traffic.
out	Applies the filter to the outbound traffic.

Default Values

By default, there are no URL filters applied to any interfaces.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the virtual local area network (VLAN) interfaces.

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be created by using the **ip urlfilter** <*name*> **http** command before applying it to the interface. Refer to *ip urlfilter allowmode on page 1493* for more information on using this command.

Usage Examples

The following example performs URL filtering on all traffic entering through the demand interface (labeled **demand 1**) and matches the URL filter named **MyFilter**:

(config)**#interface demand 1**
(config-demand 1)**#ip urlfilter MyFilter in**

keepalive *<value>*

Use the **keepalive** command to enable the transmission of keepalive packets on the interface and specify the time interval in seconds between transmitted packets. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Defines the time interval (in seconds) between transmitted keepalive packets. Range is **0** to **32767** seconds.

Default Values

By default, the time interval between transmitted keepalive packets is **10** seconds.

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

If three keepalive packets are sent to an interface with no response, the interface is considered down. To detect interface failures quickly, specify a smaller keepalive time.

Usage Examples

The following example specifies a keepalive time of 5 seconds on the virtual demand interface:

(config)**#interface demand 1**
(config-demand 1)**#keepalive 5**

lldp receive

Use the **lldp receive** command to allow Link Layer Discovery Protocol (LLDP) packets to be received on this interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, all interfaces are configured to send and receive LLDP packets.

Command History

Release 9.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Usage Examples

The following example configures the demand interface to receive LLDP packets:

(config)**#interface demand 1**
(config-demand 1)**#lldp receive**

lldp send

Use the **lldp send** command to configure this interface to transmit Link Layer Discovery Protocol (LLDP) packets or to control the types of information contained in the LLDP packets transmitted by this interface. Use the **no** form of this command to disable this feature. Variations of this command include:

lldp send
lldp send management-address
lldp send port-description
lldp send system-capabilities
lldp send system-description
lldp send system-name
lldp send-and-receive

Syntax Description

management-address	Enables transmission of management address information on this interface.
port-description	Enables transmission of port description information on this interface.
system-capabilities	Enables transmission of this device's system capabilities on this interface.
system-description	Enables transmission of this device's system description on this interface.
system-name	Enables transmission of this device's system name on this interface.
and-receive	Configures this interface to both transmit and receive LLDP packets.

Default Values

By default, all interfaces are configured to transmit and receive LLDP packets of all types.

Command History

Release 9.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

Individual LLDP information can be enabled or disabled using the various forms of the **lldp send** command. For example, use the **lldp send-and-receive** command to enable transmit and receive of all LLDP information. Then use the **no lldp send port-description** command to prevent LLDP from transmitting port description information.

Usage Examples

The following example configures the demand interface to transmit LLDP packets containing all enabled information types:

(config)**#interface demand 1**
(config-demand 1)**#lldp send**

The following example configures the demand interface to transmit and receive LLDP packets containing all information types:

(config)**#interface demand 1**
(config-demand 1)**#lldp send-and-receive**

match-interesting ip

Use the **match-interesting ip** command to allow an access control list (ACL) to specify which traffic attempting to cross this interface will be considered interesting. Use the **no** form of this command to restore the default value. Variations of this command include:

match-interesting ip list <*name*>
match-interesting ip list <*name*> **in**
match-interesting ip list <*name*> **out**
match-interesting ip reverse list <*name*>
match-interesting ip reverse list <*name*> **in**
match-interesting ip reverse list <*name*> **out**

Syntax Description

list <*name*>	Specifies using an ACL with normal (source, destination) ACL matching logic.
reverse list <*name*>	Specifies using an ACL with reverse (destination, source) ACL matching logic.
in	Optional. Specifies that only incoming traffic is interesting.
out	Optional. Specifies that only outgoing traffic is interesting.

Default Values

By default, no interesting traffic is defined.

Command History

Release 11.1	Command was introduced.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Usage Examples

The following example instructs demand interface **1** to use the access control list **MyACL** when checking for interesting traffic:

(config)**#interface demand 1**
(config-demand 1)**#match-interesting ip list MyACL in**

max-reserved-bandwidth <*value*>

Use the **max-reserved-bandwidth** command to specify the percentage of interface bandwidth reserved for use in user-defined (priority or class-based) queues. The remainder of the interface bandwidth is reserved for system-critical traffic and is not available to user-defined queues. Use the **no** form of this command to restore the default value.

Reserving a portion of the interface bandwidth for system-critical traffic is necessary for proper operation. Specifying the entire interface bandwidth for use in user-defined queues can cause undesirable operation.

Syntax Description

<*value*>	Specifies the maximum percentage of bandwidth to reserve for quality of service (QoS). This setting is configured as a percentage of the total interface speed. Range is **1** to **100** percent.

Default Values

By default, **max-reserved-bandwidth** is set to 75 percent, which reserves 25 percent of the interface bandwidth for system-critical traffic.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example specifies **85** percent of the bandwidth on the demand interface 1 be available for use in user-defined queues:

(config)**#interface demand 1**
(config-demand 1)**#max-reserved-bandwidth 85**

ospfv3 <*process id*> **area** <*area id*>

Use the **ospfv3 area** command to add an interface to an Open Shortest Path First version 3 (OSPFv3) process, and to configure the OSPFv3 process on the interface. This command places the interface in the specified area for the specified Internet Protocol version 6 (IPv6) OSPFv3 address family, and optionally defines the instance ID that is used to represent this OSPFv3 process in messages on the interface's link. Use the **no** form of this command to remove the OSPFv3 process from the interface. Variations of this command include:

ospfv3 <*process id*> **area** <*area id*> **ipv6**
ospfv3 <*process id*> **area** <*area id*> **ipv6 instance** <*instance id*>

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join, for the specified address family. The process ID is locally significant to the device, and must be unique among all OSPFv3 processes on the device. Valid range is **1** to **65535**.
<*area id*>	Specifies the ID of the area to which this interface is assigned for the given OSPFv3 process. Valid range is **0** to **4294967295**.
ipv6	Identifies the OSPFv3 address family as IPv6.
instance <*instance id*>	Optional. Specifies the value to use in the instance ID field of messages sent or received by this OSPFv3 process on the interface's link. Valid range is **0** to **31**.

Default Values

By default, an OSPFv3 process is not configured on an interface. By default, process IDs, area IDs, and instance IDs are not defined.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

When using this command to enable an OSPFv3 process on an interface, keep the following rules in mind:

- The interface must have the address family enabled on the interface. If the address family is not enabled on the interface, the command is rejected and an error is displayed.
- Only interfaces on the default virtual routing and forwarding (VRF) instance support this command. Interfaces on a nondefault VRF will display an error when you attempt to configure OSPFv3 settings.
- The interface and the specified OSPFv3 process (if defined in the global configuration) must be in the same VRF or the command will fail.
- The address family must match that specified for the OSPFv3 process if the process has been defined in the global configuration or the command will fail.
- If the OSPFv3 process identified by the process ID does not exist in the global configuration, it is automatically created, along with the specified address family, and it is assigned to the VRF of which the interface is a member.

- If the specified OSPFv3 process is already at its maximum limit of processes or address families, the command fails.
- If the specified OSPFv3 process already exists in the global configuration, but its configuration does not include an address family, the specified address family is added to the OSPFv3 router configuration.
- A given OSPFv3 process can only have one address family.
- Multiple OSPFv3 instances per address family, per VRF, can be created and can be assigned to a given interface.
- If the interface's VRF changes, all OSPFv3 assignments are removed.
- To change an OSPFv3 process's VRF, the process must first be removed and then recreated. Removing the process removes all OSPFv3 assignments for that process form all interfaces.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

To add an interface to the OSPFv3 process **5**, in area **10**, with an instance ID of **10**, enter the command as follows:

(config)**#interface demand 1**
(config-demand 1)**#ospfv3 5 area 10 ipv6 instance 10**

ospfv3 authentication

Use the **ospfv3 authentication** command to authenticate an interface that is performing Internet Protocol version 6 (IPv6) Open Shortest Path First version 3 (OSPFv3) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ospfv3 authentication ipsec spi <*spi*> **md5** <*key*>
ospfv3 authentication ipsec spi <*spi*> **sha1** <*key*>
ospfv3 authentication null

Syntax Description

ipsec	Specifies that IP security (IPsec) authentication is used.
spi <*spi*>	Specifies the security parameter index (SPI). Valid range is **256** to **4294967295**.
md5 <*key*>	Specifies that MD5 authentication is used. Keys are specified in 32 hexadecimal characters.
sha1 <*key*>	Specifies that SHA-1 authentication is used. Keys are specified in 40 hexadecimal characters.
null	Specifies that no OSPFv3 authentication is used.

Default Values

By default, this is set to **null** (meaning no authentication is used).

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example specifies that no OSPFv3 authentication will be used on the interface:

(config)**#interface demand 1**
(config-demand 1)**#ospfv3 authentication null**

ospfv3 <*process id*> cost <*cost*>

Use the **ospfv3 cost** command to specify a value that represents the cost of sending an Open Shortest Path First version 3 (OSPFv3) packet over the interface. Use the **no** form of this command to return the cost to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2695*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
cost <*cost*>	Specifies the OSPFv3 cost of the interface. This value overrides any automatically computed cost value (default value). Valid range is **1** to **65535**.

Default Values

By default, the OSPFv3 cost of the interface is automatically computed. The automatic cost computation is the reference bandwidth divided by the interface bandwidth. The reference bandwidth is set by the command *auto-cost reference-bandwidth <value> on page 4150*, and defaults to **100** Mbps.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the OSPFv3 cost of the interface as **10**:

(config)**#interface demand 1**
(config-demand 1)**#ospfv3 5 cost 10**

ospfv3 <*process id*> dead-interval <*value*>

Use the **ospfv3 dead-interval** command to specify the maximum interval allowed between Open Shortest Path First version 3 (OSPFv3) Hello packets on the interface. If the maximum interval is exceeded, neighboring devices will assume that the device is down. This value must be the same across all interfaces on a link. Use the **no** form of this command to return the dead interval to the default value.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2695*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
dead-interval <*value*>	Specifies the maximum number of seconds allowed between OSPFv3 Hello packets. It is recommended that this value be **4** times the Hello packet interval (set with the command *ospfv3 <process id> hello-interval <value> on page 2702*). Valid range is **1** to **65535** seconds.

Default Values

By default, the maximum interval allowed between OSPFv3 Hello packets is set to **40** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

To specify the dead interval between OSPFv3 Hello packets on the interface, enter the command as follows:

(config)**#interface demand 1**
(config-demand 1)**#ospfv3 5 dead-interval 100**

ospfv3 encryption

Use the **ospfv3 encryption** command to specify a symmetrical, bidirectional Open Shortest Path First version 3 (OSPFv3) security association (SA) that uses encapsulating security payload (ESP) for encryption and authentication of all OSPFv3 messages that are sent or received on the interface. This command allows you to specify OSPFv3 security at the interface level. Use the **no** form of this command to remove IP security (IPsec) protection of OSPFv3 messages on the interface. Variations of this command include:

ospfv3 encryption ipsec spi <*spi*> **esp** <*encryption type*> <*encryption key*> <*authentication type*> <*authentication key*>
ospfv3 encryption ipsec spi <*spi*> **esp null** <*authentication type*> <*authentication key*>
ospfv3 encryption null

Syntax Description

ipsec	Specifies that IPsec encryption is used on the interface for OSPFv3 SAs.
spi <*spi*>	Specifies the security parameter index (SPI) for the SA. The value specified must not be in used by any other IPsec function on the system, or an error message is generated. If the same SPI is already in use in the same OSPFv3 area, entering this command with the same value will overwrite the current configuration. Valid SPI range is **256** to **4294967295**.
esp	Specifies that ESP is used.
null	Specifies that OSPFv3 messages on this interface are not encrypted when used in the **ospfv3 encryption null** format (even when encryption is specified by the OSPFv3 area configuration). When used in the **ospfv3 encryption ipsec spi** <*spi*> **esp null** format, **null** indicates that messages on the interface will not be encrypted, but will be authenticated.
<*encryption type*>	Specifies the type of algorithm used to encrypt OSPFv3 messages. Valid values for encryption are: **3des** uses triple data encryption standard (DES). **aes-cbc** uses advanced encryption standard (AES) with cipher block chaining (CBC). Select from **aes-cbc 128**, **aes-cbc 192**, or **aes-cbc 256**. **des** uses DES.
<*encryption key*>	Specifies the hexadecimal encryption key. The size of the encryption key is determined by the respective encryption algorithm, as follows: **3des** uses a **48** character key size. **aes-cbc 128** uses a **32** character key size. **aes-cbc 192** uses a **48** character key size. **aes-cbc 256** uses a **64** character key size. **des** uses a **16** character key size.
<*authentication type*>	Specifies the algorithm used for authenticating OSPFv3 messages. Valid authentication methods are Message-Digest 5 (**md5**) and Secure-Hash 1 (**sha1**) algorithms.

<authentication key> Specifies the hexadecimal authentication key. The size of the authentication key is determined by the respective authentication algorithm, as follows:

md5 uses a **32** character key size.

sha1 uses a **40** character key size.

Default Values

By default, there is no security for OSPFv3 messages on an interface.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

This commands specifies OSPFv3 security at the interface level. Protection specified with this command overrides any area-level OSPFv3 protection that might apply to the interface.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures OSPFv3 messages with an SPI of **120**, no encryption, and **md5** as the authentication method:

(config)**#interface demand 1**
(config-demand 1)**#ospfv3 encryption ipsec spi 120 esp null md5 NeWtStpsswdLoonGpsswDhtThmnWoKEY**

ospfv3 <*process id*> **hello-interval** <*value*>

Use the **ospfv3 hello-interval** command to specify the interval between Open Shortest Path First version 3 (OSPFv3) Hello packets sent on the interface. This value must be the same across all interfaces on the link. Use the **no** form of this command to return the Hello packet interval to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2695*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
hello-interval <*value*>	Specifies the number of seconds allowed between OSPFv3 Hello packets. Valid range is **1** to **65535** seconds.

Default Values

By default, the Hello packet interval for OSPFv3 is **10** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the interval between OSPFv3 Hello packets on the interface is **20** seconds:

```
(config)#interface demand 1
(config-demand 1)#ospfv3 5 hello-interval 20
```

ospfv3 <*process id*> network

Use the **ospfv3 network** command to specify the network type for Open Shortest Path First version 3 (OSPFv3) enabled interfaces. Use the **no** form of this command to return the interface's network type to the default value. Variations of this command include:

ospfv3 <*process id*> **network broadcast**
ospfv3 <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2695*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
broadcast	Specifies that the OSPFv3 network type for the interface is set to broadcast.
point-to-point	Specifies that the OSPFv3 network type for the interface is set to point-to-point.

Default Values

By default, Ethernet interfaces are set to network type broadcast, and point-to-point (PPP), Frame Relay, and loopback interfaces are set to network type point-to-point.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the network interface as point-to-point:

(config)**#interface demand 1**
(config-demand 1)**#ospfv3 5 network point-to-point**

ospfv3 <*process id*> priority <*value*>

Use the **ospfv3 priority** command to specify the Open Shortest Path First version 3 (OSPFv3) priority for the interface. Use the **no** form of this command to return the interface's priority to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2695*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
priority <*value*>	Specifies the OSPFv3 priority for the interface. Valid range is **0** to **255**.

Default Values

By default, the OSPFv3 priority of an interface is set to **1**.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

Priority is used in the election of the designated router and backup designated router on multi-access networks. Interfaces connected to multi-access networks (such as Ethernet interfaces) perform an election for a designated and backup designated router. The router interface with the highest OSPFv3 priority on the link becomes the designated router for that link. The interface with the next highest priority becomes the designated backup router. In the event there is a tie, the router interface with the highest router ID takes precedence. A priority value of **0** indicates the router is ineligible to become either the designated or backup designated router.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example changes the interface's OSPFv3 priority value to **6**:

(config)**#interface demand 1**
(config-demand 1)**#ospfv3 5 priority 6**

ospfv3 <*process id*> retransmit-interval <*value*>

Use the **ospfv3 retransmit-interval** command to specify the interval between Open Shortest Path First version 3 (OSPFv3) link-state advertisements (LSAs) sent on the interface. Use the **no** form of this command to return the OSPFv3 LSA interval to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2695*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
retransmit-interval <*value*>	Specifies the number of seconds between OSPFv3 LSAs sent on the interface. Valid range is **1** to **65535** seconds.

Default Values

By default, the LSA retransmit interval is set to **5** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the LSA retransmit interval is **10** seconds:

(config)**#interface demand 1**
(config-demand 1)**#ospfv3 5 retransmit-interval 10**

ospfv3 <*process id*> shutdown

Use the **ospfv3 shutdown** command to disable an Open Shortest Path First version 3 (OSPFv3) process on the interface. When this command is used, the OSPFv3 commands remain in place, but logically it appears to the interface as though the OSPFv3 process has been removed from the configuration. This command can be useful in troubleshooting. Use the **no** form of this command to reinstate the OSPFv3 process.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2695*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.

Default Values

No default values are necessary for this command.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example disables OSPFv3 process **5** on the interface:

(config)**#interface demand 1**
(config-demand 1)**#ospfv3 5 shutdown**

ospfv3 <*process id*> transmit-delay <*value*>

Use the **ospfv3 transmit-delay** command to specify the estimated time that is required to propagate an Open Shortest Path First version 3 (OSPFv3) link-state advertisement (LSA) on the interface. Use the **no** form of this command to return the transmit delay to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2695*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
transmit-delay <*value*>	Specifies the number of seconds required to send LSAs from the interface. Valid range is **1** to **65535** seconds.

Default Values

By default, the LSA transmit delay is set to **1** second.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example changes the interface's LSA transmit delay to **2** seconds:

(config)**#interface demand 1**
(config-demand 1)**#ospfv3 5 transmit-delay 2**

peer default ip address *<ipv4 address>*

Use the **peer default ip address** command to specify the default Internet Protocol version 4 (IPv4) address of the remote end of this interface. Use the **no** form of this command to remove a configured default IPv4 address.

Syntax Description

<ipv4 address>	Specifies the default IPv4 address for the remote end. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, there is no assigned peer default IPv4 address.

Command History

Release 3.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

This command is useful if the peer does not send the IPv4 address option during Point-to-Point Protocol (PPP) negotiations.

Usage Examples

The following example sets the default peer IPv4 address to **192.22.71.50**:

(config)**#interface demand 1**
(config-demand 1)**#peer default ip address 192.22.71.50**

ppp authentication

Use the **ppp authentication** command to specify the authentication protocol on the Point-to-Point Protocol (PPP) virtual interface that the peer should use to authenticate itself. Use the **no** form of this command to remove configured PPP authentication. Variations of this command include:

ppp authentication chap
ppp authentication pap

Syntax Description

chap	Configures Challenge-Handshake Authentication Protocol (CHAP) authentication on the interface.
pap	Configures Password Authentication Protocol (PAP) authentication on the interface.

Default Values

By default, PPP endpoints have no authentication configured.

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Technology Review

CHAP and PAP are two authentication methods that enjoy widespread support. Both methods are included in AOS and are easily configured.

The authentication method set up on the local router can be different from that on the peer. Also, just because one router requires authentication from its peer does not mean it also has to authenticate itself to the peer.

Defining PAP

The PAP is used to verify that the PPP peer is a permitted device by checking a user name and password configured on the peer. The user name and password are both sent unencrypted across the connecting private circuit.

PAP requires a two-way message passing. First, the router that is required to be authenticated (for example, the peer) sends an authentication request with its user name and password to the router requiring authentication (for example, the local router). The local router then looks up the user name and password in the user name database within the PPP interface and, if they match, sends an authentication acknowledge back to the peer.

The PPP user name and password database is separate and distinct from the global user name password database. For PAP and CHAP, use the database under the PPP interface configuration.

Several example scenarios are given below for clarity.

Configuring PAP Example 1: Only the local router requires the peer to authenticate itself.

On the local router (host name Local):

Local(config-demand 1)**#ppp authentication pap**
Local(config-demand 1)**#username farend password same**

On the peer (host name Peer):

Peer(config-demand 1)**#ppp pap sent-username farend password same**

The first line of the configuration sets the authentication mode as PAP. This means the peer is required to authenticate itself to the local router via PAP. The second line is the user name and password expected to be sent from the peer. On the peer, the **ppp pap sent-username** command is used to specify the appropriate matching user name and password.

Configuring PAP Example 2: Both routers require the peer to authenticate itself.

On the local router (host name Local):

Local(config-demand 1)**#ppp authentication pap**
Local(config-demand 1)**#username farend password far**
Local(config-demand 1)**#ppp pap sent-username nearend password near**

On the peer (host name Peer):

Peer(config-demand 1)**#ppp authentication pap**
Peer(config-demand 1)**#username nearend password near**
Peer(config-demand 1)**#ppp pap sent-username farend password far**

Now both routers send the authentication request, verify that the user name and password sent match what is expected in the database, and send an authentication acknowledge.

Defining CHAP

The CHAP is a three-way authentication protocol composed of a challenge response and success or failure. The message digest 5 (MD5) protocol is used to protect user names and passwords in the response.

First, the local router (requiring its peer to be authenticated) sends a challenge containing only its own unencrypted user name to the peer. The peer then looks up the user name in the user name database within the PPP interface and, if found, takes the corresponding password and its own host name and sends a response back to the local router. This data is encrypted. The local router verifies that the user name and password are in its own user name database within the PPP interface and, if so, sends a success back to the peer.

The PPP user name and password database is separate and distinct from the global user name password database. For PAP and CHAP, use the database under the PPP interface configuration.

Several example scenarios are given below for clarity.

Configuring CHAP Example 1: Only the local router requires the peer to authenticate itself.

On the local router (host name **Local**):

Local(config-demand 1)**#ppp authentication chap**
Local(config-demand 1)**#username Peer password same**

On the peer (host name **Peer**):

Peer(config-demand 1)**#ppp chap password same**

The first line of this configuration sets the authentication mode to CHAP. This means the peer is required to authenticate itself to the local router via CHAP. The second line is the user name and password expected to be sent from the peer. The peer uses its **hostname** and **ppp chap password** commands to send the proper authentication information.

Both ends must have identical passwords.

Configuring CHAP Example 2: Using the ppp chap hostname command as an alternate solution.

On the local router (host name **Local**):

Local(config-demand 1)**#ppp authentication chap**
Local(config-demand 1)**#username farend password same**

On the peer (host name **Peer**):

Peer(config-demand 1)**#ppp chap hostname farend**
Peer(config-demand 1)**#ppp chap password same**

Notice the local router is expecting user name **farend** even though the peer router's host name is **Peer**. Therefore, the peer router can use the **ppp chap hostname** command to send the correct name in the challenge.

Both ends must have identical passwords.

Configuring CHAP Example 3: Both routers require each other to authenticate themselves using the same shared password.

On the local router (host name **Local**):

Local(config-demand 1)**#ppp authentication chap**
Local(config-demand 1)**#username Peer password same**

On the peer (host name **Peer**):

Peer(config-demand 1)**#ppp authentication chap**
Peer(config-demand 1)**#username Local password same**

This is basically identical to Example 1 except that both routers will now challenge each other and respond.

Both ends must have identical passwords.

Configuring CHAP Example 4: Both routers require each other to authenticate themselves using two separate shared passwords.

On the local router (host name **Local**):

Local(config-demand 1)**#ppp authentication chap**
Local(config-demand 1)**#username Peer password far**
Local(config-demand 1)**#ppp chap password near**

On the peer (host name **Peer**):

Peer(config-demand 1)**#ppp authentication chap**
Peer(config-demand 1)**#username Local password near**
Peer(config-demand 1)**#ppp chap password far**

This is basically identical to Example 3, except that there are two separate shared passwords.

Notice this example has both ends using different sets of passwords.

Configuring CHAP Example 5: Using the ppp chap hostname command as an alternate solution.

On the local router (host name **Local**):

Local(config-demand 1)**#ppp authentication chap**
Local(config-demand 1)**#username farend password far**
Local(config-demand 1)**#ppp chap hostname nearend**
Local(config-demand 1)**#ppp chap password near**

On the peer (host name **Peer**):

Peer(config-demand 1)**#ppp authentication chap**
Peer(config-demand 1)**#username nearend password near**
Peer(config-demand 1)**#ppp chap hostname farend**
Peer(config-demand 1)**#ppp chap password far**

Notice the local router is expecting user name **farend** even though the peer router's host name is **Peer**. Therefore, the peer router can use the **ppp chap hostname** command to send the correct name on the challenge.

Notice this example has both ends using different sets of passwords.

ppp bcp tagged-frame

Use the **ppp bcp tagged-frame** command to allow negotiation of IEEE 802.1Q-tagged packets over Bridging Control Protocol (BCP). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release 14.1	Command was introduced.

Usage Examples

The following example configures the interface to negotiate tagged frames over **bcp**:

(config)**#interface demand 1**
(config-demand 1)**#ppp bcp tagged-frame**

ppp chap hostname *<name>*

Use the **ppp chap hostname** command to configure an alternate host name for Challenge-Handshake Authentication Protocol (CHAP) Point-to-Point Protocol (PPP) authentication. Use the **no** form of this command to remove a configured host name. For more information on Password Authentication Protocol (PAP) and CHAP functionality, refer to the *Technology Review* section for the command *ppp authentication on page 2709*.

Syntax Description

<name>	Specifies a host name using an alphanumeric string up to 80 characters in length.

Default Values

By default, there are no configured PPP CHAP host names.

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Usage Examples

The following example specifies a PPP CHAP host name of **my_host**:

(config)**#interface demand 1**
(config-demand 1)**#ppp chap hostname my_host**

ppp chap password *<password>*

Use the **ppp chap password** command to configure an alternate password when the peer requires Challenge-Handshake Authentication Protocol (CHAP) Point-to-Point Protocol (PPP) authentication. Use the **no** form of this command to remove a configured password. For more information on Password Authentication Protocol (PAP) and CHAP functionality, refer to the *Technology Review* section for the command *ppp authentication on page 2709*.

