last-member-query-interval <*milliseconds*>	Controls the timeout (in milliseconds) used to detect whether any group receivers remain on an interface after a receiver leaves a group. If a receiver sends a leave-group message (IGMP Version 2), the router sends a group-specific query on that interface. After twice the time specified by this command plus as much as one second longer, if no receiver responds, the router removes that interface from the group and stops sending that group's multicast packets to the interface. Range is **100** to **65535** ms. Use the **no** form of this command to return to the default setting.
querier-timeout <*seconds*>	Specifies the interval (in seconds) that the router waits after the current querier's last query before it takes over as querier (IGMP V2). Range is **60** to **300** seconds. Use the **no** form of this command to return to the default setting.
query-interval <*seconds*>	Specifies the interval (in seconds) at which IGMP queries are sent on an interface. Host query messages are addressed to the all-hosts multicast group with an IP time to live (TTL) of 1. The router uses queries to detect whether multicast group members are on the interface and to select an IGMP designated router (DR) for the attached segment (if more than one multicast router exists). Only the DR for the segment sends queries. For IGMP V2, the DR is the router with the lowest IP address on the segment. Range is **0** to **65535** seconds. Use the **no** form of this command to return to the default setting.
query-max-response-time <*seconds*>	Specifies the maximum response time (in seconds) advertised by this interface in queries when using IGMP V2. Hosts are allowed a random time within this period to respond, reducing response bursts. Use the **no** form of this command to return to the default setting.

Syntax Description

static-group <*address*>	Configures the router's interface to be a statically connected member of the specified group. Packets received on the correct reverse path forwarding (RPF) interface are forwarded to this interface regardless of whether any receivers have joined the specified group using IGMP. Use the **no** form of this command to remove a configured static group.
version [1 | 2]	Sets the interface's IGMP version. Use the **no** form of this command to return to the default setting.

Default Values

ip igmp immediate-leave	No default
ip igmp last-member-query-interval	**1000** milliseconds
ip igmp querier-timeout	2x the **query-interval** value
ip igmp query-interval	**60** seconds
ip igmp query-max-response-time	**10** seconds
ip igmp static-group	No default
ip igmp version	Version **1**

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example sets the query message interval on the interface to **200** milliseconds:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip igmp last-member-query-interval 200**

ip mcast-stub downstream

Use the **ip mcast-stub downstream** command to enable multicast forwarding and Internet Group Management Protocol (IGMP) (router mode) on an interface and place it in multicast stub downstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 9.1	Command was introduced.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub upstream** commands. Downstream interfaces connect to segments with multicast hosts. Multiple interfaces may be configured in downstream mode; however, interfaces connecting to the multicast network (upstream) should not be configured in downstream mode. Interfaces configured as downstream should have the lowest IP address of all IGMP-capable routers on the connected segment in order to be selected as the designated router (DR) and ensure proper forwarding. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub upstream on page 2934* for more information.

Usage Examples

The following example enables multicast forwarding and IGMP on the high level data link control (HDLC) interface:

```
(config)#interface hdlc 1
(config-hdlc 1)#ip mcast-stub downstream
```

ip mcast-stub fixed

Use the **ip mcast-stub fixed** command to allow forwarding of multicast traffic on a selected interface after enabling multicast routing. Use the **no** form of this command to disable this mode.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 12.1	Command was introduced.

Functional Notes

Multicast routing must be enabled prior to setting **ip mcast-stub fixed** on the selected interface. Also, use the **ip igmp static-group** <*address*> command (refer to *ip igmp on page 2929*) to receive multicast traffic without host-initiated Internet Group Management Protocol (IGMP) activity on the selected interface. Otherwise, all host-initiated IGMP transactions will enter multicast routes on the router's interface involved with IGMP activities.

Usage Examples

The following example enables multicast traffic forwarding and IGMP on the interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip mcast-stub fixed**

ip mcast-stub helper-enable

Use the **ip mcast-stub helper-enable** command to assign the **ip mcast-stub helper-address** as the Internet Group Management Protocol (IGMP) proxy. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.
Release 10.1	Command was expanded to include high level data link control (HDLC) interfaces.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address**, **ip mcast-stub upstream**, and **ip mcast-stub downstream** commands. When enabled, the interface becomes a helper forwarding interface. The IGMP host function is dynamically enabled and the interface becomes the active upstream interface, enabling the unit to perform as an IGMP proxy. Refer to *ip mcast-stub helper-address <ip address> on page 1418*, *ip mcast-stub downstream on page 2931*, and *ip mcast-stub upstream on page 2934* for more information.

Usage Examples

The following example sets the helper address as the IGMP proxy:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip mcast-stub helper-enable**

ip mcast-stub upstream

Use the **ip mcast-stub upstream** command to enable multicast forwarding on an interface and place it in multicast stub upstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 9.1	Command was introduced.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub downstream** commands. When enabled, the interface becomes a candidate to be a helper forwarding interface. If chosen as the best path toward the helper address by the router's unicast route table, the Internet Group Management Protocol (IGMP) host function is dynamically enabled and the interface becomes the active upstream interface, enabling the router to perform as an IGMP proxy. Though multiple interfaces may be candidates, no more than one interface will actively serve as the helper forwarding interface. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub downstream on page 2931* for more information.

Usage Examples

The following example enables multicast forwarding on the high level data link control (HDLC) interface:

```
(config)#interface hdlc 1
(config-hdlc 1)#ip mcast-stub upstream
```

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces	(all types)1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

Open shortest path first (OSPF) will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip mtu 1200**

ip ospf

Use the **ip ospf** command to customize Open Shortest Path First version 2 (OSPFv2) settings (if needed). Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **area** <*area id*>
ip ospf <*process id*> **authentication-key** <*password*>
ip ospf <*process id*> **cost** <*value*>
ip ospf <*process id*> **dead-interval** <*seconds*>
ip ospf <*process id*> **hello-interval** <*seconds*>
ip ospf <*process id*> **message-digest-key [1 | 2] md5** <*key*>
ip ospf <*process id*> **priority** <*value*>
ip ospf <*process id*> **retransmit-interval** <*seconds*>
ip ospf <*process id*> **shutdown**
ip ospf <*process id*> **transmit-delay** <*seconds*>

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
area <*area id*>	Specifies the ID of the area to which this interface is assigned for the specified OSPFv2 process. Valid range is **0** to **4294967295**.
authentication-key <*password*>	Assigns a simple-text authentication password to be used by other routers using the OSPF simple password authentication.
cost <*value*>	Specifies the OSPF cost of sending a packet on the interface. This value overrides any computed cost value. Range is **1** to **65535**.
dead-interval <*seconds*>	Sets the maximum interval (in seconds) allowed between hello packets. If the maximum is exceeded, neighboring devices will determine that the device is down. Range is **0** to **32767** seconds.
hello-interval <*seconds*>	Specifies the interval (in seconds) between hello packets sent on the interface. Range is **0** to **32767** seconds.
message-digest-key [1 | 2] md5 <*key*>	Configures OSPF message digest 5 (MD5) authentication (16 byte maximum) keys.
priority <*value*>	Sets the OSPF priority. The value set in this field helps determine the designated router (DR) for this network. Range is **0** to **255**.
retransmit-interval <*seconds*>	Specifies the interval (in seconds) between link state advertisements (LSAs). Range is **0** to **32767** seconds.

shutdown	Disables the OSPFv2 process on the interface. When this keyword is used, the OSPFv2 settings remain in place, but logically it appears to the interface as though the process has been removed from the configuration. This parameter can be useful in troubleshooting.
transmit-delay <*seconds*>	Sets the estimated time (in seconds) required to send a link state advertisement (LSA) on the interface. Range is **0** to **32767** seconds.

Default Values

The defaults for this command are:

dead-interval <*seconds*>	40 seconds
hello-interval <*seconds*>	10 seconds: Ethernet, Frame Relay, and Point-to-Point Protocol (PPP)
priority <*value*>	1
retransmit-interval <*seconds*>	5 seconds
transmit-delay <*seconds*>	1 second

Command History

Release 9.1	Command was introduced.
Release R11.3.0	Command was expanded to include the <*process id*>, **area** <*area id*>, and **shutdown** parameters.

Usage Examples

The following example sets the maximum number of seconds allowed between hello packets to **25000**:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip ospf 1 dead-interval 25000**

ip ospf <*process id*> authentication

Use the **ip ospf authentication** command to authenticate an interface that is performing open shortest path first (OSPF) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **authentication**
ip ospf <*process id*> **authentication message-digest**
ip ospf <*process id*> **authentication null**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
message-digest	Optional. Selects message digest authentication type.
null	Optional. Specifies that no authentication be used.

Default Values

By default, **ip ospf authentication** is set to **null** (meaning no authentication is used).

Command History

Release 9.1	Command was introduced.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Usage Examples

The following example specifies that no authentication will be used on the high level data link control (HDLC) interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip ospf 1 authentication null**

ip ospf <*process id*> network

Use the **ip ospf network** command to specify the type of network on this interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **network broadcast**
ip ospf <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
broadcast	Sets the network type for broadcast.
point-to-point	Sets the network type for point-to-point.

Default Values

By default, Ethernet defaults to **broadcast**. Point-to-Point Protocol (PPP) and Frame Relay default to **point-to-point**.

Command History

Release 9.1	Command was introduced.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Functional Notes

A point-to-point network will not elect designated routers.

Usage Examples

The following example designates a broadcast network type:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip ospf 1 network broadcast**

ip pim sparse-mode

Use the **ip pim sparse-mode** command to enable protocol-independent multicast (PIM) sparse mode for this interface. Use the **no** form of this command to disable PIM sparse mode.

Syntax Description

No subcommands.

Default Values

By default, PIM sparse mode for this interface is disabled.

Command History

Release 11.1	Command was introduced.

Functional Notes

PIM sparse mode is a multicast routing protocol that makes use of the unicast forwarding table. It builds unidirectional shared trees rooted at a rendezvous point (RP) for a multicast group or a shortest-path tree rooted at a specific source for a multicast group.

Usage Examples

The following example enables PIM sparse mode on the high level data link control (HDLC) 1 interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip pim sparse-mode**

ip pim-sparse dr-priority <*value*>

Use the **ip pim-sparse dr-priority** command to specify the priority for the designated router (DR). This command modifies the router's priority in the DR election process. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the priority of this interface (to be used when determining the DR). Valid range is **1** to **4294967295**.

Default Values

By default, the priority of all protocol-independent multicast (PIM) interfaces is **1**.

Command History

Release 11.1	Command was introduced.

Functional Notes

Interfaces advertise their configured priority values in the hello messages transmitted on the interface. Routers use the priority values to determine the appropriate DR. The router on the network segment with the highest priority is selected as the DR. If a hello message is received on the interface from a router on the network segment and it does not contain a priority, the entire network segment defaults to DR selection based on IP addresses instead of priority. In this instance, the DR is selected as the router on the network segment that has the highest IP address. AOS will always include a priority in all transmitted hello messages. If no priority is specifically designated by the user, the priority is set as the default of 1.

Usage Examples

The following example specifies a priority of **100** on the high level data link control (HDLC) 1 interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip pim-sparse dr-priority 5**

ip pim-sparse hello-timer <*value*>

Use the **ip pim-sparse hello-timer** command to specify protocol-independent multicast (PIM) sparse hello timer period. This is the time interval at which periodic hellos are sent out on all interfaces of a PIM-capable router. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the interval (in seconds) at which periodic hellos are sent out of the interface. Valid range is **10** to **3600** seconds.

Default Values

By default, the hellos are transmitted on PIM interfaces every **60** seconds.

Command History

Release 11.1	Command was introduced.

Functional Notes

Hello messages are used to inform neighbors of a router's presence. Hello messages normally generate a small amount of traffic on an interface. Setting the **hello-timer** to a small interval increases the number of hellos sent (thus increasing the amount of traffic). Set the **hello-timer** to a reasonable value, taking into consideration the bandwidth available on the interface.

Usage Examples

The following example specifies hellos be sent on the high level data link control (HDLC) 1 interface every **3600** seconds:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip pim-sparse hello-timer 3600**

ip pim-sparse nbr-timeout <*value*>

Use the **ip pim-sparse nbr-timeout** command to specify protocol-independent multicast (PIM) sparse neighbor timeout. This is the time interval after which a PIM-capable router will consider a neighbor not present. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the time interval in seconds after which a neighbor is considered not present. Valid range is **30** to **10800** seconds.

Default Values

By default, the nbr-timeout is set to **105** seconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the nbr-timeout to **300** seconds:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip pim-sparse nbr-timeout 300**

ip pim-sparse override-interval <*value*>

Use the **ip pim-sparse override-interval** command to specify the protocol-independent multicast (PIM) sparse join/prune override interval. This delay interval is the period after a join/prune that another router on the local area network (LAN) may override a join/prune. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the delay time in milliseconds. Valid range is **0** to **65535** milliseconds.

Default Values

By default, the override interval is set to **2500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the override interval to **3000** milliseconds:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip pim-sparse override-interval 3000**

ip pim-sparse propagation-delay *<value>*

Use the **ip pim-sparse propagation-delay** command to specify the expected propagation delay for join/prune messages. Set the propagation delay (in milliseconds) to estimate the amount of delay found in the local link. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the expected propagation delay in the local link in milliseconds. Valid range is **0** to **32767** milliseconds.

Default Values

By default, the propagation delay is set to **500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the expected propagation delay to **300** milliseconds on the high level data link control (HDLC) 1 interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip pim-sparse propagation-delay 300**

ip policy route-map *<name>*

Use the **ip policy route-map** command to assign a policy route map to this interface. Use the **no** form of this command to remove the route-map policy.

Syntax Description

<name>	Specifies the name of the policy route map to assign to this interface.

Default Values

By default, no policy route map is assigned to this interface.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example assigns the policy route map **policy1** to the high level data link control (HDLC) 1 interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip policy route-map policy1**

ip proxy-arp

Use the **ip proxy-arp** command to enable proxy Address Resolution Protocol (ARP) on the interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, proxy ARP is enabled.

Command History

Release 9.1	Command was introduced.

Functional Notes

In general, the principle of proxy ARP allows a router to insert its IP address in the source IP address field of a packet (if the packet is from a host on one of its subnetworks). This allows hosts to reach devices on other subnetworks without implementing routing or specifying a default gateway.

If proxy ARP is enabled, AOS will respond to all proxy ARP requests with its specified medium access control (MAC) address and forward packets accordingly.

Enabling proxy ARP on an interface may introduce unnecessary ARP traffic on the network.

Usage Examples

The following example enables proxy ARP on the high level data link control (HDLC) interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip proxy-arp**

ip rip receive version

Use the **ip rip receive version** command to configure the Routing Information Protocol (RIP) version the unit accepts in all RIP packets received on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip receive version 1
ip rip receive version 2

Syntax Description

1	Accepts only received RIP version 1 packets on the interface.
2	Accepts only received RIP version 2 packets on the interface.

Default Values

By default, all interfaces implement RIP version 1 (the default value for the version command).

Command History

Release 9.1	Command was introduced.

Functional Notes

Use the **ip rip receive version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only accepts one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the high level data link control (HDLC) interface to accept only RIP version 2 packets:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip rip receive version 2**

ip rip send version

Use the **ip rip send version** command to configure the Routing Information Protocol (RIP) version the unit sends in all RIP packets transmitted on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip send version 1
ip rip send version 2

Syntax Description

1	Transmits only RIP version 1 packets on the interface.
2	Transmits only RIP version 2 packets on the interface.

Default Values

By default, all interfaces transmit RIP **version 1** (the default value for the **version** command).

Command History

Release 9.1	Command was introduced.

Functional Notes

Use the **ip rip send version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only transmits one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the high level data link control (HDLC) interface to transmit only RIP version 2 packets:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip rip send version 2**

ip rip summary-address *<ip address> <subnet mask>*

Use the **ip rip summary-address** command to manually summarize the routes Routing Information Protocol (RIP) will advertise and send out a specified interface. Use the **no** form of this command to disable this mode.

Syntax Description

<ip address>	Specifies the summarized network IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.0**).
<subnet mask>	Specifies the subnet mask that corresponds to the range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no manual summarization is applied by RIP.

Command History

Release 12.1	Command was introduced.

Functional Notes

Unlike the automatic summarization on classful network boundaries, only specific network advertisements are made by RIP using the **ip rip summary-address** command. This command is only effective if RIP version 2 is configured.

Usage Examples

The following example enables manual summarization on the specified IP address:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip rip summary-address 10.10.123.0 255.255.255.0**

ip route-cache

Use the **ip route-cache** command to enable fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

*Using network address translation (NAT) or the AOS firewall capabilities on an interface requires process switching mode (using the **no ip route-cache** command).*

Syntax Description

No subcommands.

Default Values

By default, fast caching is enabled on all interfaces.

Command History

Release 9.1	Command was introduced.

Functional Notes

Fast switching allows an IP interface to provide optimum performance when processing IP traffic.

Usage Examples

The following example enables fast switching on the high level data link control (HDLC) interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip route-cache**

ip unnumbered *<interface>*

Use the **ip unnumbered** command to use the IP address assigned to the specified interface for all IP processing on the active interface. Use the **no** form of this command to remove the unnumbered configuration.

Syntax Description

<interface>	Specifies the interface that contains the IP address to use as the source address for all packets transmitted on this interface. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip unnumbered ?** for a list of valid interfaces.

Default Values

By default, all interfaces are configured to use a specified IP address (using the **ip address** command).

Command History

Release 9.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface.