Syntax Description

<password>	Specifies a password using an alphanumeric string up to 80 characters in length.

Default Values

By default, there is no defined PPP CHAP password.

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Usage Examples

The following example specifies a PPP CHAP password of **my_password**:

(config)**#interface demand 1**
(config-demand 1)**#ppp chap password my_password**

ppp multilink

Use the **ppp multilink** command to enable Multilink Point-to-Point Protocol (MLPPP) operation on an existing Point-to-Point Protocol (PPP) interface. Use the **no** form of this command to disable this feature. Variations of this command include:

ppp multilink
ppp multilink fragmentation
ppp multilink interleave
ppp multilink maximum <*number*>

Syntax Description

fragmentation	Enables multilink fragmentation operation.
interleave	Enables multilink interleave operation.
maximum <*number*>	Specifies the maximum number of links allowed in a PPP multilink bundle.

Default Values

By default, MLPPP is disabled.

Command History

Release 7.1	Command was introduced.
Release 7.2	Fragmentation and interleave operation were added.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

When enabled, this interface is capable of the following:

- Combining multiple physical links into one logical link.
- Receiving upper layer protocol data units (PDUs), fragmenting and transmitting over the physical links.
- Receiving fragments over the physical links and reassembling them into PDUs.

The fragmentation and interleave options can be used to enhance the multilink operation. Fragmentation is used to reduce serialization delays of large packets. The fragmentation process evenly divides the data among all links in the bundle with a minimum packet size of 96 bytes. The interleave operation is used with streaming protocols to reduce delay by giving priority to packets identified as being high priority. Delivery in order is guaranteed with multilink fragmentation, but is not guaranteed with multilink interleave operation.

The multilink bundle will remain active with a minimum of one physical link. Physical links may be dynamically added or removed from the multilink bundle with minor interruption to traffic flow.

Usage Examples

The following example enables MLPPP:

(config)**#interface demand 1**
(config-demand 1)**#ppp multilink**

ppp mtu *<size>*

Use the **ppp mtu** command to configure the Point-to-Point Protocol (PPP) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<size>	Configures the window size for transmitted packets. The valid range is **64** to **2100** bytes.

Default Values

By default, the PPP MTU on an interface is set to **1500** bytes.

Command History

Release 17.9	Command was introduced.

Usage Examples

The following example specifies a PPP MTU of **1200** on the virtual demand interface:

(config)**#interface demand 1**
(config-demand 1)**#ppp mtu 1200**

ppp pap sent-username <*username*> password <*password*>

Use the **ppp pap sent-username password** command to configure a user name and password when the peer requires Password Authentication Protocol (PAP) Point-to-Point Protocol (PPP) authentication. Use the **no** form of this command to remove a configured password. For more information on PAP and Challenge-Handshake Authentication Protocol (CHAP) functionality, refer to the *Technology Review* section for the command *ppp authentication on page 2709*.

Syntax Description

<username>	Specifies a user name by alphanumeric string up to 80 characters in length (the user name is case sensitive).
<password>	Specifies a password by alphanumeric string up to 80 characters in length (the password is case sensitive).

Default Values

By default, there is no defined **ppp pap sent-username** and **password**.

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Usage Examples

The following example specifies a PPP PAP sent-user name of **local** and a password of **my_password**:

(config)**#interface demand 1**
(config-demand 1)**#ppp pap sent-username local password my_password**

qos-policy

Use the **qos-policy** command to apply a previously configured quality of service (QoS) map to incoming or outgoing packets on an interface. Use the **no** form of this command to remove the map from the interface. Variations of this command include:

qos-policy in <*name*>
qos-policy out <*name*>

Syntax Description

<*name*>	Specifies the name of a previously created QoS map (refer to *qos map <name> <number> on page 1673* for more information).
in	Assigns a QoS map to this interface's input.
out	Assigns a QoS map to this interface's output.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 15.1	Command was expanded to include the **in** parameter.

Usage Examples

The following example applies the QoS map **VOICEMAP** to the demand 1 interface:

(config)**#interface demand 1**
(config-demand 1)**#qos-policy out VOICEMAP**

resource pool *<name>*

Use the **resource pool** command to associate a resource pool with the demand interface. No more than one resource pool may be associated with an interface. Refer to *resource pool-member <name> on page 2101* for more information. Use the **no** form of this command to restore the default value.

Syntax Description

<name>	Specifies the resource pool that this interface will use to originate/answer demand connections.

Default Values

By default, no resource pool is associated with this interface.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example associates the resource pool named **Pool1** with demand interface **1**:

(config)**#interface demand 1**
(config-demand 1)**#resource pool Pool1**

rtp quality-monitoring

Use the **rtp quality-monitoring** command to enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets on this interface. If the global command (**ip rtp quality-monitoring**) is disabled when this command is issued, the system will return the following warning: "Applied but not used, you must globally enable **ip rtp quality-monitoring** to use VQM." Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, VQM is enabled on all wide area network (WAN) and local area network (LAN) interfaces.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables RTP quality monitoring on the virtual demand interface:

(config)**#interface demand 1**
(config-demand 1)**#rtp quality-monitoring**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release 17.2	Command was expanded to the cellular interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the virtual demand interface:

(config)**#interface demand 1**
(config-demand 1)**#no snmp trap link-status**

username *<username>* **password** *<password>*

Use the **username password** command to configure the user name and password of the peer to use for demand authentication. Use the **no** form of this command to remove a configured user name and password.

Syntax Description

<username>	Specifies a user name by alphanumerical string up to 30 characters in length (the user name is case sensitive).
<password>	Specifies a password by alphanumerical string up to 30 characters in length (the password is case sensitive).

Default Values

By default, there is no established user name and password.

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

Password Authentication Protocol (PAP) uses this entry to check received information from the peer. Challenge-Handshake Authentication Protocol (CHAP) uses this entry to check the received peer host name and a common password.

Usage Examples

The following example creates a user name of **Adtran** with password **Adtran** for the demand link labeled **5**:

(config)**#interface demand 5**
(config-demand 5)**#username Adtran password Adtran**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an interface to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the interface from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an interface's VRF association will clear all IP-related settings on that interface.

Syntax Description

<name>	Specifies the name of the VRF to which to assign the interface.

Default Values

By default, interfaces are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release 17.8	The keyword **ip** was removed from this command.

Functional Notes

VRF instances must be created first before an interface can be assigned. An interface can only be assigned to one VRF, but multiple interfaces can be assigned to the same VRF.

An interface will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the virtual demand interface to the VRF instance named **RED**:

(config)**#interface demand 1**
(config-demand 1)**#vrf forwarding RED**

FRAME RELAY INTERFACE COMMAND SET

To create a virtual Frame Relay interface and activate the Frame Relay Interface Configuration mode, enter the **interface frame-relay** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface frame-relay 1
(config-fr 1)#
```

By default, Frame Relay interfaces are created as point-to-point links. This default setting cannot be altered. The following command creates the exact same interface as that mentioned above:

```
>enable
#configure terminal
(config)#interface frame-relay 1 point-to-point
(config-fr 1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

bandwidth <value> on page 2728
encapsulation frame-relay ietf on page 2729
fair-queue on page 2730
frame-relay commands begin on page 2731
hold-queue <value> out on page 2742
max-reserved-bandwidth <value> on page 2743
qos-policy on page 2744
snmp trap on page 2746
snmp trap link-status on page 2747

bandwidth <*value*>

Use the **bandwidth** command to provide the bandwidth value of an interface to the higher level protocols. This value is used in cost calculations. Use the **no** form of this command to restore the default value.

Syntax Description

<*value*>	Specifies bandwidth in kbps. Range is **1** to **4294967295** kbps.

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.

Functional Notes

It is important to note that there is an order of precedence in determining the interface bandwidth reported by the router for QoS. Under normal circumstances, the Layer 1 bandwidth is reported based on the interface type. For example, a T1 interface will report the available bandwidth as 1.536 Mbps. This can be misleading in QoS configurations if the **bandwidth** command has been applied to the IP interface for routing purposes because the command overrides the reported available bandwidth that can be utilized for QoS. Using the **bandwidth** command can severely disrupt the configuration of QoS on the interface, therefore, use the **max-reserved-bandwidth** command (*page 2743*) to adjust the bandwidth appropriately for QoS configurations.

Usage Examples

The following example sets bandwidth of the Frame Relay interface to 10 Mbps:

(config)**#interface frame-relay 1**
(config-fr 1)**#bandwidth 10000**

encapsulation frame-relay ietf

Use the **encapsulation frame-relay ietf** command to configure the encapsulation on a virtual Frame Relay interface as IETF (RFC 1490). Currently, this is the only encapsulation setting. Settings for this option must match the far-end router's settings in order for the Frame Relay interface to become active.

Syntax Description

No subcommands.

Default Values

By default, all Frame Relay interfaces use IETF encapsulation.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example configures the endpoint for IETF encapsulation:

(config)**#interface frame-relay 1**
(config-fr 1)**#encapsulation frame-relay ietf**

fair-queue

Use the **fair-queue** command to enable weighted fair queuing (WFQ) on an interface. Use the **no** form of this command to disable WFQ and enable first in, first out (FIFO) queueing for an interface. Variations of this command include:

fair-queue
fair-queue <*value*>

WFQ must be enabled on an interface to use priority queuing. By default, WFQ is enabled for all interfaces with maximum bandwidth speeds equivalent to T1/E1 and below.

Syntax Description

<*value*>	Optional. Specifies the maximum number of packets that can be present in each conversation subqueue. Packets received for a conversation after this limit is reached are discarded. Range is **16** to **512** packets.

Default Values

By default, **fair-queue** is enabled with a threshold of 64 packets.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example enables WFQ on the interface with a threshold set at 100 packets:

(config)**#interface frame-relay 1**
(config-fr 1)**#fair-queue 100**

frame-relay intf-type

Use the **frame-relay intf-type** command to define the Frame Relay signaling role needed for the endpoint. Use the **no** form of this command to return to the default value. Variations of this command include:

frame-relay intf-type dce
frame-relay intf-type dte
frame-relay intf-type nni

Syntax Description

dce	Specifies data communication equipment (DCE) or network-signaling role. Use this interface type when you need the unit to emulate the frame switch.
dte	Specifies data terminal equipment (DTE) or user-signaling role. Use this interface type when connecting to a Frame Relay switch (or piece of equipment emulating a frame switch).
nni	Configures the interface to support both network and user signaling (DTE or DCE) when necessary.

Default Values

By default, **frame-relay intf-type** is set to **dte**.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example configures the Frame Relay endpoint for DCE signaling:

(config)**#interface frame-relay 1**
(config-fr 1)**#frame-relay intf-type dce**

frame-relay lmi-n391dte <*value*>

Use the **frame-relay lmi-n391dte** command to set the N391 full status polling counter for the data terminal equipment (DTE) endpoint. Typical applications should leave the default value for this timer. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Sets the poll counter value. Valid range is **1** to **255**.

Default Values

By default, the polling counter for the DTE endpoint is set to six polls.

Command History

Release 1.1	Command was introduced.

Functional Notes

The N391 counter determines how many link integrity polls occur in between full status polls. The number of link integrity polls between full status polls is n - 1, where n represents the full status poll. n can be set to any number between 1 and 255, but the default is used for most applications.

Usage Examples

The following example sets the N391 counter for three polls:

(config)**#interface frame-relay 1**
(config-fr 1)**#frame-relay lmi-n391dte 3**

frame-relay lmi-n392dce <*value*>

Use the **frame-relay lmi-n392dce** command to set the N392 error threshold for the data communication equipment (DCE) endpoint. Typical applications should leave the default value for this setting. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Sets the error threshold value. Valid range is **1** to **10** errors.

Default Values

By default, the error threshold for the DCE endpoint is set to three errors.

Command History

Release 1.1	Command was introduced.

Functional Notes

If the error threshold is met, the signaling state status is changed to down, indicating a service-affecting condition. This condition is cleared once N393 consecutive error-free events are received. N392 defines the number of errors required in a given event window, while N393 defines the number of polling events in each window.

For example:

If N392 = 3 and N393 = 4, then if three errors occur within any four events, the interface is determined inactive.

Usage Examples

The following example sets the N392 threshold for 5 seconds:

(config)**#interface frame-relay 1**
(config-fr 1)**#frame-relay lmi-n392dce 5**

frame-relay lmi-n392dte <*value*>

Use the **frame-relay lmi-n392dte** command to set the N392 error threshold for the data terminal equipment (DTE) endpoint. Typical applications should leave the default value for this setting. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Sets the error threshold value. Valid range is **1** to **10** errors.

Default Values

By default, the error threshold for the DTE endpoint is set to three errors.

Command History

Release 1.1	Command was introduced.

Functional Notes

If the error threshold is met, the signaling state status is changed to down, indicating a service-affecting condition. This condition is cleared once N393 consecutive error-free events are received. N392 defines the number of errors required in a given event window, while N393 defines the number of polling events in each window.

For example:

If N392 = 3 and N393 = 4, then if three errors occur within any four events, the interface is determined inactive.

Usage Examples

The following example sets the N392 threshold for five errors:

(config)**#interface frame-relay 1**
(config-fr 1)**#frame-relay lmi-n392dte 5**

frame-relay lmi-n393dce <*value*>

Use the **frame-relay lmi-n393dce** command to set the N393 local management interface (LMI) monitored event counter for the data communication equipment (DCE) endpoint. Typical applications should leave the default value for this counter. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Sets the event counter value. Valid range is **1** to **10** events.

Default Values

By default, the LMI monitored event counter for the DCE endpoint is set to four events.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example sets the N393 threshold for five events:

(config)**#interface frame-relay 1**
(config-fr 1)**#frame-relay lmi-n393dce 5**

frame-relay lmi-n393dte <*value*>

Use the **frame-relay lmi-n393dte** command to set the N393 local management interface (LMI) monitored event counter for the data terminal equipment (DTE) endpoint. Typical applications should leave the default value for this counter. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Sets the event counter value. Valid range is **1** to **10** events.

Default Values

By default, the LMI monitored event counter for the DTE endpoint is set to four events.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example sets the N393 threshold for five events:

(config)**#interface frame-relay 1**
(config-fr 1)**#frame-relay lmi-n393dte 5**

frame-relay lmi-t391dte <*value*>

Use the **frame-relay lmi-t391dte** command to set the T391 signal polling timer for the data terminal equipment (DTE) endpoint. Typical applications should leave the default value for this timer. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Sets the signal polling timer value in seconds. Valid range is **5** to **30** seconds.

Default Values

By default, the signal polling timer for the DTE endpoint is set to **10** seconds.

Command History

Release 1.1	Command was introduced.

Functional Notes

The T391 timer sets the time (in seconds) between polls to the Frame Relay network.

Usage Examples

The following example sets the T391 timer for 15 seconds:

(config)**#interface frame-relay 1**
(config-fr 1)**#frame-relay lmi-t391dte 15**

frame-relay lmi-t392dce <*value*>

Use the **frame-relay lmi-t392dce** command to set the T392 polling verification timer for the data communication equipment (DCE) endpoint. Typical applications should leave the default value for this timer. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Sets the polling verification timer value in seconds. Valid range is **5** to **30** seconds.

Default Values

By default, the polling verification timer for the DCE endpoint is set to **10** seconds.

Command History

Release 1.1	Command was introduced.

Functional Notes

The T392 sets the timeout (in seconds) between polling intervals. This parameter needs to be a few seconds longer than the T391 setting of the attached Frame Relay device.

Usage Examples

The following example sets the T392 timer for 15 seconds:

(config)**#interface frame-relay 1**
(config-fr 1)**#frame-relay lmi-t392dce 15**

frame-relay lmi-type

Use the **frame-relay lmi-type** command to define the Frame Relay signaling (local management interface (LMI)) type. Use the **no** form of this command to return to the default value. Variations of this command include:

frame-relay lmi-type ansi
frame-relay lmi-type auto
frame-relay lmi-type cisco
frame-relay lmi-type none
frame-relay lmi-type q933a

Syntax Description

ansi	Specifies Annex D signaling method.
auto	Automatically determines signaling type by messages received on the frame circuit.
cisco	Specifies Group of 4 signaling method.
none	Turns off signaling on the endpoint. This is used for dial-backup connections to Adtran IQ and Express Series products.
q933a	Specifies Annex A signaling method.

Default Values

By default, the Frame Relay signaling type is set to **ansi**.

Command History

Release 1.1	Command was introduced.
Release 2.1	Added signaling type **none** to provide support for dial-backup to Adtran IQ and Express Series products.

Usage Examples

The following example sets the signaling method for the endpoint to **cisco**:

(config)**#interface frame-relay 1**
(config-fr 1)**#frame-relay lmi-type cisco**

frame-relay multilink

Use the **frame-relay multilink** command to enable the Frame Relay multilink interface. When the **no** form of this command is issued, all configuration options associated with this command and cross connects made to this interface are removed. Variations of this command include:

frame-relay multilink
frame-relay multilink ack <*value*>
frame-relay multilink bandwidth-class [A | B]
frame-relay multilink bandwidth-class C <*threshold*>
frame-relay multilink bid <*string*>
frame-relay multilink hello <*value*>
frame-relay multilink retry <*number*>

Syntax Description

ack <*value*>	Optional. Specifies a wait for acknowledgement time (in seconds) for every bundle link in the bundle. Range is **1** to **180** seconds.
bandwidth-class	Optional. Specifies the class of operation, placing a minimum limit on the acceptable amount of bandwidth required for a bundle to be up.
[A | B]	Optional. Specifies the class of operation. Class A A single active link is sufficient for the bundle to be up. Class B All defined bundle links must be active for the bundle to be up.
C <*threshold*>	Optional. Specifies the minimum number of active bundle links required for a Class C bundle to be in the up state. This option will not be available unless Class C is specified. Range is **1** to **65535** links.
bid <*string*>	Optional. Specifies a bundle ID (up to 48 characters) for the multilink bundle. All hello messages sent on links belonging to the multilink bundle contain the bundle ID. By default, AOS creates a generic bundle ID for each configured multilink bundle using the following: **MFR** <*interface number*> where the interface number corresponds to the interface number of the Frame Relay interface. For example, if multilink is enabled on Frame Relay interface 1, by default the bundle ID is **MFR1**. Changing the bundle ID causes the multilink connection to go down for renegotiation.
hello <*value*>	Optional. Specifies the time (in seconds) between hello messages for every bundle link in the bundle. Range is **1** to **180** seconds.
retry <*number*>	Optional. Specifies the number of times a bundle link will retransmit a message while waiting for acknowledgement. Range is **1** to **5** times.

Default Values

The default **ack** value is 4 seconds. The default **hello** value is 10 seconds. The default <*class*> value is A. The default **retry** value is 2.

Command History

Release 9.1	Command was introduced.

Functional Notes

This command is different from **ppp multilink**. In **ppp multilink**, if multiple cross connects are configured for the Point-to-Point Protocol (PPP) interface without multilink PPP being enabled, the first link to bring up Link Control Protocol (LCP) will be the only link actually cross connected. In Frame Relay multilink, since there is no protocol corresponding to LCP, all cross connects will be removed and the user will be free to re-issue any cross connect.

Usage Examples

The following example enables the Frame Relay multilink interface and sets the time between **hello** messages to **45** seconds:

(config)**#interface frame-relay 1**
(config-fr 1)**#frame-relay multilink hello 45**

The following example specifies Class B operation:

(config)**#interface frame-relay 1**
(config-fr 1)**#frame-relay multilink bandwidth-class B**

The following example specifies Class C operation with a threshold of **5**:

(config)**#interface frame-relay 1**
(config-fr 1)**#frame-relay multilink bandwidth-class C 5**

hold-queue <*value*> out

Use the **hold-queue out** command to change the overall size of an interface's wide area network (WAN) output queue. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the total number of packets the output queue can contain before packets are dropped. Range is **16** to **1000** packets.

Default Values

The default queue size for weighted fair queuing (WFQ) is 400. The default queue size for Point-to-Point Protocol (PPP) first in, first out (FIFO) and Frame Relay round robin is 200.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example sets the overall output queue size to 700:

(config)**#interface frame-relay 1**
(config-fr 1)**#hold-queue 700 out**

max-reserved-bandwidth *<value>*

Use the **max-reserved-bandwidth** command to specify the percentage of interface bandwidth reserved for use in user-defined (priority or class-based) queues. The remainder of the interface bandwidth is reserved for system-critical traffic and is not available to user-defined queues. Use the **no** form of this command to restore the default value.

Reserving a portion of the interface bandwidth for system-critical traffic is necessary for proper operation. Specifying the entire interface bandwidth for use in user-defined queues can cause undesirable operation.

Syntax Description

<value>	Specifies the maximum percentage of bandwidth to reserve for quality of service (QoS). This setting is configured as a percentage of the total interface speed. Range is **1** to **100** percent.

Default Values

By default, **max-reserved-bandwidth** is set to 75 percent, which reserves 25 percent of the interface bandwidth for system-critical traffic.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example specifies **85** percent of the bandwidth on the Frame Relay 1 interface to be available for use in user-defined queues:

(config)**#interface frame-relay 1**
(config-fr 1)**#max-reserved-bandwidth 85**

qos-policy

Use the **qos-policy** command to apply a previously configured quality of service (QoS) map to incoming or outgoing packets on an interface. Use the **no** form of this command to remove the map from the interface. Variations of this command include:

qos-policy in *<name>*
qos-policy out *<name>*

Syntax Description

<name>	Specifies the name of a previously created QoS map (refer to *qos map <name> <number> on page 1673* for more information).
in	Assigns a QoS map to this interface's input.
out	Assigns a QoS map to this interface's output.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.
Release 15.1	Command was expanded to include the **in** parameter.

Functional Notes

When a QoS policy is applied to an interface, it may be disabled if the interface bandwidth is not adequate to support the requested bandwidth on the map set. Once the bandwidth problem is resolved, the map will work again. The bandwidth will be rechecked on any of the following changes:

1. A priority or class-based entry is added to, deleted from, or changed in a QoS map set.
2. The interface bandwidth is changed by the **bandwidth** command on the interface.
3. A QoS policy is applied to an interface.
4. A cross connect is created that includes an interface with a QoS policy.
5. The interface queuing method is changed to fair-queue to use weighted fair queuing (WFQ).
6. The interface operational status changes.
7. The interface bandwidth changes for other reasons (e.g., when asymmetric digital subscriber line (ADSL) finishes training).

In order to prevent the map from being disabled in cases of temporary inadequate bandwidth (e.g., a single link goes down in a dual T1 multilink configuration where the map requests more than one T1's worth of bandwidth), the QoS map uses the maximum theoretical bandwidth on an interface, not the actual bandwidth at that time. This actually helps QoS keep higher priority class-based traffic working better than best-effort traffic when the bandwidth drops.

Usage Examples

The following example applies the QoS map **VOICEMAP** to the Frame Relay interface:

(config)**#interface frame-relay 1**
(config-fr 1)**#qos-policy out VOICEMAP**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.