Functional Notes

If **ip unnumbered** is enabled on an interface, all IP traffic from the interface will use a source IP address taken from the specified interface. For example, specifying **ip unnumbered eth 0/1** while in the Frame Relay Subinterface Configuration mode configures the Frame Relay subinterface to use the IP address assigned to the Ethernet interface for all IP processing. In addition, AOS uses the specified interface information when sending route updates over the unnumbered interface.

Usage Examples

The following example configures the high level data link control (HDLC) interface to use the IP address assigned to the Ethernet interface 0/1:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip unnumbered eth 0/1**

ip urlfilter <*name*>

Use the **ip urlfilter** command to apply a universal resource locator (URL) filter to the interface for all inbound or outbound traffic. Use the **no** form of this command to remove the URL filter from an interface. Variations of this command include:

ip urlfilter <*name*> **in**
ip urlfilter <*name*> **out**

Syntax Description

<*name*>	Specifies the URL filter name to use on the interface.
in	Applies the filter to the inbound traffic.
out	Applies the filter to the outbound traffic.

Default Values

By default, there are no URL filters applied to any interfaces.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the virtual local area network (VLAN) interfaces.

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be created by using the **ip urlfilter** <*name*> **http** command before applying it to the interface. Refer to *ip urlfilter allowmode on page 1493* for more information on using this command.

Usage Examples

The following example performs URL filtering on all traffic entering through the high level data link control (HDLC) interface and matches the URL filter named **MyFilter**:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ip urlfilter MyFilter in**

ipv6 dhcp relay destination *<ipv6 address>*

Use the **ipv6 dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 6 (IPv6) and to specify the IPv6 address for the DHCPv6 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv6 relay functionality is disabled on the interface. Variations of this command include:

ipv6 dhcp relay destination *<ipv6 address>*
ipv6 dhcp relay destination *<ipv6 address> <interface>*

Syntax Description

<ipv6 address>	Specifies the IPv6 address for the DHCPv6 messages. IPv6 addresses should be specified in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
<interface>	Optional. Specifies an output interface to use when sending messages to the DHCPv6 server. If no interface is specified, the interface is selected by the routing table. This parameter is only required when the IPv6 address is a link-scoped address. Interfaces are specified in the *<interface type> <slot/port | interface id>* format. For example, for an Ethernet interface, use **eth 0/1**. Type **ipv6 dhcp relay destination** *<ipv6 address>* **?** to display a list of valid interfaces.

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.1.0	Command was expanded to include the Tunnel interface.

Functional Notes

To configure an interface to function as a DHCPv6 relay agent, you must first enable IPv6 on the interface using the command **ipv6**.

Usage Examples

The following example enables DHCPv6 relay agent functionality and specifies the destination address as **2001:DB8:2::1**:

(config)**#interface hdlc 1**
(config-hdlc 1)**#ipv6**
(config-hdlc 1)**#ipv6 dhcp relay destination 2001:DB8:2::1**

keepalive <*value*>

Use the **keepalive** command to enable the transmission of keepalive packets on the interface and specify the time interval in seconds between transmitted packets. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Defines the time interval (in seconds) between transmitted keepalive packets. Valid range is **0** to **32767** seconds.

Default Values

By default, the time interval between transmitted keepalive packets is **10** seconds.

Command History

Release 9.1	Command was introduced.

Functional Notes

If three keepalive packets are sent to an interface with no response, the interface is considered down. To detect interface failures quickly, specify a smaller keepalive time.

Usage Examples

The following example specifies a keepalive time of 5 seconds on the high level data link control (HDLC) interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#keepalive 5**

lldp receive

Use the **lldp receive** command to allow Link Layer Discovery Protocol (LLDP) packets to be received on this interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, all interfaces are configured to send and receive LLDP packets.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example configures the high level data link control (HDLC) interface to receive LLDP packets:

(config)**#interface hdlc 1**
(config-hdlc 1)**#lldp receive**

lldp send

Use the **lldp send** command to configure this interface to transmit Link Layer Discovery Protocol (LLDP) packets or to control the types of information contained in the LLDP packets transmitted by this interface. Use the **no** form of this command to disable this feature. Variations of this command include:

lldp send
lldp send management-address
lldp send port-description
lldp send system-capabilities
lldp send system-description
lldp send system-name
lldp send-and-receive

Syntax Description

management-address	Enables transmission of management address information on this interface.
port-description	Enables transmission of port description information on this interface.
system-capabilities	Enables transmission of this device's system capabilities on this interface.
system-description	Enables transmission of this device's system description on this interface.
system-name	Enables transmission of this device's system name on this interface.
and-receive	Configures this interface to both transmit and receive LLDP packets.

Default Values

By default, all interfaces are configured to transmit and receive LLDP packets of all types.

Command History

Release 9.1	Command was introduced.

Functional Notes

Individual LLDP information can be enabled or disabled using the various forms of the **lldp send** command. For example, use the **lldp send-and-receive** command to enable transmit and receive of all LLDP information. Then use the **no lldp send port-description** command to prevent LLDP from transmitting port description information.

Usage Examples

The following example configures the high level data link control (HDLC) interface to transmit LLDP packets containing all enabled information types:

(config)**#interface hdlc 1**
(config-hdlc 1)**#lldp send**

The following example configures the HDLC to transmit and receive LLDP packets containing all information types:

(config)**#interface hdlc 1**
(config-hdlc 1)**#lldp send-and-receive**

max-reserved-bandwidth <*value*>

Use the **max-reserved-bandwidth** command to specify the percentage of interface bandwidth reserved for use in user-defined (priority or class-based) queues. The remainder of the interface bandwidth is reserved for system-critical traffic and is not available to user-defined queues. Use the **no** form of this command to restore the default value.

Reserving a portion of the interface bandwidth for system-critical traffic is necessary for proper operation. Specifying the entire interface bandwidth for use in user-defined queues can cause undesirable operation.

Syntax Description

<*value*>	Specifies the maximum percentage of bandwidth to reserve for quality of service (QoS). This setting is configured as a percentage of the total interface speed. Range is **1** to **100** percent.

Default Values

By default, **max-reserved-bandwidth** is set to 75 percent, which reserves 25 percent of the interface bandwidth for system-critical traffic.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example specifies **85** percent of the bandwidth on the high level data link control (HDLC) 1 be available for use in user-defined queues:

(config)**#interface hdlc 1**
(config-hdlc 1)**#max-reserved-bandwidth 85**

media-gateway ip

Use the **media-gateway ip** command to associate an Internet Protocol version 4 (IPv4) address source to use for Realtime Transport Protocol (RTP) traffic. When configuring Voice over Internet Protocol (VoIP), RTP traffic must have an IPv4 address associated with it. However, some interfaces allow dynamic configuration of IPv4 addresses, causing this value to change periodically. Use the **no** form of this command to disable this function. Variations of this command include:

media-gateway ip loopback <*interface id*>
media-gateway ip primary
media-gateway ip secondary <*ipv4 address*>

Syntax Description

loopback <*interface id*>	Specifies an IPv4 address statically defined to a loopback interface for RTP traffic. This is helpful when using a single IPv4 address across multiple wide area network (WAN) interfaces for RTP traffic. The valid range for loopback interface identifiers is **1** to **1024**. The interface ID is used to uniquely identify a loopback interface. The entered value cannot be in use by another loopback interface.
primary	Specifies using this interface's configured primary IPv4 address for RTP traffic. Applies to static, Dynamic Host Configuration Protocol (DHCP), or negotiated addresses.
secondary <*ipv4 address*>	Specifies using this interface's statically defined secondary IPv4 address for RTP traffic. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, **media-gateway ip** is disabled.

Command History

Release 10.1	Command was introduced.
Release 17.3	Command was updated with the loopback interface identification option.
Release A4.01	Command was expanded to include the Metro Ethernet forum (MEF) Ethernet interface.

Usage Examples

The following example configures the unit to use the primary IPv4 address for RTP traffic:

(config)**#interface hdlc 1**
(config-hdlc 1)**#media-gateway ip primary**

packet-capture <*name*>

Use the **packet-capture** command to apply a previously configured packet capture instance to the interface. Use the **no** form of this command to remove the packet capture instance.

Syntax Description

<*name*>	Specifies the name of the packet capture instance to apply to the interface.

Default Values

By default, no packet capture instances are configured or applied to the interface.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

The AOS packet capture feature is used with network monitoring to effectively capture data packets as they traverse the network. For more information about packet capturing, its uses, and its implementation in AOS, refer to the configuration guide *Configuring Packet Capture in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example applies the previously configured packet capture **1CAPTURE** to the interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#packet-capture 1CAPTURE**

qos-policy

Use the **qos-policy** command to apply a previously configured quality of service (QoS) map to incoming or outgoing packets on an interface. Use the **no** form of this command to remove the map from the interface. Variations of this command include:

qos-policy in *<name>*
qos-policy out *<name>*

Syntax Description

<name>	Specifies the name of a previously created QoS map (refer to *qos map <name> <number> on page 1673* for more information).
in	Assigns a QoS map to this interface's input.
out	Assigns a QoS map to this interface's output.

Default Values

No default values are necessary for this command.

Command History

Release 9.1	Command was introduced.
Release 15.1	Command was expanded to include the **in** parameter.

Functional Notes

When a QoS policy is applied to an interface, it may be disabled if the interface bandwidth is not adequate to support the requested bandwidth on the map set. Once the bandwidth problem is resolved, the map will work again. The bandwidth will be rechecked on any of the following changes:

1. A priority or class-based entry is added to, deleted from, or changed in a QoS map set.
2. The interface bandwidth is changed by the **bandwidth** command on the interface.
3. A QoS policy is applied to an interface.
4. A cross connect is created that includes an interface with a QoS policy.
5. The interface queuing method is changed to fair-queue to use weighted fair queuing (WFQ).
6. The interface operational status changes.
7. The interface bandwidth changes for other reasons (e.g., when asymmetric digital subscriber line (ADSL) finishes training).

In order to prevent the map from being disabled in cases of temporary inadequate bandwidth (e.g., a single link goes down in a dual T1 multilink configuration where the map requests more than one T1's worth of bandwidth), the QoS map uses the maximum theoretical bandwidth on an interface, not the actual bandwidth at that time. This actually helps QoS keep higher priority class-based traffic working better than best-effort traffic when the bandwidth drops.

Usage Examples

The following example applies the QoS map **VOICEMAP** to the high level data link control (HDLC) interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#qos-policy out VOICEMAP**

rtp quality-monitoring

Use the **rtp quality-monitoring** command to enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets on this interface. If the global command (**ip rtp quality-monitoring**) is disabled when this command is issued, the system will return the following warning: "Applied but not used, you must globally enable **ip rtp quality-monitoring** to use VQM." Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, VQM is enabled on all wide area network (WAN) and local area network (LAN) interfaces.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables RTP quality monitoring on the high level data link control (HDLC) interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#rtp quality-monitoring**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.

Usage Examples

The following example disables the link-status trap on the HDLC interface:

(config)**#interface hdlc 1**
(config-hdlc 1)**#no snmp trap link-status**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an interface to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the interface from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an interface's VRF association will clear all IP-related settings on that interface.

Syntax Description

<name>	Specifies the name of the VRF to which to assign the interface.

Default Values

By default, interfaces are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release 17.8	The keyword **ip** was removed from this command.

Functional Notes

VRF instances must be created first before an interface can be assigned. An interface can only be assigned to one VRF, but multiple interfaces can be assigned to the same VRF.

An interface will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the HDLC interface to the VRF instance named **RED**:

(config)**#interface hdlc 1**
(config-hdlc 1)**#vrf forwarding RED**

LOOPBACK INTERFACE COMMAND SET

To create a virtual loopback interface and/or activate the Loopback Interface Configuration mode, enter the **interface loopback** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface loopback 1
(config-loop 1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

bandwidth <value> on page 2969
dynamic-dns on page 2970
ip commands begin on page 2972
ipv6 commands begin on page 3009
ospfv3 <process id> area <area id> on page 3027
ospfv3 <process id> shutdown on page 3029
rtp quality-monitoring on page 3030
snmp trap on page 3031
snmp trap link-status on page 3032
vrf forwarding <name> on page 3033

bandwidth <*value*>

Use the **bandwidth** command to provide the bandwidth value of an interface to the higher level protocols. This value is used in cost calculations. Use the **no** form of this command to restore the default value.

Syntax Description

<*value*>	Specifies bandwidth in kbps. Range is **1** to **4294967295** kbps.

Default Values

To view the default values, use the **show interfaces** command.

Command History

Release 3.1	Command was introduced.

Functional Notes

It is important to note that there is an order of precedence in determining the interface bandwidth reported by the router for QoS. Under normal circumstances, the Layer 1 bandwidth is reported based on the interface type. For example, a T1 interface will report the available bandwidth as 1.536 Mbps. This can be misleading in QoS configurations if the **bandwidth** command has been applied to the IP interface for routing purposes because the command overrides the reported available bandwidth that can be utilized for QoS. Using the **bandwidth** command can severely disrupt the configuration of QoS on the interface.

Usage Examples

The following example sets bandwidth of the loopback interface to 10 Mbps:

(config)**#interface loopback 1**
(config-loop 1)**#bandwidth 10000**

dynamic-dns

Use the **dynamic-dns** command to configure Dynamic DNS service provided by Dynamic Network Services, Inc. (www.dyndns.org). Use the **no** form of this command to disable this feature. Variations of this command include:

dynamic-dns custom <*hostname*> <*minutes*>
dynamic-dns dyndns <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-custom <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-static <*hostname*> <*username*> <*password*>

Syntax Description

<*hostname*>	Specifies the host name for the server that updates the dynamic domain naming system (DNS).
<*minutes*>	Specifies the intervals in minutes to update the server with information (updates also occur when the interface's IP address changes regardless of the update intervals).
<*username*>	Specifies a user name using an alphanumerical string up to 30 characters in length (the user name is case sensitive).
<*password*>	Specifies a password using an alphanumerical string up to 30 characters in length (the password is case sensitive). Refer to *Functional Notes* below for additional argument descriptions.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.
Release 12.1	Command was expanded.

Functional Notes

custom - Constanttime.com's Custom Dynamic DNS^{SM} service allows you complete access and management control over your domain name regardless of where you purchased/registered it. This allows you to manage IP address mappings (A records), domain aliases (CNAME records), and mail servers (mail exchange (MX) records).

dyndns - The Dynamic DNS^{SM} offered by Dynamic Network Services, Inc. (DynDNS.org) allows you to alias a dynamic IP address to a static host name in various domains. This allows your unit to be more easily accessed from various locations on the Internet. This service is provided for up to five host names.

dyndns-custom - DynDNS.org's Custom DNS^{SM} service provides a full DNS solution, giving you complete control over an entire domain name. A Web-based interface provides two levels of control over your domain, catering to average or advanced users. Five globally redundant DNS servers ensure that your domain will always resolve.

A choice of two interfaces is available. The basic interface is designed for most users. It comes preconfigured for most common configurations and allows for easy creation of most common record types. The advanced interface is designed for system administrators with a solid DNS background, and provides layout and functionality similar to a BIND zone file allowing for the creation of nearly any record type.

Custom DNS^{SM} can be used with both static and dynamic IPs, and has the same automatic update capability through Custom DNS-aware clients as Dynamic DNS.

dyndns-static - The Static DNS service is similar to DynDNS.org's Dynamic DNS^{SM} service in that it allows a host name, such as yourname.dyndns.org, to point to your IP address. Unlike a Dynamic DNS host, a Static DNS host does not expire after 35 days without updates, but updates take longer to propagate through the DNS system. This service is provided for up to five host names.

If your IP address does not change often or at all, but you still want an easy name to remember it by (without having to purchase your own domain name), Static DNS service is ideal for you.

If you would like to use your own domain name (such as yourname.com), you need Custom DNS service that also provides full dynamic and static IP address support.

Usage Examples

The following example sets the Dynamic DNS to **dyndns-custom** with host name **host**, user name **user**, and password **pass**:

(config)**#interface loopback 1**
(config-loop 1)**#dynamic-dns dyndns-custom host user pass**

ip access-group *<ipv4 acl name>*

Use the **ip access-group** command to create an Internet Protocol version 4 (IPv4) access control list (ACL) to be used for packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ip access-group *<ipv4 acl name>* **in**
ip access-group *<ipv4 acl name>* **out**

Syntax Description

<ipv4 acl name>	Specifies IPv4 ACL name.
in	Enables access control on packets received on the specified interface.
out	Enables access control on packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 3.1	Command was introduced.

Functional Notes

When this command is enabled, the IPv4 destination address of each packet must be validated before being passed through. If the packet is not acceptable per these settings, it is dropped.

Usage Examples

The following example sets up the router to allow only Telnet traffic into the loopback interface:

(config)**#ip access-list extended TelnetOnly**
(config-ext-nacl)**#permit tcp any any eq telnet**
(config-ext-nacl)**#interface loopback 1**
(config-loop 1)**#ip access-group TelnetOnly in**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to an interface. IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

> NOTE *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an interface.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the Ethernet interface 0/1:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the loopback interface 1:

(config)**#interface loopback 1**
(config-loop 1)**#ip access-policy PRIVATE**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the specified interface. Use the optional **secondary** keyword to define a secondary IPv4 address. Use the **no** form of this command to remove a configured IPv4 address. Variations of this command include:

ip address <*ipv4 address*> <*subnet mask*>
ip address <*ipv4 address*> <*subnet mask*> **secondary**

Syntax Description

<ipv4 address>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the specified interface.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 1.1	Command was introduced.
Release 2.1	Added **ip address dhcp** for Dynamic Host Configuration Protocol (DHCP) client support.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IP addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a secondary IPv4 address of **192.22.72.101 255.255.255.252**:

(config)**#interface loopback 1**
(config-loop 1)**#ip address 192.22.72.101 255.255.255.252 secondary**

ip address range *<start ip address> <end ip address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the specified interface. Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#interface loopback 1**
(config-loop 1)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip crypto map *<name>*

Use the **ip crypto map** command to associate Internet Protocol version 4 (IPv4) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

When you apply a map to an interface, you are applying all crypto maps with the given map name. This allows you to apply multiple crypto maps if you have created maps that share the same name, but have different map index numbers.