Usage Examples

The following example enables SNMP on the virtual Frame Relay interface:

(config)**#interface frame-relay 1**
(config-fr 1)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the Frame Relay interface:

(config)**#interface frame-relay 1**
(config-fr 1)**#no snmp trap link-status**

FRAME RELAY SUBINTERFACE COMMAND SET

To create a virtual Frame Relay subinterface and activate the Frame Relay Subinterface Configuration mode, enter the **interface frame-relay** command (and specify a subinterface) at the Global Configuration mode prompt. For example:

```
>enable
#configure terminalF
(config)#interface frame-relay 1.16
(config-fr 1.16)#
```

By default, Frame Relay subinterfaces are created as point-to-point links. This default setting cannot be altered. The following command creates the exact same interface as that mentioned above:

```
>enable
#configure terminal
(config)#interface frame-relay 1.16 point-to-point
(config-fr 1.16)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

bandwidth <value> on page 2750
bridge-group <number> on page 2751
bridge-group <number> vlan-transparent on page 2752
dial-backup commands begin on page 2753

rtp quality-monitoring on page 2878
snmp trap on page 2879
snmp trap link-status on page 2880
spanning-tree commands begin on page 2881
vrf forwarding <name> on page 2887

bandwidth <*value*>

Use the **bandwidth** command to provide the bandwidth value of an interface to the higher level protocols. This value is used in cost calculations. Use the **no** form of this command to restore the default value.

Syntax Description

<*value*>	Specifies bandwidth in kbps. Range is **1** to **4294967295** kbps.

Default Values

To view the default values, use the **show interfaces** command.

Command History

Release 3.1	Command was introduced.

Functional Notes

It is important to note that there is an order of precedence in determining the interface bandwidth reported by the router for QoS. Under normal circumstances, the Layer 1 bandwidth is reported based on the interface type. For example, a T1 interface will report the available bandwidth as 1.536 Mbps. This can be misleading in QoS configurations if the **bandwidth** command has been applied to the IP interface for routing purposes because the command overrides the reported available bandwidth that can be utilized for QoS. Using the **bandwidth** command can severely disrupt the configuration of QoS on the interface.

Usage Examples

The following example sets bandwidth of the Frame Relay interface to 10 Mbps:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#bandwidth 10000**

bridge-group *<number>*

Use the **bridge-group** command to assign an interface to the specified bridge group. This command is supported on all Ethernet interfaces, Point-to-Point Protocol (PPP) virtual interfaces, and Frame Relay virtual subinterfaces. Use the **no** form of this command to remove the interface from the bridge group.

Syntax Description

<number>	Specifies the bridge group number. Range is **1** to **255**.

Default Values

By default, there are no configured bridge groups.

Command History

Release 1.1	Command was introduced.

Functional Notes

A bridged network can provide excellent traffic management to reduce collisions and limit the amount of bandwidth wasted with unnecessary transmissions when routing is not necessary. Any two interfaces can be bridged (Ethernet to T1 bridge, Ethernet to Frame Relay subinterface).

Usage Examples

The following example assigns the Frame Relay subinterface labeled 1.16 to bridge group 1:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#bridge-group 1**

bridge-group <*number*> vlan-transparent

Use the **bridge-group vlan-transparent** command to prevent an interface from removing the virtual local area network (VLAN) tag. Use the **no** form of this command to allow the interface to remove the VLAN tag from the packet.

*The **bridge-group vlan-transparent** command is not a global command. The command must be applied on all interfaces of the bridge group.*

Syntax Description

<number>	Specifies the bridge group number. Valid range is **1** to **255**.

Default Values

By default, VLAN tags are removed from the data.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the high level data link control (HDLC) interface and Frame Relay subinterface.

Usage Examples

The following example removes the VLAN tags from the packets on the Frame Relay subinterface labeled 1.16:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#bridge-group 1 vlan-transparent**

dial-backup auto-backup

Use the **dial-backup auto-backup** command to configure the interface to automatically attempt a dial backup upon failure. Use the **no** form of this command to disable this feature. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2756*.

Syntax Description

No subcommands.

Default Values

By default, all backup endpoints will automatically attempt dial backup upon a failure.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example enables automatic dial backup on the endpoint:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dial-backup auto-backup**

dial-backup auto-restore

Use the **dial-backup auto-restore** command to configure the interface to automatically discontinue dial-backup when all network conditions are operational. Use the **no** form of this command to disable the auto-restore feature. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2756*.

Syntax Description

No subcommands.

Default Values

By default, all backup endpoints will automatically restore the primary connection when the failure condition clears.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example configures AOS to automatically restore the primary connection when the failure condition clears:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dial-backup auto-restore**

dial-backup backup-delay *<value>*

Use the **dial-backup backup-delay** command to configure the amount of time the router will wait after the failure condition is recognized before attempting to backup the link. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2756*.

Syntax Description

<value>	Specifies the delay period (in seconds) a failure must be active before AOS will enter backup operation on the interface. Range is **10** to **86400** seconds.

Default Values

By default, the **dial-backup backup-delay** period is set to 10 seconds.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example configures AOS to wait **60** seconds (on an endpoint with an active alarm condition) before attempting dial-backup operation:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dial-backup backup-delay 60**

dial-backup call-mode

Use the **dial-backup call-mode** command to specify whether the configured backup interface answers or originates (or a combination of both) backup calls. Use the **no** form of this command to return to the default value. Variations of this command include:

dial-backup call-mode answer
dial-backup call-mode answer-always
dial-backup call-mode originate
dial-backup call-mode originate-answer
dial-backup call-mode originate-answer-always

Syntax Description

answer	Answers and backs up primary link on failure.
answer-always	Answers and backs up regardless of primary link state.
originate	Originates backup call on primary link failure.
originate-answer	Originates or answers call on primary link failure.
originate-answer-always	Originates on failure; answers and backs up always.

Default Values

By default, the **dial-backup call-mode** is set to **originate-answer**.

Command History

Release 1.1	Command was introduced.

Functional Notes

The majority of the configuration for AOS dial-backup implementation is configured via the dial-backup Point-to-Point Protocol (PPP) interface configuration commands. However, the numbers dialed are configured in the primary interface. Full sample configurations follow:

Sample configuration for remote router (dialing out)

```
hostname “Remote3200”
enable password adtran
!
interface eth 0/1
 ip address 192.168.1.254 255.255.255.0
 no shutdown
!
interface modem 1/3
 no shutdown
!
interface t1 1/1
 coding b8zs
 framing esf
```

```
 clock source line
 tdm-group 1 timeslots 1-24
 no shutdown
!
interface fr 1 point-to-point
 frame-relay lmi-type ansi
 no shutdown
 cross-connect 1 t1 1/1 1 fr 1
!
interface fr 1.16 point-to-point
 frame-relay interface-dlci 16
 ip address 10.1.1.2 255.255.255.252
 dial-backup call-mode originate
 dial-backup number 5551111 analog ppp1
 dial-backup number 5552222 analog ppp1
no shutdown
!
interface ppp 1
 ip address 172.22.56.1 255.255.255.252
 ppp authentication chap
 username remoterouter password remotepass
 ppp chap hostname localrouter
 ppp chap password adtran
 no shutdown
!
ip route 192.168.2.0 255.255.255.0 172.22.56.2 255.255.255.252
!
line telnet 0 4
 password password
```

Sample configuration for central router (dialing in)

```
hostname “Central3200”
enable password adtran
!
interface eth 0/1
 ip address 192.168.100.254 255.255.255.0
 no shutdown
!
interface modem 1/3
 no shutdown
!
interface t1 1/1
 coding b8zs
 framing esf
 clock source line
 tdm-group 1 timeslots 1-24
 no shutdown
```

```
!
interface fr 1 point-to-point
 frame-relay lmi-type ansi
 no shutdown
 cross-connect 1 t1 1/1 1 fr 1
!
interface fr 1.100 point-to-point
 frame-relay interface-dlci 100
 ip address 10.1.1.1 255.255.255.252
 dial-backup call-mode answer
 dial-backup number 555-8888 analog ppp 1
!
interface ppp 1
 ip address 172.22.56.2 255.255.255.252
 ppp authentication chap
 username localrouter password adtran
 ppp chap hostname remoterouter
 ppp chap password remotepass
 no shutdown
!
ip route 192.168.1.0 255.255.255.0 172.22.56.1 255.255.255.252

line telnet 0 4
 password password
```

Usage Examples

The following example configures AOS to generate backup calls for this endpoint using an analog modem interface (to phone number 555 1111), but never answer calls and specifies **ppp 1** as the backup interface:

```
(config)#interface frame-relay 1.16
(config-fr 1.16)#dial-backup call-mode originate
(config-fr 1.16)#dial-backup number 555 1111 analog ppp 1
```

Technology Review

This technology review provides information regarding specific dial-backup router behavior (i.e., when the router will perform dial backup, where in the configuration AOS accesses specific routing information, etc.):

Dialing Out

1. AOS determines to place an outbound call when either the Layer 1 or Layer 2 has a failure.
2. When placing outbound calls, AOS matches the number dialed to a PPP interface. This is accomplished with an addition to the **dial-backup number** command (refer to *dial-backup number <number> on page 2763*).
3. When placing the call, AOS uses the configuration of the related PPP interface for authentication and IP negotiation.
4. If the call fails to connect on the first number dialed, AOS places a call to the second number (if a second number is configured). The second number to be dialed references a separate PPP interface.

Dialing In

1. AOS receives an inbound call on a physical interface.
2. Caller ID is used to match the **dial-backup number** command to the configured PPP interface.
3. If a match is found, the call connects and AOS pulls down the primary connection if it is not already in a down state.
4. If no match is found from caller ID, the call is terminated.

dial-backup connect-timeout <*value*>

Use the **dial-backup connect-timeout** command to specify the number of seconds to wait for a connection after a call is attempted before trying to call again or dialing a different number. It is recommended this number be greater than 60. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2756*.

Syntax Description

<*value*>	Selects the amount of time (in seconds) that the router will wait for a connection before attempting another call. Valid range is **10** to **300** seconds.

Default Values

By default, the **dial-backup connect-timeout** period is set to 60 seconds.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example configures AOS to wait **120** seconds before retrying a failed dial-backup call:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dial-backup connect-timeout 120**

dial-backup force

Use the **dial-backup force** command to manually override the automatic dial-backup feature. This can be used to force a link into backup to allow maintenance to be performed on the primary link without disrupting data. Use the **no** form of this command to return to the normal dial-backup operation state. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2756*. Variations of this command include:

dial-backup force backup
dial-backup force primary

Syntax Description

backup	Force backup regardless of primary link state.
primary	Force primary link regardless of its state.

Default Values

By default, this feature is disabled.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example configures AOS to force this interface into dial backup:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dial-backup force backup**

dial-backup maximum-retry <*value*>

Use the **dial-backup maximum-retry** command to select the number of calls the router will make when attempting to backup a link. Use the **no** form of this command to return to the default state. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2756*.

Syntax Description

<*value*>	Selects the number of call retries that will be made after a link failure. Valid range is **0** to **15** attempts. Setting this value to 0 will allow unlimited retries during the time the network is failed.

Default Values

By default, **dial-backup maximum-retry** is set to 0 attempts.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example configures AOS to retry a dial-backup call four times before considering backup operation not available:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dial-backup maximum-retry 4**

dial-backup number <*number*>

Use the **dial-backup number** command to configure the phone number and the call type the router will dial upon network failure. Multiple entries can be made for an interface to allow alternate sites to be dialed. Use the **no** form of this command to disable this feature. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2756*. Variations of this command include:

dial-backup number <*number*> **analog ppp** <*interface*>
dial-backup number <*number*> **digital-56k** <*isdn min chan*> <*isdn max chan*> **ppp** <*interface*>
dial-backup number <*number*> **digital-64k** <*isdn min chan*> <*isdn max chan*> **ppp** <*interface*>

Syntax Description

<*number*>	Specifies the phone numbers to call when the backup is initiated.
analog	Indicates the number connects to an analog modem.
digital-56k	Indicates the number belongs to a digital 56 kbps per DS0 connection.
digital-64k	Indicates the number belongs to a digital 64 kbps per DS0 connection.
<*isdn min chan*>	Specifies the minimum number of DS0s required for a digital 56 or 64 kbps connection. Range is **1** to **24** DS0s.
<*isdn max chan*>	Specifies the maximum number of DS0s desired for a digital 56 or 64 kbps connection. Range is **1** to **24** DS0s.
ppp <*interface*>	Specifies the Point-to-Point Protocol (PPP) interface to use as the backup for this interface (for example, **ppp 1**).

Default Values

By default, there are no configured dial-backup numbers.

Command History

Release 1.1	Command was introduced.
Release 17.2	Command was expanded to include the cellular connections.
Release 17.3	Cellular connections were removed from this command.

Usage Examples

The following example configures AOS to dial **704-555-1212** (digital 64 kbps connection) to initiate dial-backup operation for this endpoint using the configured **ppp 1** backup interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dial-backup number 7045551212 digital-64k 1 1 ppp 1**

dial-backup priority <*value*>

Use the **dial-backup priority** command to select the backup priority for this interface. This command allows the user to establish the highest priority backup link and ensure that link will override backups attempted by lower priority links. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2756*.

Syntax Description

<*value*>	Sets the relative priority of this link. Valid range is **0** to **100**. A value of 100 designates the highest priority.

Default Values

By default, **dial-backup priority** is set to 50.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example assigns the highest priority to this endpoint:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dial-backup priority 100**

dial-backup randomize-timers

Use the **dial-backup randomize-timers** command to randomize the call timers to minimize potential contention for resources. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2756*.

Syntax Description

No subcommands.

Default Values

By default, AOS does not randomize the dial-backup call timers.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example configures AOS to randomize the dial-backup timers associated with this endpoint:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dial-backup randomize-timers**

dial-backup redial-delay <*value*>

Use the **dial-backup redial-delay** command to configure the delay after an unsuccessful call until the call will be re-tried. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2756*.

Syntax Description

<*value*>	Specifies the delay in seconds between attempting to redial a failed backup attempt. Range is **10** to **3600** seconds.

Default Values

By default, **dial-backup redial-delay** is set to **10** seconds.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example configures a redial delay of **25** seconds on this endpoint:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dial-backup redial-delay 25**

dial-backup restore-delay *<value>*

Use the **dial-backup restore-delay** command to configure the amount of time the router will wait after the network is restored before disconnecting the backup link and reverting to the primary. This setting is used to prevent disconnecting the backup link if the primary link is bouncing in and out of alarm. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2756*.

Syntax Description

<value>	Specifies the number of seconds AOS will wait (after a primary link is restored) before disconnecting dial-backup operation. Range is **10** to **86400** seconds.

Default Values

By default, **dial-backup restore-delay** is set to **10** seconds.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example configures AOS to wait **30** seconds before disconnecting dial-backup operation and restoring the primary connection for this endpoint:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dial-backup restore-delay 30**

dial-backup schedule

Use the **dial-backup schedule** command to set the time of day that backup will be enabled. Use this command if backup is desired only during normal business hours and on specific days of the week. Use the **no** form of this command to disable dial backup (as specified). For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2756*. Variations of this command include:

dial-backup schedule day <*name*>
dial-backup schedule enable-time <*value*>
dial-backup schedule disable-time <*value*>

Syntax Description

day <*name*>	Sets the days to allow backup. Valid range is Monday through Sunday.
enable-time <*value*>	Sets the time of day to enable backup. Time is entered in a 24-hour format (00:00).
disable-time <*value*>	Sets the time of day to disable backup. Time is entered in a 24-hour format (00:00).

Default Values

By default, dial backup is enabled for all days and times if the **dial-backup auto-backup** command has been issued and the dial-backup schedule has not been entered.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example enables dial backup Monday through Friday 8:00 a.m. to 7:00 p.m.:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dial-backup schedule enable-time 08:00**
(config-fr 1.16)**#dial-backup schedule disable-time 19:00**
(config-fr 1.16)**#no dial-backup schedule day Saturday**
(config-fr 1.16)**#no dial-backup schedule day Sunday**

dial-backup shutdown

Use the **dial-backup shutdown** command to deactivate all dial-backup functionality in the unit. Dial-backup configuration parameters are kept intact, but the unit will not initiate (or respond) to dial-backup sequences in the event of a network outage. Use the **no** form of this command to reactivate the dial-backup interface. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2756*.

Syntax Description

No subcommands.

Default Values

By default, all AOS interfaces are disabled.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example deactivates the configured dial-backup interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dial-backup shutdown**

dynamic-dns

Use the **dynamic-dns** command to configure Dynamic DNS service provided by Dynamic Network Services, Inc. (www.dyndns.org). Use the **no** form of this command to disable this feature. Variations of this command include:

dynamic-dns custom <*hostname*> <*minutes*>
dynamic-dns dyndns <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-custom <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-static <*hostname*> <*username*> <*password*>

Syntax Description

<*hostname*>	Specifies the host name for the server that updates the dynamic domain naming system (DNS).
<*minutes*>	Specifies the intervals in minutes to update the server with information (updates also occur when the interface's IP address changes regardless of the update intervals).
<*username*>	Specifies a user name using an alphanumerical string up to 30 characters in length (the user name is case sensitive).
<*password*>	Specifies a password using an alphanumerical string up to 30 characters in length (the password is case sensitive). Refer to *Functional Notes* below for additional argument descriptions.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.
Release 12.1	Command was expanded.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

custom - Constanttime.com's Custom Dynamic DNS^{SM} service allows you complete access and management control over your domain name regardless of where you purchased/registered it. This allows you to manage IP address mappings (A records), domain aliases (CNAME records), and mail servers (mail exchange (MX) records).

dyndns - The Dynamic DNS^{SM} offered by Dynamic Network Services, Inc. (DynDNS.org) allows you to alias a dynamic IP address to a static host name in various domains. This allows your unit to be more easily accessed from various locations on the Internet. This service is provided for up to five host names.

dyndns-custom - DynDNS.org's Custom DNS^{SM} service provides a full DNS solution, giving you complete control over an entire domain name. A Web-based interface provides two levels of control over your domain, catering to average or advanced users. Five globally redundant DNS servers ensure that your domain will always resolve.

A choice of two interfaces is available. The basic interface is designed for most users. It comes preconfigured for most common configurations and allows for easy creation of most common record types. The advanced interface is designed for system administrators with a solid DNS background, and provides layout and functionality similar to a BIND zone file allowing for the creation of nearly any record type.

Custom DNS^{SM} can be used with both static and dynamic IPs, and has the same automatic update capability through Custom DNS-aware clients as Dynamic DNS.

dyndns-static - The Static DNS service is similar to DynDNS.org's Dynamic DNS^{SM} service in that it allows a host name, such as yourname.dyndns.org, to point to your IP address. Unlike a Dynamic DNS host, a Static DNS host does not expire after 35 days without updates, but updates take longer to propagate through the DNS system. This service is provided for up to five host names.

If your IP address does not change often or at all, but you still want an easy name to remember it by (without having to purchase your own domain name), Static DNS service is ideal for you.

If you would like to use your own domain name (such as yourname.com), you need Custom DNS service that also provides full dynamic and static IP address support.

Usage Examples

The following example sets the Dynamic DNS to **dyndns-custom** with host name **host**, user name **user**, and password **pass**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#dynamic-dns dyndns-custom host user pass**

frame-relay bc *<value>*

Use the **frame-relay bc** command to set the b_c (committed burst) value for a Frame Relay sublink. The value is in bits. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the committed burst value (in bits) for the sublink.

Default Values

By default, the committed burst value is set to **0** (no limit).

Command History

Release 4.1	Command was introduced.

Functional Notes

The time interval is always one second, so this can also be considered bits per second. Shaping is performed on a sliding one-second window to make maximum use of configured bandwidth. Note that when both b_c and b_e are nonzero, shaping is performed on the virtual circuit. The circuit is limited to the sum of b_c and b_e , and it is recommended that the sum always be greater than 8000.

Usage Examples

The following example configures the Frame Relay sublink with a committed burst value of 128,000 bits:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#frame-relay bc 128000**

frame-relay be *<value>*

Use the **frame-relay be** command to set the b_e (excessive burst) value for a Frame Relay sublink. The value is in bits. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the excessive burst value (in bits) for the sublink.

Default Values

By default, the excessive burst value is set to **0** (no limit).

Command History

Release 4.1	Command was introduced.

Functional Notes

The time interval is always one second, so this can also be considered bits per second. Shaping is performed on a sliding one-second window to make maximum use of configured bandwidth. Note that when both b_c and b_e are nonzero, shaping is performed on the virtual circuit. The circuit is limited to the sum of b_c and b_e, and it is recommended that the sum always be greater than 8000.

Usage Examples

The following example configures the Frame Relay sublink with an excessive burst value of 64,000 bits:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#frame-relay be 64000**

frame-relay fragment <*value*>

Use the **frame-relay fragment** command to set the FRF.12 fragmentation threshold. Use the **no** form of this command to erase the configured threshold.

Syntax Description

<*value*>	Specifies the fragmentation threshold. Valid fragmentation thresholds are greater than or equal to 64 and less than or equal to 1600.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.

Functional Notes

For Frame Relay fragmentation to take effect, rate-limiting must be enabled by setting the committed burst rate and excessive burst rate. Refer to *frame-relay bc <value> on page 2772* and *frame-relay be <value> on page 2773* for more information.

Usage Examples

The following example enables FRF.12 fragmentation on a sublink:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#frame-relay bc 64000**
(config-fr 1.16)**#frame-relay be 16**
(config-fr 1.16)**#frame-relay fragment 100**

The following example disables FRF.12 fragmentation on a sublink:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#no frame-relay fragment**

frame-relay interface-dlci <*value*>

Use the **frame-relay interface-dlci** command to configure the data link connection identifier (DLCI) for the Frame Relay subinterface. This setting should match the DLCI supplied by your Frame Relay service provider. Use the **no** form of this command to remove the configured DLCI.

Syntax Description

<*value*>	Specifies numeric value of the DLCI supplied by your provider.

Default Values

By default, the DLCI is populated with the subinterface identifier. For example, if configuring the virtual Frame Relay subinterface labeled **fr 1.20**, the default DLCI is **20**.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example configures a DLCI of **72** for this Frame Relay endpoint:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#frame-relay interface-dlci 72**

ip access-group *<ipv4 acl name>*

Use the **ip access-group** command to create an Internet Protocol version 4 (IPv4) access control list (ACL) to be used for packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ip access-group *<ipv4 acl name>* **in**
ip access-group *<ipv4 acl name>* **out**

Syntax Description

<ipv4 acl name>	Specifies the IPv4 ACL name.
in	Enables access control on packets received on the specified interface.
out	Enables access control on packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 3.1	Command was introduced.

Functional Notes

When this command is enabled, the IPv4 destination address of each packet must be validated before being passed through. If the packet is not acceptable per these settings, it is dropped.

Usage Examples

The following example sets up the router to only allow Telnet traffic into the Frame Relay subinterface:

(config)**#interface frame-relay 1.16**
(config)**#ip access-list extended TelnetOnly**
(config-ext-nacl)**#permit tcp any any eq telnet**
(config-ext-nacl)**#int frame-relay 1.16**
(config-fr 1.16)**#ip access-group TelnetOnly in**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to an interface. IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

> NOTE *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an interface.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the Ethernet interface 0/1:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip access-policy PRIVATE**

ip address dhcp

Use the **ip address dhcp** command to use Dynamic Host Configuration Protocol (DHCP) to obtain an address on the interface. Use the **no** form of this command to remove a configured IP address (using DHCP) and disable DHCP operation on the interface. Variables that may be used with this command to further define the DHCP configuration include:

ip address dhcp class-id [ascii <*string*> **| hex** <*value*>**] [client-id [**<*interface*> **|** <*identifier*>**]] [hostname** <*"string"*>**] [track** <*name*>**] [**<*administrative distance*>**]**
ip address dhcp client-id [<*interface*> **|** <*identifier*>**] [hostname** <*"string"*>**] [track** <*name*>**] [**<*administrative distance*>**]**
ip address dhcp hostname *"*<*string*>*"* **[no-default-route | no-domain-name | no-nameservers] [track** <*name*>**] [**<*administrative distance*>**]**
ip address dhcp [no-default-route | no-domain-name | no-nameservers] [track <*name*>**] [**<*administrative distance*>**]**
ip address dhcp track <*name*> **[**<*administrative distance*>**]**

Syntax Description

<*administrative distance*>	Optional. Specifies the administrative distance to use when adding the DHCP gateway into the route table. It is used to determine the best route when multiple routes to the same destination exist. The lower the administrative distance, the more reliable the route. Range is **1** to **255**.
class-id	Optional. Specifies the vendor class identifier for the interface.
ascii <*string*>	Specifies the vendor class identifier in an ASCII string of up to **255** bytes.
hex <*value*>	Specfies the vendor class identifier in hexadecimal format. Valid range is up to **510** hexadecimal numbers. An even number of digits is required.
client-id	Optional. Specifies the client identifier used when obtaining an IP address from a DHCP server.
<*interface*>	Specifies an interface, thus defining the client identifier as the hexadecimal medium access control (MAC) address of the specified interface (including a hexadecimal number added to the front of the MAC address to identify the media type). For example, specifying the **client-id ethernet 0/1** (where the Ethernet interface has a MAC address of d217.0491.1150) defines the client identifier as **01:d2:17:04:91:11:50** (where 01 defines the media type as Ethernet). Refer to *hardware-address on page 4344* for a detailed listing of media types.
<*identifier*>	Specifies a custom client-identifier using a text string (that is converted to a hexadecimal equivalent) or 7 to 28 hexadecimal numbers (with colon delimiters). For example, a custom client identifier of **0f:ff:ff:ff:ff:51:04:99:a1** may be entered using the <*identifier*> option.
hostname <*"string"*>	Optional. Specifies a text string (to override the global router name) to use as the name in the DHCP option 12 field. The string is enclosed in quotation marks and can consist of up to 35 characters.

no-default-route Optional. Specifies that no default route is obtained via DHCP.

no-domain-name Optional. Specifies that no domain name is obtained via DHCP.

no-nameservers Optional. Specifies that no domain naming system (DNS) servers are obtained via DHCP.

track *<name>* Optional. Attaches a network monitoring track to the DHCP client. The DHCP gateway route for this client will only reside in the route table while the track is in the pass state. For more information on configuring track objects, refer to *track <name> on page 1886*.

Default Values

<administrative distance> By default, the administrative distance value is 1.

class-id Optional. By default, no vendor class identifier is configured.

client-id Optional. By default, the client identifier is populated using the following formula:

TYPE: INTERFACE SPECIFIC INFO : MAC ADDRESS

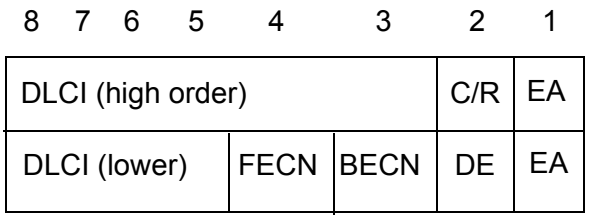
Where TYPE specifies the media type in the form of one hexadecimal byte (refer to *hardware-address on page 4344* for a detailed listing of media types), and the MAC ADDRESS is the medium access control (MAC) address assigned to the first Ethernet interface in the unit in the form of six hexadecimal bytes. (For units with a single Ethernet interface, the MAC ADDRESS assigned to Ethernet 0/1 is used in this field.)

INTERFACE SPECIFIC INFO is only used for Frame Relay interfaces and can be determined using the following:

FR_PORT#: Q.922 ADDRESS

Where the FR_PORT# specifies the label assigned to the virtual Frame Relay interface using four hexadecimal bytes. For example, a virtual Frame Relay interface labeled 1 would have a FR_PORT# of 00:00:00:01.

The Q.922 ADDRESS field is populated using the following:



Where the FECN, BECN, C/R, DE, and high order extended address (EA) bits are assumed to be 0 and the lower order EA bit is set to 1.

The following list provides a few example DLCIs and associated Q.922 address:

DLCI (decimal) / Q.922 address (hex)

16 / 0x0401
50 / 0x0C21
60 / 0x0CC1
70 / 0x1061
80 / 0x1401

hostname *“<string>”* By default, the host name is the name configured using the Global Configuration **hostname** command.

Command History

Release 2.1	Command was introduced.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 13.1	Command was expanded to include the track and administrative distance.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.10.0	Command was expanded to include the **class-id** parameter in support of DHCP Option 60.

Functional Notes

DHCP allows interfaces to acquire a dynamically assigned IP address from a configured DHCP server on the network. Many service providers require the use of DHCP when connecting to their services. Using DHCP reduces the number of dedicated IP addresses the ISP must obtain. Consult your ISP to determine the proper values for the **client-id** and **hostname** fields.

The vendor class identifier is sent to the DHCP server in DHCP discover and request messages via DHCP Option 60. This option gives the DHCP server details regarding DHCP client configuration and also allows the server to send any vendor-specific information to the client in DHCP offer messages via Option 43.

Usage Examples

The following example enables DHCP operation on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip address dhcp**

The following example enables DHCP operation on the interface utilizing host name **adtran** and does not allow obtaining a default route, domain name, or name servers. It also sets the administrative distance as **5**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip address dhcp hostname “adtran” no-default-route no-domain-name no-nameservers 5**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the specified interface. Use the optional **secondary** keyword to define a secondary IPv4 address. Use the **no** form of this command to remove a configured IPv4 address. Variations of this command include:

ip address <*ipv4 address*> <*subnet mask*>
ip address <*ipv4 address*> <*subnet mask*> **secondary**

Syntax Description

<ipv4 address>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the specified interface.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 1.1	Command was introduced.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a secondary IPv4 address of **192.22.72.101 255.255.255.252**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip address 192.22.72.101 255.255.255.252 secondary**

ip address range *<start ip address> <end ip address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the specified interface. Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip crypto map *<name>*

Use the **ip crypto map** command to associate Internet Protocol version 4 (IPv4) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

> NOTE *When you apply a map to an interface, you are applying all crypto maps with the given map name. This allows you to apply multiple crypto maps if you have created maps that share the same name, but have different map index numbers.*

Syntax Description

<name>	Specifies the IPv4 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

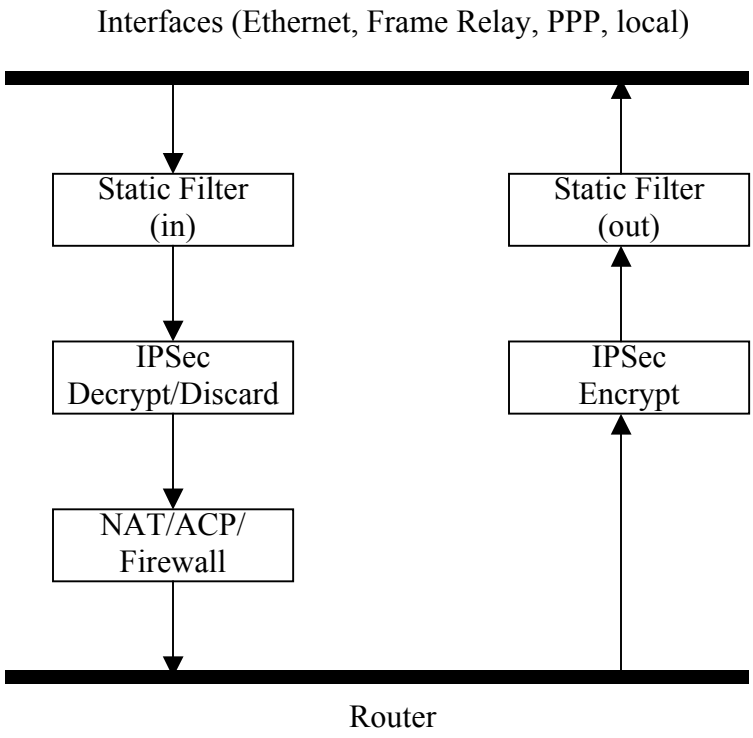
Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 9.1	Command was expanded to include the High-Levell Data Link Control (HDLC) interface.
Release 11.1	Command was expanded to include the demand interface.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.7.0	Command syntax was changed to require the **ip** keyword.

Functional Notes

When configuring a system to use both the stateful inspection firewall and Internet key exchange (IKE) negotiation for VPN, keep the following notes in mind.

When defining the IPv4 policy class and associated access control lists (ACLs) that describe the behavior of the IPv4 firewall, do not forget to include the traffic coming into the system over a VPN tunnel terminated by the system. The firewall should be set up with respect to the unencrypted traffic that is destined to be sent or received over the VPN tunnel. The following diagram represents typical AOS data-flow logic.



As shown in the diagram above, data coming into the product is first processed by the static filter associated with the interface on which the data is received. This access group is a true static filter and is available for use regardless of whether the IPv4 firewall is enabled or disabled. Next (if the data is encrypted), it is sent to the IPSec engine for decryption. The decrypted data is then processed by the stateful inspection firewall. Therefore, given a terminating VPN tunnel, only unencrypted data is processed by the firewall.

The IPv4 ACLs for a crypto map on an interface work in reverse logic to the ACLs for a policy class on an interface. When specifying the ACLs for a crypto map, the source information is the private local side, unencrypted source of the data. The destination information will be the far-end, unencrypted destination of the data. However, ACLs for a policy class work in reverse. The source information for the ACL in a policy class is the far end. The destination information is the local side.

Usage Examples

The following example applies all IPv4 crypto maps with the name **MyMap** to the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip crypto map MyMap**

ip dhcp

Use the **ip dhcp** command to release or renew the Dynamic Host Configuration Protocol (DHCP) Internet Protocol version 4 (IPv4) address. This command is only applicable when using DHCP for IP address assignment. Variations of this command include:

ip dhcp release
ip dhcp renew

Syntax Description

release	Releases the DHCP IPv4 address.
renew	Renews the DHCP IPv4 address.

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.
Release 8.1	Command was added to the asynchronous transfer mode (ATM) subinterface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release R10.1.0	Command was added to the bridged virtual interface (BVI).

Usage Examples

The following example releases the IPv4 DHCP address for the virtual interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip dhcp release**

ip dhcp relay destination *<ipv4 address>*

Use the **ip dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 4 (IPv4) and to specify the IPv4 address for the DHCPv4 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv4 relay functionality is disabled on the interface.

Syntax Description

<ipv4 address>	Specifies the IPv4 address for the DHCPv4 messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.

Usage Examples

The following example enables DHCPv4 relay agent functionality and specifies the destination address as **192.33.4.251**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip dhcp relay destination 192.33.4.251**

ip directed-broadcast

Use the **ip directed-broadcast** command to allow reception/forwarding of directed broadcasts. Use the **no** form of this command to disable this feature. Variations of this command include:

ip directed-broadcast
ip directed-broadcast <*name*>

Syntax Description

<*name*>	Specifies IP access control list (ACL) name.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.

Functional Notes

A directed broadcast is a packet intended for all nodes on a nonlocal network. For example, the broadcast address 255.255.255.255 reaches all nodes on a network; the directed broadcast address 128.1.255.255 is intended for all nodes whose network address is 128.1.0.0. A router not directly attached to 128.1.0.0 simply forwards the directed broadcast packet to the next hop. A router on network 128.1.0.0 that has **ip directed-broadcast** enabled, accepts and forwards the packet to all nodes whose network address is 128.1.0.0. Routers connecting subnets of 128.1.0.0 also accept and forward the packet to the nodes on their respective subnets. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is distributed as a broadcast on the destination subnet. The packet is then sent as a link-layer broadcast.

The **ip directed-broadcast** command controls the distribution of directed broadcasts when they reach their target subnets. Only the final transmission of the directed broadcast on its ultimate destination subnet is affected. It does not affect the transit unicast routing of IP directed broadcasts.

If **ip directed-broadcast** is enabled for this interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which this interface is attached will be forwarded as broadcasts on that subnet. Forwarding of the packets can be limited by specifying an ACL with this command. In this case, only directed broadcasts that are permitted by the specified ACL will be forwarded, and all other directed broadcasts directed to this interface subnet will be dropped.

Disabling the **ip directed-broadcast** command will cause directed broadcasts destined for the subnet to which this interface is attached to be dropped.

This option is a requirement for routers as described in RFC 1812, section 4.2.2.11. Furthermore, it is disabled by default (RFC 2644), with the intended goal of reducing the efficacy of certain types of denial of service (DoS) attacks.

Usage Examples

The following example enables forwarding of directed broadcasts on the interface **frame-relay 1.16**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip directed-broadcast**

ip ffe

Use the **ip ffe** command to enable the RapidRoute fast forwarding engine (FFE) on this Internet Protocol version 4 (IPv4) interface with the default number of entries. Use the **no** form of this command to disable this feature. Variations of this command include:

ip ffe
ip ffe max-entries <*value*>

Issuing this command will cause all RapidRoute entries to be cleared from this IPv4 interface.

Syntax Description

max-entries <*value*>	Optional. Specifies the maximum number of entries stored in the flow table. Valid range is from **1** to **500000**.

Default Values

By default, the RapidRoute Engine is enabled. The default number of **max-entries** is **4096**.

Command History

Release 13.1	Command was introduced.
Release 17.6	Command was expanded to include the high level data link control (HDLC) and tunnel interfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.4.0	Maximum number of stored entries was expanded to **500000** and RapidRoute is now enabled by default.

Functional Notes

RapidRoute can be used to help reduce routing overhead, and thus reduce overall routing times. Routing times are reduced by the creation of a flow table on the ingress interface. The maximum number of entries that can be stored in the flow table at any one time may be specified by using the **max-entries** parameters.

Usage Examples

The following example disables RapidRoute on the IPv4 interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#no ip ffe**

Technology Review

The RapidRoute system goal is to increase IP packet throughput by moving as much of the packet processing into the engine as possible. Packets are classified into flows based upon the IP protocol (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol (ICMP), etc.), the source and destination IP addresses, IP type of service (ToS), and the protocol-specific information, such as the source and destination port numbers. Flows are defined as the unidirectional representation of a conversation between two IP hosts. Each ingress interface keeps its own flow table, a collection of flow entries.

The first packet in a flow that is forwarded through the unit will build a flow entry. When a flow entry is looked up but no entry is found, a RapidRouteBuilder object is allocated and attached to the packet. As the packet passes through the various processing layers, each subsystem will add processing to the RapidRouteBuilder. When packet is about to be forwarded out of the egress interface, the RapidRouteBuilder will be finalized. That is, the flow entry being built will be checked for completeness and committed to the flow table on the ingress interface. Subsequent flow matches can then bypass the normal processing layers.

ip flow

Use the **ip flow** command to enable integrated traffic monitoring (ITM) for all traffic received or forwarded on an interface. Use the **no** form of this command to disable traffic monitoring. Variations of this command include:

ip flow egress
ip flow egress <*name*>
ip flow ingress
ip flow ingress <*name*>

Syntax Description

egress	Specifies that all outgoing traffic be monitored.
ingress	Specifies that all incoming traffic be monitored.
<*name*>	Optional. Specifies the name of an access control list (ACL) to use for filtering traffic.

Default Values

By default, no traffic monitoring is enabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables traffic monitoring on a **Frame Relay** interface to monitor **incoming** traffic through an ACL called **myacl**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip flow ingress myacl**

ip helper-address *<ip address>*

Use the **ip helper-address** command to configure AOS to forward User Datagram Protocol (UDP) broadcast packets received on the interface. Use the **no** form of this command to disable forwarding packets.

> NOTE *The **ip helper** command must be used in conjunction with the **ip forward-protocol** command to configure AOS to forward UDP broadcast packets. Refer to ip forward-protocol udp <value> on page 1398 for more information.*

Syntax Description

<ip address>	Specifies the destination IP address for the forwarded UDP packets. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, broadcast UDP packets are not forwarded.

Command History

Release 1.1	Command was introduced.

Functional Notes

When used in conjunction with the **ip forward-protocol** command, the **ip helper-address** feature allows you to customize which broadcast packets are forwarded.

To implement the helper address feature, assign a helper-address(es) (specifying the device that needs to receive the broadcast traffic) to the interface closest to the host that transmits the broadcast packets. When broadcast packets (of the specified type forwarded using the **ip forward-protocol** command) are received on the interface, they will be forwarded to the device that needs the information.

Only packets meeting the following criteria are considered eligible by the **ip helper-address** feature:

1. The packet IP protocol is UDP.
2. Any UDP port specified using the **ip forward-protocol** command.
3. The medium access control (MAC) address of the frame is an all-ones broadcast address (ffff.ffff.ffff).
4. The destination IP address is broadcast defined by all ones (**255.255.255.255**) or a subnet broadcast (for example, **192.33.4.251** for the **192.33.4.248 /30** subnet).

Usage Examples

The following example forwards all DNS broadcast traffic to the DNS server with IP address **192.33.5.99**:

(config)**#interface frame-relay 1.16**
(config)**#ip forward-protocol udp domain**
(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip helper-address 192.33.5.99**

ip igmp

Use the **ip igmp** command to configure multicasting related functions for the interface. Variations of this command include:

ip igmp immediate-leave
ip igmp last-member-query-interval <*milliseconds*>
ip igmp querier-timeout <*seconds*>
ip igmp query-interval <*seconds*>
ip igmp query-max-response-time <*seconds*>
ip igmp static-group <*address*>
ip igmp version [1 | 2]

Syntax Description

immediate-leave	Specifies that if only one host (or Internet Group Management Protocol (IGMP) snooping switch) is connected to the interface, when a leave is received, multicast of that group is immediately terminated as opposed to sending a group query and timing out the group if no device responds. Works in conjunction with **ip igmp last-member-query-interval**. Applies to all groups when configured. Use the **no** form of this command to disable the **immediate-leave** feature.
last-member-query-interval <*milliseconds*>	Controls the timeout (in milliseconds) used to detect whether any group receivers remain on an interface after a receiver leaves a group. If a receiver sends a leave-group message (IGMP Version 2), the router sends a group-specific query on that interface. After twice the time specified by this command plus as much as one second longer, if no receiver responds, the router removes that interface from the group and stops sending that group's multicast packets to the interface. Range is **100** to **65535** ms. Use the **no** form of this command to return to the default setting.
querier-timeout <*seconds*>	Specifies the interval (in seconds) that the router waits after the current querier's last query before it takes over as querier (IGMP V2). Range is **60** to **300** seconds. Use the **no** form of this command to return to the default setting.
query-interval <*seconds*>	Specifies the interval (in seconds) at which IGMP queries are sent on an interface. Host query messages are addressed to the all-hosts multicast group with an IP time to live (TTL) of 1. The router uses queries to detect whether multicast group members are on the interface and to select an IGMP designated router (DR) for the attached segment (if more than one multicast router exists). Only the DR for the segment sends queries. For IGMP V2, the DR is the router with the lowest IP address on the segment. Range is **0** to **65535** seconds. Use the **no** form of this command to return to the default setting.
query-max-response-time <*seconds*>	Specifies the maximum response time (in seconds) advertised by this interface in queries when using IGMP V2. Hosts are allowed a random time within this period to respond, reducing response bursts. Use the **no** form of this command to return to the default setting.

Syntax Description

static-group <*address*>	Configures the router's interface to be a statically connected member of the specified group. Packets received on the correct reverse path forwarding (RPF) interface are forwarded to this interface regardless of whether any receivers have joined the specified group using IGMP. Use the **no** form of this command to remove a configured static group.
version [1 | 2]	Sets the interface's IGMP version. Use the **no** form of this command to return to the default setting.

Default Values

ip igmp immediate-leave	No default
ip igmp last-member-query-interval	**1000** milliseconds
ip igmp querier-timeout	2x the **query-interval** value
ip igmp query-interval	**60** seconds
ip igmp query-max-response-time	**10** seconds
ip igmp static-group	No default
ip igmp version	Version **1**

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example sets the query message interval on the interface to **200** milliseconds:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip igmp last-member-query-interval 200**

ip mcast-stub downstream

Use the **ip mcast-stub downstream** command to enable multicast forwarding and Internet Group Management Protocol (IGMP) (router mode) on an interface and place it in multicast stub downstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub upstream** commands. Downstream interfaces connect to segments with multicast hosts. Multiple interfaces may be configured in downstream mode; however, interfaces connecting to the multicast network (upstream) should not be configured in downstream mode. Interfaces configured as downstream should have the lowest IP address of all IGMP-capable routers on the connected segment in order to be selected as the designated router (DR) and ensure proper forwarding. Refer to *ip mcast-stub helper-address <ip address> on page 1418* for more information.

Usage Examples

The following example enables multicast forwarding and IGMP on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip mcast-stub downstream**

ip mcast-stub fixed

Use the **ip mcast-stub fixed** command to allow forwarding of multicast traffic on a selected interface after enabling multicast routing. Use the **no** form of this command to disable this mode.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 12.1	Command was introduced.

Functional Notes

Multicast routing must be enabled prior to setting **ip mcast-stub fixed** on the selected interface. Also, use the **ip igmp static-group** <*address*> command (refer to *ip igmp on page 2795*) to receive multicast traffic without host-initiated Internet Group Management Protocol (IGMP) activity on the selected interface. Otherwise, all host-initiated IGMP transactions will enter multicast routes on the router's interface involved with IGMP activities.

Usage Examples

The following example enables multicast traffic forwarding and IGMP on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip mcast-stub fixed**

ip mcast-stub helper-enable

Use the **ip mcast-stub helper-enable** command to assign the **ip mcast-stub helper-address** as the Internet Group Management Protocol (IGMP) proxy. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 8.1	Command was introduced.
Release 10.1	Command was expanded to include the Frame Relay subinterfaces.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address**, **ip mcast-stub upstream**, and **ip mcast-stub downstream** commands. When enabled, the interface becomes a helper forwarding interface. The IGMP host function is dynamically enabled and the interface becomes the active upstream interface, enabling the unit to perform as an IGMP proxy. Refer to *ip mcast-stub helper-address <ip address> on page 1418*, *ip mcast-stub downstream on page 2797*, and *ip mcast-stub upstream on page 2800* for more information.

Usage Examples

The following example sets the helper address as the IGMP proxy:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip mcast-stub helper-enable**

ip mcast-stub upstream

Use the **ip mcast-stub upstream** command to enable multicast forwarding on an interface and place it in multicast stub upstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub downstream** commands. When enabled, the interface becomes a candidate to be a helper forwarding interface. If chosen as the best path toward the helper address by the router's unicast route table, the Internet Group Management Protocol (IGMP) host function is dynamically enabled and the interface becomes the active upstream interface, enabling the router to perform as an IGMP proxy. Though multiple interfaces may be candidates, no more than one interface will actively serve as the helper forwarding interface. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub downstream on page 2797* for more information.

Usage Examples

The following example enables multicast forwarding on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip mcast-stub upstream**

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces	(all types)1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

Open shortest path first (OSPF) will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip mtu 1200**

ip ospf

Use the **ip ospf** command to customize Open Shortest Path First version 2 (OSPFv2) settings (if needed). Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **area** <*area id*>
ip ospf <*process id*> **authentication-key** <*password*>
ip ospf <*process id*> **cost** <*value*>
ip ospf <*process id*> **dead-interval** <*seconds*>
ip ospf <*process id*> **hello-interval** <*seconds*>
ip ospf <*process id*> **message-digest-key [1 | 2] md5** <*key*>
ip ospf <*process id*> **priority** <*value*>
ip ospf <*process id*> **retransmit-interval** <*seconds*>
ip ospf <*process id*> **shutdown**
ip ospf <*process id*> **transmit-delay** <*seconds*>

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
area <*area id*>	Specifies the ID of the area to which this interface is assigned for the specified OSPFv2 process. Valid range is **0** to **4294967295**.
authentication-key <*password*>	Assigns a simple-text authentication password to be used by other routers using the OSPF simple password authentication.
cost <*value*>	Specifies the OSPF cost of sending a packet on the interface. This value overrides any computed cost value. Range is **1** to **65535**.
dead-interval <*seconds*>	Sets the maximum interval (in seconds) allowed between hello packets. If the maximum is exceeded, neighboring devices will determine that the device is down. Range is **0** to **32767** seconds.
hello-interval <*seconds*>	Specifies the interval (in seconds) between hello packets sent on the interface. Range is **0** to **32767** seconds.
message-digest-key [1 | 2] md5 <*key*>	Configures OSPF message digest 5 (MD5) authentication (16 byte maximum) keys.
priority <*value*>	Sets the OSPF priority. The value set in this field helps determine the designated router (DR) for this network. Range is **0** to **255**.
retransmit-interval <*seconds*>	Specifies the interval (in seconds) between link state advertisements (LSAs). Range is **0** to **32767** seconds.

shutdown	Disables the OSPFv2 process on the interface. When this keyword is used, the OSPFv2 settings remain in place, but logically it appears to the interface as though the process has been removed from the configuration. This parameter can be useful in troubleshooting.
transmit-delay <*seconds*>	Sets the estimated time (in seconds) required to send a link state advertisement (LSA) on the interface. Range is **0** to **32767** seconds.

Default Values

The defaults for this command are:

dead-interval <*seconds*>	40 seconds
hello-interval <*seconds*>	10 seconds: Ethernet, Frame Relay, and Point-to-Point Protocol (PPP)
priority <*value*>	1
retransmit-interval <*seconds*>	5 seconds
transmit-delay <*seconds*>	1 second

Command History

Release 3.1	Command was introduced.
Release R11.3.0	Command was expanded to include the <*process id*>, **area** <*area id*>, and **shutdown** parameters.

Usage Examples

The following example sets the maximum number of seconds allowed between hello packets to **25000**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip ospf 1 dead-interval 25000**

ip ospf <*process id*> authentication

Use the **ip ospf authentication** command to authenticate an interface that is performing open shortest path first (OSPF) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **authentication**
ip ospf <*process id*> **authentication message-digest**
ip ospf <*process id*> **authentication null**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
message-digest	Optional. Selects message digest authentication type.
null	Optional. Specifies that no authentication be used.

Default Values

By default, **ip ospf authentication** is set to **null** (meaning no authentication is used).

Command History

Release 3.1	Command was introduced.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Usage Examples

The following example specifies that no authentication will be used on the Frame Relay interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip ospf 1 authentication null**

ip ospf <*process id*> network

Use the **ip ospf network** command to specify the type of network on this interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **network broadcast**
ip ospf <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
broadcast	Sets the network type for broadcast.
point-to-point	Sets the network type for point-to-point.

Default Values

By default, Ethernet defaults to **broadcast**. Point-to-Point Protocol (PPP) and Frame Relay default to **point-to-point**.

Command History

Release 3.1	Command was introduced.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Functional Notes

A point-to-point network will not elect designated routers.

Usage Examples

The following example designates a broadcast network type:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip ospf 1 network broadcast**

ip pim sparse-mode

Use the **ip pim sparse-mode** command to enable protocol-independent multicast (PIM) sparse mode for this interface. Use the **no** form of this command to disable PIM sparse mode.

Syntax Description

No subcommands.

Default Values

By default, PIM sparse mode for this interface is disabled.

Command History

Release 11.1	Command was introduced.

Functional Notes

PIM sparse mode is a multicast routing protocol that makes use of the unicast forwarding table. It builds unidirectional shared trees rooted at a rendezvous point (RP) for a multicast group or a shortest-path tree rooted at a specific source for a multicast group.

Usage Examples

The following example enables PIM sparse mode on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip pim sparse-mode**

ip pim-sparse dr-priority <*value*>

Use the **ip pim-sparse dr-priority** command to specify the priority for the designated router (DR). This command modifies the router's priority in the DR election process. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the priority of this interface (to be used when determining the DR). Valid range is **1** to **4294967295**.

Default Values

By default, the priority of all protocol-independent multicast (PIM) interfaces is **1**.

Command History

Release 11.1	Command was introduced.

Functional Notes

Interfaces advertise their configured priority values in the hello messages transmitted on the interface. Routers use the priority values to determine the appropriate DR. The router on the network segment with the highest priority is selected as the DR. If a hello message is received on the interface from a router on the network segment and it does not contain a priority, the entire network segment defaults to DR selection based on IP addresses instead of priority. In this instance, the DR is selected as the router on the network segment that has the highest IP address. AOS will always include a priority in all transmitted hello messages. If no priority is specifically designated by the user, the priority is set as the default of 1.

Usage Examples

The following example specifies a priority of **100** on the Frame Relay subinterface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip pim-sparse dr-priority 100**

ip pim-sparse hello-timer <*value*>

Use the **ip pim-sparse hello-timer** command to specify protocol-independent multicast (PIM) sparse hello timer period. This is the time interval at which periodic hellos are sent out on all interfaces of a PIM-capable router. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the interval (in seconds) at which periodic hellos are sent out of the interface. Valid range is **10** to **3600** seconds.

Default Values

By default, the hellos are transmitted on PIM interfaces every **60** seconds.

Command History

Release 11.1	Command was introduced.

Functional Notes

Hello messages are used to inform neighbors of a router's presence. Hello messages normally generate a small amount of traffic on an interface. Setting the **hello-timer** to a small interval increases the number of hellos sent (thus increasing the amount of traffic). Set the **hello-timer** to a reasonable value, taking into consideration the bandwidth available on the interface.

Usage Examples

The following example specifies hellos be sent on the Frame Relay subinterface every **3600** seconds:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip pim-sparse hello-timer 3600**

ip pim-sparse nbr-timeout <*value*>

Use the **ip pim-sparse nbr-timeout** command to specify protocol-independent multicast (PIM) sparse neighbor timeout. This is the time interval after which a PIM-capable router will consider a neighbor not present. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the time interval in seconds after which a neighbor is considered not present. Valid range is **30** to **10800** seconds.

Default Values

By default, the nbr-timeout is set to **105** seconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the nbr-timeout to **300** seconds:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip pim-sparse nbr-timeout 300**

ip pim-sparse override-interval <*value*>

Use the **ip pim-sparse override-interval** command to specify the protocol-independent multicast (PIM) sparse join/prune override interval. This delay interval is the period after a join/prune that another router on the local area network (LAN) may override a join/prune. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the delay time in milliseconds. Valid range is **0** to **65535** milliseconds.

Default Values

By default, the override interval is set to **2500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the override interval to **3000** milliseconds:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip pim-sparse override-interval 3000**

ip pim-sparse propagation-delay *<value>*

Use the **ip pim-sparse propagation-delay** command to specify the expected propagation delay for join/prune messages. Set the propagation delay (in milliseconds) to estimate the amount of delay found in the local link. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the expected propagation delay in the local link in milliseconds. Valid range is **0** to **32767** milliseconds.

Default Values

By default, the propagation delay is set to **500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the propagation delay to **300** milliseconds on the Frame Relay subinterface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip pim-sparse propagation-delay 300**

ip policy route-map *<name>*

Use the **ip policy route-map** command to assign a policy route map to this interface. Use the **no** form of this command to remove the route-map policy.

Syntax Description

<name>	Specifies the name of the policy route map to assign to this interface.

Default Values

By default, no policy route map is assigned to this interface.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example assigns the policy route map **policy1** to the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip policy route-map policy1**

ip proxy-arp

Use the **ip proxy-arp** command to enable proxy Address Resolution Protocol (ARP) on the interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, proxy ARP is enabled.

Command History

Release 1.1	Command was introduced.

Functional Notes

In general, the principle of proxy ARP allows a router to insert its IP address in the source IP address field of a packet (if the packet is from a host on one of its subnetworks). This allows hosts to reach devices on other subnetworks without implementing routing or specifying a default gateway.

If proxy ARP is enabled, AOS will respond to all proxy ARP requests with its specified medium access control (MAC) address and forward packets accordingly.

Enabling proxy ARP on an interface may introduce unnecessary ARP traffic on the network.

Usage Examples

The following example enables proxy ARP on the Frame Relay subinterface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip proxy-arp**

ip rip receive version

Use the **ip rip receive version** command to configure the Routing Information Protocol (RIP) version the unit accepts in all RIP packets received on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip receive version 1
ip rip receive version 2

Syntax Description

1	Accepts only received RIP version 1 packets on the interface.
2	Accepts only received RIP version 2 packets on the interface.

Default Values

By default, all interfaces implement RIP **version 1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.

Functional Notes

Use the **ip rip receive version** command to specify a RIP version that will override the **version** (in the Router RIP) configuration.

AOS only accepts one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures a Frame Relay subinterface to accept only RIP version 2 packets:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip rip receive version 2**

ip rip send version

Use the **ip rip send version** command to configure the Routing Information Protocol (RIP) version the unit sends in all RIP packets transmitted on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip send version 1
ip rip send version 2

Syntax Description

1	Transmits only RIP version 1 packets on the interface.
2	Transmits only RIP version 2 packets on the interface.

Default Values

By default, all interfaces transmit RIP **version 1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.

Functional Notes

Use the **ip rip send version** to specify a RIP version that will override the **version** (in the Router RIP) configuration.

AOS only transmits one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures a Frame Relay subinterface to transmit only RIP version 2 packets:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip rip send version 2**

ip rip summary-address *<ip address> <subnet mask>*

Use the **ip rip summary-address** command to manually summarize the routes Routing Information Protocol (RIP) will advertise and send out a specified interface. Use the **no** form of this command to disable this mode.

Syntax Description

<ip address>	Specifies the summarized network IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.0**).
<subnet mask>	Specifies the subnet mask that corresponds to the range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no manual summarization is applied by RIP.

Command History

Release 12.1	Command was introduced.

Functional Notes

Unlike the automatic summarization on classful network boundaries, only specific network advertisements are made by RIP using the **ip rip summary-address** command. This command is only effective if RIP version 2 is configured.

Usage Examples

The following example enables manual summarization on the specified IP address:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip rip summary-address 10.10.123.0 255.255.255.0**

ip route-cache

Use the **ip route-cache** command to enable Internet Protocol version 4 (IPv4) fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

*Using network address translation (NAT) or the AOS firewall capabilities on an interface requires process switching mode (using the **no ip route-cache** command).*

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Fast switching allows an IPv4 interface to provide optimum performance when processing IPv4 traffic.

Usage Examples

The following example enables IPv4 fast switching on the Frame Relay subinterface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip route-cache**

ip unnumbered *<interface>*

Use the **ip unnumbered** command to use the IP address assigned to the specified interface for all IP processing on the active interface. Use the **no** form of this command to remove the unnumbered configuration.

Syntax Description

<interface>	Specifies the interface that contains the IP address to use as the source address for all packets transmitted on this interface. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip unnumbered ?** for a list of valid interfaces.

Default Values

By default, all interfaces are configured to use a specified IP address (using the **ip address** command).

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface.

Functional Notes

If **ip unnumbered** is enabled on an interface, all IP traffic from the interface will use a source IP address taken from the specified interface. For example, specifying **ip unnumbered eth 0/1** while in the Frame Relay Subinterface Configuration mode configures the Frame Relay subinterface to use the IP address assigned to the Ethernet interface for all IP processing. In addition, AOS uses the specified interface information when sending route updates over the unnumbered interface.

Usage Examples

The following example configures the Frame Relay interface (labeled **frame-relay 1.16**) to use the IP address assigned to the Ethernet interface (**eth 0/1**):

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip unnumbered eth 0/1**

ip urlfilter <*name*>

Use the **ip urlfilter** command to apply a universal resource locator (URL) filter to the interface for all inbound or outbound traffic. Use the **no** form of this command to remove the URL filter from an interface. Variations of this command include:

ip urlfilter <*name*> **in**
ip urlfilter <*name*> **out**

Syntax Description

<*name*>	Specifies the URL filter name to use on the interface.
in	Applies the filter to the inbound traffic.
out	Applies the filter to the outbound traffic.

Default Values

By default, there are no URL filters applied to any interfaces.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the virtual local area network (VLAN) interfaces.

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be created by using the **ip urlfilter** <*name*> **http** command before applying it to the interface. Refer to *ip urlfilter allowmode on page 1493* for more information on using this command.

Usage Examples

The following example performs URL filtering on all traffic entering through a Frame Relay subinterface and matches the URL filter named **MyFilter**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ip urlfilter MyFilter in**

ipv6

Use the **ipv6** command to enable Internet Protocol version 6 (IPv6) processing and create a link-local address on an interface. Use the **no** form of this command to disable IPv6 processing and remove all IPv6 configuration on the interface.

Syntax Description

No subcommands.

Default Values

By default, IPv6 is not enabled on the interface.

Command History

Release 18.1	Command was introduced.

Functional Notes

Because AOS uses the dual-stack for IPv6 implementation, IPv6 features must be enabled for the supported IPv6 features to be used. Enabling IPv6 in AOS is completed by using an IPv6 address or using the **ipv6** keyword with specific commands. For example, to enable IPv6 on an interface and cause the interface to join the link scoped all-nodes and all-routers multicast group, enter an IPv6 address on the interface.

Use the **ipv6** command to enable IPv6 processing and create a link-local address on an interface when other unicast IPv6 addresses are not needed on the interface. This command is not necessary nor effectual when any other form of an IPv6 address command is also present on the interface.

Usage Examples

The following example enables IPv6 and creates a link-local IPv6 address on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6**

ipv6 access-group *<ipv6 acl name>*

Use the **ipv6 access-group** command to apply an Internet Protocol version 6 (IPv6) access control list (ACL) to be used for IPv6 packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ipv6 access-group <*ipv6 acl name*> **in**
ipv6 access-group <*ipv6 acl name*> **out**

Syntax Description

<ipv6 acl name>	Applies the named IPv6 ACL to the interface.
in	Enables access control on IPv6 packets received on the specified interface.
out	Enables access control on IPv6 packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 18.1	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.

Functional Notes

Only one IPv6 ACL can be applied in each traffic direction.

Unlike in IPv4, IPv6 traffic filters include an implicit **permit** for neighbor solicitation and advertisement packets in an ACL before the traditional implicit **deny** at the end of the ACL. This prevents blocking of address resolution and unreachability detection, although this can be overridden by entering explicit **deny** commands in the IPv6 ACL.

Usage Examples

The following example applies the IPv6 ACL **Privatev6** to incoming IPv6 traffic on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 access-group Private6 in**

ipv6 access-policy *<ipv6 acp>*

Use the **ipv6 access-policy** command to assign a specified Internet Protocol version 6 (IPv6) access control policy (ACP) to an interface. IPv6 ACPs are applied to IPv6 traffic entering an interface. Use the **no** form of this command to remove an ACP association.

Syntax Description

<ipv6 acp>	Identifies the configured IPv6 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv6 ACPs associated with an interface.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example applies the IPv6 ACP **PRIVATEv6** to the interface:

Enable the AOS security features:
(config)**#ipv6 firewall**

Associate the ACP with the Frame Relay subinterface 1.16:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 access-policy PRIVATEv6**

ipv6 address *<ipv6 address/prefix-length>*

Use the **ipv6 address** command to assign a unicast Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<ipv6 address/prefix-length>	Specifies the IPv6 unicast address to add to the interface. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

Default Values

By default, no IPv6 address is configured on the interface and IPv6 processing is not enabled on the interface.

Command History

Release 18.1	Command was introduced.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the interface using the command *ipv6 address <ipv6 link-local address> link-local on page 2826*.

The address created by this command is a manually configured IPv6 address, which must have all parts (prefix and host bits) specified.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example adds a unicast IPv6 address to the interface and enables IPv6 processing on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 address 2001:DB8::/32**

ipv6 address *<ipv6 prefix/prefix-length>* eui-64

Use the **ipv6 address eui-64** command to assign a unicast Internet Protocol version 6 (IPv6) address and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<ipv6 prefix/prefix-length>	Specifies the IPv6 prefix. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
eui-64	Specifies that the IPv6 address is constructed using the specified prefix in the high-order bits and followed by the EUI-64 Interface ID in the lower 64 bits.

Default Values

By default, no IPv6 address is configured on the interface and IPv6 processing is not enabled on the interface.

Command History

Release 18.1	Command was introduced.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the interface using the command *ipv6 address <ipv6 link-local address> link-local on page 2826*.

The address created by this command is an EUI-64 unicast address. For this type of address, the EUI-64 interface ID is automatically placed in the IPv6 address. Any manually configured bits beyond the address's prefix length are set to **0**; however, any manually configured bits within the prefix length that extend into the lower 64 bits take precedence over the Interface ID bits.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example adds a unicast IPv6 address with an EUI-64 Interface ID to the interface and enables IPv6 processing on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 address 2001:DB8:3F::/48 eui-64**

ipv6 address *<ipv6 link-local address>* link-local

Use the **ipv6 address link-local** command to manually assign a link-local Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<ipv6 link-local address>	Specifies the link-local IPv6 address. Link-local addresses are specified in colon hexadecimal notation, and begin with **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since link-local addresses have no prefix, the bits entered form the entire IPv6 address.
link-local	Specifies this is a manually configured link-local address. Manually configured link-local addresses replace automatically configured link-local addresses on the interface.

Default Values

By default, no IPv6 address is configured for the interface and IPv6 processing is not enabled.

Command History

Release 18.1	Command was introduced.

Functional Notes

A single link-local address can be manually configured on an interface. The lower 64 bits of the specified address become the Interface ID for the interface, overriding the default interface ID. Any other address that uses the EUI-64 parameter to automatically place the interface ID in the lower 64 bits of the IPv6 address use the new value for the interface ID.

The <*ipv6 address*> for a link-local IPv6 address is specified in the format **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since this form of address has no prefix, the bits entered form the entire IPv6 address. These bits also become the new interface ID for the interface and can be derived from the interface's medium access control (MAC) address.

The **link-local** parameter specifies this is a manually configured link-local address. Any manually configured link-local address will replace an automatically configured link-local address for the interface.

Using the **no** form of this command with a specified IPv6 address removes that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example manually creates a link-local IPv6 address on the interface and enables IPv6 processing:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 address FE80::220:8FF:FE54:F9D8 link-local**

ipv6 address autoconfig

Use the **ipv6 address autoconfig** command to enable Internet Protocol version 6 (IPv6) processing on the interface, create a local-link IPv6 address for the interface, and allow the interface to automatically configure itself based on advertisements from other routers on the link. Use the **no** form of this command to remove all autoconfigured addresses, prefixes, and any resulting routes from the interface and also causes the interface to cease processing received router advertisements (RAs).Variations of this command include:

ipv6 address autoconfig
ipv6 address autoconfig default
ipv6 address autoconfig default metric <*value*>

Syntax Description

default	Optional. Specifies that the interface maintain a list of advertising routers that are willing to be IPv6 default routers.
metric <*value*>	Optional. Specifies the administrative distance for a default router maintained in the default router list. Range is **1** to **255**. Routes with lower administrative distance are favored.

Default Values

By default, no IPv6 addresses are configured for the interface and IPv6 processing is not enabled. When an IPv6 address is configured automatically, the administrative distance for default routers is **2** by default.

Command History

Release 18.1	Command was introduced.

Functional Notes

When autoconfiguration is enabled, the interface listens for RA messages that tell the interface how it should be configured. The interface then creates addresses for advertised 64-bit prefixes with the A flag in the IPv6 address set using stateless address autoconfiguration (SLAAC). The addresses use the EUI-64 interface ID in the lower 64 bits of the address. A route type of *Connected* is added to the route table if the L flag on the prefix advertisement (on-link flag) is also set.

Usage Examples

The following example enables IPv6 processing on the interface, creates a link-local IPv6 address for the interface, and allows the interface to automatically configure itself for IPv6:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 address autoconfig**

ipv6 address dhcp

Use the **ipv6 address dhcp** command to enable Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) on the interface, place the interface in DHCPv6 client mode, and configure the address parameters of the DHCPv6 client. Use the **no** form of this command to disable the DHCPv6 client on the interface. Variations of this command include:

ipv6 address dhcp
ipv6 address dhcp hostname <*partial fqdn*>
ipv6 address dhcp hostname fqdn <*fqdn*>
ipv6 address dhcp no-domain-name
ipv6 address dhcp no-nameservers
ipv6 address dhcp no-ntp
ipv6 address dhcp no-sntp-server
ipv6 address dhcp rapid-commit

Syntax Description

hostname <*partial fqdn*>	Optional. Specifies the name to be sent to the DHCPv6 server as the host portion of its fully qualified domain name (FQDN). FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
fqdn <*fqdn*>	Optional. Specifies a name to be sent to the DHCPv6 server as the system's FQDN. FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
no-domain-name	Optional. Specifies that no domain names are obtained using this DHCPv6 client.
no-nameservers	Optional. Specifies that no domain naming server (DNS) addresses are obtained through DHCPv6.
no-ntp	Optional. Specifies that no Network Time Protocol (NTP) server values are obtained through this DHCPv6 client.
no-sntp-server	Optional. Specifies that no Simple Network Time Protocol (SNTP) server values are obtained through this DHCPv6 client.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Functional Notes

To enable an interface as a DHCPv6 client, you must first enable IPv6 on the interface using the command *ipv6 on page 2821*.

Enabling the interface as a DHCPv6 client using the **ipv6 address dhcp** command places the interface into DHCPv6 client mode. DHCPv6 modes (**client**, **server**, **relay**) are mutually exclusive at the interface. Any existing mode must be removed before a different mode can be applied. For example, if the interface is configured as a DHCPv6 relay agent, you must first disable the **relay** mode before you can specify the interface is in **client** mode.

Usage Examples

The following example enables the interface as a DHCPv6 client and specifies the client's host name:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 address 2001:DB8:1::1/64**
(config-fr 1.16)**#ipv6 address dhcp fqdn client@company.com**

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*

Use the **ipv6 address named-prefix** command to create an Internet Protocol version 6 (IPv6) address for the interface using the values in a named prefix. Use the **no** form of this command to remove the address from the interface. Variations of this command include:

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*
ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>* **eui-64**

Syntax Description

<prefix name>	Specifies the named prefix to use to create the address.
<ipv6 address/prefix-length>	Specifies the address portion appended to the named prefix to create a 128-bit host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
eui-64	Optional. Indicates that the interface ID is to be placed in the lower 64 bits of the address.

Default Values

By default, no IPv6 addresses are specified on the interface.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example creates an IPv6 address on the interface using the named prefix **PREFIX1**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 address named-prefix PREFIX1 2001:1:0:/48**

ipv6 crypto map *<name>*

Use the **ipv6 crypto map** command to associate Internet Protocol version 6 (IPv6) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

Syntax Description

<name>	Specifies the IPv6 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

Command History

Release R10.7.0	Command was introduced.

Functional Notes

Only one IPv6 crypto map can be specified per interface, and the crypto map is applied within the virtual routing and forwarding (VRF) instance to which the interface belongs. To apply the IPv6 crypto map, the interface must have IPv6 enabled. In addition, the interface must have an IPv6 address of appropriate scope to allow connectivity to peer's addresses as specified in the crypto map's entries.

Usage Examples

The following example applies all IPv6 crypto maps with the name **MyMap** to the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6**
(config-fr 1.16)**#ipv6 crypto map MyMap**

ipv6 dhcp client information refresh minimum <*seconds*>

Use the **ipv6 dhcp client information refresh minimum** command to specify the minimum value the Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) client on the interface accepts as its information refresh timer. Use the **no** version of this command to return to the default setting.

Syntax Description

<*seconds*>	Specifies the refresh timer in seconds. Valid range is **600** to **3600** seconds.

Default Values

By default, the DHCPv6 client refresh timer is set to **600** seconds.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example specifies the DHCPv6 client refresh timer for the interface is **800** seconds:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 dhcp client information refresh minimum 800**

ipv6 dhcp client pd <*prefix name*>

Use the **ipv6 dhcp client pd** command to enable the Dynamic Control Host Protocol for Internet Protocol version 6 (DHCPv6) client on the interface and specify that the interface acquires an IPv6 prefix for the DHCPv6 client. Use the **no** form of this command to disable this feature. Variations of this command include:

ipv6 dhcp client pd <*prefix name*>
ipv6 dhcp client pd <*prefix name*> **no-aggregate-route**
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*>
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*> **tag** <*value*>
ipv6 dhcp client pd <*prefix name*> **rapid-commit**

Syntax Description

<*prefix name*>	Specifies the variable of the prefix stored on the AOS system. Variables are expressed in ASCII text of up to **80** characters.
no-aggregate-route	Optional. Specifies that a route to the null 0 interface is not injected into the route table for the prefixes assigned.
distance <*distance*>	Optional. Specifies the administrative distance to assign to the injected route. Valid range is **1** to **255** with a default distance of **1**.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.
tag <*value*>	Optional. Specifies a number to use as a tag for labeling and filtering routers. Valid range is **1** to **65535**.

Default Values

By default, the DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Usage Examples

The following example enables the DHCPv6 client on the interface and assigns the prefix **PREFIX1**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 dhcp client pd PREFIX1**

ipv6 dhcp relay destination *<ipv6 address>*

Use the **ipv6 dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 6 (IPv6) and to specify the IPv6 address for the DHCPv6 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv6 relay functionality is disabled on the interface. Variations of this command include:

ipv6 dhcp relay destination *<ipv6 address>*
ipv6 dhcp relay destination *<ipv6 address>* *<interface>*
ipv6 dhcp relay destination *<ipv6 address>* **mef-ethernet** *<slot/port>*
ipv6 dhcp relay destination *<ipv6 address>* **system-control-evc**
ipv6 dhcp relay destination *<ipv6 address>* **system-management-evc**

Syntax Description

<ipv6 address>	Specifies the IPv6 address for the DHCPv6 messages. IPv6 addresses should be specified in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<interface>	Optional. Specifies an output interface to use when sending messages to the DHCPv6 server. If no interface is specified, the interface is selected by the routing table. This parameter is only required when the IPv6 address is a link-scoped address. Interfaces are specified in the *<interface type> <slot/port | interface id>* format. For example, for an Ethernet interface, use **eth 0/1**. Type **ipv6 dhcp relay destination** *<ipv6 address>* **?** to display a list of valid interfaces.
mef-ethernet *<slot/port>*	Specifies the Metro Ethernet Forum (MEF) Ethernet interface.
system-control-evc	Optional. Specifies the system control Ethernet virtual connection (EVC) is used when sending messages to the DHCPv6 server.
system-management-evc	Optional. Specifies the system management EVC is used when sending messages to the DHCPv6 server.

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.
Release R10.5.0	Command was expanded to include the loopback interface.
Release R10.10.0	Command was expanded to include the system control and system management EVCs.
Release R10.11.0	Command was expanded to include the MEF Ethernet interface.

Functional Notes

To configure an interface to function as a DHCPv6 relay agent, you must first enable IPv6 on the interface using the command *ipv6 on page 2821*.

Usage Examples

The following example enables DHCPv6 relay agent functionality and specifies the destination address as **2001:DB8:2::1**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6**
(config-fr 1.16)**#ipv6 dhcp relay destination 2001:DB8:2::1**

Technology Review

DHCPv6, like DHCP in IPv4, is used in IP networks to supply hosts with IP addresses and other networking information. DHCPv6, however, functions slightly differently than DHCPv4 by providing relay agents with the ability to send relay-forward and relay-reply messages. In addition, in DHCPv4, when DHCP messages are sent to a DHCP server whose address is not known, the IPv4 client uses the broadcast address. In DHCPv6, the IPv6 client sends messages using the link-scoped mulitcast address. This address is the All DHCP Relay Agents and Servers link, designated as **FF02::1:2**.

In AOS, DHCPv6 relay agents are used when the DHCP server is not on the same link as the DHCP client. The relay is typically a router on the same link as the client, which acts as an intermediary to help the client's DHCP messages reach the DHCP server. DHCPv6 relay agents operate transparently to the DHCP client, and can be configured in chains, meaning that information about each agent encountered is encapsulated into the relay message. Relay agents add fields to the DHCP message as they send these messages to the server, thus providing a method to properly manage the DHCP client.

For more information about DHCPv6 functionality in AOS, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

ipv6 dhcp server

Use the **ipv6 dhcp server** command to enable Internet Protocol version 6 (IPv6) Dynamic Host Control Protocol (DHCP) on the interface and specify that the interface is functioning as a DHCPv6 server. This command not only enables the DHCPv6 server on the interface, it also configures specific parameters of the DHCPv6 server. Hence, the parameters of this command can be entered multiple times and in any order. Use the **no** form of this command to disable DHCPv6 on the interface. Variations of this command include:

ipv6 dhcp server automatic
ipv6 dhcp server automatic allow-hint
ipv6 dhcp server automatic preference <*number*>
ipv6 dhcp server automatic rapid-commit
ipv6 dhcp server <*pool name*>
ipv6 dhcp server <*pool name*> **allow-hint**
ipv6 dhcp server <*pool name*> **preference** <*number*>
ipv6 dhcp server <*pool name*> **rapid-commit**

Syntax Description

automatic	Enables automatic selection of the DHCPv6 server pool based on information extracted from the DHCPv6 client's request. You must specify the pool selection method before configuring other options for this command.
<*pool name*>	Specifies the DHCPv6 server pool that services this interface. All DHCPV^ requests received on this interface are serviced from this pool. If a pool name is not specified, the server pool is selected automatically. You must specify the pool selection method before configuring the other options for this command.
allow-hint	Optional. Specifies that the DHCPv6 server attempts to honor the DHCPv6 client's request for specific values as hinted in the client's request (if they are valid and not already assigned). If this option is not specified, any hints from the DHCPv6 client are ignored.
preference <*number*>	Optional. Specifies the preference value advertised by the server. This option is sent by the server to a DHCPv6 client to influence the selection of a server when there are multiple servers from which to choose. Valid range is **0** to **255**, with a default value of **0**. When the preference value is set to a non-zero value, the server includes a preference option containing the value. If the preference value is not set, or is set to 0, the option is omitted and the client assumes the value is 0.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 server mode is not enabled on the interface.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

Enabling the interface as a DHCPv6 server using this command places the interface into DHCPv6 server mode. DHCPv6 modes (server or relay) are mutually exclusive at the interface. Any existing mode will be removed if a different mode is specified, and a message will be shown indicating the change in DHCPv6 mode.

Usage Examples

The following example enables the interface as a DHCPv6 server, and specifies that the DHCPv6 server pool **POOL1** is associated with the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 address 2001:DB8:1::1/64**
(config-fr 1.16)**#ipv6 dhcp server POOL1**

ipv6 ffe

Use the **ipv6 ffe** command to enable the RapidRoute fast forwarding engine (FFE) on this Internet Protocol version 6 (IPv6) interface with the default number of entries. Use the **no** form of this command to disable this feature. Variations of this command include:

ipv6 ffe
ipv6 ffe max-entries <*value*>

> NOTE *Issuing this command will cause all RapidRoute entries to be cleared from this IPv6 interface.*

Syntax Description

max-entries <*value*>	Optional. Specifies the maximum number of entries stored in the flow table. Valid range is from **1** to **500000**.

Default Values

By default, the RapidRoute Engine is enabled on IPv6-enabled interfaces (using the command *ipv6 on page 2231*). The default number of **max-entries** is **4096**.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

RapidRoute can be used to help reduce routing overhead, and thus reduce overall routing times. Routing times are reduced by the creation of a flow table on the ingress interface. The maximum number of entries that can be stored in the flow table at any one time may be specified by using the **max-entries** parameters.

Usage Examples

The following example disables RapidRoute on the IPv6 interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#no ipv6 ffe**

Technology Review

The RapidRoute system goal is to increase IP packet throughput by moving as much of the packet processing into the engine as possible. Packets are classified into flows based upon the IP protocol (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol (ICMP), etc.), the source and destination IP addresses, IP type of service (ToS), and the protocol-specific information, such as the source and destination port numbers. Flows are defined as the unidirectional representation of a conversation between two IP hosts. Each ingress interface keeps its own flow table, a collection of flow entries.

The first packet in a flow that is forwarded through the unit will build a flow entry. When a flow entry is looked up but no entry is found, a RapidRouteBuilder object is allocated and attached to the packet. As the packet passes through the various processing layers, each subsystem will add processing to the RapidRouteBuilder. When packet is about to be forwarded out of the egress interface, the RapidRouteBuilder will be finalized. That is, the flow entry being built will be checked for completeness and committed to the flow table on the ingress interface. Subsequent flow matches can then bypass the normal processing layers.

ipv6 mode host unicast

Use the **ipv6 mode host unicast** command to place the interface in host mode using an Internet Protocol version 6 (IPv6) unicast address. Use the **no** form of this command to disable host mode on the interface.

Syntax Description

No subcommands.

Default Values

By default, host mode is disabled.

Command History

Release R10.9.0	Command was introduced.

Command History

When this command is configured on an interface, the MTU value is learned from received router advertisements. Link MTU value is learned in host mode from the following locations (in decreasing order of priority): the provisioned MTU value in the interface configuration, the router advertisements received on the interface, and the default MTU value (1500).

Usage Examples

The following example places the interface in host mode:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 mode host unicast**

ipv6 mtu *<size>*

Use the **ipv6 mtu** command to specify the maximum transmission unit (MTU) for Internet Protocol version 6 (IPv6) packets on the interface. Use the **no** form of this command to return to the default value.

Syntax Description

<size>	Specifies the MTU value. Valid range is **1280** to **1500** bytes.

Default Values

By default, the MTU of the interface is set to **1280** bytes.

Command History

Release 18.1	Command was introduced.

Functional Notes

In IPv6, the minimum MTU is 1280 octets. Any link that has an MTU less than 1280 octets must use link fragmentation and reassembly that is transparent to IPv6 (for example, the Fragmentation Header). Sources in the IPv6 network are expected to perform path maximum transmission unit (PMTU) discovery to send packets larger than 1280 octets. PMTU works in the following manner: First, the sending node assumes the link MTU of the interface from which the traffic is being forwarded and then sends the IPv6 packet at the link MTU size. If a router on the path is unable to forward the packet, it sends an ICMP *Packet Too Big* message back to the sending node containing the link MTU of the link on which the packet forwarding failed. The sending node then rests the PMTU to the value of the MTU field in the Internet Control Message Protocol version 6 (ICMPv6) *Packet Too Big* message, and the packet is resent.

The MTU for IPv6 packets can be set on a per-interface basis. There are two methods for setting MTUs for interfaces if required: one for Layer 3 interfaces, and one for the underlying Layer 1 and Layer 2 interfaces. For all interface types, use the **ipv6 mtu** *<size>* command to specify the IPv6 MTU in bytes from the interface's configuration mode. The minimum MTU setting for IPv6 is **1280** bytes, and the maximum is **1500** bytes. The IPv6 MTU value is independent of the IPv4 MTU setting (set with the command *ip mtu <size> on page 2801*).

When the interface is forwarding the IPv6 packet as a router, if the packet size exceeds the IPv6 MTU of the egress interface, the packet is dropped and ICMPv6 *Packet Too Big* message is sent to the source. When originating an IPv6 packet from the local IPv6 stack, and the packet is larger than the IPv6 MTU of the egress interface, the packet is fragmented and sent.

Usage Examples

The following example specifies the IPv6 MTU value for the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 mtu 1350**

ipv6 nd advertisement-interval

Use the **ipv6 nd advertisement-interval** command to specify that the Advertisement Interval Option is sent in Internet Protocol version 6 (IPv6) router advertisement (RA) messages from the router. This command is effectual only when the interface is in router mode. Use the **no** form of this command to return to the default interval.

Syntax Description

No subcommands.

Default Values

By default, Advertisement Interval Options are not sent in RA messages.

Command History

Release 18.1	Command was introduced.

Functional Notes

Sending the Advertisement Interval Option should be enabled when the router is functioning in a mobile IP environment to aid movement detection by mobile nodes. This option contains the current value of the maximum router advertisement interval configured using the command *ipv6 nd ra interval on page 2852*.

Usage Examples

The following example specifies that the interface include Advertisement Interval Options in RA messages sent from the router:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd advertisement-interval**

ipv6 nd cache max-incomplete <*number*>

Use the **ipv6 nd cache max-incomplete** command to specify the maximum number of incomplete entries the Neighbor Discovery (ND) cache retains. Use the **no** form of this command to return to the default value.

Syntax Description

<*number*>	Specifies the number of incomplete ND entries to retain in the cache. Valid range is **1** to **321**.

Default Values

By default, the incomplete ND entries can take at maximum one-third of the possible ND cache entries (varies by product).

Command History

Release R11.10.0	Command was introduced.

Usage Examples

The following example specifies that the interface stores **150** incomplete entries in the ND cache:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd cache max-incomplete 150**

ipv6 nd dad attempts <*number*>

Use the **ipv6 nd dad attempts** command to specify the number of neighbor solicitation (NS) messages sent by the interface when performing Internet Protocol version 6 (IPv6) duplicate address detection (DAD). This command is effectual when the interface is in either host or router mode. Use the **no** form of this command to return to the default value.

Syntax Description

<*number*>	Specifies the number of NS messages that will be sent. Range is **0** to **10** messages. A value of **0** disables DAD on the interface.

Default Values

By default, the interface sends **1** NS message.

Command History

Release 18.1	Command was introduced.

Functional Notes

DAD is used by devices to determine if IPv6 addresses are unique before they are applied to interfaces. DAD is used in NS messages to detect duplicate unicast addresses. The Target Address fields in the NS messages are set to the IPv6 address for which duplication is being detected. Destination IPv6 addresses for DAD in NS messages are the solicited-node multicast version of the address being tested. Source IPv6 addresses for DAD are set to the IPv6 unspecified address (::). Once the IPv6 address is determined by DAD to be unique, it can be applied to the IPv6 interface on the node.

DAD in AOS is performed when an interface transitions state from DOWN to UP or when manually configuring an address. When performing DAD because of an interface transition, DAD will happen immediately after the interface transition and again 40 seconds later to cooperate with the port being connected to an Ethernet switch.

Usage Examples

The following example specifies that **3** NS messages are sent by the interface when performing DAD:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd dad attempts 3**

ipv6 nd managed-config-flag

Use the **ipv6 nd managed-config-flag** command to specify the M flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. The M flag instructs hosts receiving the RA that they can use stateful Dynamic Host Configuration Protocol version 6 (DHCPv6) to configure addresses and nonaddress information. Use the **no** form of this command to disable the setting of the M flag.

Syntax Description

No subcommands.

Default Values

By default, the M flag is not set in RAs.

Command History

Release 18.1	Command was introduced.

Functional Notes

If you specify that the M flag is set in RA messages, you do not need to set the 0 flag (it becomes redundant).

Usage Examples

The following example sets the M flag for RA messages sent by the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd managed-config-flag**

ipv6 nd ns-interval *<value>*

Use the **ipv6 nd ns-interval** command to specify the interval between transmission of certain Internet Protocol version 6 (IPv6) Neighbor Discovery (ND) messages and to control what ND value is advertised in router advertisement (RA) messages. This command is effectual whether the interface is in host or router mode. Use the **no** form of this command to return the interval to the default value.

Syntax Description

<value>	Specifies the time (in milliseconds) between neighbor message transmissions. Valid range is **1000** to **3600000** ms.

Default Values

By default, the interval is set to **1000** ms for internal use by the router and **0** (unspecified) is sent in RA messages.

Command History

Release 18.1	Command was introduced.

Functional Notes

This command controls the spacing of neighbor solicitation (NS) messages for functions such as address resolution, reachability detection, and duplicate address detection (DAD). For DAD it also serves as the amount of time after the last transmission before the detection phase of autoconfiguration terminates. In addition, the command controls the interval between unsolicited neighbor advertisement (NA) messages.

Usage Examples

The following example changes the interval between RA messages sent from the interface to **2000** ms:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd ns-interval 2000**

ipv6 nd other-config-flag

Use the **ipv6 nd other-config-flag** command to specify the O flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the interface is in router mode. When the O flag is set, hosts receiving the RA messages are instructed that they may use stateless Dynamic Host Configuration Protocol version 6 (DHCPv6) to receive information that is not IPv6 addressing information, and to use some other method (whether through manual configuration, stateless address autoconfiguration (SLAAC), etc.) for addressing information. Use the **no** form of this command to disable the O flag setting.

Syntax Description

No subcommands.

Default Values

By default, the O flag is not set in RA messages.

Command History

Release 18.1	Command was introduced.

Functional Notes

If the M flag is set for RA messages, you do not need to set the O flag.

Usage Examples

The following example sets the O flag in RA messages from the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd other-config-flag**

ipv6 nd prefix

Use the **ipv6 nd prefix** command to specify the Internet Protocol version 6 (IPv6) address prefixes used in router advertisement (RA) messages sent from the interface. Use the **no** form of this command to remove the specified prefix configuration from the interface. Variations of this command include:

ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise] [**<*valid lifetime*> | **infinite]** <*preferred lifetime* | **infinite**>
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite] [no-advertise] [no-autoconfig] [no-rtr-address] [no-onlink] [off-link]**

Syntax Description

named-prefix <*prefix name*>	Optional. Specifies that a named prefix is used in RA messages. When a named prefix is used, the default prefix cannot be used.
<*ipv6 prefix/prefix-length*>	Specifies the IPv6 prefix and length to be advertised. Pv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
default	Specifies the default values for the IPv6 prefix parameters. Refer to the *Functional Notes* below for more information.
<*valid lifetime*>	Optional. Specifies the valid lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
<*preferred lifetime*>	Optional. Specifies the preferred lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
infinite	Optional. Specifies that the the valid and preferred lifetimes of the prefix do not expire.
no-advertise	Optional. Specifies that the prefix is excluded from the RA message.
no-autoconfig	Optional. Sets the A flag in the RA message to **0**, indicating that hosts may not create an address for this prefix using stateless address autoconfiguration (SLAAC). This parameter only affects hosts receiving the RA message, it does not affect the operation of the local router.
no-rtr-address	Optional. Sets the R flag in the RA message to **0** and specifies the full router IPv6 address is not included in the RA message.
no-onlink	Optional. Specifies that the IPv6 prefix in the RA message is not to be used for on-link determination.
off-link	Optional. Sets the L flag value to **0** in RA messages, which indicates the RA makes no statement about the on-link or off-link properties of the IPv6 prefix.

Default Values

By default, all prefixes derived from the interface's configured IPv6 addresses are advertised using the system default values.

By default, the valid lifetime advertised for a prefix is **2592000** seconds and the preferred lifetime advertised is **604800** seconds.

By default, the L flag is set to **1**, the R flag is set to **1**, and the A flag is set to **1**.

Command History

Release 18.1	Command was introduced.
Release R10.9.0	Command was expanded to include the **named-prefix** and *<prefix name>* options.

Functional Notes

This command works for both routers and hosts, but in host implementations it is used to manually add on-link prefixes that do not have an IPv6 address or to make off-link a prefix generated by an IPv6 address command. Hosts do not send RA messages, so the command only adds prefixes to RA messages when the interface is in router mode. This command can also be used to change the defaults used on configured prefixes when all options are not specified.

Changing the prefix defaults will affect prefixes derived from configured IPv6 addresses, as well as prefixes configured using the ***ipv6 nd prefix*** *command.*

Prefixes advertised can be a subset or a superset of the prefixes derived from the IPv6 addresses configured on the interface. Prefixes for IPv6 addresses configured on a router interface are automatically eligible to be advertised on that interface using system or configured default values without having to enter a prefix command. To impose additional controls on those prefixes, an entry must be made using this command with the desired settings.

The **default** parameter is used to change the default settings for the IPv6 prefix parameters. Changing these settings can be useful when multiple prefixes are implemented that will use the same set of parameters. When configuring IPv6 prefixes, the prefix default values are only used if no other parameters are specified after specifying the IPv6 prefix and length (for example, **ipv6 nd prefix 2001:DB8::/64**). If additional parameters are specified, any unspecified parameters use the system default values rather than the configured default values. When the default values are changed, any prefix that uses them will also change. Using this command to change prefix default values also affects prefixes derived from configured IPv6 addresses on the interface.

The optional *<valid lifetime>* parameter specifies the valid lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep this prefix until the valid lifetime expires.

The optional <*preferred lifetime*> parameter specifies the preferred lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep the prefix in the preferred state during this time period. After the preferred time period expires, the prefix transitions to the deprecated state where it remains until the valid lifetime expires and the route is removed. The <*preferred lifetime*> value must be set to be shorter than the <*valid lifetime*> value.

The optional **off-link** parameter sets the L flag (on-link flag) value to **0** in RA messages. When the L flag is set to 0, the advertisement makes no statement about on-link or off-link properties of the prefix. When the L flag is set, the prefix is considered on-link and locally reachable by hosts on the link (meaning a router is not needed). Hosts attached to the link will add on-link prefixes to their prefix list or route table. When off-link is not specified, a connected route is added to the route table of this router for this prefix. When off-link is specified, no route is added to the route table. By default, prefixes are advertised as on-link with the L flag set to 1.

The optional **no-rtr-address** parameter sets the R flag (router flag) of the RA to **0** and does not include the full router address in the advertisement. The router address is typically included in the RA to assist in Mobile IP environments. By default, the R flag is set to 1 and the router address is sent in RA messages.

The optional **no-autoconfig** parameter sets the A flag of the RA to **0**, indicating that hosts may not create an address for this prefix using SLAAC. If the A flag is set to **1** (the default setting), hosts perform SLAAC to generate an address based on the prefix. This parameter only affects hosts receiving the RA, it does not effect the operation of the local router.

The optional **no-advertise** parameter specifies that the prefix is excluded from RA messages. By default, the prefix is included in RA messages. The **no-onlink** parameter informs the router that the prefix is not to be used for on-link determination.

By default, all prefixes derived from the interface's configured IPv6 addresses are advertised using the system default values.

Usage Examples

The following example specifies that the IPv6 prefix **2001:DB8:3F::/48** has an infinite valid and preferred lifetime advertised in RA messages sent from the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd prefix 2001:DB8:3F::/48 infinite infinite**

The following example changes the default values and behaviors of prefixes included in RA messages to infinite valid and preferred lifetimes, and specifies that the on- or off-link state of the prefix is not included in the RA and that hosts receiving the RA may not use the prefix for creating an IPv6 address:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd prefix default infinite infinite off-link no-autoconfig**

ipv6 nd purge-timer <*value*>

Use the **ipv6 nd purge-timer** command to specify the maximum amount of time an unused Internet Protocol version 6 (IPv6) neighbor entry remains in the neighbor cache. This command applies to interfaces in either host or router mode. Use the **no** form of this command to return the purging interval to the default value.

Syntax Description

<*value*>	Specifies the neighbor cache entry storage time in minutes. Valid range is **10** to **1440** minutes.

Default Values

By default, idle (STALE) neighbor cache entries are cleared after **1440** minutes (24 hours).

Command History

Release 18.1	Command was introduced.

Functional Notes

This command applies to interfaces in either router or host mode. A neighbor entry is typically purged when neighbor unreachability detection (NUD) is invoked and the neighbor is determined to no longer be reachable. However, NUD is not performed on idle (STALE) neighbor entries, so this command provides a method for purging unused entries after a specified amount of time.

Usage Examples

The following example specifies that idle neighbor entries in the neighbor cache are removed after **800** minutes:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd purge-timer 800**

ipv6 nd ra interval

Use the **ipv6 nd ra interval** command to specify the interval between transmission of Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the interface is in router mode. Use the **no** form of this command to return to the default value. Variations of this command include:

ipv6 nd ra interval *<max time>*
ipv6 nd ra interval *<max time> <min time>*
ipv6 nd ra interval msec *<max time>*
ipv6 nd ra interval msec *<max time> <min time>*

Syntax Description

<max time>	Specifies the maximum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **4** to **1800** seconds and **70** to **1800000** ms.
<min time>	Optional. Specifies the minimum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **3** seconds to 75 percent of the configured maximum time value in seconds, or **30** ms to 75 percent of the configured maximum time value in ms.
msec	Optional. Specifies that the time values are in milliseconds.

Default Values

By default, the interval is set in seconds and has a maximum interval time of **200** seconds and a minimum interval time of 75 percent of the maximum seconds value, but not less than **3** seconds.

Command History

Release 18.1	Command was introduced.

Functional Notes

If this router is used as a default router, the interval between RA messages should not be set to a larger value than the RA lifetime set by the command *ipv6 nd ra lifetime <value> on page 2853*, which has a default value of **1800** seconds.

Usage Examples

The following example specifies that the maximum interval in seconds between RA message transmissions is **300**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd ra interval 300**

ipv6 nd ra lifetime <*value*>

Use the **ipv6 nd ra lifetime** command to specify the router lifetime advertised in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is effectual when the interface is in router mode. Use the **no** form of this command to return to the default setting. Variations of this command include:

ipv6 nd ra lifetime <*value*>
ipv6 nd ra lifetime default-route

Syntax Description

<*value*>	Specifies the router lifetime in seconds. Range is **0** to **9000** seconds. A value of **0** indicates this is not a default router. A value other than 0 indicates to other nodes that this router can be used as a default router.
default-route	Specifies the RA lifetime is **0** if no default route exists on any IPv6 interface.

Default Values

By default, the router lifetime is set to **1800** seconds.

Command History

Release 18.1	Command was introduced.
Release R11.5.0	Command was expanded to include the **default-route** parameter.

Functional Notes

A value other than **0** for a router lifetime should be larger than the router advertisement interval specified in the command *ipv6 nd ra interval on page 2852*.

Usage Examples

In the following example, the router lifetime advertised in RA messages is **3000** seconds:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd ra lifetime 3000**

ipv6 nd ra reachable-time <*value*>

Use the **ipv6 nd ra reachable-time** command to specify the value advertised for reachable time in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command also specifies the internal base reachable time used by the router. This command is effectual for interfaces in either host or router mode. Use the **no** form of this command to return the reachability value to the default setting.

Syntax Description

<*value*>	Specifies the reachability time in milliseconds. Range is **0** to **3600000** ms. A value of **0** indicates the reachable time is unspecified.

Default Values

By default, the router advertises a reachability time of **0** ms and uses an internal value of **30000** ms.

Command History

Release 18.1	Command was introduced.

Functional Notes

This command is effectual for interfaces in either router or host mode. For hosts, this value sets the internal reachable time used by the host if no RAs are received specifying a different value. For routers, the value indicates the amount of time a device is considered reachable after having received a reachability confirmation in neighbor unreachabililty detection (NUD).

Usage Examples

The following example specifies that a reachability time of **50000** ms is advertised in RA messages:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd ra reachable-time 50000**

ipv6 nd ra suppress

Use the **ipv6 nd ra suppress** command to specify whether Internet Protocol version 6 (IPv6) router advertisement (RA) messages will be suppressed. This command only applies to interfaces in router mode. Use the **no** form of this command to begin sending RA messages.

Syntax Description

No subcommands.

Default Values

By default, RA messages are not suppressed. When IPv6 routing is not enabled on the router, or when implemented in a host-only mode, the default setting is to suppress advertisements on all interface types.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example suppresses RA messages on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd ra suppress**

ipv6 nd router-preference

Use the **ipv6 nd router-preference** command to specify the default router preference value set in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. Setting this preference helps the receivers of RA messages to determine the preference of one router over another as a default router in environments with multiple routers. Use the **no** form of this command to return the preference to the default setting. Variations of this command include:

ipv6 nd router-preference high
ipv6 nd router-preference low
ipv6 nd router-preference medium

Syntax Description

high	Specifies the preference value is high.
low	Specifies the preference value is low.
medium	Specifies the preference value is medium.

Default Values

By default, the router preference is set to medium.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example specifies that the advertised default router preference is high:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 nd router-preference high**

ipv6 route-cache

Use the **ipv6 route-cache** command to enable Internet Protocol version 6 (IPv6) fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 18.2	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.

Functional Notes

Fast switching allows an IPv6 interface to provide optimum performance when processing IPv6 traffic.

Usage Examples

The following example enables IPv6 fast switching on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ipv6 route-cache**

lldp receive

Use the **lldp receive** command to allow Link Layer Discovery Protocol (LLDP) packets to be received on this interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, all interfaces are configured to send and receive LLDP packets.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example configures the Frame Relay subinterface to receive LLDP packets:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#lldp receive**

lldp send

Use the **lldp send** command to configure this interface to transmit Link Layer Discovery Protocol (LLDP) packets or to control the types of information contained in the LLDP packets transmitted by this interface. Use the **no** form of this command to disable this feature. Variations of this command include:

lldp send
lldp send management-address
lldp send port-description
lldp send system-capabilities
lldp send system-description
lldp send system-name
lldp send-and-receive

Syntax Description

management-address	Enables transmission of management address information on this interface.
port-description	Enables transmission of port description information on this interface.
system-capabilities	Enables transmission of this device's system capabilities on this interface.
system-description	Enables transmission of this device's system description on this interface.
system-name	Enables transmission of this device's system name on this interface.
and-receive	Configures this interface to both transmit and receive LLDP packets.

Default Values

By default, all interfaces are configured to transmit and receive LLDP packets of all types.

Command History

Release 9.1	Command was introduced.

Functional Notes

Individual LLDP information can be enabled or disabled using the various forms of the **lldp send** command. For example, use the **lldp send-and-receive** command to enable transmit and receive of all LLDP information. Then use the **no lldp send port-description** command to prevent LLDP from transmitting port description information.

Usage Examples

The following example configures the Frame Relay subinterface to transmit LLDP packets containing all enabled information types:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#lldp send**

The following example configures the Frame Relay subinterface to transmit and receive LLDP packets containing all information types:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#lldp send-and-receive**

media-gateway ip

Use the **media-gateway ip** command to associate an Internet Protocol version 4 (IPv4) address source to use for Realtime Transport Protocol (RTP) traffic. When configuring Voice over Internet Protocol (VoIP), RTP traffic must have an IPv4 address associated with it. However, some interfaces allow dynamic configuration of IPv4 addresses, causing this value to change periodically. Use the **no** form of this command to disable this function. Variations of this command include:

media-gateway ip loopback <*interface id*>
media-gateway ip primary
media-gateway ip primary vrrp <*number*>
media-gateway ip primary vrrpv3 <*number*>
media-gateway ip secondary <*ipv4 address*>
media-gateway ip secondary vrrp <*number*>
media-gateway ip secondary vrrp <*number*> <*ipv4 address*>
media-gateway ip secondary vrrpv3 <*number*>
media-gateway ip secondary vrrpv3 <*number*> <*ipv4 address*>

Syntax Description

loopback <*interface id*>	Specifies an IPv4 address statically defined to a loopback interface for RTP traffic. This is helpful when using a single IPv4 address across multiple wide area network (WAN) interfaces for RTP traffic. The valid range for loopback interface identifiers is **1** to **1024**. The interface ID is used to uniquely identify a loopback interface. The entered value cannot be in use by another loopback interface.
primary	Specifies using this interface's configured primary IPv4 address for RTP traffic. Applies to static, Dynamic Host Configuration Protocol (DHCP), or negotiated addresses.
secondary <*ipv4 address*>	Specifies using this interface's statically defined secondary IPv4 address for RTP traffic. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
vrrp <*number*>	Specifies that the IPv4 address of the Virtual Router Redundancy Protocol version 2 (VRRP) router group's virtual router ID (VRID) is used as the media gateway address on the interface. Valid VRID range is **1** to **255**.
vrrpv3 <*number*>	Specifies that the IPv4 address of the VRRP version 3 (VRRPv3) VRID is used as the media gateway address on the interface. Valid VRID range is **1** to **255**.
<*ipv4 address*>	Optional. Specifies a secondary IPv4 address of the VRRP or VRRPv3 VRID is used as the media gateway address on the interface. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, **media-gateway ip** is disabled.

Command History

Release 10.1	Command was introduced.
Release 17.3	Command was updated with the loopback interface identification option.
Release A4.01	Command was expanded to include the Metro Ethernet forum (MEF) Ethernet interface.
Release R12.2.0	Command was expanded to include the **vrrp** and **vrrpv3** parameters.

Functional Notes

To use VRRP or VRRPv3 addresses as the media gateway on the interface, you must first have configured VRRP or VRRPv3.

Usage Examples

The following example configures the unit to use the primary IPv4 address for RTP traffic:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#media-gateway ip primary**

media-gateway ipv6

Use the **media-gateway ipv6** command to associate an Internet Protocol version 6 (IPv6) address source to use for Realtime Transport Protocol (RTP) traffic. When configuring Voice over Internet Protocol (VoIP), RTP traffic must have an IPv6 address associated with it. However, some interfaces allow dynamic configuration of IPv6 addresses, causing this value to change periodically. Use the **no** form of this command to disable this function. Variations of this command include:

media-gateway ipv6
media-gateway ipv6 <*ipv6 address*>
media-gateway ipv6 loopback <*interface id*>
media-gateway ipv6 vrrpv3 <*number*>
media-gateway ipv6 vrrpv3 <*number*> <*ipv6 address*>

Syntax Description

<*ipv6 address*>	Specifies an IPv6 address to use for the media gateway. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
loopback <*interface id*>	Specifies an IPv6 address statically defined to a loopback interface for RTP traffic. This is helpful when using a single IPv6 address across multiple wide area network (WAN) interfaces for RTP traffic. The valid range for loopback interface identifiers is **1** to **1024**. The interface ID is used to uniquely identify a loopback interface. The entered value cannot be in use by another loopback interface.
vrrpv3 <*number*>	Specifies that all the secondary IPv6 addresses of the Virtual Routing Redundancy Protocol version 3 (VRRPv3) virtual router ID (VRID) are used as media gateway addresses on the interface. Valid VRID range is **1** to **255**.
<*ipv6 address*>	Optional. Specifies a single IPv6 address of the VRRPv3 VRID is used as the media gateway address on the interface. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.

Default Values

By default, **media-gateway ipv6** is disabled.

Command History

Release R10.8.0	Command was introduced.
Release R12.2.0	Command was expanded to include the **vrrpv3** parameters.

Functional Notes

To use VRRPv3 addresses as the media gateway on the interface, you must first have configured VRRPv3.

Usage Examples

The following example configures the unit to use the IPv6 address for RTP traffic:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#media-gateway ipv6**

ospfv3 <*process id*> **area** <*area id*>

Use the **ospfv3 area** command to add an interface to an Open Shortest Path First version 3 (OSPFv3) process, and to configure the OSPFv3 process on the interface. This command places the interface in the specified area for the specified Internet Protocol version 6 (IPv6) OSPFv3 address family, and optionally defines the instance ID that is used to represent this OSPFv3 process in messages on the interface's link. Use the **no** form of this command to remove the OSPFv3 process from the interface. Variations of this command include:

ospfv3 <*process id*> **area** <*area id*> **ipv6**
ospfv3 <*process id*> **area** <*area id*> **ipv6 instance** <*instance id*>

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join, for the specified address family. The process ID is locally significant to the device, and must be unique among all OSPFv3 processes on the device. Valid range is **1** to **65535**.
<*area id*>	Specifies the ID of the area to which this interface is assigned for the given OSPFv3 process. Valid range is **0** to **4294967295**.
ipv6	Identifies the OSPFv3 address family as IPv6.
instance <*instance id*>	Optional. Specifies the value to use in the instance ID field of messages sent or received by this OSPFv3 process on the interface's link. Valid range is **0** to **31**.

Default Values

By default, an OSPFv3 process is not configured on an interface. By default, process IDs, area IDs, and instance IDs are not defined.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

When using this command to enable an OSPFv3 process on an interface, keep the following rules in mind:

- The interface must have the address family enabled on the interface. If the address family is not enabled on the interface, the command is rejected and an error is displayed.
- Only interfaces on the default virtual routing and forwarding (VRF) instance support this command. Interfaces on a nondefault VRF will display an error when you attempt to configure OSPFv3 settings.
- The interface and the specified OSPFv3 process (if defined in the global configuration) must be in the same VRF or the command will fail.
- The address family must match that specified for the OSPFv3 process if the process has been defined in the global configuration or the command will fail.
- If the OSPFv3 process identified by the process ID does not exist in the global configuration, it is automatically created, along with the specified address family, and it is assigned to the VRF of which the interface is a member.

- If the specified OSPFv3 process is already at its maximum limit of processes or address families, the command fails.
- If the specified OSPFv3 process already exists in the global configuration, but its configuration does not include an address family, the specified address family is added to the OSPFv3 router configuration.
- A given OSPFv3 process can only have one address family.
- Multiple OSPFv3 instances per address family, per VRF, can be created and can be assigned to a given interface.
- If the interface's VRF changes, all OSPFv3 assignments are removed.
- To change an OSPFv3 process's VRF, the process must first be removed and then recreated. Removing the process removes all OSPFv3 assignments for that process form all interfaces.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

To add an interface to the OSPFv3 process **5**, in area **10**, with an instance ID of **10**, enter the command as follows:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ospfv3 5 area 10 ipv6 instance 10**

ospfv3 authentication

Use the **ospfv3 authentication** command to authenticate an interface that is performing Internet Protocol version 6 (IPv6) Open Shortest Path First version 3 (OSPFv3) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ospfv3 authentication ipsec spi <*spi*> **md5** <*key*>
ospfv3 authentication ipsec spi <*spi*> **sha1** <*key*>
ospfv3 authentication null

Syntax Description

ipsec	Specifies that IP security (IPsec) authentication is used.
spi <*spi*>	Specifies the security parameter index (SPI). Valid range is **256** to **4294967295**.
md5 <*key*>	Specifies that MD5 authentication is used. Keys are specified in 32 hexadecimal characters.
sha1 <*key*>	Specifies that SHA-1 authentication is used. Keys are specified in 40 hexadecimal characters.
null	Specifies that no OSPFv3 authentication is used.

Default Values

By default, this is set to **null** (meaning no authentication is used).

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example specifies that no OSPFv3 authentication will be used on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ospfv3 authentication null**

ospfv3 <*process id*> cost <*cost*>

Use the **ospfv3 cost** command to specify a value that represents the cost of sending an Open Shortest Path First version 3 (OSPFv3) packet over the interface. Use the **no** form of this command to return the cost to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2865*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
cost <*cost*>	Specifies the OSPFv3 cost of the interface. This value overrides any automatically computed cost value (default value). Valid range is **1** to **65535**.

Default Values

By default, the OSPFv3 cost of the interface is automatically computed. The automatic cost computation is the reference bandwidth divided by the interface bandwidth. The reference bandwidth is set by the command *auto-cost reference-bandwidth <value> on page 4150*, and defaults to **100** Mbps.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the OSPFv3 cost of the interface as **10**:

```
(config)#interface frame-relay 1.16
(config-fr 1.16)#ospfv3 5 cost 10
```

ospfv3 <*process id*> dead-interval <*value*>

Use the **ospfv3 dead-interval** command to specify the maximum interval allowed between Open Shortest Path First version 3 (OSPFv3) Hello packets on the interface. If the maximum interval is exceeded, neighboring devices will assume that the device is down. This value must be the same across all interfaces on a link. Use the **no** form of this command to return the dead interval to the default value.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2865*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
dead-interval <*value*>	Specifies the maximum number of seconds allowed between OSPFv3 Hello packets. It is recommended that this value be **4** times the Hello packet interval (set with the command *ospfv3 <process id> hello-interval <value> on page 2872*). Valid range is **1** to **65535** seconds.

Default Values

By default, the maximum interval allowed between OSPFv3 Hello packets is set to **40** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

To specify the dead interval between OSPFv3 Hello packets on the interface, enter the command as follows:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ospfv3 5 dead-interval 100**

ospfv3 encryption

Use the **ospfv3 encryption** command to specify a symmetrical, bidirectional Open Shortest Path First version 3 (OSPFv3) security association (SA) that uses encapsulating security payload (ESP) for encryption and authentication of all OSPFv3 messages that are sent or received on the interface. This command allows you to specify OSPFv3 security at the interface level. Use the **no** form of this command to remove IP security (IPsec) protection of OSPFv3 messages on the interface. Variations of this command include:

ospfv3 encryption ipsec spi <*spi*> **esp** <*encryption type*> <*encryption key*> <*authentication type*> <*authentication key*>
ospfv3 encryption ipsec spi <*spi*> **esp null** <*authentication type*> <*authentication key*>
ospfv3 encryption null

Syntax Description

ipsec	Specifies that IPsec encryption is used on the interface for OSPFv3 SAs.
spi <*spi*>	Specifies the security parameter index (SPI) for the SA. The value specified must not be in used by any other IPsec function on the system, or an error message is generated. If the same SPI is already in use in the same OSPFv3 area, entering this command with the same value will overwrite the current configuration. Valid SPI range is **256** to **4294967295**.
esp	Specifies that ESP is used.
null	Specifies that OSPFv3 messages on this interface are not encrypted when used in the **ospfv3 encryption null** format (even when encryption is specified by the OSPFv3 area configuration). When used in the **ospfv3 encryption ipsec spi** <*spi*> **esp null** format, **null** indicates that messages on the interface will not be encrypted, but will be authenticated.
<*encryption type*>	Specifies the type of algorithm used to encrypt OSPFv3 messages. Valid values for encryption are: **3des** uses triple data encryption standard (DES). **aes-cbc** uses advanced encryption standard (AES) with cipher block chaining (CBC). Select from **aes-cbc 128**, **aes-cbc 192**, or **aes-cbc 256**. **des** uses DES.
<*encryption key*>	Specifies the hexadecimal encryption key. The size of the encryption key is determined by the respective encryption algorithm, as follows: **3des** uses a **48** character key size. **aes-cbc 128** uses a **32** character key size. **aes-cbc 192** uses a **48** character key size. **aes-cbc 256** uses a **64** character key size. **des** uses a **16** character key size.
<*authentication type*>	Specifies the algorithm used for authenticating OSPFv3 messages. Valid authentication methods are Message-Digest 5 (**md5**) and Secure-Hash 1 (**sha1**) algorithms.

<authentication key> Specifies the hexadecimal authentication key. The size of the authentication key is determined by the respective authentication algorithm, as follows:

md5 uses a **32** character key size.

sha1 uses a **40** character key size.

Default Values

By default, there is no security for OSPFv3 messages on an interface.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

This commands specifies OSPFv3 security at the interface level. Protection specified with this command overrides any area-level OSPFv3 protection that might apply to the interface.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures OSPFv3 messages with an SPI of **120**, no encryption, and **md5** as the authentication method:

```
(config)#interface frame-relay 1.16
(config-fr 1.16)#ospfv3 encryption ipsec spi 120 esp null md5
    NeWtStpsswdLoonGpsswDhtThmnWoKEY
```

ospfv3 <*process id*> hello-interval <*value*>

Use the **ospfv3 hello-interval** command to specify the interval between Open Shortest Path First version 3 (OSPFv3) Hello packets sent on the interface. This value must be the same across all interfaces on the link. Use the **no** form of this command to return the Hello packet interval to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2865*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
hello-interval <*value*>	Specifies the number of seconds allowed between OSPFv3 Hello packets. Valid range is **1** to **65535** seconds.

Default Values

By default, the Hello packet interval for OSPFv3 is **10** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the interval between OSPFv3 Hello packets on the interface is **20** seconds:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ospfv3 5 hello-interval 20**

ospfv3 <*process id*> network

Use the **ospfv3 network** command to specify the network type for Open Shortest Path First version 3 (OSPFv3) enabled interfaces. Use the **no** form of this command to return the interface's network type to the default value. Variations of this command include:

ospfv3 <*process id*> **network broadcast**
ospfv3 <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2865*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
broadcast	Specifies that the OSPFv3 network type for the interface is set to broadcast.
point-to-point	Specifies that the OSPFv3 network type for the interface is set to point-to-point.

Default Values

By default, Ethernet interfaces are set to network type broadcast, and point-to-point (PPP), Frame Relay, and loopback interfaces are set to network type point-to-point.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the network interface as point-to-point:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ospfv3 5 network point-to-point**

ospfv3 <*process id*> priority <*value*>

Use the **ospfv3 priority** command to specify the Open Shortest Path First version 3 (OSPFv3) priority for the interface. Use the **no** form of this command to return the interface's priority to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2865*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
priority <*value*>	Specifies the OSPFv3 priority for the interface. Valid range is **0** to **255**.

Default Values

By default, the OSPFv3 priority of an interface is set to **1**.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

Priority is used in the election of the designated router and backup designated router on multi-access networks. Interfaces connected to multi-access networks (such as Ethernet interfaces) perform an election for a designated and backup designated router. The router interface with the highest OSPFv3 priority on the link becomes the designated router for that link. The interface with the next highest priority becomes the designated backup router. In the event there is a tie, the router interface with the highest router ID takes precedence. A priority value of **0** indicates the router is ineligible to become either the designated or backup designated router.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example changes the interface's OSPFv3 priority value to **6**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ospfv3 5 priority 6**

ospfv3 <*process id*> retransmit-interval <*value*>

Use the **ospfv3 retransmit-interval** command to specify the interval between Open Shortest Path First version 3 (OSPFv3) link-state advertisements (LSAs) sent on the interface. Use the **no** form of this command to return the OSPFv3 LSA interval to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2865*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
retransmit-interval <*value*>	Specifies the number of seconds between OSPFv3 LSAs sent on the interface. Valid range is **1** to **65535** seconds.

Default Values

By default, the LSA retransmit interval is set to **5** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the LSA retransmit interval is **10** seconds:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ospfv3 5 retransmit-interval 10**

ospfv3 <*process id*> shutdown

Use the **ospfv3 shutdown** command to disable an Open Shortest Path First version 3 (OSPFv3) process on the interface. When this command is used, the OSPFv3 commands remain in place, but logically it appears to the interface as though the OSPFv3 process has been removed from the configuration. This command can be useful in troubleshooting. Use the **no** form of this command to reinstate the OSPFv3 process.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2865*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.

Default Values

No default values are necessary for this command.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example disables OSPFv3 process **5** on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ospfv3 5 shutdown**

ospfv3 <*process id*> transmit-delay <*value*>

Use the **ospfv3 transmit-delay** command to specify the estimated time that is required to propagate an Open Shortest Path First version 3 (OSPFv3) link-state advertisement (LSA) on the interface. Use the **no** form of this command to return the transmit delay to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 2865*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
transmit-delay <*value*>	Specifies the number of seconds required to send LSAs from the interface. Valid range is **1** to **65535** seconds.

Default Values

By default, the LSA transmit delay is set to **1** second.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example changes the interface's LSA transmit delay to **2** seconds:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#ospfv3 5 transmit-delay 2**

rtp quality-monitoring

Use the **rtp quality-monitoring** command to enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets on this interface. If the global command (**ip rtp quality-monitoring**) is disabled when this command is issued, the system will return the following warning: "Applied but not used, you must globally enable **ip rtp quality-monitoring** to use VQM." Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, VQM is enabled on all wide area network (WAN) and local area network (LAN) interfaces.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables RTP quality monitoring on the Frame Relay interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#rtp quality-monitoring**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.
Release 17.9	Command was expanded to the Frame Relay and the ATM subinterfaces.

Usage Examples

The following example enables SNMP on the virtual Frame Relay subinterface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release 17.9	Command was explanded to the Frame Relay and the ATM subinterfaces.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the Frame Relay subinterface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#no snmp trap link-status**

spanning-tree bpdufilter

Use the **spanning-tree bpdufilter** command to block bridge protocol data units (BPDUs) from being transmitted and received on this interface. To return to the default value, use the **no** form of this command. Variations of this command include:

spanning-tree bpdufilter disable
spanning-tree bpdufilter enable

Syntax Description

disable	Disables the BPDU filter.
enable	Enables the BPDU filter.

Default Values

By default, this command is set to disable.

Command History

Release 5.1	Command was introduced.

Functional Notes

The purpose of this command is to remove a port from participation in the spanning tree. This might be beneficial while debugging a network setup. It normally should not be used in a live network.

Usage Examples

The following example enables the BPDU filter on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#spanning-tree bpdufilter enable**

spanning-tree bpduguard

Use the **spanning-tree bpduguard** command to block bridge protocol data units (BPDUs) from being received on this interface. To return to the default value, use the **no** form of this command. Variations of this command include:

spanning-tree bpduguard disable
spanning-tree bpduguard enable

Syntax Description

disable	Disables the BPDU block.
enable	Enables the BPDU block.

Default Values

By default, this command is set to disable.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example enables the BPDU guard on the interface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#spanning-tree bpduguard enable**

spanning-tree edgeport

Use the **spanning-tree edgeport** command to set this interface to be an edgeport. This command overrides the global setting (refer to *spanning-tree edgeport default on page 1837*). Use the **no** form of this command to return to the default value.

Syntax Description

No subcommands.

Default Values

By default, this command is set to disable.

Command History

Release 5.1	Command was introduced.
Release 8.1	Command was added to the ATM Subinterface command set.

Functional Notes

When an interface is designated as an edgeport, the interface will immediately go to a forwarding state when the link becomes active. When an interface is not designated as an edgeport, the interface must go through the listening and learning states before going to the forwarding state.

Usage Examples

The following example configures the interface to be an edgeport:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#spanning-tree edgeport**

An individual interface can be configured to not be considered an edgeport. For example:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#spanning-tree edgeport disable**

or

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#no spanning-tree edgeport**

spanning-tree link-type

Use the **spanning-tree link-type** command to configure the spanning-tree protocol link type for an interface. To return to the default value, use the **no** form of this command. Variations of this command include:

spanning-tree link-type auto
spanning-tree link-type point-to-point
spanning-tree link-type shared

Syntax Description

auto	Determines link type by the port's duplex settings.
point-to-point	Manually sets link type to point-to-point regardless of duplex settings.
shared	Manually sets link type to shared regardless of duplex settings.

Default Values

By default, a port is set to auto.

Command History

Release 5.1	Command was introduced.

Functional Notes

This command overrides the default link-type setting determined by the duplex of the individual port. By default, a port configured for half-duplex is set to **shared** link type, and a port configured for full-duplex is set to **point-to-point** link type. Setting the link type manually overrides the default and forces the port to use the specified link type. Using the **link-type auto** command, restores the convention of determining link type based on duplex settings.

Usage Examples

The following example forces the link type to point-to-point, even if the port is configured to be half-duplex:

(config)**#bridge 1 protocol ieee**
(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#spanning-tree link-type point-to-point**

Technology Review

Rapid transitions are possible in Rapid Spanning Tree Protocol (RSTP) by taking advantage of point-to-point links (a port is connected to exactly one other bridge) and edge-port connections (a port is not connected to any additional bridges). Setting the link type to **auto** allows the spanning tree to automatically configure the link type based on the duplex of the link. Setting the link type to **point-to-point** allows a half-duplex link to act as if it were a point-to-point link.

spanning-tree path-cost *<value>*

Use the **spanning-tree path-cost** command to assign a cost to a bridge group that is used when computing the spanning-tree root path. To return to the default path-cost value, use the **no** form of this command.

Syntax Description

<value>	Assigns a number to the bridge interface to be used as the path cost in spanning calculations. Valid range is **0** to **65535**.

Default Values

By default, the path-cost value is set to **19**.

Command History

Release 1.1	Command was introduced.
Release 8.1	Command was added to the ATM subinterface command set.
Release R10.1.0	Command was added to the Ethernet interface command set.

Functional Notes

The specified value is inversely proportional to the likelihood the bridge interface will be chosen as the root path. Set the path-cost value lower to increase the chance the interface will be the root. To obtain the most accurate spanning-tree calculations, develop a system for determining path costs for links and apply it to all bridged interfaces.

Usage Examples

The following example assigns a path cost of 100 on a Frame Relay subinterface:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#spanning-tree path-cost 100**

Technology Review

Spanning-tree protocol provides a way to prevent loopback or parallel paths in bridged networks. Using the priority values and path costs assigned to each bridging interface, the spanning-tree protocol determines the root path and identifies whether to block or allow other paths.

spanning-tree port-priority <*value*>

Use the **spanning-tree port-priority** command to select the priority level of a port associated with a bridge. To return to the default bridge-group priority value, use the **no** form of this command.

Syntax Description

<*value*>	Priority value for the bridge group; the lower the value, the higher the priority. Valid range is **0** to **255**.

Default Values

By default, the bridge-group priority value is set at **28**.

Command History

Release 1.1	Command was introduced.

Functional Notes

The only time that this priority level is used is when two interfaces with a path to the root have equal cost. At that point, the level set in this command will determine which port the bridge will use. Set the priority value lower to increase the chance the interface will be used.

Usage Examples

The following example sets the maximum priority on the Frame Relay subinterface labeled 1.16:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#spanning-tree port-priority 0**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an interface to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the interface from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an interface's VRF association will clear all IP-related settings on that interface.

Syntax Description

<*name*>	Specifies the name of the VRF to which to assign the interface.

Default Values

By default, interfaces are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release 17.8	The keyword **ip** was removed from this command.

Functional Notes

VRF instances must be created first before an interface can be assigned. An interface can only be assigned to one VRF, but multiple interfaces can be assigned to the same VRF.

An interface will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the **frame-relay 1.16** interface to the VRF instance named **RED**:

(config)**#interface frame-relay 1.16**
(config-fr 1.16)**#vrf forwarding RED**

HDLC INTERFACE COMMAND SET

To create a virtual high level data link control (HDLC) interface and/or activate the HDLC Interface Configuration mode, enter the **interface hdlc** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface hdlc 1
(config-hdlc 1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

alias link "<text>" on page 2890
bandwidth <value> on page 2891
bridge-group <value> on page 2892
bridge-group <number> vlan-transparent on page 2893
dial-backup commands begin on page 2894
dynamic-dns on page 2911
fair-queue on page 2913
hold-queue <value> out on page 2914
ip commands begin on page 2915
ipv6 dhcp relay destination <ipv6 address> on page 2955
keepalive <value> on page 2956
lldp receive on page 2957
lldp send on page 2958
max-reserved-bandwidth <value> on page 2960
media-gateway ip on page 2961
packet-capture <name> on page 2962
qos-policy on page 2963
rtp quality-monitoring on page 2965

snmp trap link-status on page 2966
vrf forwarding <name> on page 2967

alias link "*<text>*"

Each configured high level data link control (HDLC) interface (when referenced using Signaling Network Management Protocol (SNMP)) contains a link (physical port) and a bundle (group of links). RFC 1471 (for Link Connection Protocol) provides an interface table to manage lists of bundles and associated links. The **alias link** command provides the management station an identifying description for each link (HDLC physical).

Syntax Description

"*<text>***"**	Describes the interface (for SNMP) using an alphanumeric character string enclosed in quotation marks.

Default Values

By default, the HDLC identification string appears as empty quotation marks (" ").

Command History

Release 10.1	Command was introduced.

Functional Notes

The **alias link** string should be used to uniquely identify an HDLC link. Enter a string that clearly identifies the link.

Usage Examples

The following example defines a unique character string for the virtual HDLC interface (1):

(config)**#interface hdlc 1**
(config-hdlc 1)**#alias link "HDLC_link_1"**

Technology Review

Please refer to RFC 1990 for a more detailed discussion on HDLC links and bundles.

bandwidth <*value*>

Use the **bandwidth** command to provide the bandwidth value of an interface to the higher level protocols. This value is used in cost calculations. Use the **no** form of this command to restore the default value.

Syntax Description

<*value*>	Specifies the bandwidth in kbps. Range is **1** to **4294967295** kbps.

Default Values

To view the default values, use the command *show interfaces on page 673*.

Command History

Release 9.1	Command was introduced.

Functional Notes

It is important to note that there is an order of precedence in determining the interface bandwidth reported by the router for QoS. Under normal circumstances, the Layer 1 bandwidth is reported based on the interface type. For example, a T1 interface will report the available bandwidth as 1.536 Mbps. This can be misleading in QoS configurations if the **bandwidth** command has been applied to the IP interface for routing purposes because the command overrides the reported available bandwidth that can be utilized for QoS. Using the **bandwidth** command can severely disrupt the configuration of QoS on the interface, therefore, use the **max-reserved-bandwidth** command (*page 2960*) to adjust the bandwidth appropriately for QoS configurations.

Usage Examples

The following example sets bandwidth of the high level data link control (HDLC) interface to 10 Mbps:

(config)**#interface hdlc 1**
(config-hdlc 1)**#bandwidth 10000**

bridge-group *<value>*

Use the **bridge-group** command to assign an interface to the specified bridge group. Use the **no** form of this command to remove the interface from the bridge group.

Syntax Description

<value>	Specifies the bridge group (by number) to which to assign this interface. Range is **1** to **255**.

Default Values

By default, there are no configured bridge groups.

Command History

Release 9.1	Command was introduced.

Functional Notes

A bridged network can provide excellent traffic management to reduce collisions and limit the amount of bandwidth wasted with unnecessary transmissions when routing is not necessary. Any two interfaces can be bridged (Ethernet to T1 bridge, Ethernet to Frame Relay subinterface, etc.).

Usage Examples

The following example assigns the high level data link control (HDLC) interface labeled 1 to bridge group 1:

(config)**#interface hdlc 1**
(config-hdlc 1)**#bridge-group 1**

bridge-group <*number*> vlan-transparent

Use the **bridge-group vlan-transparent** command to prevent an interface from removing the virtual local area network (VLAN) tag. Use the **no** form of this command to allow the interface to remove the VLAN tag from the packet.

*The **bridge-group vlan-transparent** command is not a global command. The command must be applied on all interfaces of the bridge group.*

Syntax Description

<number>	Specifies the bridge group number. Valid range is **1** to **255**.

Default Values

By default, VLAN tags are removed from the data.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the high level data link control (HDLC) interface and Frame Relay subinterface.

Usage Examples

The following example removes the VLAN tags from the packets on the HDLC 1 interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#bridge-group 1 vlan-transparent**

dial-backup auto-backup

Use the **dial-backup auto-backup** command to configure the interface to automatically attempt a dial backup upon failure. Use the **no** form of this command to disable this feature. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2897*.

Syntax Description

No subcommands.

Default Values

By default, all backup endpoints will automatically attempt dial backup upon a failure.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example enables automatic dial backup on the endpoint:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dial-backup auto-backup**

dial-backup auto-restore

Use the **dial-backup auto-restore** command to configure the interface to automatically discontinue dial backup when all network conditions are operational. Use the **no** form of this command to disable the auto-restore feature. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2897*.

Syntax Description

No subcommands.

Default Values

By default, all backup endpoints will automatically restore the primary connection when the failure condition clears.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to automatically restore the primary connection when the failure condition clears:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dial-backup auto-restore**

dial-backup backup-delay *<value>*

Use the **dial-backup backup-delay** command to configure the amount of time the router will wait after the failure condition is recognized before attempting to backup the link. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 2897*.

Syntax Description

<value>	Specifies the delay period (in seconds) a failure must be active before AOS will enter backup operation on the interface. Range is **10** to **86400** seconds.

Default Values

By default, the **dial-backup backup-delay** period is set to **10** seconds.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to wait **60** seconds (on an endpoint with an active alarm condition) before attempting dial-backup operation:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dial-backup backup-delay 60**

dial-backup call-mode

Use the **dial-backup call-mode** command to specify whether the configured backup interface answers or originates (or a combination of both) backup calls. Use the **no** form of this command to return to the default value. Variations of this command include:

dial-backup call-mode answer
dial-backup call-mode answer-always
dial-backup call-mode originate
dial-backup call-mode originate-answer
dial-backup call-mode originate-answer-always

Syntax Description

answer	Answers and backs up primary link on failure.
answer-always	Answers and backs up regardless of primary link state.
originate	Originates backup call on primary link failure.
originate-answer	Originates or answers call on primary link failure.
originate-answer-always	Originates on failure; answers and backs up always.

Default Values

By default, the **dial-backup call-mode** is set to **originate-answer**.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Functional Notes

The majority of the configuration for AOS dial-backup implementation is configured via the dial-backup PPP interface configuration commands. However, the numbers dialed are configured in the primary interface. Full sample configurations follow:

Sample configuration for remote router (dialing out)