Syntax Description

<name>	Specifies the IPv4 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

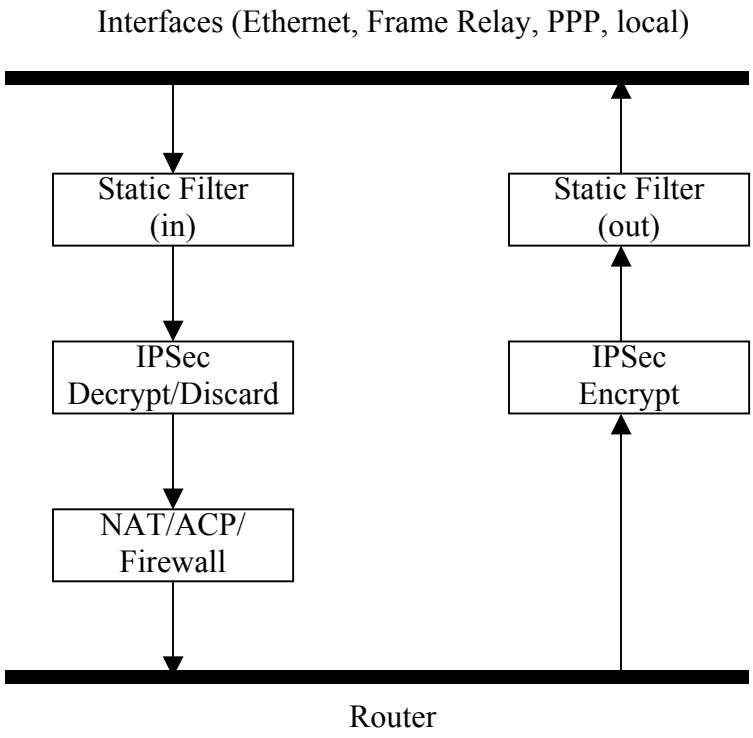
Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 9.1	Command was expanded to include the High-Levell Data Link Control (HDLC) interface.
Release 11.1	Command was expanded to include the demand interface.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.7.0	Command syntax was changed to require the **ip** keyword.

Functional Notes

When configuring a system to use both the stateful inspection firewall and Internet key exchange (IKE) negotiation for VPN, keep the following notes in mind.

When defining the IPv4 policy class and associated access control lists (ACLs) that describe the behavior of the IPv4 firewall, do not forget to include the traffic coming into the system over a VPN tunnel terminated by the system. The firewall should be set up with respect to the unencrypted traffic that is destined to be sent or received over the VPN tunnel. The following diagram represents typical AOS data-flow logic.



As shown in the diagram above, data coming into the product is first processed by the static filter associated with the interface on which the data is received. This access group is a true static filter and is available for use regardless of whether the IPv4 firewall is enabled or disabled. Next (if the data is encrypted), it is sent to the IPSec engine for decryption. The decrypted data is then processed by the stateful inspection firewall. Therefore, given a terminating VPN tunnel, only unencrypted data is processed by the firewall.

The IPv4 ACLs for a crypto map on an interface work in reverse logic to the ACLs for a policy class on an interface. When specifying the ACLs for a crypto map, the source information is the private local side, unencrypted source of the data. The destination information will be the far-end, unencrypted destination of the data. However, ACLs for a policy class work in reverse. The source information for the ACL in a policy class is the far end. The destination information is the local side.

Usage Examples

The following example applies all IPv4 crypto maps with the name **MyMap** to the interface:

(config)**#interface loopback 1**
(config-loop 1)**#ip crypto map MyMap**

ip dhcp relay destination *<ipv4 address>*

Use the **ip dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 4 (IPv4) and to specify the IPv4 address for the DHCPv4 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv4 relay functionality is disabled on the interface.

Syntax Description

<ipv4 address>	Specifies the IPv4 address for the DHCPv4 messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.

Usage Examples

The following example enables DHCPv4 relay agent functionality and specifies the destination address as **192.33.4.251**:

(config)**#interface loopback 1**
(config-loop 1)**#ip dhcp relay destination 192.33.4.251**

ip directed-broadcast

Use the **ip directed-broadcast** command to allow reception/forwarding of directed broadcasts. Use the **no** form of this command to disable this feature. Variations of this command include:

ip directed-broadcast
ip directed-broadcast <*name*>

Syntax Description

<*name*>	Specifies IP access control list (ACL) name.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.

Functional Notes

A directed broadcast is a packet intended for all nodes on a nonlocal network. For example, the broadcast address 255.255.255.255 reaches all nodes on a network; the directed broadcast address 128.1.255.255 is intended for all nodes whose network address is 128.1.0.0. A router not directly attached to 128.1.0.0 simply forwards the directed broadcast packet to the next hop. A router on network 128.1.0.0 that has **ip directed-broadcast** enabled, accepts and forwards the packet to all nodes whose network address is 128.1.0.0. Routers connecting subnets of 128.1.0.0 also accept and forward the packet to the nodes on their respective subnets. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is distributed as a broadcast on the destination subnet. The packet is then sent as a link-layer broadcast.

The **ip directed-broadcast** command controls the distribution of directed broadcasts when they reach their target subnets. Only the final transmission of the directed broadcast on its ultimate destination subnet is affected. It does not affect the transit unicast routing of IP directed broadcasts.

If **ip directed-broadcast** is enabled for this interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which this interface is attached will be forwarded as broadcasts on that subnet. Forwarding of the packets can be limited by specifying an ACL with this command. In this case, only directed broadcasts that are permitted by the specified ACL will be forwarded, and all other directed broadcasts directed to this interface subnet will be dropped.

Disabling the **ip directed-broadcast** command will cause directed broadcasts destined for the subnet to which this interface is attached to be dropped.

This option is a requirement for routers as described in RFC 1812, section 4.2.2.11. Furthermore, it is disabled by default (RFC 2644), with the intended goal of reducing the efficacy of certain types of denial of service (DoS) attacks.

Usage Examples

The following example enables forwarding of directed broadcasts on the interface **loopback 1**:

(config)**#interface loopback 1**
(config-loop 1)**#ip directed-broadcast**

ip flow

Use the **ip flow** command to enable integrated traffic monitoring (ITM) for all traffic received or forwarded on an interface. Use the **no** form of this command to disable traffic monitoring. Variations of this command include:

ip flow egress
ip flow egress <*name*>
ip flow ingress
ip flow ingress <*name*>

Syntax Description

egress	Specifies that all outgoing traffic be monitored.
ingress	Specifies that all incoming traffic be monitored.
<*name*>	Optional. Specifies the name of an access control list (ACL) to use for filtering traffic.

Default Values

By default, no traffic monitoring is enabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables traffic monitoring on a **loopback** interface to monitor **incoming** traffic through an ACL called **myacl**:

(config)**#interface loopback 1**
(config-loop 1)**#ip flow ingress myacl**

ip helper-address *<ip address>*

Use the **ip helper-address** command to configure AOS to forward User Datagram Protocol (UDP) broadcast packets received on the interface. Use the **no** form of this command to disable forwarding packets.

> NOTE *The **ip helper** command must be used in conjunction with the **ip forward-protocol** command to configure AOS to forward UDP broadcast packets. Refer to ip forward-protocol udp <value> on page 1398 for more information.*

Syntax Description

<ip address>	Specifies the destination IP address for the forwarded UDP packets. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, broadcast UDP packets are not forwarded.

Command History

Release 1.1	Command was introduced.

Functional Notes

When used in conjunction with the **ip forward-protocol** command, the **ip helper-address** feature allows you to customize which broadcast packets are forwarded.

To implement the helper address feature, assign a helper-address(es) (specifying the device that needs to receive the broadcast traffic) to the interface closest to the host that transmits the broadcast packets. When broadcast packets (of the specified type forwarded using the **ip forward-protocol** command) are received on the interface, they will be forwarded to the device that needs the information.

Only packets meeting the following criteria are considered eligible by the **ip helper-address** feature:

1. The packet IP protocol is UDP.
2. Any UDP port specified using the **ip forward-protocol** command.
3. The medium access control (MAC) address of the frame is an all-ones broadcast address (ffff.ffff.ffff).
4. The destination IP address is broadcast defined by all ones (255.255.255.255) or a subnet broadcast (for example, 192.33.4.251 for the 192.33.4.248 /30 subnet).

Usage Examples

The following example forwards all DNS broadcast traffic to the DNS server with IP address **192.33.5.99**:

(config)**#ip forward-protocol udp domain**
(config)**#interface loopback 1**
(config-loop 1)**#ip helper-address 192.33.5.99**

ip igmp

Use the **ip igmp** command to configure multicasting related functions for the interface. Variations of this command include:

ip igmp immediate-leave
ip igmp last-member-query-interval <*milliseconds*>
ip igmp querier-timeout <*seconds*>
ip igmp query-interval <*seconds*>
ip igmp query-max-response-time <*seconds*>
ip igmp static-group <*address*>
ip igmp version [1 | 2]

Syntax Description

immediate-leave	Specifies that if only one host (or Internet Group Management Protocol (IGMP) snooping switch) is connected to the interface, when a leave is received, multicast of that group is immediately terminated as opposed to sending a group query and timing out the group if no device responds. Works in conjunction with **ip igmp last-member-query-interval**. Applies to all groups when configured. Use the **no** form of this command to disable the **immediate-leave** feature.
last-member-query-interval <*milliseconds*>	Controls the timeout (in milliseconds) used to detect whether any group receivers remain on an interface after a receiver leaves a group. If a receiver sends a leave-group message (IGMP Version 2), the router sends a group-specific query on that interface. After twice the time specified by this command plus as much as one second longer, if no receiver responds, the router removes that interface from the group and stops sending that group's multicast packets to the interface. Range is **100** to **65535** ms. Use the **no** form of this command to return to the default setting.
querier-timeout <*seconds*>	Specifies the interval (in seconds) that the router waits after the current querier's last query before it takes over as querier (IGMP V2). Range is **60** to **300** seconds. Use the **no** form of this command to return to the default setting.
query-interval <*seconds*>	Specifies the interval (in seconds) at which IGMP queries are sent on an interface. Host query messages are addressed to the all-hosts multicast group with an IP time to live (TTL) of 1. The router uses queries to detect whether multicast group members are on the interface and to select an IGMP designated router (DR) for the attached segment (if more than one multicast router exists). Only the DR for the segment sends queries. For IGMP V2, the DR is the router with the lowest IP address on the segment. Range is **0** to **65535** seconds. Use the **no** form of this command to return to the default setting.
query-max-response-time <*seconds*>	Specifies the maximum response time (in seconds) advertised by this interface in queries when using IGMP V2. Hosts are allowed a random time within this period to respond, reducing response bursts. Use the **no** form of this command to return to the default setting.

Syntax Description

static-group <*address*>	Configures the router's interface to be a statically connected member of the specified group. Packets received on the correct reverse path forwarding (RPF) interface are forwarded to this interface regardless of whether any receivers have joined the specified group using IGMP. Use the **no** form of this command to remove a configured static group.
version [1 | 2]	Sets the interface's IGMP version. Use the **no** form of this command to return to the default setting.

Default Values

ip igmp immediate-leave	No default
ip igmp last-member-query-interval	**1000** milliseconds
ip igmp querier-timeout	2x the **query-interval** value
ip igmp query-interval	**60** seconds
ip igmp query-max-response-time	**10** seconds
ip igmp static-group	No default
ip igmp version	Version **1**

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example sets the query message interval on the interface to **200** milliseconds:

(config)**#interface loopback 1**
(config-loop 1)**#ip igmp last-member-query-interval 200**

ip mcast-stub downstream

Use the **ip mcast-stub downstream** command to enable multicast forwarding and Internet Group Management Protocol (IGMP) (router mode) on an interface and place it in multicast stub downstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub upstream** commands. Downstream interfaces connect to segments with multicast hosts. Multiple interfaces may be configured in downstream mode; however, interfaces connecting to the multicast network (upstream) should not be configured in downstream mode. Interfaces configured as downstream should have the lowest IP address of all IGMP-capable routers on the connected segment in order to be selected as the designated router (DR) and ensure proper forwarding. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub upstream on page 2990* for more information.

Usage Examples

The following example enables multicast forwarding and IGMP on the interface:

(config)**#interface loopback 1**
(config-loop 1)**#ip mcast-stub downstream**

ip mcast-stub fixed

Use the **ip mcast-stub fixed** command to allow forwarding of multicast traffic on a selected interface after enabling multicast routing. Use the **no** form of this command to disable this mode.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 12.1	Command was introduced.

Functional Notes

Multicast routing must be enabled prior to setting **ip mcast-stub fixed** on the selected interface. Also, use the **ip igmp static-group** <*ip address*> command to receive multicast traffic without host-initiated Internet Group Management Protocol (IGMP) activity on the selected interface. Otherwise, all host-initiated IGMP transactions will enter multicast routes on the router's interface involved with IGMP activities.

Usage Examples

The following example enables multicast traffic forwarding and IGMP on the interface:

(config)**#interface loopback 1**
(config-loop 1)**#ip mcast-stub fixed**

ip mcast-stub helper-enable

Use the **ip mcast-stub helper-enable** command to assign the **ip mcast-stub helper-address** as the Internet Group Management Protocol (IGMP) proxy. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 8.1	Command was introduced.
Release 10.1	Command was expanded to include the loopback interfaces.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address**, **ip mcast-stub upstream**, and **ip mcast-stub downstream** commands. When enabled, the interface becomes a helper forwarding interface. The IGMP host function is dynamically enabled and the interface becomes the active upstream interface, enabling the unit to perform as an IGMP proxy. Refer to *ip mcast-stub helper-address <ip address> on page 1418*, *ip mcast-stub downstream on page 2987*, and *ip mcast-stub upstream on page 2990* for more information.

Usage Examples

The following example sets the helper address as the IGMP proxy:

(config)**#interface loopback 1**
(config-loop 1)**#ip mcast-stub helper-enable**

ip mcast-stub upstream

Use the **ip mcast-stub upstream** command to enable multicast forwarding on an interface and place it in multicast stub upstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub downstream** commands. When enabled, the interface becomes a candidate to be a helper forwarding interface. If chosen as the best path toward the helper address by the router's unicast route table, the Internet Group Management Protocol (IGMP) host function is dynamically enabled and the interface becomes the active upstream interface, enabling the router to perform as an IGMP proxy. Though multiple interfaces may be candidates, no more than one interface will actively serve as the helper forwarding interface. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub downstream on page 2987* for more information.

Usage Examples

The following example enables multicast forwarding on the interface:

```
(config)#interface loopback 1
(config-loop 1)#ip mcast-stub upstream
```

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces	(all types)1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

Open shortest path first (OSPF) will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the interface:

(config)**#interface loopback 1**
(config-loop 1)**#ip mtu 1200**

ip ospf <*process id*> area <*area id*>

Use the **ip ospf area** command to add an interface to an Open Shortest Path First version 2 (OSPFv2) process, and to configure the OSPFv2 process on the interface. This command places the interface in the specified area. Use the **no** form of this command to remove the OSPFv2 process from the interface.

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
<*area id*>	Specifies the ID of the area to which this interface is assigned for the specified OSPFv2 process. Valid range is **0** to **4294967295**.

iDefault Values

By default, an OSPFv2 process is not configured on an interface. By default, process IDs and area IDs.

Command History

Release R11.3.0	Command was introduced.

Usage Examples

To add an interface to the OSPFv2 process **5** in area **10**:

(config)**#interface loopback 1**
(config-loop 1)**#ip ospf 5 area 10**

ip ospf <*process id*> shutdown

Use the **ip ospf shutdown** command to disable an Open Shortest Path First version 2 (OSPFv2) process on the interface. When this command is used, the OSPFv2 setting remain in place, but logically it appears to the interface as though the OSPFv2 process has been removed from the configuration. This command can be useful in troubleshooting. Use the **no** form of this command to reinstate the OSPFv2 process.

Syntax Description

<process id>	Specifies the OSPFv2 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ip ospf <process id> area <area id> on page 2993*), entering this command will not create the ID. Only one OSPFv2 process can be configured at a time; if another OSPFv2 process exists, an error is reported.

Default Values

No default values are necessary for this command.

Command History

Release R11.3.0	Command was introduced.

Usage Examples

The following example disables OSPFv2 process **5** on the interface:

(config)**#interface loopback 1**
(config-loop 1)**#ip ospf 5 shutdown**

ip pim sparse-mode

Use the **ip pim sparse-mode** command to enable protocol-independent multicast (PIM) sparse mode for this interface. Use the **no** form of this command to disable PIM sparse mode.

Syntax Description

No subcommands.

Default Values

By default, PIM sparse mode for this interface is disabled.

Command History

Release 11.1	Command was introduced.

Functional Notes

PIM sparse mode is a multicast routing protocol that makes use of the unicast forwarding table. It builds unidirectional shared trees rooted at a rendezvous point (RP) for a multicast group or a shortest-path tree rooted at a specific source for a multicast group.