```
hostname “Remote3200”
enable password adtran
!
interface eth 0/1
  ip address 192.168.1.254 255.255.255.0
  no shutdown
!
interface modem 1/3
 no shutdown
!
interface t1 1/1
```

```
  coding b8zs
  framing esf
  clock source line
  tdm-group 1 timeslots 1-24
  no shutdown
!
interface fr 1 point-to-point
  frame-relay lmi-type ansi
  no shutdown
  cross-connect 1 t1 1/1 1 fr 1
!
interface fr 1.16 point-to-point
  frame-relay interface-dlci 16
  ip address 10.1.1.2 255.255.255.252
  dial-backup call-mode originate
  dial-backup number 5551111 analog ppp1
  dial-backup number 5552222 analog ppp1
no shutdown
!
interface ppp 1
  ip address  172.22.56.1  255.255.255.252
  ppp authentication chap
 username remoterouter password remotepass
 ppp chap hostname localrouter
  ppp chap password adtran
  no shutdown
!
ip route 192.168.2.0 255.255.255.0 172.22.56.2 255.255.255.252
!
line telnet 0 4
  password password
```

Sample configuration for central router (dialing in)

```
hostname “Central3200”
enable password adtran
!
interface eth 0/1
  ip address  192.168.100.254  255.255.255.0
  no shutdown
!
interface modem 1/3
 no shutdown
!
interface t1 1/1
  coding b8zs
  framing esf
  clock source line
```