Usage Examples

The following example enables PIM sparse mode on the interface:

(config)**#interface loopback 1**
(config-loop 1)**#ip pim sparse-mode**

ip pim-sparse dr-priority <*value*>

Use the **ip pim-sparse dr-priority** command to specify the priority for the designated router (DR). This command modifies the router's priority in the DR election process. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the priority of this interface (to be used when determining the DR). Valid range is **1** to **4294967295**.

Default Values

By default, the priority of all protocol-independent multicast (PIM) interfaces is **1**.

Command History

Release 11.1	Command was introduced.

Functional Notes

Interfaces advertise their configured priority values in the hello messages transmitted on the interface. Routers use the priority values to determine the appropriate DR. The router on the network segment with the highest priority is selected as the DR. If a hello message is received on the interface from a router on the network segment and it does not contain a priority, the entire network segment defaults to DR selection based on IP addresses instead of priority. In this instance, the DR is selected as the router on the network segment that has the highest IP address. AOS will always include a priority in all transmitted hello messages. If no priority is specifically designated by the user, the priority is set as the default of 1.

Usage Examples

The following example specifies a priority of **100** on the loopback 1 interface:

(config)**#interface loopback 1**
(config-loop 1)**#ip pim-sparse dr-priority 100**

ip pim-sparse hello-timer <*value*>

Use the **ip pim-sparse hello-timer** command to specify protocol-independent multicast (PIM) sparse hello timer period. This is the time interval at which periodic hellos are sent out on all interfaces of a PIM-capable router. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the interval (in seconds) at which periodic hellos are sent out of the interface. Valid range is **10** to **3600** seconds.

Default Values

By default, the hellos are transmitted on PIM interfaces every **60** seconds.

Command History

Release 11.1	Command was introduced.

Functional Notes

Hello messages are used to inform neighbors of a router's presence. Hello messages normally generate a small amount of traffic on an interface. Setting the **hello-timer** to a small interval increases the number of hellos sent (thus increasing the amount of traffic). Set the **hello-timer** to a reasonable value, taking into consideration the bandwidth available on the interface.

Usage Examples

The following example specifies hellos be sent on the loopback 1 interface every **3600** seconds:

(config)**#interface loopback 1**
(config-loop 1)**#ip pim-sparse hello-timer 3600**

ip pim-sparse nbr-timeout <*value*>

Use the **ip pim-sparse nbr-timeout** command to specify protocol-independent multicast (PIM) sparse neighbor timeout. This is the time interval after which a PIM-capable router will consider a neighbor not present. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the time interval in seconds after which a neighbor is considered not present. Valid range is **30** to **10800** seconds.

Default Values

By default, the PIM sparse neighbor timeout is set to **105** seconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the nbr-timeout to 300 seconds:

(config)**#interface loopback 1**
(config-loop 1)**#ip pim-sparse nbr-timeout 300**

ip pim-sparse override-interval <*value*>

Use the **ip pim-sparse override-interval** command to specify the protocol-independent multicast (PIM) sparse join/prune override interval. This delay interval is the period after a join/prune that another router on the local area network (LAN) may override a join/prune. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the delay time in milliseconds. Valid range is **0** to **65535** milliseconds.

Default Values

By default, the override interval is set to **2500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the override interval to **3000** milliseconds:

(config)**#interface loopback 1**
(config-loop 1)**#ip pim-sparse override-interval 3000**

ip pim-sparse propagation-delay *<value>*

Use the **ip pim-sparse propagation-delay** command to specify the expected propagation delay for join/prune messages. Set the propagation delay (in milliseconds) to estimate the amount of delay found in the local link. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the expected propagation delay in the local link in milliseconds. Valid range is **0** to **32767** milliseconds.

Default Values

By default, the propagation delay is set to **500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the propagation delay to **300** milliseconds:

(config)**#interface loopback 1**
(config-loop 1)**#ip pim-sparse propagation-delay 300**

ip policy route-map *<name>*

Use the **ip policy route-map** command to assign a policy route map to this interface. Use the **no** form of this command to remove the route-map policy.

Syntax Description

<name>	Specifies the name of the policy route map to assign to this interface.

Default Values

By default, no policy route map is assigned to this interface.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example assigns the policy route map **policy1** to the interface:

(config)**#interface loopback 1**
(config-loop 1)**#ip policy route-map policy1**

ip proxy-arp

Use the **ip proxy-arp** command to enable proxy Address Resolution Protocol (ARP) on the interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, proxy ARP is enabled.

Command History

Release 1.1	Command was introduced.

Functional Notes

In general, the principle of proxy ARP allows a router to insert its IP address in the source IP address field of a packet (if the packet is from a host on one of its subnetworks). This allows hosts to reach devices on other subnetworks without implementing routing or specifying a default gateway.

If proxy ARP is enabled, AOS will respond to all proxy ARP requests with its specified medium access control (MAC) address and forward packets accordingly.

Enabling proxy ARP on an interface may introduce unnecessary ARP traffic on the network.

Usage Examples

The following example enables proxy ARP on the loopback interface:

(config)**#interface loopback 1**
(config-loop 1)**#ip proxy-arp**

ip rip receive version

Use the **ip rip receive version** command to configure the Routing Information Protocol (RIP) version the unit accepts in all RIP packets received on the interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip rip receive version 1
ip rip receive version 2

Syntax Description

1	Accepts only received RIP version 1 packets on the interface.
2	Accepts only received RIP version 2 packets on the interface.

Default Values

By default, all interfaces implement RIP version 1 (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.

Functional Notes

Use the **ip rip receive version** to specify a RIP version that overrides the **version** (in the Router RIP) configuration.

AOS only accepts one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the loopback interface to accept only RIP version 2 packets:

(config)**#interface loopback 1**
(config-loop 1)**#ip rip receive version 2**

ip rip send version

Use the **ip rip send version** command to configure the Routing Information Protocol (RIP) version the unit sends in all RIP packets transmitted on the interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip rip send version 1
ip rip send version 2

Syntax Description

1	Transmits only RIP version 1 packets on the interface.
2	Transmits only RIP version 2 packets on the interface.

Default Values

By default, all interfaces transmit RIP **version 1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.

Functional Notes

Use the **ip rip send version** to specify a RIP version that overrides the **version** (in the Router RIP) configuration.

AOS only transmits one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the loopback interface to transmit only RIP version 2 packets:

(config)**#interface loopback 1**
(config-loop 1)**#ip rip send version 2**

ip rip summary-address *<ip address> <subnet mask>*

Use the **ip rip summary-address** command to manually summarize the routes Routing Information Protocol (RIP) will advertise and send out a specified interface. Use the **no** form of this command to disable this mode.

Syntax Description

<ip address>	Specifies the summarized network IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.0**).
<subnet mask>	Specifies the subnet mask that corresponds to the range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no manual summarization is applied by RIP.

Command History

Release 12.1	Command was introduced.

Functional Notes

Unlike the automatic summarization on classful network boundaries, only specific network advertisements are made by RIP using the **ip rip summary-address** command. This command is only effective if RIP version 2 is configured.

Usage Examples

The following example enables manual summarization on the specified IP address:

(config)**#interface loopback 1**
(config-loop 1)**#ip rip summary-address 10.10.123.0 255.255.255.0**

ip route-cache

Use the **ip route-cache** command to enable fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

*Using network address translation (NAT) or the AOS firewall capabilities on an interface requires process switching mode (using the **no ip route-cache** command).*

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route-cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 2.1	Command was introduced.

Functional Notes

Fast switching allows an IP interface to provide optimum performance when processing IP traffic.

Usage Examples

The following example enables fast switching on the loopback interface:

(config)**#interface loopback 1**
(config-loop 1)**#ip route-cache**

ip unnumbered *<interface>*

Use the **ip unnumbered** command to use the IP address assigned to the specified interface for all IP processing on the active interface. Use the **no** form of this command to remove the unnumbered configuration.

Syntax Description

<interface>	Specifies an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip unnumbered ?** for a complete list of valid interfaces.

Default Values

By default, all interfaces are configured to use a specified IP address (using the **ip address** command).

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface.

Functional Notes

If **ip unnumbered** is enabled on an interface, all IP traffic from the interface will use a source IP address taken from the specified interface. For example, specifying **ip unnumbered ppp 1** while in the Ethernet Interface Configuration mode configures the Ethernet interface to use the IP address assigned to the Point-to-Point Protocol (PPP) interface for all IP processing. In addition, AOS uses the specified interface information when sending route updates over the unnumbered interface.

Usage Examples

The following example configures the loopback interface (labeled **loop 1**) to use the IP address assigned to the PPP interface (**ppp 1**):

(config)**#interface loopback 1**
(config-loop 1)**#ip unnumbered ppp 1**

ip urlfilter <*name*>

Use the **ip urlfilter** command to apply a universal resource locator (URL) filter to the interface for all inbound or outbound traffic. Use the **no** form of this command to remove the URL filter from an interface. Variations of this command include:

ip urlfilter <*name*> **in**
ip urlfilter <*name*> **out**

Syntax Description

<*name*>	Specifies the URL filter name to use on the interface.
in	Applies the filter to the inbound traffic.
out	Applies the filter to the outbound traffic.

Default Values

By default, there are no URL filters applied to any interfaces.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the virtual local area network (VLAN) interfaces.

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be created by using the **ip urlfilter** <*name*> **http** command before applying it to the interface. Refer to *ip urlfilter allowmode on page 1493* for more information on using this command.

Usage Examples

The following example performs URL filtering on all traffic entering through the loopback interface (labeled **loop 1**) and matches the URL filter named **MyFilter**:

(config)**#interface loopback 1**
(config-loop 1)**#ip urlfilter MyFilter in**

ipv6

Use the **ipv6** command to enable Internet Protocol version 6 (IPv6) processing and create a link-local address on an interface. Use the **no** form of this command to disable IPv6 processing and remove all IPv6 configuration on the interface.

Syntax Description

No subcommands.

Default Values

By default, IPv6 is not enabled on the interface.

Command History

Release 18.1	Command was introduced.
Release R10.5.0	Command was expanded to include the loopback interface.

Functional Notes

Because AOS uses the dual-stack for IPv6 implementation, IPv6 features must be enabled for the supported IPv6 features to be used. Enabling IPv6 in AOS is completed by using an IPv6 address or using the **ipv6** keyword with specific commands. For example, to enable IPv6 on an interface and cause the interface to join the link scoped all-nodes and all-routers multicast group, enter an IPv6 address on the interface.

Use the **ipv6** command to enable IPv6 processing and create a link-local address on an interface when other unicast IPv6 addresses are not needed on the interface. This command is not necessary nor effectual when any other form of an IPv6 address command is also present on the interface.

Usage Examples

The following example enables IPv6 and creates a link-local IPv6 address on the interface:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6**

ipv6 access-policy *<ipv6 acp name>*

Use the **ipv6 access-policy** command to assign a specified Internet Protocol version 6 (IPv6) access control policy (ACP) to an interface. IPv6 ACPs are applied to IPv6 traffic entering an interface. Use the **no** form of this command to remove an ACP association.

Syntax Description

<ipv6 acp name>	Identifies the configured IPv6 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv6 ACPs associated with an interface.

Command History

Release 18.1	Command was introduced.
Release R10.5.0	Command was expanded to include the loopback interface.

Usage Examples

The following example applies the IPv6 ACP **PRIVATEv6** to the interface:

Enable the AOS security features:
(config)**#ipv6 firewall**

Associate the ACP with the PPP interface:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6 access-policy PRIVATEv6**

ipv6 address *<ipv6 address/prefix-length>*

Use the **ipv6 address** command to assign a unicast Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<ipv6 address/prefix-length>	Specifies the IPv6 unicast address to add to the interface. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

Default Values

By default, no IPv6 address is configured on the interface and IPv6 processing is not enabled on the interface.

Command History

Release 18.1	Command was introduced.
Release R10.5.0	Command was expanded to include the loopback interface.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the interface using the command *ipv6 address <ipv6 link-local address> link-local on page 3013*.

The address created by this command is a manually configured IPv6 address, which must have all parts (prefix and host bits) specified.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example adds a unicast IPv6 address to the interface and enables IPv6 processing on the interface:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6 address 2001:DB8::/32**

ipv6 address *<ipv6 prefix/prefix-length>* eui-64

Use the **ipv6 address eui-64** command to assign a unicast Internet Protocol version 6 (IPv6) address and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<ipv6 prefix/prefix-length>	Specifies the IPv6 prefix. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
eui-64	Specifies that the IPv6 address is constructed using the specified prefix in the high-order bits and followed by the EUI-64 Interface ID in the lower 64 bits.

Default Values

By default, no IPv6 address is configured on the interface and IPv6 processing is not enabled on the interface.

Command History

Release 18.1	Command was introduced.
Release R10.5.0	Command was expanded to include the loopback interface.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the interface using the command *ipv6 address <ipv6 link-local address> link-local on page 3013*.

The address created by this command is an EUI-64 unicast address. For this type of address, the EUI-64 interface ID is automatically placed in the IPv6 address. Any manually configured bits beyond the address's prefix length are set to **0**; however, any manually configured bits within the prefix length that extend into the lower 64 bits take precedence over the Interface ID bits.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example adds a unicast IPv6 address with an EUI-64 Interface ID to the interface and enables IPv6 processing on the interface:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6 address 2001:DB8:3F::/48 eui-64**

ipv6 address <*ipv6 link-local address*> link-local

Use the **ipv6 address link-local** command to manually assign a link-local Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<*ipv6 link-local address*>	Specifies the link-local IPv6 address. Link-local addresses are specified in colon hexadecimal notation, and begin with **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since link-local addresses have no prefix, the bits entered form the entire IPv6 address.
link-local	Specifies this is a manually configured link-local address. Manually configured link-local addresses replace automatically configured link-local addresses on the interface.

Default Values

By default, no IPv6 address is configured for the interface and IPv6 processing is not enabled.

Command History

Release 18.1	Command was introduced.
Release R10.5.0	Command was expanded to include the loopback interface.

Functional Notes

A single link-local address can be manually configured on an interface. The lower 64 bits of the specified address become the Interface ID for the interface, overriding the default interface ID. Any other address that uses the EUI-64 parameter to automatically place the interface ID in the lower 64 bits of the IPv6 address use the new value for the interface ID.

The <*ipv6 address*> for a link-local IPv6 address is specified in the format **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since this form of address has no prefix, the bits entered form the entire IPv6 address. These bits also become the new interface ID for the interface and can be derived from the interface's medium access control (MAC) address.

The **link-local** parameter specifies this is a manually configured link-local address. Any manually configured link-local address will replace an automatically configured link-local address for the interface.

Using the **no** form of this command with a specified IPv6 address removes that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example manually creates a link-local IPv6 address on the interface and enables IPv6 processing:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6 address FE80::220:8FF:FE54:F9D8 link-local**

ipv6 address dhcp

Use the **ipv6 address dhcp** command to enable Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) on the interface, place the interface in DHCPv6 client mode, and configure the address parameters of the DHCPv6 client. Use the **no** form of this command to disable the DHCPv6 client on the interface. Variations of this command include:

ipv6 address dhcp
ipv6 address dhcp hostname <*partial fqdn*>
ipv6 address dhcp hostname fqdn <*fqdn*>
ipv6 address dhcp no-domain-name
ipv6 address dhcp no-nameservers
ipv6 address dhcp no-ntp
ipv6 address dhcp no-sntp-server
ipv6 address dhcp rapid-commit

Syntax Description

hostname <*partial fqdn*>	Optional. Specifies the name to be sent to the DHCPv6 server as the host portion of its fully qualified domain name (FQDN). FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
fqdn <*fqdn*>	Optional. Specifies a name to be sent to the DHCPv6 server as the system's FQDN. FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
no-domain-name	Optional. Specifies that no domain names are obtained using this DHCPv6 client.
no-nameservers	Optional. Specifies that no domain naming server (DNS) addresses are obtained through DHCPv6.
no-ntp	Optional. Specifies that no Network Time Protocol (NTP) server values are obtained through this DHCPv6 client.
no-sntp-server	Optional. Specifies that no Simple Network Time Protocol (SNTP) server values are obtained through this DHCPv6 client.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Functional Notes

To enable an interface as a DHCPv6 client, you must first enable IPv6 on the interface using the command *ipv6 on page 3009*.

Enabling the interface as a DHCPv6 client using the **ipv6 address dhcp** command places the interface into DHCPv6 client mode. DHCPv6 modes (**client**, **server**, **relay**) are mutually exclusive at the interface. Any existing mode must be removed before a different mode can be applied. For example, if the interface is configured as a DHCPv6 relay agent, you must first disable the **relay** mode before you can specify the interface is in **client** mode.

Usage Examples

The following example enables the interface as a DHCPv6 client and specifies the client's host name:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6 address 2001:DB8:1::1/64**
(config-loop 1)**#ipv6 address dhcp fqdn client@company.com**

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*

Use the **ipv6 address named-prefix** command to create an Internet Protocol version 6 (IPv6) address for the interface using the values in a named prefix. Use the **no** form of this command to remove the address from the interface. Variations of this command include:

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*
ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>* **eui-64**

Syntax Description

<prefix name>	Specifies the named prefix to use to create the address.
<ipv6 address/prefix-length>	Specifies the address portion appended to the named prefix to create a 128-bit host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
eui-64	Optional. Indicates that the interface ID is to be placed in the lower 64 bits of the address.

Default Values

By default, no IPv6 addresses are specified on the interface.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example creates an IPv6 address on the interface using the named prefix **PREFIX1**:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6 address named-prefix PREFIX1 2001:1:0:/48**

ipv6 dhcp client information refresh minimum <*seconds*>

Use the **ipv6 dhcp client information refresh minimum** command to specify the minimum value the Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) client on the interface accepts as its information refresh timer. Use the **no** version of this command to return to the default setting.

Syntax Description

<*seconds*>	Specifies the refresh timer in seconds. Valid range is **600** to **3600** seconds.

Default Values

By default, the DHCPv6 client refresh timer is set to **600** seconds.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example specifies the DHCPv6 client refresh timer for the interface is **800** seconds:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6 dhcp client information refresh minimum 800**

ipv6 dhcp client pd <*prefix name*>

Use the **ipv6 dhcp client pd** command to enable the Dynamic Control Host Protocol for Internet Protocol version 6 (DHCPv6) client on the interface and specify that the interface acquires an IPv6 prefix for the DHCPv6 client. Use the **no** form of this command to disable this feature. Variations of this command include:

ipv6 dhcp client pd <*prefix name*>
ipv6 dhcp client pd <*prefix name*> **no-aggregate-route**
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*>
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*> **tag** <*value*>
ipv6 dhcp client pd <*prefix name*> **rapid-commit**

Syntax Description

<*prefix name*>	Specifies the variable of the prefix stored on the AOS system. Variables are expressed in ASCII text of up to **80** characters.
no-aggregate-route	Optional. Specifies that a route to the null 0 interface is not injected into the route table for the prefixes assigned.
distance <*distance*>	Optional. Specifies the administrative distance to assign to the injected route. Valid range is **1** to **255** with a default distance of **1**.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.
tag <*value*>	Optional. Specifies a number to use as a tag for labeling and filtering routers. Valid range is **1** to **65535**.

Default Values

By default, the DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Usage Examples

The following example enables the DHCPv6 client on the interface and assigns the prefix **PREFIX1**:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6 dhcp client pd PREFIX1**

ipv6 dhcp relay destination <*ipv6 address*>

Use the **ipv6 dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 6 (IPv6) and to specify the IPv6 address for the DHCPv6 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv6 relay functionality is disabled on the interface. Variations of this command include:

ipv6 dhcp relay destination <*ipv6 address*>
ipv6 dhcp relay destination <*ipv6 address*> <*interface*>
ipv6 dhcp relay destination <*ipv6 address*> **mef-ethernet** <*slot/port*>
ipv6 dhcp relay destination <*ipv6 address*> **system-control-evc**
ipv6 dhcp relay destination <*ipv6 address*> **system-management-evc**

Syntax Description

<*ipv6 address*>	Specifies the IPv6 address for the DHCPv6 messages. IPv6 addresses should be specified in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<*interface*>	Optional. Specifies an output interface to use when sending messages to the DHCPv6 server. If no interface is specified, the interface is selected by the routing table. This parameter is only required when the IPv6 address is a link-scoped address. Interfaces are specified in the <*interface type*> <*slot/port* | *interface id*> format. For example, for an Ethernet interface, use **eth 0/1**. Type **ipv6 dhcp relay destination** <*ipv6 address*> **?** to display a list of valid interfaces.
mef-ethernet <*slot/port*>	Specifies the Metro Ethernet Forum (MEF) Ethernet interface.
system-control-evc	Optional. Specifies the system control Ethernet virtual connection (EVC) is used when sending messages to the DHCPv6 server.
system-management-evc	Optional. Specifies the system management EVC is used when sending messages to the DHCPv6 server.

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.
Release R10.5.0	Command was expanded to include the loopback interface.
Release R10.10.0	Command was expanded to include the system control and system management EVCs.
Release R10.11.0	Command was expanded to include the MEF Ethernet interface.

Functional Notes

To configure an interface to function as a DHCPv6 relay agent, you must first enable IPv6 on the interface using the command *ipv6 on page 3009*.

Usage Examples

The following example enables DHCPv6 relay agent functionality and specifies the destination address as **2001:DB8:2::1**:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6**
(config-loop 1)**#ipv6 dhcp relay destination 2001:DB8:2::1**

Technology Review

DHCPv6, like DHCP in IPv4, is used in IP networks to supply hosts with IP addresses and other networking information. DHCPv6, however, functions slightly differently than DHCPv4 by providing relay agents with the ability to send relay-forward and relay-reply messages. In addition, in DHCPv4, when DHCP messages are sent to a DHCP server whose address is not known, the IPv4 client uses the broadcast address. In DHCPv6, the IPv6 client sends messages using the link-scoped mulitcast address. This address is the All DHCP Relay Agents and Servers link, designated as **FF02::1:2**.

In AOS, DHCPv6 relay agents are used when the DHCP server is not on the same link as the DHCP client. The relay is typically a router on the same link as the client, which acts as an intermediary to help the client's DHCP messages reach the DHCP server. DHCPv6 relay agents operate transparently to the DHCP client, and can be configured in chains, meaning that information about each agent encountered is encapsulated into the relay message. Relay agents add fields to the DHCP message as they send these messages to the server, thus providing a method to properly manage the DHCP client.

For more information about DHCPv6 functionality in AOS, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

ipv6 dhcp server

Use the **ipv6 dhcp server** command to enable Internet Protocol version 6 (IPv6) Dynamic Host Control Protocol (DHCP) on the interface and specify that the interface is functioning as a DHCPv6 server. This command not only enables the DHCPv6 server on the interface, it also configures specific parameters of the DHCPv6 server. Hence, the parameters of this command can be entered multiple times and in any order. Use the **no** form of this command to disable DHCPv6 on the interface. Variations of this command include:

ipv6 dhcp server automatic
ipv6 dhcp server automatic allow-hint
ipv6 dhcp server automatic preference <*number*>
ipv6 dhcp server automatic rapid-commit
ipv6 dhcp server <*pool name*>
ipv6 dhcp server <*pool name*> **allow-hint**
ipv6 dhcp server <*pool name*> **preference** <*number*>
ipv6 dhcp server <*pool name*> **rapid-commit**

Syntax Description

automatic	Enables automatic selection of the DHCPv6 server pool based on information extracted from the DHCPv6 client's request. You must specify the pool selection method before configuring other options for this command.
<*pool name*>	Specifies the DHCPv6 server pool that services this interface. All DHCPV^ requests received on this interface are serviced from this pool. If a pool name is not specified, the server pool is selected automatically. You must specify the pool selection method before configuring the other options for this command.
allow-hint	Optional. Specifies that the DHCPv6 server attempts to honor the DHCPv6 client's request for specific values as hinted in the client's request (if they are valid and not already assigned). If this option is not specified, any hints from the DHCPv6 client are ignored.
preference <*number*>	Optional. Specifies the preference value advertised by the server. This option is sent by the server to a DHCPv6 client to influence the selection of a server when there are multiple servers from which to choose. Valid range is **0** to **255**, with a default value of **0**. When the preference value is set to a non-zero value, the server includes a preference option containing the value. If the preference value is not set, or is set to 0, the option is omitted and the client assumes the value is 0.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 server mode is not enabled on the interface.

Command History

Release R10.1.0	Command was introduced.
Release R10.5.0	Command was expanded to include the loopback interface.

Functional Notes

Enabling the interface as a DHCPv6 server using this command places the interface into DHCPv6 server mode. DHCPv6 modes (server or relay) are mutually exclusive at the interface. Any existing mode will be removed if a different mode is specified, and a message will be shown indicating the change in DHCPv6 mode.

Usage Examples

The following example enables the interface as a DHCPv6 server, and specifies that the DHCPv6 server pool **POOL1** is associated with the interface:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6 address 2001:DB8:1::1/64**
(config-loop 1)**#ipv6 dhcp server POOL1**

ipv6 mode host unicast

Use the **ipv6 mode host unicast** command to place the interface in host mode using an Internet Protocol version 6 (IPv6) unicast address. Use the **no** form of this command to disable host mode on the interface.

Syntax Description

No subcommands.

Default Values

By default, host mode is disabled.

Command History

Release R10.9.0	Command was introduced.

Command History

When this command is configured on an interface, the MTU value is learned from received router advertisements. Link MTU value is learned in host mode from the following locations (in decreasing order of priority): the provisioned MTU value in the interface configuration, the router advertisements received on the interface, and the default MTU value (1500).

Usage Examples

The following example places the interface in host mode:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6 mode host unicast**

ipv6 nd prefix

Use the **ipv6 nd prefix** command to specify the Internet Protocol version 6 (IPv6) address prefixes used in router advertisement (RA) messages sent from the interface. Use the **no** form of this command to remove the specified prefix configuration from the interface. Variations of this command include:

ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise] [**<*valid lifetime*> | **infinite]** <*preferred lifetime* | **infinite**>
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite] [no-advertise] [no-autoconfig] [no-rtr-address] [no-onlink] [off-link]**

Syntax Description

named-prefix <*prefix name*>	Optional. Specifies that a named prefix is used in RA messages. When a named prefix is used, the default prefix cannot be used.
<*ipv6 prefix/prefix-length*>	Specifies the IPv6 prefix and length to be advertised. Pv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
default	Specifies the default values for the IPv6 prefix parameters. Refer to the *Functional Notes* below for more information.
<*valid lifetime*>	Optional. Specifies the valid lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
<*preferred lifetime*>	Optional. Specifies the preferred lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
infinite	Optional. Specifies that the the valid and preferred lifetimes of the prefix do not expire.
no-advertise	Optional. Specifies that the prefix is excluded from the RA message.
no-autoconfig	Optional. Sets the A flag in the RA message to **0**, indicating that hosts may not create an address for this prefix using stateless address autoconfiguration (SLAAC). This parameter only affects hosts receiving the RA message, it does not affect the operation of the local router.
no-rtr-address	Optional. Sets the R flag in the RA message to **0** and specifies the full router IPv6 address is not included in the RA message.
no-onlink	Optional. Specifies that the IPv6 prefix in the RA message is not to be used for on-link determination.
off-link	Optional. Sets the L flag value to **0** in RA messages, which indicates the RA makes no statement about the on-link or off-link properties of the IPv6 prefix.

Default Values

By default, all prefixes derived from the interface's configured IPv6 addresses are advertised using the system default values.

By default, the valid lifetime advertised for a prefix is **2592000** seconds and the preferred lifetime advertised is **604800** seconds.

By default, the L flag is set to **1**, the R flag is set to **1**, and the A flag is set to **1**.

Command History

Release 18.1	Command was introduced.
Release R10.9.0	Command was expanded to include the **named-prefix** and *<prefix name>* options.

Functional Notes

This command works for both routers and hosts, but in host implementations it is used to manually add on-link prefixes that do not have an IPv6 address or to make off-link a prefix generated by an IPv6 address command. Hosts do not send RA messages, so the command only adds prefixes to RA messages when the interface is in router mode. This command can also be used to change the defaults used on configured prefixes when all options are not specified.

Changing the prefix defaults will affect prefixes derived from configured IPv6 addresses, as well as prefixes configured using the ***ipv6 nd prefix*** *command.*

Prefixes advertised can be a subset or a superset of the prefixes derived from the IPv6 addresses configured on the interface. Prefixes for IPv6 addresses configured on a router interface are automatically eligible to be advertised on that interface using system or configured default values without having to enter a prefix command. To impose additional controls on those prefixes, an entry must be made using this command with the desired settings.

The **default** parameter is used to change the default settings for the IPv6 prefix parameters. Changing these settings can be useful when multiple prefixes are implemented that will use the same set of parameters. When configuring IPv6 prefixes, the prefix default values are only used if no other parameters are specified after specifying the IPv6 prefix and length (for example, **ipv6 nd prefix 2001:DB8::/64**). If additional parameters are specified, any unspecified parameters use the system default values rather than the configured default values. When the default values are changed, any prefix that uses them will also change. Using this command to change prefix default values also affects prefixes derived from configured IPv6 addresses on the interface.

The optional *<valid lifetime>* parameter specifies the valid lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep this prefix until the valid lifetime expires.

The optional <*preferred lifetime*> parameter specifies the preferred lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep the prefix in the preferred state during this time period. After the preferred time period expires, the prefix transitions to the deprecated state where it remains until the valid lifetime expires and the route is removed. The <*preferred lifetime*> value must be set to be shorter than the <*valid lifetime*> value.

The optional **off-link** parameter sets the L flag (on-link flag) value to **0** in RA messages. When the L flag is set to 0, the advertisement makes no statement about on-link or off-link properties of the prefix. When the L flag is set, the prefix is considered on-link and locally reachable by hosts on the link (meaning a router is not needed). Hosts attached to the link will add on-link prefixes to their prefix list or route table. When off-link is not specified, a connected route is added to the route table of this router for this prefix. When off-link is specified, no route is added to the route table. By default, prefixes are advertised as on-link with the L flag set to 1.

The optional **no-rtr-address** parameter sets the R flag (router flag) of the RA to **0** and does not include the full router address in the advertisement. The router address is typically included in the RA to assist in Mobile IP environments. By default, the R flag is set to 1 and the router address is sent in RA messages.

The optional **no-autoconfig** parameter sets the A flag of the RA to **0**, indicating that hosts may not create an address for this prefix using SLAAC. If the A flag is set to **1** (the default setting), hosts perform SLAAC to generate an address based on the prefix. This parameter only affects hosts receiving the RA, it does not effect the operation of the local router.

The optional **no-advertise** parameter specifies that the prefix is excluded from RA messages. By default, the prefix is included in RA messages. The **no-onlink** parameter informs the router that the prefix is not to be used for on-link determination.

By default, all prefixes derived from the interface's configured IPv6 addresses are advertised using the system default values.

Usage Examples

The following example specifies that the IPv6 prefix **2001:DB8:3F::/48** has an infinite valid and preferred lifetime advertised in RA messages sent from the interface:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6 nd prefix 2001:DB8:3F::/48 infinite infinite**

The following example changes the default values and behaviors of prefixes included in RA messages to infinite valid and preferred lifetimes, and specifies that the on- or off-link state of the prefix is not included in the RA and that hosts receiving the RA may not use the prefix for creating an IPv6 address:

(config)**#interface loopback 1**
(config-loop 1)**#ipv6 nd prefix default infinite infinite off-link no-autoconfig**

ospfv3 <*process id*> **area** <*area id*>

Use the **ospfv3 area** command to add an interface to an Open Shortest Path First version 3 (OSPFv3) process, and to configure the OSPFv3 process on the interface. This command places the interface in the specified area for the specified Internet Protocol version 6 (IPv6) OSPFv3 address family, and optionally defines the instance ID that is used to represent this OSPFv3 process in messages on the interface's link. Use the **no** form of this command to remove the OSPFv3 process from the interface. Variations of this command include:

ospfv3 <*process id*> **area** <*area id*> **ipv6**
ospfv3 <*process id*> **area** <*area id*> **ipv6 instance** <*instance id*>

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join, for the specified address family. The process ID is locally significant to the device, and must be unique among all OSPFv3 processes on the device. Valid range is **1** to **65535**.
<*area id*>	Specifies the ID of the area to which this interface is assigned for the given OSPFv3 process. Valid range is **0** to **4294967295**.
ipv6	Identifies the OSPFv3 address family as IPv6.
instance <*instance id*>	Optional. Specifies the value to use in the instance ID field of messages sent or received by this OSPFv3 process on the interface's link. Valid range is **0** to **31**.

Default Values

By default, an OSPFv3 process is not configured on an interface. By default, process IDs, area IDs, and instance IDs are not defined.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

When using this command to enable an OSPFv3 process on an interface, keep the following rules in mind:

- The interface must have the address family enabled on the interface. If the address family is not enabled on the interface, the command is rejected and an error is displayed.
- Only interfaces on the default virtual routing and forwarding (VRF) instance support this command. Interfaces on a nondefault VRF will display an error when you attempt to configure OSPFv3 settings.
- The interface and the specified OSPFv3 process (if defined in the global configuration) must be in the same VRF or the command will fail.
- The address family must match that specified for the OSPFv3 process if the process has been defined in the global configuration or the command will fail.
- If the OSPFv3 process identified by the process ID does not exist in the global configuration, it is automatically created, along with the specified address family, and it is assigned to the VRF of which the interface is a member.

- If the specified OSPFv3 process is already at its maximum limit of processes or address families, the command fails.
- If the specified OSPFv3 process already exists in the global configuration, but its configuration does not include an address family, the specified address family is added to the OSPFv3 router configuration.
- A given OSPFv3 process can only have one address family.
- Multiple OSPFv3 instances per address family, per VRF, can be created and can be assigned to a given interface.
- If the interface's VRF changes, all OSPFv3 assignments are removed.
- To change an OSPFv3 process's VRF, the process must first be removed and then recreated. Removing the process removes all OSPFv3 assignments for that process form all interfaces.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

To add an interface to the OSPFv3 process **5**, in area **10**, with an instance ID of **10**, enter the command as follows:

(config)**#interface loopback 1**
(config-loop 1)**#ospfv3 5 area 10 ipv6 instance 10**

ospfv3 <*process id*> shutdown

Use the **ospfv3 shutdown** command to disable an Open Shortest Path First version 3 (OSPFv3) process on the interface. When this command is used, the OSPFv3 commands remain in place, but logically it appears to the interface as though the OSPFv3 process has been removed from the configuration. This command can be useful in troubleshooting. Use the **no** form of this command to reinstate the OSPFv3 process.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3027*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.

Default Values

No default values are necessary for this command.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example disables OSPFv3 process **5** on the interface:

(config)**#interface loopback 1**
(config-loop 1)**#ospfv3 5 shutdown**

rtp quality-monitoring

Use the **rtp quality-monitoring** command to enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets on this interface. If the global command (**ip rtp quality-monitoring**) is disabled when this command is issued, the system will return the following warning: "Applied but not used, you must globally enable **ip rtp quality-monitoring** to use VQM." Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, VQM is enabled on all wide area network (WAN) and local area network (LAN) interfaces.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables RTP quality monitoring on the loopback interface:

(config)**#interface loopback 1**
(config-loop 1)**#rtp quality-monitoring**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.