```
  tdm-group 1 timeslots 1-24
  no shutdown
!
interface fr 1 point-to-point
  frame-relay lmi-type ansi
  no shutdown
  cross-connect 1 t1 1/1 1 fr 1
!
interface fr 1.100 point-to-point
  frame-relay interface-dlci 100
  ip address 10.1.1.1 255.255.255.252
  dial-backup call-mode answer
  dial-backup number 555-8888 analog ppp 1
!
interface ppp 1
  ip address  172.22.56.2 255.255.255.252
  ppp authentication chap
 username localrouter password adtran
 ppp chap hostname remoterouter
 ppp chap password remotepass
  no shutdown
!
ip route 192.168.1.0 255.255.255.0 172.22.56.1 255.255.255.252

line telnet 0 4
  password password
```

Usage Examples

The following example configures AOS to generate backup calls for this endpoint using an analog modem interface (to phone number 555 1111), but never answer calls and specifies **ppp 1** as the backup interface:

```
(config)#interface hdlc 1
(config-hdlc 1)#dial-backup call-mode originate
(config-hdlc 1)#dial-backup number 555 1111 analog ppp 1
```

Technology Review

This technology review provides information regarding specific dial-backup router behavior (i.e., when the router will perform dial backup, where in the configuration AOS accesses specific routing information, etc.):

Dialing Out

1. AOS determines to place an outbound call when either the Layer 1 or Layer 2 has a failure.
2. When placing outbound calls, AOS matches the number dialed to a PPP interface. This is accomplished with an addition to the dial-backup number command (refer to *dial-backup number <number> on page 2904*).
3. When placing the call, AOS uses the configuration of the related PPP interface for authentication and IP negotiation.
4. If the call fails to connect on the first number dialed, AOS places a call to the second number (if a second number is configured). The second number to be dialed references a separate PPP interface.

Dialing In

1. AOS receives an inbound call on a physical interface.
2. Caller ID is used to match the **dial-backup number** command to the configured PPP interface.
3. If a match is found, the call connects and AOS pulls down the primary connection if it is not already in a down state.
4. If no match is found from caller ID, the call is terminated.

dial-backup connect-timeout <*value*>

Use the **dial-backup connect-timeout** command to specify the number of seconds to wait for a connection after a call is attempted before trying to call again or dialing a different number. It is recommended this number be greater than 60. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2897*.

Syntax Description

<*value*>	Selects the amount of time (in seconds) that the router will wait for a connection before attempting another call. Valid range is **10** to **300** seconds.

Default Values

By default, the **dial-backup connect-timeout** period is set to **60** seconds.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to wait **120** seconds before retrying a failed dial-backup call:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dial-backup connect-timeout 120**

dial-backup force

Use the **dial-backup force** command to manually override the automatic dial-backup feature. This can be used to force a link into backup to allow maintenance to be performed on the primary link without disrupting data. Use the **no** form of this command to return to the normal dial-backup operation state. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2897*. Variations of this command include:

dial-backup force backup
dial-backup force primary

Syntax Description

backup	Forces backup regardless of primary link state.
primary	Forces primary link regardless of its state.

Default Values

By default, this feature is disabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to force this interface into dial backup:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dial-backup force backup**

dial-backup maximum-retry <*value*>

Use the **dial-backup maximum-retry** command to select the number of calls the router will make when attempting to backup a link. Use the **no** form of this command to return to the default state. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2897*.

Syntax Description

<*value*>	Selects the number of call retry attempts that will be made after a link failure. Valid range is **0** to **15** attempts. Setting this value to 0 will allow unlimited retries during the time the network is failed.

Default Values

By default, **dial-backup maximum-retry** is set to **0** attempts.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to retry a dial-backup call four times before considering backup operation not available:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dial-backup maximum-retry 4**

dial-backup number <*number*>

Use the **dial-backup number** command to configure the phone number and the call type the router will dial upon network failure. Multiple entries can be made for an interface to allow alternate sites to be dialed. Use the **no** form of this command to remove a configured dial-backup number. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2897*. Variations of this command include:

dial-backup number <*number*> **analog ppp** <*interface*>
dial-backup number <*number*> **digital-56k** <*isdn min chan*> <*isdn max chan*> **ppp** <*interface*>
dial-backup number <*number*> **digital-64k** <*isdn min chan*> <*isdn max chan*> **ppp** <*interface*>

Syntax Description

<*number*>	Specifies the phone numbers to call when the backup is initiated.
analog	Indicates the number connects to an analog modem.
digital-56k	Indicates the number belongs to a digital 56 kbps per DS0 connection.
digital-64k	Indicates the number belongs to a digital 64 kbps per DS0 connection.
<*isdn min chan*>	Specifies the minimum number of DS0s required for a digital 56 or 64 kbps connection. Range is **1** to **24** DS0s.
<*isdn max chan*>	Specifies the maximum number of DS0s desired for a digital 56 or 64 kbps connection. Range is **1** to **24** DS0s.
ppp <*interface*>	Specifies the Point-to-Point Protocol (PPP) interface to use as the backup for this interface (for example, **ppp 1**).

Default Values

By default, there are no configured dial-backup numbers.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the PPP interface.
Release 17.2	Command was expanded to include the cellular connections.
Release 17.3	Cellular connections were removed from this command.

Usage Examples

The following example configures AOS to dial **704-555-1212** (digital 64 kbps connection) to initiate dial-backup operation for this endpoint using the configured **ppp 1** backup interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dial-backup number 7045551212 digital-64k 1 1 ppp 1**

dial-backup priority <*value*>

Use the **dial-backup priority** command to select the backup priority for this interface. This allows the user to establish the highest priority backup link and ensure that link will override backups attempted by lower priority links. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2897*.

Syntax Description

<*value*>	Sets the relative priority of this link. Valid range is **0** to **100**. A value of 100 designates the highest priority.

Default Values

By default, **dial-backup priority** is set to **50**.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example assigns the highest priority to this endpoint:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dial-backup priority 100**

dial-backup randomize-timers

Use the **dial-backup randomize-timers** command to randomize the call timers to minimize potential contention for resources. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2897*.

Syntax Description

No subcommands.

Default Values

By default, AOS does not randomize the dial-backup call timers.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to randomize the dial-backup timers associated with this endpoint:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dial-backup randomize-timers**

dial-backup redial-delay <*value*>

Use the **dial-backup redial-delay** command to configure the delay after an unsuccessful call until the call will be re-tried. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2897*.

Syntax Description

<*value*>	Specifies the delay in seconds between attempting to redial a failed backup attempt. Range is **10** to **3600** seconds.

Default Values

By default, **dial-backup redial-delay** is set to **10** seconds.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures a redial delay of **25** seconds on this endpoint:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dial-backup redial-delay 25**

dial-backup restore-delay *<value>*

Use the **dial-backup restore-delay** command to configure the amount of time the router will wait after the network is restored before disconnecting the backup link and reverting to the primary. This setting is used to prevent disconnecting the backup link if the primary link is bouncing in and out of alarm. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2897*.

Syntax Description

<value>	Specifies the number of seconds AOS will wait (after a primary link is restored) before disconnecting dial-backup operation. Range is **10** to **86400** seconds.

Default Values

By default, **dial-backup restore-delay** is set to **10** seconds.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to wait **30** seconds before disconnecting dial-backup operation and restoring the primary connection for this endpoint:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dial-backup restore-delay 30**

dial-backup schedule

Use the **dial-backup schedule** command to set the time of day that backup will be enabled. Use this command if backup is desired only during normal business hours and on specific days of the week. Use the **no** form of this command to disable dial backup (as specified). For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2897*. Variations of this command include:

dial-backup schedule day <*name*>
dial-backup schedule enable-time <*value*>
dial-backup schedule disable-time <*value*>

Syntax Description

day <*name*>	Sets the days to allow backup. Valid range is Monday through Sunday.
enable-time <*value*>	Sets the time of day to enable backup. Time is entered in a 24-hour format (00:00).
disable-time <*value*>	Sets the time of day to disable backup. Time is entered in a 24-hour format (00:00).

Default Values

By default, dial backup is enabled for all days and times if the **dial-backup auto-backup** command has been issued and the dial-backup schedule has not been entered.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example enables dial backup Monday through Friday 8:00 a.m. to 7:00 p.m.:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dial-backup schedule enable-time 08:00**
(config-hdlc 1)**#dial-backup schedule disable-time 19:00**
(config-hdlc 1)**#no dial-backup schedule day Saturday**
(config-hdlc 1)**#no dial-backup schedule day Sunday**

dial-backup shutdown

Use the **dial-backup shutdown** command to deactivate all dial-backup functionality in the unit. Dial-backup configuration parameters are kept intact, but the unit will not initiate (or respond) to dial-backup sequences in the event of a network outage. Use the **no** form of this command to reactivate the dial-backup interface. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 2897*.

Syntax Description

No subcommands.

Default Values

By default, all AOS interfaces are disabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example deactivates the configured dial-backup interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dial-backup shutdown**

dynamic-dns

Use the **dynamic-dns** command to configure Dynamic DNS service provided by Dynamic Network Services, Inc. (www.dyndns.org). Use the **no** form of this command to disable this feature. Variations of this command include:

dynamic-dns custom <*hostname*> <*minutes*>
dynamic-dns dyndns <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-custom <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-static <*hostname*> <*username*> <*password*>

Syntax Description

<*hostname*>	Specifies the host name for the server that updates the dynamic domain naming system (DNS).
<*minutes*>	Specifies the intervals in minutes to update the server with information (updates also occur when the interface's IP address changes regardless of the update intervals).
<*username*>	Specifies a user name using an alphanumerical string up to 30 characters in length (the user name is case sensitive).
<*password*>	Specifies a password using an alphanumerical string up to 30 characters in length (the password is case sensitive). Refer to *Functional Notes* below for additional argument descriptions.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.
Release 12.1	Command was expanded.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

custom - Constanttime.com's Custom Dynamic DNS^{SM} service allows you complete access and management control over your domain name regardless of where you purchased/registered it. This allows you to manage IP address mappings (A records), domain aliases (CNAME records), and mail servers (mail exchange (MX) records).

dyndns - The Dynamic DNS^{SM} offered by Dynamic Network Services, Inc. (DynDNS.org) allows you to alias a dynamic IP address to a static host name in various domains. This allows your unit to be more easily accessed from various locations on the Internet. This service is provided for up to five host names.

dyndns-custom - DynDNS.org's Custom DNS^{SM} service provides a full DNS solution, giving you complete control over an entire domain name. A Web-based interface provides two levels of control over your domain, catering to average or advanced users. Five globally redundant DNS servers ensure that your domain will always resolve.

A choice of two interfaces is available. The basic interface is designed for most users. It comes preconfigured for most common configurations and allows for easy creation of most common record types. The advanced interface is designed for system administrators with a solid DNS background, and provides layout and functionality similar to a BIND zone file allowing for the creation of nearly any record type.

Custom DNS^{SM} can be used with both static and dynamic IPs, and has the same automatic update capability through Custom DNS-aware clients as Dynamic DNS.

dyndns-static - The Static DNS service is similar to DynDNS.org's Dynamic DNS^{SM} service in that it allows a host name, such as yourname.dyndns.org, to point to your IP address. Unlike a Dynamic DNS host, a Static DNS host does not expire after 35 days without updates, but updates take longer to propagate through the DNS system. This service is provided for up to five host names.

If your IP address does not change often or at all, but you still want an easy name to remember it by (without having to purchase your own domain name), Static DNS service is ideal for you.

If you would like to use your own domain name (such as yourname.com), you need Custom DNS service that also provides full dynamic and static IP address support.

Usage Examples

The following example sets the Dynamic DNS to **dyndns-custom** with host name **host**, user name **user**, and password **pass**:

(config)**#interface hdlc 1**
(config-hdlc 1)**#dynamic-dns dyndns-custom host user pass**

fair-queue

Use the **fair-queue** command to enable weighted fair queuing (WFQ) on an interface. Use the **no** form of this command to disable WFQ and enable first in, first out (FIFO) queueing for an interface. Variations of this command include:

fair-queue
fair-queue <*value*>

WFQ must be enabled on an interface to use priority queuing. By default, WFQ is enabled for all interfaces with maximum bandwidth speeds equivalent to T1/E1 and below.

Syntax Description

<*value*>	Optional. Value that specifies the maximum number of packets that can be present in each conversation subqueue. Packets received for a conversation after this limit is reached are discarded. Range is **16** to **512** packets.

Default Values

By default, fair queue is enabled with a threshold of **64** packets.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example enables WFQ on the interface with a threshold set at 100 packets:

(config)**#interface hdlc 1**
(config-hdlc 1)**#fair-queue 100**

hold-queue <*value*> out

Use the **hold-queue out** command to change the overall size of an interface's wide area network (WAN) output queue. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	The total number of packets the output queue can contain before packets are dropped. Range is **16** to **1000** packets.

Default Values

The default queue size for weighted fair queuing (WFQ) is 400. The default queue size for Point-to-Point Protocol (PPP) first in, first out (FIFO) and Frame Relay round-robin is 200.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example sets the overall output queue size to **700**:

(config)**#interface hdlc 1**
(config-hdlc 1)**#hold-queue 700 out**

ip access-group *<ipv4 acl name>*

Use the **ip access-group** command to create an Internet Protocol version 4 (IPv4) access control list (ACL) to be used for packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ip access-group *<ipv4 acl name>* **in**
ip access-group *<ipv4 acl name>* **out**

Syntax Description

<ipv4 acl name>	Assigned IPv4 ACL name.
in	Enables access control on packets received on the specified interface.
out	Enables access control on packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 9.1	Command was introduced.

Functional Notes

When this command is enabled, the IPv4 destination address of each packet must be validated before being passed through. If the packet is not acceptable per these settings, it is dropped.

Usage Examples

The following example sets up the unit to only allow Telnet traffic (as defined in the user-configured **TelnetOnly** IP ACL) into the high level data link control (HDLC) interface:

(config)**#ip access-list extended TelnetOnly**
(config-ext-nacl)**#permit tcp any any eq telnet**
(config-ext-nacl)**#int hdlc 1**
(config-hdlc 1)**#ip access-group TelnetOnly in**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to an interface. IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

*Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an interface.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the Ethernet interface 0/1:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the HDLC interface 1:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip access-policy PRIVATE**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the specified interface. Use the **no** form of this command to remove a configured IPv4 address. Variations of this command include:

ip address *<ipv4 address> <subnet mask>*
ip address *<ipv4 address> <subnet mask>* **secondary**

Syntax Description

<ipv4 address>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the specified interface.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 9.1	Command was introduced

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a secondary IPv4 address of **192.22.72.101 /30**:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip address 192.22.72.101 255.255.255.252 secondary**

ip address range *<start ip address> <end ip address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the specified interface. Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip crypto map *<name>*

Use the **ip crypto map** command to associate Internet Protocol version 4 (IPv4) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

When you apply a map to an interface, you are applying all crypto maps with the given map name. This allows you to apply multiple crypto maps if you have created maps that share the same name, but have different map index numbers.

Syntax Description

<name>	Specifies the IPv4 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

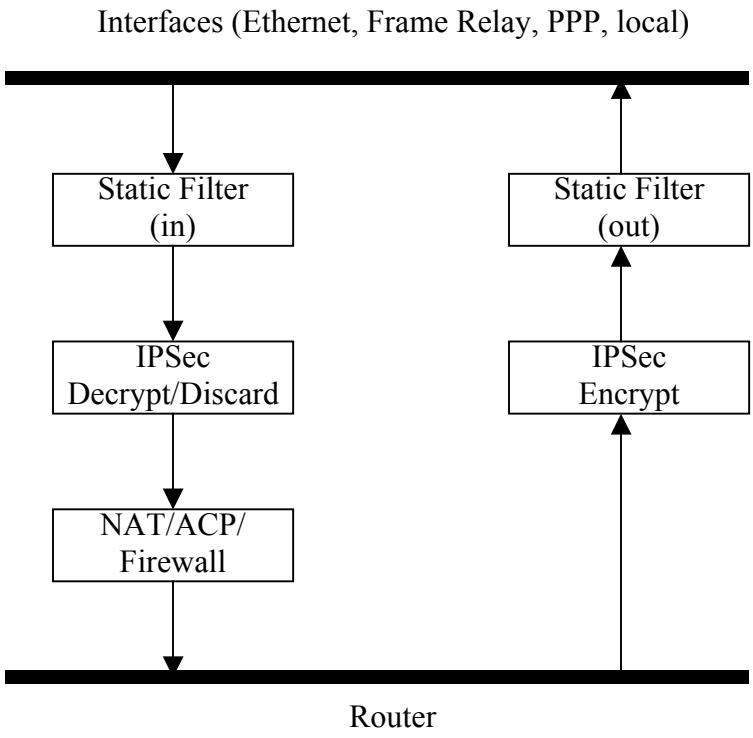
Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 9.1	Command was expanded to include the High-Levell Data Link Control (HDLC) interface.
Release 11.1	Command was expanded to include the demand interface.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.7.0	Command syntax was changed to require the **ip** keyword.

Functional Notes

When configuring a system to use both the stateful inspection firewall and Internet key exchange (IKE) negotiation for VPN, keep the following notes in mind.

When defining the IPv4 policy class and associated access control lists (ACLs) that describe the behavior of the IPv4 firewall, do not forget to include the traffic coming into the system over a VPN tunnel terminated by the system. The firewall should be set up with respect to the unencrypted traffic that is destined to be sent or received over the VPN tunnel. The following diagram represents typical AOS data-flow logic.



As shown in the diagram above, data coming into the product is first processed by the static filter associated with the interface on which the data is received. This access group is a true static filter and is available for use regardless of whether the IPv4 firewall is enabled or disabled. Next (if the data is encrypted), it is sent to the IPSec engine for decryption. The decrypted data is then processed by the stateful inspection firewall. Therefore, given a terminating VPN tunnel, only unencrypted data is processed by the firewall.

The IPv4 ACLs for a crypto map on an interface work in reverse logic to the ACLs for a policy class on an interface. When specifying the ACLs for a crypto map, the source information is the private local side, unencrypted source of the data. The destination information will be the far-end, unencrypted destination of the data. However, ACLs for a policy class work in reverse. The source information for the ACL in a policy class is the far end. The destination information is the local side.

Usage Examples

The following example applies all IPv4 crypto maps with the name **MyMap** to the interface:

(config)**#hdlc 1**
(config-hdlc 1)**#ip crypto map MyMap**

ip dhcp relay destination *<ipv4 address>*

Use the **ip dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 4 (IPv4) and to specify the IPv4 address for the DHCPv4 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv4 relay functionality is disabled on the interface.

Syntax Description

<ipv4 address>	Specifies the IPv4 address for the DHCPv4 messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.

Usage Examples

The following example enables DHCPv4 relay agent functionality and specifies the destination address as **192.33.4.251**:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip dhcp relay destination 192.33.4.251**

ip directed-broadcast

Use the **ip directed-broadcast** command to allow reception/forwarding of directed broadcasts. Use the **no** form of this command to disable this feature. Variations of this command include:

ip directed-broadcast
ip directed-broadcast <*name*>

Syntax Description

<*name*>	Specifies IP access control list (ACL) name.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.

Functional Notes

A directed broadcast is a packet intended for all nodes on a nonlocal network. For example, the broadcast address 255.255.255.255 reaches all nodes on a network; the directed broadcast address 128.1.255.255 is intended for all nodes whose network address is 128.1.0.0. A router not directly attached to 128.1.0.0 simply forwards the directed broadcast packet to the next hop. A router on network 128.1.0.0 that has **ip directed-broadcast** enabled, accepts and forwards the packet to all nodes whose network address is 128.1.0.0. Routers connecting subnets of 128.1.0.0 also accept and forward the packet to the nodes on their respective subnets. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is distributed as a broadcast on the destination subnet. The packet is then sent as a link-layer broadcast.

The **ip directed-broadcast** command controls the distribution of directed broadcasts when they reach their target subnets. Only the final transmission of the directed broadcast on its ultimate destination subnet is affected. It does not affect the transit unicast routing of IP directed broadcasts.

If **ip directed-broadcast** is enabled for this interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which this interface is attached will be forwarded as broadcasts on that subnet. Forwarding of the packets can be limited by specifying an ACL with this command. In this case, only directed broadcasts that are permitted by the specified ACL will be forwarded, and all other directed broadcasts directed to this interface subnet will be dropped.

Disabling the **ip directed-broadcast** command will cause directed broadcasts destined for the subnet to which this interface is attached to be dropped.

This option is a requirement for routers as described in RFC 1812, section 4.2.2.11. Furthermore, it is disabled by default (RFC 2644), with the intended goal of reducing the efficacy of certain types of denial of service (DoS) attacks.

Usage Examples

The following example enables forwarding of directed broadcasts on the interface **hdlc 1**:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip directed-broadcast**

ip ffe

Use the **ip ffe** command to enable the RapidRoute Engine on this interface with the default number of entries. Use the **no** form of this command to disable this feature. Variations of this command include:

ip ffe
ip ffe max-entries <*value*>

Issuing this command will cause all RapidRoute entries on this interface to be cleared.

Syntax Description

max-entries <*value*>	Optional. Specifies the maximum number of entries stored in the flow table. Valid range is from **1** to **8192**.

Default Values

By default, the RapidRoute Engine is disabled. The default number of **max-entries** is **4096**.

Command History

Release 13.1	Command was introduced.
Release 17.6	Command was expanded to include the tunnel and high level data link control (HDLC) interface.

Functional Notes

RapidRoute can be used to help reduce routing overhead, and thus reduce overall routing times. Routing times are reduced by the creation of a flow table on the ingress interface. The maximum number of entries that can be stored in the flow table at any one time may be specified by using the **max-entries** parameters.

Usage Examples

The following example enables RapidRoute and sets the maximum number of entries in the flow table to **50**:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip ffe max-entries 50**

Technology Review

The RapidRoute system goal is to increase IP packet throughput by moving as much of the packet processing into the engine as possible. Packets are classified into flows based upon the IP protocol (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol (ICMP), etc.), the source and destination IP addresses, IP type of service (ToS), and the protocol-specific information, such as the source and destination port numbers. Flows are defined as the unidirectional representation of a conversation between two IP hosts. Each ingress interface keeps its own flow table, a collection of flow entries.

The first packet in a flow that is forwarded through the unit will build a flow entry. When a flow entry is looked up but no entry is found, a RapidRouteBuilder object is allocated and attached to the packet. As the packet passes through the various processing layers, each subsystem will add processing to the RapidRouteBuilder. When packet is about to be forwarded out of the egress interface, the RapidRouteBuilder will be finalized. That is, the flow entry being built will be checked for completeness and committed to the flow table on the ingress interface. Subsequent flow matches can then bypass the normal processing layers.

ip flow

Use the **ip flow** command to enable integrated traffic monitoring (ITM) for all traffic received or forwarded on an interface. Use the **no** form of this command to disable traffic monitoring. Variations of this command include:

ip flow egress
ip flow egress <*name*>
ip flow ingress
ip flow ingress <*name*>

Syntax Description

egress	Specifies that all outgoing traffic be monitored.
ingress	Specifies that all incoming traffic be monitored.
<*name*>	Optional. Specifies the name of an access control list (ACL) to use for filtering traffic.

Default Values

By default, no traffic monitoring is enabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables traffic monitoring on an high level data link control (**HDLC)** interface to monitor **incoming** traffic through an ACL called **myacl**:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip flow ingress myacl**

ip helper-address *<ip address>*

Use the **ip helper-address** command to configure AOS to forward User Datagram Protocol (UDP) broadcast packets received on the interface. Use the **no** form of this command to disable forwarding packets.

> NOTE *The **ip helper-address** command must be used in conjunction with the **ip forward-protocol** command to configure AOS to forward UDP broadcast packets. Refer to ip forward-protocol udp <value> on page 1398 for more information.*

Syntax Description

<ip address>	Specifies the destination IP address for the forwarded UDP packets. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, broadcast UDP packets are not forwarded.

Command History

Release 9.1	Command was introduced.

Functional Notes

When used in conjunction with the **ip forward-protocol** command, the **ip helper-address** feature allows you to customize which broadcast packets are forwarded.

To implement the helper address feature, assign a helper address(es) (specifying the device that needs to receive the broadcast traffic) to the interface closest to the host that transmits the broadcast packets. When broadcast packets (of the specified type forwarded using the **ip forward-protocol** command) are received on the interface, they will be forwarded to the device that needs the information.

Only packets meeting the following criteria are considered eligible by the **ip helper-address** feature:

1. The packet IP protocol is UDP.
2. Any UDP port specified using the **ip forward-protocol** command.
3. The medium access control (MAC) address of the frame is an all-ones broadcast address (ffff.ffff.ffff).
4. The destination IP address is broadcast defined by all ones (**255.255.255.255**) or a subnet broadcast (for example, **192.33.4.251** for the **192.33.4.248 /30** subnet).

Usage Examples

The following example forwards all domain naming system (DNS) broadcast traffic to the DNS server with IP address **192.33.5.99**:

(config)**#ip forward-protocol udp domain**
(config)**#interface hdlc 1**
(config-hdlc 1)**#ip helper-address 192.33.5.99**

ip igmp

Use the **ip igmp** command to configure multicasting related functions for the interface. Variations of this command include:

ip igmp immediate-leave
ip igmp last-member-query-interval <*milliseconds*>
ip igmp querier-timeout <*seconds*>
ip igmp query-interval <*seconds*>
ip igmp query-max-response-time <*seconds*>
ip igmp static-group <*address*>
ip igmp version [1 | 2]

Syntax Description

immediate-leave	Specifies that if only one host (or Internet Group Management Protocol (IGMP) snooping switch) is connected to the interface, when a leave is received, multicast of that group is immediately terminated as opposed to sending a group query and timing out the group if no device responds. Works in conjunction with **ip igmp last-member-query-interval**. Applies to all groups when configured. Use the **no** form of this command to disable the **immediate-leave** feature.