Usage Examples

The following example enables SNMP capability on the loopback interface:

(config)**#interface loopback 1**
(config-loop 1)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI)
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release 17.2	Command was expanded to the cellular interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the loopback interface:

(config)**#interface loopback 1**
(config-loop 1)**#no snmp trap link-status**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an interface to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the interface from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an interface's VRF association will clear all IP-related settings on that interface.

Syntax Description

<name>	Specifies the name of the VRF to which to assign the interface.

Default Values

By default, interfaces are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release 17.8	The keyword **ip** was removed from this command.

Functional Notes

VRF instances must be created first before an interface can be assigned. An interface can only be assigned to one VRF, but multiple interfaces can be assigned to the same VRF.

An interface will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the loopback interface to the VRF instance named **RED**:

(config)**#interface loopback 1**
(config-loop 1)**#vrf forwarding RED**

PORT CHANNEL INTERFACE COMMAND SET

To create a virtual link aggregation interface and/or activate the Port Channel Interface Configuration mode, enter the **interface port-channel** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface port-channel 1
(config-p-chan1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

arp arpa on page 3035
lldp receive on page 3036
lldp send on page 3037
qos on page 3039
snmp trap on page 3040
snmp trap link-status on page 3041
spanning tree commands begin on page 3042
storm-control action shutdown on page 3048
storm-control level on page 3049
storm-control rate on page 3051
switchport commands begin on page 3053

arp arpa

Use the **arp arpa** command to set ARPA as the standard Address Resolution Protocol (ARP) on this interface. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

The default for this command is **arpa**.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example enables standard ARP for the port channel interface:

```
(config)#interface port-channel 1
(config-p-chan1)#arp arpa
```

lldp receive

Use the **lldp receive** command to allow Link Layer Discovery Protocol (LLDP) packets to be received on this interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, all interfaces are configured to send and receive LLDP packets.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example configures the port channel interface to receive LLDP packets:

(config)**#interface port-channel 1**
(config-p-chan1)**#lldp receive**

lldp send

Use the **lldp send** command to configure this interface to transmit Link Layer Discovery Protocol (LLDP) packets or to control the types of information contained in the LLDP packets transmitted by this interface. Use the **no** form of this command to disable this feature. Variations of this command include:

lldp send management-address
lldp send port-description
lldp send system-capabilities
lldp send system-description
lldp send system-name
lldp send-and-receive

Syntax Description

management-address	Enables transmission of management address information on this interface.
port-description	Enables transmission of port description information on this interface.
system-capabilities	Enables transmission of this device's system capabilities on this interface.
system-description	Enables transmission of this device's system description on this interface.
system-name	Enables transmission of this device's system name on this interface.
and-receive	Configures this interface to both transmit and receive LLDP packets.

Default Values

By default, all interfaces are configured to transmit and receive LLDP packets of all types.

Command History

Release 9.1	Command was introduced.

Functional Notes

Individual LLDP information can be enabled or disabled using the various forms of the **lldp send** command. For example, use the **lldp send-and-receive** command to enable transmit and receive of all LLDP information. Then use the **no lldp send port-description** command to prevent LLDP from transmitting port description information.

Usage Examples

The following example configures the port channel interface to transmit LLDP packets containing all enabled information types:

(config)**#interface port-channel 1**
(config-p-chan1)**#lldp send**

The following example configures the port channel interface to transmit and receive LLDP packets containing all information types:

(config)**#interface port-channel 1**
(config-p-chan1)**#lldp send-and-receive**

qos

Use the **qos** command to set the interface to the trusted state and to set the default class of service (CoS) value. Use the **no** form of this command to return to the default setting. Variations of this command include:

qos default-cos <*value*>
qos trust cos

Syntax Description

default-cos <*value*>	Sets the default CoS value for untrusted ports and all untagged packets. Range is **0** to **7**.
trust cos	Sets the interface to the trusted state.

Default Values

By default, the interface is untrusted with a default CoS of **0**.

Command History

Release 5.1	Command was introduced.

Functional Notes

Set the interface to **trust cos** if received 802.1P. CoS values are considered valid (i.e., no need to reclassify) and do not need to be tagged with the default value. When set to untrusted, the **default-cos** value for the interface is used.

Usage Examples

The following example sets port channel 1 as a trusted interface and assigns untagged packets a CoS value of 1:

(config)**#interface port-channel 1**
(config-p-chan1)**#qos trust cos**
(config-p-chan1)**#qos default-cos 1**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.

Usage Examples

The following example enables SNMP capability on the port channel interface:

(config)**#interface port-channel 1**
(config-p-chan1)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release 17.2	Command was expanded to the cellular interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the port channel interface:

(config)**#interface port-channel 1**
(config-p-chan1)**#no snmp trap link-status**

spanning-tree bpdufilter

Use the **spanning-tree bpdufilter** command to enable or disable the bridge protocol data unit (BPDU) filter on a specific interface. This setting overrides the related global setting (refer to *spanning-tree edgeport default on page 1837*). Use the **no** form of this command to return to the default setting. Variations of this command include:

spanning-tree bpdufilter disable
spanning-tree bpdufilter enable

Syntax Description

disable	Disables BPDU filter for this interface.
enable	Enables BPDU filter for this interface.

Default Values

By default, this setting is disabled.

Command History

Release 5.1	Command was introduced.

Functional Notes

The bpdufilter blocks any BPDUs from being transmitted and received on an interface.

Usage Examples

The following example enables the BPDU filter on the port channel interface:

(config)**#interface port-channel 3**
(config-p-chan3)**#spanning-tree bpdufilter enable**

The BPDU filter can be disabled on port channel 3 by issuing the following commands:

(config)**#interface port-channel 3**
(config-p-chan3)**#spanning-tree bpdufilter disable**

spanning-tree bpduguard

Use the **spanning-tree bpduguard** command to enable or disable the bridge protocol data unit (BPDU) guard on a specific interface. This setting overrides the related global setting (refer to *spanning-tree edgeport default on page 1837*). Use the **no** form of this command to return to the default setting. Variations of this command include:

spanning-tree bpduguard disable
spanning-tree bpduguard enable

Syntax Description

disable	Disables BPDU guard for this interface.
enable	Enables BPDU guard for this interface.

Default Values

By default, this setting is disabled.

Command History

Release 5.1	Command was introduced.

Functional Notes

The bpduguard blocks any BPDUs from being received on an interface.

Usage Examples

The following example enables the BPDU guard on the port channel interface:

(config)**#interface port-channel 3**
(config-p-chan3)**#spanning-tree bpduguard enable**

The BPDU guard can be disabled on port channel 3 by issuing the following commands:

(config)**#interface port-channel 3**
(config-p-chan3)**#spanning-tree bpduguard disable**

spanning-tree cost <*value*>

Use the **spanning-tree cost** command to assign a cost to the interface. The cost value is used when computing the spanning-tree root path. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies a cost value of **1** to **200000000**.

Default Values

By default, the cost value is set to **1000**/(link speed in Mbps).

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example sets the interface to a path cost of **1200**:

(config)**#interface port-channel 3**
(config-p-chan3)**#spanning-tree cost 1200**

spanning-tree edgeport

Use the **spanning-tree edgeport** command to configure the interface to be an edgeport. This command overrides the global setting (refer to *spanning-tree edgeport default on page 1837*). Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, this setting is disabled.

Command History

Release 5.1	Command was introduced.
Release 8.1	Command was added to the ATM Subinterface command set.

Functional Notes

When an interface is designated as an edgeport, the interface will immediately go to a forwarding state when the link becomes active. When an interface is not designated as an edgeport, the interface must go through the listening and learning states before going to the forwarding state.

Usage Examples

The following example configures the interface to be an edgeport:

(config)**#interface port-channel 1**
(config-p-chan1)**#spanning-tree edgeport**

An individual interface can be configured to not be considered an edgeport. For example:

(config)**#interface port-channel 1**
(config-p-chan1)**#spanning-tree edgeport disable**

or

(config)**#interface port-channel 1**
(config-p-chan1)**#no spanning-tree edgeport**

spanning-tree link-type

Use the **spanning-tree link-type** command to configure the spanning tree protocol link type for each interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

spanning-tree link-type auto
spanning-tree link-type point-to-point
spanning-tree link-type shared

Syntax Description

auto	Determines link type by the port's duplex settings.
point-to-point	Manually sets link type to point-to-point regardless of duplex settings.
shared	Manually sets link type to shared regardless of duplex settings.

Default Values

By default, the interface is set to **auto**.

Command History

Release 5.1	Command was introduced.

Functional Notes

This command overrides the default link type setting determined by the duplex of the individual port. By default, a port configured for half-duplex is set to **shared** link type, and a port configured for full-duplex is set to **point-to-point** link type. Setting the link type manually overrides the default and forces the port to use the specified link type. Use the **link-type auto** command to restore the convention of determining link type based on duplex settings.

Usage Examples

The following example forces the link type to **point-to-point**, even if the port is configured to be half-duplex:

(config)**#interface port-channel 1**
(config-p-chan1)**#spanning-tree link-type point-to-point**

Technology Review

Rapid transitions are possible in Rapid Spanning Tree Protocol (RSTP) by taking advantage of point-to-point links (a port is connected to exactly one other bridge) and edge-port connections (a port is not connected to any additional bridges). Setting the link type to **point-to-point** allows a half-duplex link to act as if it were a point-to-point link.

spanning-tree port-priority <*value*>

Use the **spanning-tree port-priority** command to select the priority level of this interface. To return to the default setting, use the **no** form of this command.

Syntax Description

<*value*>	Specifies a priority-level value from **0** to **240** (this value must be in increments of 16).

Default Values

By default, the **spanning-tree port-priority** is set to **128**.

Command History

Release 5.1	Command was introduced.

Functional Notes

The only time that this priority level is used is when two interfaces with a path to the root have equal cost. At that point, the level set in this command will determine which port the spanning tree will use. Set the priority value lower to increase the chance the interface will be used.

Usage Examples

The following example sets the interface to a priority of **96**:

(config)**#interface port-channel 4**
(config-p-chan4)**#spanning-tree port-priority 96**

storm-control action shutdown

Use the **storm-control action shutdown** command to specify that the unit should shutdown when a broadcast, multicast, or unicast storm occurs. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled; the interface will only filter traffic.

Command History

Release 5.1	Command was introduced.

Functional Notes

Enabling this option shuts down the interface if a multicast, unicast, or broadcast storm occurs.

Usage Examples

The following example shuts down the port channel interface if a storm is detected:

(config)**#interface port-channel 1**
(config-p-chan1)**#storm-control action shutdown**

storm-control level

Use the **storm-control level** command to configure limits on the rates of broadcast, multicast, and unicast traffic on a port. Use the **no** form of this command to disable this feature. Variations of this command include:

storm-control broadcast level *<rising level>*
storm-control broadcast level *<rising level> <falling level>*
storm-control multicast level *<rising level>*
storm-control multicast level *<rising level> <falling level>*
storm-control unicast level *<rising level>*
storm-control unicast level *<rising level> <falling level>*

Syntax Description

broadcast level	Sets levels for broadcast traffic.
multicast level	Sets levels for multicast traffic.
unicast level	Sets levels for unicast traffic.
<rising level>	Specifies a rising level which determines the percentage of total bandwidth the port accepts before it begins blocking packets. Range is **1** to **100** percent.
<falling level>	Optional. Specifies a falling level which determines when the storm is considered over, causing AOS to no longer block packets. This level must be less than the rising level. Range is **1** to **100** percent.

Default Values

By default, **storm-control** is disabled.

Command History

Release 5.1	Command was introduced.

Functional Notes

This setting configures the rising and falling suppression values. When the selected rising level (which is a percentage of total bandwidth) is reached, the port begins blocking packets of the specified type (i.e., broadcast, multicast, or unicast). AOS uses the rising level as its falling level if no falling level is specified.

Usage Examples

The following example sets the rising suppression level to **85** percent for multicast packets:

(config)**#interface port-channel 1**
(config-p-chan1)**#storm-control multicast level 85**

The following example sets the rising suppression level to **80** percent for broadcast packets, with a falling level of **50** percent:

(config)**#interface port-channel 1**
(config-p-chan1)**#storm-control broadcast level 80 50**

storm-control rate

Use the **storm-control rate** command to configure maximum ingress data rates for broadcast, unknown multicast, and unknown unicast traffic on a switch port. Use the **no** form of this command to disable the feature. Variations of this command include:

storm-control broadcast rate <*rate*>
storm-control broadcast rate <*rate*> **burst** <*size*>
storm-control multicast-unknown rate <*rate*>
storm-control multicast-unknown rate <*rate*> **burst** <*size*>
storm-control unicast-unknown rate <*rate*>
storm-control unicast-unknown rate <*rate*> **burst** <*size*>

Syntax Description

broadcast	Specifies the maximum data rate for all ingress broadcast traffic.
multicast-unknown	Specifies the maximum data rate for ingress unknown multicast traffic.
unicast-unknown	Specifies the maximum data rate for ingress unknown unicast traffic.
rate <*rate*>	Specifies the maximum ingress data rate in Kilobytes per second. Valid range is **64** to **33554368** Kbps.
burst <*size*>	Optional. Specifies the maximum traffic burst (in bytes) of the specified traffic type that can ingress the port. Valid selections are **4K**, **16K**, **64K**, **256K**, **1M**, **4M**, **8M**, and **16M** bytes.

Default Values

By default, storm control is disabled. When enabled, the burst size is set to **64K** bytes by default.

Command History

Release R11.8.0	Command was introduced.

Functional Notes

Storm control is used to lessen the impacts of traffic flooding on certain ports.

Address Resolution Protocol (ARP), Dynamic Host Control Protocol (DHCP), and other protocols commonly use broadcasts, so setting the broadcast storm control rate too low can adversely impact these protocols in an otherwise healthy network.

The configured multicast storm control rate applies only to multicast traffic with addresses not learned by Internet Group Management Protocol (IGMP) snooping.

Unknown unicast traffic usually exist only for initial traffic to a client or traffic sent to a client that was unlearned or that timed out. Setting the unicast storm control rate too low can impact traffic to clients that actually exist but are temporarily unknown to the switch. Spanning tree topology change notifications (TCNs) clear the known unicast addresses on some ports of the switch and cause all unicast traffic from these clients to be unknown until the addresses are relearned. This behavior can cause the temporary rate of unknown unicast frames to spike. Switching networks that have relatively static topologies should use the spanning tree edge-port setting to limit spanning tree TCNs so that a lower storm control unicast rate can be set. If the network topology changes frequently, a larger unicast storm control rate should be set so that traffic is not adversely impacted after a spanning tree TCN.

All traffic is received on switchports at full line rate, meaning that the momentary rate of received traffic will almost always exceed any storm control rate configured lower than the port's linked rate. The configured burst size determines how many bytes can burst over the configured rate before storm control makes a decision to begin dropping traffic for a configured traffic type. A smaller storm control burst size causes the rate to be imposed on received frames earlier in the storm of undesired frames. Setting a higher burst rate is less likely to drop frames in case of many back-to-back frames, but also exposes the network to more of the initial frames of a storm of undesired frames. Once a burst is exhausted, it takes an interval of time to refill completely. This interval, in seconds, is defined as the (burst rate * 8)/rate.

When a switchport is part of a port channel, storm control settings are not allowed on the switchport. Rather, storm control rate and burst settings are only allowed on the port channel of which the switchport is a member.

Usage Examples

The following example configures broadcast traffic storm control with a rate of **1000** Kbps and the default burst size:

(config)**#interface port-channel 1**
(config-p-chan1)**#storm-control broadcast rate 1000**

switchport access vlan *<vlan id>*

Use the **switchport access vlan** command to set the port to be a member of the virtual local area network (VLAN) when in access mode. To reset the port to be a member of the default VLAN, use the **no** form of this command.

Syntax Description

<vlan id>	Specifies a valid VLAN interface ID. Range is **1** to **4094**.

Default Values

By default, this is set to VLAN 1 (the default VLAN).

Command History

Release 5.1	Command was introduced.

Functional Notes

If the port is in the trunk mode, this command will not alter the switchport mode to access. Instead, it will save the value to be applied when the port does switch to access mode. Refer to *switchport mode on page 3055* for more information.

Usage Examples

The following example sets the switchport mode to static access, and makes the port channel 1 a member of VLAN 2:

(config)**#interface port-channel 1**
(config-p-chan1)**#switchport mode access**
(config-p-chan1)**#switchport access vlan 2**

switchport gvrp

Use the **switchport gvrp** command to enable GARP VLAN Registration Protocol (GVRP) on an interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, GVRP is disabled on all ports.

Command History

Release 8.1	Command was introduced.

Functional Notes

Enabling GVRP on any interface enables GVRP globally.

Usage Examples

The following example enables GVRP on port channel 3:

```
(config)#interface port-channel 3
(config-p-chan3)#switchport gvrp
```

switchport mode

Use the **switchport mode** command to configure the virtual local area network (VLAN) membership mode. Use the **no** form of this command to reset membership mode to the default value. Variations of this command include:

switchport mode access
switchport mode trunk

Syntax Description

access	Sets port to be a single (nontrunked) port that transmits and receives no tagged packets.
trunk	Sets port to transmit and receive packets on all VLANs included within its VLAN allowed list.

Default Values

By default, this is set to **access**.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example sets the port to be a trunk port:

(config)**#interface port-channel 1**
(config-p-chan1)**#switchport mode trunk**

switchport trunk allowed vlan

Use the **switchport trunk allowed vlan** command to allow certain virtual local area networks (VLANs) to transmit and receive traffic on this port when the interface is in trunking mode. To return to the default setting, use the **no** form of this command. Variations of this command include:

switchport trunk allowed vlan <*list*>
switchport trunk allowed vlan add <*list*>
switchport trunk allowed vlan all
switchport trunk allowed vlan except <*list*>
switchport trunk allowed vlan remove <*list*>

Syntax Description

add	Adds the specified VLAN IDs to the VLAN trunking allowed list.
all	Adds all configured VLAN IDs to the VLAN trunking allowed list.
except	Adds all configured VLAN IDs to the VLAN trunking allowed list except those specified in the VLAN ID list.
remove	Removes VLAN IDs from the VLAN trunking allowed list.
<*list*>	Specifies a list of valid VLAN interface IDs. Refer to *Functional Notes* below for additional syntax considerations.

Default Values

By default, all valid VLANs are allowed.

Command History

Release 5.1	Command was introduced.

Functional Notes

A VLAN list is a set of VLAN IDs. A valid VLAN ID value must be from 1 to 4094 (inclusive). Each VLAN ID in a list is delimited by commas, yet a range of IDs may be expressed as a single element by using a hyphen between endpoints. For example, the VLAN ID range **1,2,3,4,6,7,8,9,500** may be more easily expressed as **1-4,6-9,500**. No spaces are allowed in a valid ID range.

Usage Examples

The following example adds VLANs to the previously existing list of VLANs allowed to transmit and receive on this port:

(config)**#interface port-channel 1**
(config-p-chan1)**#switchport trunk allowed vlan add 1-4,6-9,500**

switchport trunk fixed vlan

Use the **switchport trunk fixed vlan** command to change the configured list of virtual local area networks (VLANs) that remain fixed in use only when GARP VLAN Registration Protocol (GVRP) is enabled on the interface. Of these VLANs, VLANs statically or dynamically created will be available for use on the interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

switchport trunk fixed vlan *<list>*
switchport trunk fixed vlan add *<list>*
switchport trunk fixed vlan all
switchport trunk fixed vlan except *<list>*
switchport trunk fixed vlan none
switchport trunk fixed vlan remove *<list>*

Syntax Description

add	Adds VLANs to the VLAN GVRP trunking fixed list.
all	Adds all VLANs to the VLAN GVRP trunking fixed list.
except	Adds all VLAN IDs to the VLAN trunking fixed list except those in the command line VLAN ID list.
none	Removes all VLANs from the VLAN GVRP trunking fixed list.
remove	Removes VLAN from the VLAN trunking fixed list.
<list>	Specifies a list of valid VLAN interface IDs. Refer to *Functional Notes* below for additional syntax considerations.

Default Values

By default, no VLANs are in the VLAN GVRP trunking fixed list (**switchport trunk fixed vlan none**).

Command History

Release 8.1	Command was introduced.

Functional Notes

This command has no effect on VLAN membership configuration unless GVRP is enabled on the interface. Refer to *gvrp on page 1312* for information on enabling GVRP.

A VLAN list is a set of VLAN IDs. A valid VLAN ID value must be from 1 to 4094 (inclusive). Each VLAN ID in a list is delimited by commas, yet a range of IDs may be expressed as a single element by using a hyphen between endpoints. For example, the VLAN ID range **1,2,3,4,6,7,8,9,500** may be more easily expressed as **1-4,6-9,500**. No spaces are allowed in a valid ID range.

Usage Examples

The following example changes the configured list of fixed VLANs by adding VLAN 50 to the list:

(config-p-chan1)**#switchport trunk fixed vlan add 1-15,25-30,40**
(config-p-chan1)#
(config-p-chan1)**#switchport trunk fixed vlan add 50**
(config-p-chan1)#

switchport trunk native vlan <*vlan id*>

Use the **switchport trunk native vlan** command to set the virtual local area network (VLAN) native to the interface when the interface is in trunking mode. To return to defaults, use the **no** form of this command.

Syntax Description

<*vlan id*>	Specifies a valid VLAN interface ID. Range is **1** to **4094**.

Default Values

By default, **switchport trunk native vlan** is set to VLAN 1.

Command History

Release 5.1	Command was introduced.

Functional Notes

Configure which VLAN the interface uses as its native VLAN during trunking. Packets from this VLAN leaving the interface will not be tagged with the VLAN number. Any untagged packets received by the interface are considered a part of the native VLAN ID.

Usage Examples

The following example sets the native VLAN on port channel 1 to VLAN 2:

(config)**#interface port-channel 1**
(config-p-chan1)**#switchport trunk native vlan 2**

PPP INTERFACE COMMAND SET

To create a virtual Point-to-Point Protocol (PPP) interface and/or activate the PPP Interface Configuration mode, enter the **interface ppp** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface ppp 1
(config-ppp 1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

acfc accept-compressed on page 3062
alias link "<text>" on page 3063
bandwidth <value> on page 3064
bridge-group commands begin on page 3065
dial-backup commands begin on page 3067
dynamic-dns on page 3083
fair-queue on page 3085
hold-queue <value> out on page 3086
ip commands begin on page 3087
ipv6 commands begin on page 3132
keepalive <value> on page 3168
lldp receive on page 3169
lldp send on page 3170
max-reserved-bandwidth <value> on page 3172
media-gateway ip on page 3173
media-gateway ipv6 on page 3175
ospfv3 commands begin on page 3177
peer default ip address <ipv4 address> on page 3190
peer default ipv6 interface-id <interface id> on page 3191

acfc accept-compressed

Use the **acfc accept-compressed** command to enable accepting header compressed frames even if compression is not negotiated. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release 14.1	Command was introduced.

Usage Examples

The following example enables accepting compressed frames:

(config)**#interface ppp 1**
(config-ppp 1)**#acfc accept-compressed**

alias link “*<text>*”

Use the **alias link** command to provide the management station with an identifying description for each link (Point-to-Point Protocol (PPP) physical). Each configured PPP interface (when referenced using Simple Network Management Protocol (SNMP)) contains a link (physical port) and a bundle (group of links). RFC 1471 (for Link Connection Protocol) provides an interface table to manage lists of bundles and associated links. Use the **no** form of this command to return to the default setting.

Syntax Description

“<text>”	Describes the interface (for SNMP) by alphanumeric character string (must be encased in quotation marks).

Default Values

By default, the PPP identification string appears as empty quotation marks (“ ”).

Command History

Release 1.1	Command was introduced.

Functional Notes

The **alias link** string should be used to uniquely identify a PPP link. Enter a string that clearly identifies the link.

Usage Examples

The following example defines a unique character string for the virtual PPP interface (1):

(config)**#interface ppp 1**
(config-ppp 1)**#alias link “PPP_link_1”**

Technology Review

Please refer to RFC 1990 for a more detailed discussion on PPP links and bundles.

bandwidth <*value*>

Use the **bandwidth** command to provide the bandwidth value of an interface to the higher level protocols. This value is used in cost calculations. Use the **no** form of this command to restore the default value.

Syntax Description

<*value*>	Specifies the bandwidth value in kbps. Range is **1** to **4294967295** kbps.

Default Values

To view the default values, use the **show interfaces** command.

Command History

Release 3.1	Command was introduced.

Functional Notes

The **bandwidth** command is an informational value that is communicated to the higher level protocols to be used in cost calculations. While this is a routing parameter that does not affect the physical interface, it does affect the amount of bandwidth available for use in Quality of Service (QoS) configurations.

It is important to note that there is an order of precedence in determining the interface bandwidth reported by the router for QoS. Under normal circumstances, the Layer 1 bandwidth is reported based on the interface type. For example, a T1 interface will report the available bandwidth as 1.536 Mbps. This can be misleading in QoS configurations if the **bandwidth** command has been applied to the IP interface for routing purposes because the command overrides the reported available bandwidth that can be utilized for QoS. Using the **bandwidth** command can severely disrupt the configuration of QoS on the interface, therefore, use the **max-reserved-bandwidth** command (*page 3172*) to adjust the bandwidth appropriately for QoS configurations.

Usage Examples

The following example sets bandwidth of the Point-to-Point Protocol (PPP) interface to 10 Mbps:

(config)**#interface ppp 1**
(config-ppp 1)**#bandwidth 10000**

bridge-group *<number>*

Use the **bridge-group** command to assign an interface to the specified bridge group. This command is supported on all Ethernet interfaces, Point-to-Point Protocol (PPP) virtual interfaces, and Frame Relay virtual subinterfaces. Use the no form of this command to remove an interface.

Syntax Description

<number>	Specifies the bridge group (by number) to which to assign this interface. Range is **1** to **255**.

Default Values

By default, there are no configured bridge groups.

Command History

Release 1.1	Command was introduced.

Functional Notes

A bridged network can provide excellent traffic management to reduce collisions and limit the amount of bandwidth wasted with unnecessary transmissions when routing is not necessary. Any two interfaces can be bridged (Ethernet to T1 bridge, Ethernet to Frame Relay subinterface, etc.).

Usage Examples

The following example assigns the PPP interface to **bridge-group 1**:

(config)**#interface ppp 1**
(config-ppp 1)**#bridge-group 1**

bridge-group <*number*> vlan-transparent

Use the **bridge-group vlan-transparent** command to prevent an interface from removing the virtual local area network (VLAN) tag. Use the **no** form of this command to allow the interface to remove the VLAN tag from the packet.

*The **bridge-group vlan-transparent** command is not a global command. The command must be applied on all interfaces of the bridge group.*

Syntax Description

<number>	Specifies the bridge group number. Valid range is **1** to **255**.

Default Values

By default, VLAN tags are removed from the data.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the high level data link control (HDLC) interface and Frame Relay subinterface.

Usage Examples

The following example prevents the removal of VLAN tags from the packets on the Point-to-Point Protocol (PPP) interface labeled 1:

(config)**#interface ppp 1**
(config-ppp 1)**#bridge-group 1 vlan-transparent**

dial-backup auto-backup

Use the **dial-backup auto-backup** command to configure the interface to automatically attempt a dial backup upon failure. Use the **no** form of this command to disable this feature. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 3070*.

Syntax Description

No subcommands.

Default Values

By default, all backup endpoints will automatically attempt dial backup upon a failure.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example enables automatic dial backup on the endpoint:

(config)**#interface ppp 1**
(config-ppp 1)**#dial-backup auto-backup**

dial-backup auto-restore

Use the **dial-backup auto-restore** command to configure the interface to automatically discontinue dial backup when all network conditions are operational. Use the **no** form of this command to disable the auto-restore feature. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 3070*.

Syntax Description

No subcommands.

Default Values

By default, all backup endpoints will automatically restore the primary connection when the failure condition clears.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to automatically restore the primary connection when the failure condition clears:

(config)**#interface ppp 1**
(config-ppp 1)**#dial-backup auto-restore**

dial-backup backup-delay *<value>*

Use the **dial-backup backup-delay** command to configure the amount of time the router will wait after the failure condition is recognized before attempting to backup the link. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 3070*.

Syntax Description

<value>	Specifies the delay period (in seconds) a failure must be active before AOS will enter backup operation on the interface. Range is **10** to **86400** seconds.

Default Values

By default, the **dial-backup backup-delay** period is set to **10** seconds.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to wait **60** seconds (on an endpoint with an active alarm condition) before attempting dial-backup operation:

(config)**#interface ppp 1**
(config-ppp 1)**#dial-backup backup-delay 60**

dial-backup call-mode

Use the **dial-backup call-mode** command to specify whether the configured backup interface answers or originates (or a combination of both) backup calls. Use the **no** form of this command to return to the default value. Variations of this command include:

dial-backup call-mode answer
dial-backup call-mode answer-always
dial-backup call-mode originate
dial-backup call-mode originate-answer
dial-backup call-mode originate-answer-always

Syntax Description

answer	Answers and backs up primary link on failure.
answer-always	Answers and backs up regardless of primary link state.
originate	Originates backup call on primary link failure.
originate-answer	Originates or answers call on primary link failure.
originate-answer-always	Originates on failure; answers and backs up always.

Default Values

By default, the **dial-backup call-mode** is set to **originate-answer**.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Functional Notes

The majority of the configuration for AOS dial-backup implementation is configured via the dial-backup PPP interface configuration commands. However, the numbers dialed are configured in the primary interface. Full sample configurations follow:

Sample configuration for remote router (dialing out)

```
hostname “Remote3200”
enable password adtran
!
interface eth 0/1
 ip address 192.168.1.254 255.255.255.0
 no shutdown
!
interface modem 1/3
 no shutdown
!
interface t1 1/1
```

```
 coding b8zs
 framing esf
 clock source line
 tdm-group 1 timeslots 1-24
 no shutdown
!
interface fr 1 point-to-point
 frame-relay lmi-type ansi
 no shutdown
 cross-connect 1 t1 1/1 1 fr 1
!
interface fr 1.16 point-to-point
 frame-relay interface-dlci 16
 ip address 10.1.1.2 255.255.255.252
 dial-backup call-mode originate
 dial-backup number 5551111 analog ppp1
 dial-backup number 5552222 analog ppp1
no shutdown
!
interface ppp 1
 ip address 172.22.56.1 255.255.255.252
 ppp authentication chap
 username remoter outer password remotepass
 ppp chap hostname localrouter
 ppp chap password adtran
 no shutdown
!
ip route 192.168.2.0 255.255.255.0 172.22.56.2 255.255.255.252
!
line telnet 0 4
 password password
```

Sample configuration for central router (dialing in)

```
hostname “Central3200”
enable password adtran
!
interface eth 0/1
 ip address 192.168.100.254 255.255.255.0
 no shutdown
!
interface modem 1/3
 no shutdown
!
interface t1 1/1
 coding b8zs
 framing esf
 clock source line
```

```
 tdm-group 1 timeslots 1-24
 no shutdown
!
interface fr 1 point-to-point
 frame-relay lmi-type ansi
 no shutdown
 cross-connect 1 t1 1/1 1 fr 1
!
interface fr 1.100 point-to-point
 frame-relay interface-dlci 100
 ip address 10.1.1.1 255.255.255.252
 dial-backup call-mode answer
 dial-backup number 555-8888 analog ppp 1
!
interface ppp 1
 ip address 172.22.56.2 255.255.255.252
 ppp authentication chap
 username localrouter password adtran
 ppp chap hostname remoterouter
 ppp chap password remotepass
 no shutdown
!
ip route 192.168.1.0 255.255.255.0 172.22.56.1 255.255.255.252

line telnet 0 4
 password password
```

Usage Examples

The following example configures AOS to generate backup calls for this endpoint using an analog modem interface (to phone number 555 1111), but never answer calls and specifies **ppp 2** as the backup interface:

```
(config)#interface ppp 1
(config-ppp 1)#dial-backup call-mode originate
(config-ppp 1)#dial-backup number 555 1111 analog ppp 2
```

Technology Review

This technology review provides information regarding specific dial-backup router behavior (i.e., when the router will perform dial backup, where in the configuration AOS accesses specific routing information, etc.):

Dialing Out

1. AOS determines to place an outbound call when either the Layer 1 or Layer 2 has a failure.
2. When placing outbound calls, AOS matches the number dialed to a PPP interface. This is accomplished with an addition to the **dial-backup number** command (refer to *dial-backup number <number> on page 3077*).
3. When placing the call, AOS uses the configuration of the related PPP interface for authentication and IP negotiation.
4. If the call fails to connect on the first number dialed, AOS places a call to the second number (if a second number is configured). The second number to be dialed references a separate PPP interface.

Dialing In

1. AOS receives an inbound call on a physical interface.
2. Caller ID is used to match the **dial-backup number** command to the configured PPP interface.
3. If a match is found, the call connects and AOS pulls down the primary connection if it is not already in a down state.
4. If no match is found from caller ID, the call is terminated.

dial-backup connect-timeout <*value*>

Use the **dial-backup connect-timeout** command to specify the number of seconds to wait for a connection after a call is attempted before trying to call again or dialing a different number. It is recommended this number be greater than 60. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 3070*.

Syntax Description

<*value*>	Selects the amount of time (in seconds) that the router will wait for a connection before attempting another call. Valid range is **10** to **300** seconds.

Default Values

By default, the **dial-backup connect-timeout** period is set to **60** seconds.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to wait **120** seconds before retrying a failed dial-backup call:

(config)**#interface ppp 1**
(config-ppp 1)**#dial-backup connect-timeout 120**

dial-backup force

Use the **dial-backup force** command to manually override the automatic dial-backup feature. This can be used to force a link into backup to allow maintenance to be performed on the primary link without disrupting data. Use the **no** form of this command to return to the normal dial-backup operation state. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3070*. Variations of this command include:

dial-backup force backup
dial-backup force primary

Syntax Description

backup	Forces backup regardless of primary link state.
primary	Forces primary link regardless of its state.

Default Values

By default, this feature is disabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to force this interface into dial backup:

(config)**#interface ppp 1**
(config-ppp 1)**#dial-backup force backup**

dial-backup maximum-retry <*value*>

Use the **dial-backup maximum-retry** command to select the number of calls the router will make when attempting to backup a link. Use the **no** form of this command to return to the default state. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3070*.

Syntax Description

<*value*>	Selects the number of call retries that will be made after a link failure. Valid range is **0** to **15** attempts. Setting this value to **0** will allow unlimited retries during the time the network is failed.

Default Values

By default, **dial-backup maximum-retry** is set to **0** attempts.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to retry a dial-backup call four times before considering backup operation not available:

(config)**#interface ppp 1**
(config-ppp 1)**#dial-backup maximum-retry 4**

dial-backup number <*number*>

Use the **dial-backup number** command to configure the phone number and the call type the router will dial upon network failure. Multiple entries can be made for an interface to allow alternate sites to be dialed. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3070*. Variations of this command include:

dial-backup number <*number*> **analog ppp** <*interface*>
dial-backup number <*number*> **digital-56k** <*isdn min chan*> <*isdn max chan*> **ppp** <*interface*>
dial-backup number <*number*> **digital-64k** <*isdn min chan*> <*isdn max chan*> **ppp** <*interface*>

Syntax Description

<*number*>	Specifies the phone numbers to call when the backup is initiated.
analog	Indicates the number connects to an analog modem.
digital-56k	Indicates the number belongs to a digital 56 kbps per DS0 connection.
digital-64k	Indicates the number belongs to a digital 64 kbps per DS0 connection.
<*isdn min chan*>	Specifies the minimum number of DS0s required for a digital 56 or 64 kbps connection. Range is **1** to **24** DS0s.
<*isdn max chan*>	Specifies the maximum number of DS0s desired for a digital 56 or 64 kbps connection. Range is **1** to **24** DS0s.
ppp <*interface*>	Specifies the Point-to-Point Protocol (PPP) interface to use as the backup for this interface (for example, **ppp 1**).

Default Values

By default, there are no configured dial-backup numbers.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the PPP interface.
Release 17.2	Command was expanded to include the cellular connections.
Release 17.3	Cellular connections were removed from this command.

Usage Examples

The following example configures AOS to dial **704-555-1212** (digital 64 kbps connection) to initiate dial-backup operation for this endpoint using interface **ppp 3** backup interface:

(config)**#interface ppp 1**
(config-ppp 1)**#dial-backup number 7045551212 digital-64k 1 1 ppp 3**

dial-backup priority <*value*>

Use the **dial-backup priority** command to select the backup priority for this interface. This allows the user to establish the highest priority backup link and ensure that link will override backups attempted by lower priority links. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3070*.

Syntax Description

<*value*>	Sets the relative priority of this link. Valid range is **0** to **100**. A value of 100 designates the highest priority.

Default Values

By default, **dial-backup priority** is set to **50**.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example assigns the highest priority to this endpoint:

(config)**#interface ppp 1**
(config-ppp 1)**#dial-backup priority 100**

dial-backup randomize-timers

Use the **dial-backup randomize-timers** command to randomize the call timers to minimize potential contention for resources. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3070*.

Syntax Description

No subcommands.

Default Values

By default, AOS does not randomize the dial-backup call timers.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to randomize the dial-backup timers associated with this endpoint:

(config)**#interface ppp 1**
(config-ppp 1)**#dial-backup randomize-timers**

dial-backup redial-delay <*value*>

Use the **dial-backup redial-delay** command to configure the delay after an unsuccessful call until the call will be re-tried. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3070*.

Syntax Description

<*value*>	Specifies the delay in seconds between attempting to redial a failed backup attempt. Range is **10** to **3600** seconds.

Default Values

By default, **dial-backup redial-delay** is set to **10** seconds.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures a redial delay of **25** seconds on this endpoint:

(config)**#interface ppp 1**
(config-ppp 1)**#dial-backup redial-delay 25**

dial-backup restore-delay *<value>*

Use the **dial-backup restore-delay** command to configure the amount of time the router will wait after the network is restored before disconnecting the backup link and reverting to the primary. This setting is used to prevent disconnecting the backup link if the primary link is bouncing in and out of alarm. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3070*.

Syntax Description

<value>	Specifies the number of seconds AOS will wait (after a primary link is restored) before disconnecting dial-backup operation. Range is **10** to **86400** seconds.

Default Values

By default, **dial-backup restore-delay** is set to **10** seconds.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to wait **30** seconds before disconnecting dial-backup operation and restoring the primary connection for this endpoint:

(config)**#interface ppp 1**
(config-ppp 1)**#dial-backup restore-delay 30**

dial-backup schedule

Use the **dial-backup schedule** command to set the time of day that backup will be enabled. Use this command if backup is desired only during normal business hours and on specific days of the week. Use the **no** form of this command to disable dial backup (as specified). For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3070*. Variations of this command include:

dial-backup schedule day <*name*>
dial-backup schedule disable-time <*value*>
dial-backup schedule enable-time <*value*>

Syntax Description

day <*name*>	Sets the days to allow backup. Valid range is Monday through Sunday.
disable-time <*value*>	Sets the time of day to disable backup. Time is entered in a 24-hour format (00:00).
enable-time <*value*>	Sets the time of day to enable backup. Time is entered in a 24-hour format (00:00).

Default Values

By default, dial backup is enabled for all days and times if the **dial-backup auto-backup** command has been issued and the dial-backup schedule has not been entered.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example enables dial backup Monday through Friday 8:00 a.m. to 7:00 p.m.:

(config)**#interface ppp 1**
(config-ppp 1)**#dial-backup schedule enable-time 08:00**
(config-ppp 1)**#dial-backup schedule disable-time 19:00**
(config-ppp 1)**#no dial-backup schedule day Saturday**
(config-ppp 1)**#no dial-backup schedule day Sunday**

dynamic-dns

Use the **dynamic-dns** command to configure Dynamic DNS service provided by Dynamic Network Services, Inc. (www.dyndns.org). Use the **no** form of this command to disable this feature. Variations of this command include:

dynamic-dns custom <*hostname*> <*minutes*>
dynamic-dns dyndns <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-custom <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-static <*hostname*> <*username*> <*password*>

Syntax Description

<*hostname*>	Specifies the host name for the server that updates the dynamic domain naming system (DNS).
<*minutes*>	Specifies the intervals in minutes to update the server with information (updates also occur when the interface's IP address changes regardless of the update intervals).
<*username*>	Specifies a user name using an alphanumerical string up to 30 characters in length (the user name is case sensitive).
<*password*>	Specifies a password using an alphanumerical string up to 30 characters in length (the password is case sensitive). Refer to *Functional Notes* below for additional argument descriptions.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.
Release 12.1	Command was expanded.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

custom - Constanttime.com's Custom Dynamic DNS^{SM} service allows you complete access and management control over your domain name regardless of where you purchased/registered it. This allows you to manage IP address mappings (A records), domain aliases (CNAME records), and mail servers (mail exchange (MX) records).

dyndns - The Dynamic DNS^{SM} offered by Dynamic Network Services, Inc. (DynDNS.org) allows you to alias a dynamic IP address to a static host name in various domains. This allows your unit to be more easily accessed from various locations on the Internet. This service is provided for up to five host names.

dyndns-custom - DynDNS.org's Custom DNS^{SM} service provides a full DNS solution, giving you complete control over an entire domain name. A Web-based interface provides two levels of control over your domain, catering to average or advanced users. Five globally redundant DNS servers ensure that your domain will always resolve.

A choice of two interfaces is available. The basic interface is designed for most users. It comes preconfigured for most common configurations and allows for easy creation of most common record types. The advanced interface is designed for system administrators with a solid DNS background, and provides layout and functionality similar to a BIND zone file allowing for the creation of nearly any record type.

Custom DNS^{SM} can be used with both static and dynamic IPs, and has the same automatic update capability through Custom DNS-aware clients as Dynamic DNS.

dyndns-static - The Static DNS service is similar to DynDNS.org's Dynamic DNS^{SM} service in that it allows a host name, such as yourname.dyndns.org, to point to your IP address. Unlike a Dynamic DNS host, a Static DNS host does not expire after 35 days without updates, but updates take longer to propagate through the DNS system. This service is provided for up to five host names.

If your IP address does not change often or at all, but you still want an easy name to remember it by (without having to purchase your own domain name), Static DNS service is ideal for you.

If you would like to use your own domain name (such as yourname.com), you need Custom DNS service that also provides full dynamic and static IP address support.

Usage Examples

The following example sets the Dynamic DNS to **dyndns-custom** with host name **host**, user name **user**, and password **pass**:

(config)**#interface ppp 1**
(config-ppp 1)**#dynamic-dns dyndns-custom host user pass**

fair-queue

Use the **fair-queue** command to enable weighted fair queuing (WFQ) on an interface. Use the **no** form of this command to disable WFQ and enable first in, first out (FIFO) queueing for an interface. Variations of this command include:

fair-queue
fair-queue <*threshold*>

WFQ must be enabled on an interface to use priority queuing. By default, WFQ is enabled for all interfaces with maximum bandwidth speeds equivalent to T1/E1 and below.

Syntax Description

<*threshold*>	Optional. Specifies the maximum number of packets that can be present in each conversation subqueue. Packets received for a conversation after this limit is reached are discarded. Range is **16** to **512** packets.

Default Values

By default, **fair-queue** is enabled with a threshold of **64** packets.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example enables WFQ on the interface with a threshold set at **100** packets:

(config)**#interface ppp 1**
(config-ppp 1)**#fair-queue 100**

hold-queue <*value*> out

Use the **hold-queue out** command to change the overall size of an interface's wide area network (WAN) output queue. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the total number of packets the output queue can contain before packets are dropped. Range is **16** to **1000** packets.

Default Values

The default queue size for weighted fair queuing (WFQ) is **400**. The default queue size for Point-to-Point Protocol (PPP) first in, first out (FIFO) and Frame Relay round-robin is **200**.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example sets the overall output queue size to **700**:

(config)**#interface ppp 1**
(config-ppp 1)**#hold-queue 700 out**

ip access-group *<ipv4 acl name>*

Use the **ip access-group** command to apply an Internet Protocol version 4 (IPv4) access control list (ACL) to be used for IPv4 packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ip access-group *<ipv4 acl name>* **in**
ip access-group *<ipv4 acl name>* **out**

Syntax Description

<ipv4 acl name>	Applies the named IPv4 ACL to the interface.
in	Enables access control on IPv4 packets received on the specified interface.
out	Enables access control on IPv4 packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

When this command is enabled, the IPv4 destination address of each packet must be validated before being passed through. If the packet is not acceptable per these settings, it is dropped.

Usage Examples

The following example configures the router to only allow IPv4 Telnet traffic (as defined in the user-configured **TelnetOnly** ACL) into the PPP interface:

(config)**#ip access-list extended TelnetOnly**
(config-ext-nacl)**#permit tcp any any eq telnet**
(config-ext-nacl)**#interface ppp 1**
(config-ppp 1)**#ip access-group TelnetOnly in**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to an interface. IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

> NOTE *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an interface.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the Ethernet interface 0/1:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ip access-policy PRIVATE**

ip address dhcp

Use the **ip address dhcp** command to use Dynamic Host Configuration Protocol (DHCP) to obtain an address on the interface. Use the **no** form of this command to remove a configured IP address (using DHCP) and disable DHCP operation on the interface. Variables that may be used with this command to further define the DHCP configuration include:

ip address dhcp class-id [ascii *<string>* **| hex** *<value>***] [client-id [***<interface>* **|** *<identifier>***]] [hostname** *<"string">***] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp client-id [*<interface>* **|** *<identifier>***] [hostname** *<"string">***] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp hostname *"<string>"* **[no-default-route | no-domain-name | no-nameservers] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp [no-default-route | no-domain-name | no-nameservers] [track *<name>***] [***<administrative distance>***]**
ip address dhcp track *<name>* **[***<administrative distance>***]**

Syntax Description

<administrative distance>	Optional. Specifies the administrative distance to use when adding the DHCP gateway into the route table. It is used to determine the best route when multiple routes to the same destination exist. The lower the administrative distance, the more reliable the route. Range is **1** to **255**.
class-id	Optional. Specifies the vendor class identifier for the interface.
ascii *<string>*	Specifies the vendor class identifier in an ASCII string of up to **255** bytes.
hex *<value>*	Specfies the vendor class identifier in hexadecimal format. Valid range is up to **510** hexadecimal numbers. An even number of digits is required.
client-id	Optional. Specifies the client identifier used when obtaining an IP address from a DHCP server.
<interface>	Specifies an interface, thus defining the client identifier as the hexadecimal medium access control (MAC) address of the specified interface (including a hexadecimal number added to the front of the MAC address to identify the media type). For example, specifying the **client-id ethernet 0/1** (where the Ethernet interface has a MAC address of d217.0491.1150) defines the client identifier as **01:d2:17:04:91:11:50** (where 01 defines the media type as Ethernet). Refer to *hardware-address on page 4344* for a detailed listing of media types.
<identifier>	Specifies a custom client-identifier using a text string (that is converted to a hexadecimal equivalent) or 7 to 28 hexadecimal numbers (with colon delimiters). For example, a custom client identifier of **0f:ff:ff:ff:ff:51:04:99:a1** may be entered using the *<identifier>* option.
hostname *<"string">*	Optional. Specifies a text string (to override the global router name) to use as the name in the DHCP option 12 field. The string is enclosed in quotation marks and can consist of up to 35 characters.

no-default-route Optional. Specifies that no default route is obtained via DHCP.

no-domain-name Optional. Specifies that no domain name is obtained via DHCP.

no-nameservers Optional. Specifies that no domain naming system (DNS) servers are obtained via DHCP.

track *<name>* Optional. Attaches a network monitoring track to the DHCP client. The DHCP gateway route for this client will only reside in the route table while the track is in the pass state. For more information on configuring track objects, refer to *track <name> on page 1886*.

Default Values

<administrative distance> By default, the administrative distance value is 1.

class-id Optional. By default, no vendor class identifier is configured.

client-id Optional. By default, the client identifier is populated using the following formula:

TYPE: INTERFACE SPECIFIC INFO : MAC ADDRESS

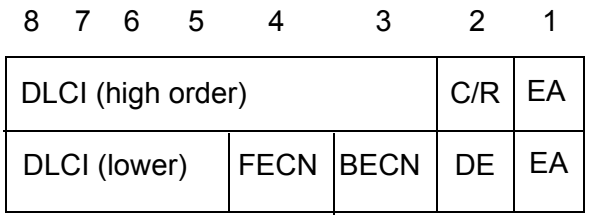
Where TYPE specifies the media type in the form of one hexadecimal byte (refer to *hardware-address on page 4344* for a detailed listing of media types), and the MAC ADDRESS is the medium access control (MAC) address assigned to the first Ethernet interface in the unit in the form of six hexadecimal bytes. (For units with a single Ethernet interface, the MAC ADDRESS assigned to Ethernet 0/1 is used in this field.)

INTERFACE SPECIFIC INFO is only used for Frame Relay interfaces and can be determined using the following:

FR_PORT#: Q.922 ADDRESS

Where the FR_PORT# specifies the label assigned to the virtual Frame Relay interface using four hexadecimal bytes. For example, a virtual Frame Relay interface labeled 1 would have a FR_PORT# of 00:00:00:01.

The Q.922 ADDRESS field is populated using the following:



Where the FECN, BECN, C/R, DE, and high order extended address (EA) bits are assumed to be 0 and the lower order EA bit is set to 1.

The following list provides a few example DLCIs and associated Q.922 address:

DLCI (decimal) / Q.922 address (hex)

16 / 0x0401
50 / 0x0C21
60 / 0x0CC1
70 / 0x1061
80 / 0x1401

hostname *"<string>"* By default, the host name is the name configured using the Global Configuration **hostname** command.

Command History

Release 2.1	Command was introduced.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 13.1	Command was expanded to include the track and administrative distance.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.10.0	Command was expanded to include the **class-id** parameter in support of DHCP Option 60.

Functional Notes

DHCP allows interfaces to acquire a dynamically assigned IP address from a configured DHCP server on the network. Many service providers require the use of DHCP when connecting to their services. Using DHCP reduces the number of dedicated IP addresses the ISP must obtain. Consult your ISP to determine the proper values for the **client-id** and **hostname** fields.

The vendor class identifier is sent to the DHCP server in DHCP discover and request messages via DHCP Option 60. This option gives the DHCP server details regarding DHCP client configuration and also allows the server to send any vendor-specific information to the client in DHCP offer messages via Option 43.

Usage Examples

The following example enables DHCP operation on the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ip address dhcp**

The following example enables DHCP operation on the interface utilizing host name **adtran** and does not allow obtaining a default route, domain name, or name servers. It also sets the administrative distance as **5**:

(config)**#interface ppp 1**
(config-ppp 1)**#ip address dhcp hostname "adtran" no-default-route no-domain-name no-nameservers 5**

ip address negotiated

Use the **ip address negotiated** command to allow the interface to negotiate (i.e., be assigned) an IP address from the far-end Point-to-Point Protocol (PPP) connection. Use the **no** form of this command to disable the negotiation for an IP address. Variations of this command include:

ip address negotiated
ip address negotiated <*administrative distance*>
ip address negotiated <*ip address*>
ip address negotiated <*ip address*> **no-default**
ip address negotiated track <*name*>
ip address negotiated track <*name*> <*administrative distance*>

Syntax Description

<*administrative distance*>	Optional. Specifies the administrative distance to use when adding the PPP route to the route table. It is used to determine the best route when multiple routes to the same destination exist. The lower the administrative distance, the more reliable the route. Range is **1** to **255**.
<*ip address*>	Optional. Specifies a valid IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
no-default	Optional. Prevents the insertion of a default route. Some systems already have a default route configured and need a static route to the PPP interface to function correctly.
track <*name*>	Optional. Attaches a network monitoring track to the PPP interface. The negotiated default route for this client will only reside in the route table while the track is in the pass state. For more information on configuring track objects, refer to *track <name> on page 1886*.

Default Values

By default, the interface is not assigned an address.

Also by default, the administrative distance value is **1**.

Command History

Release 5.1	Command was introduced.
Release 13.1	Command was expanded to include the track and administrative distance.

Usage Examples

The following example enables the PPP interface to negotiate an IP address from the far-end connection:

(config)**#interface ppp 1**
(config-ppp 1)**#ip address negotiated**

The following example enables the PPP interface to negotiate an IP address from the far-end connection without inserting a default route:

(config)**#interface ppp 1**
(config-ppp 1)**#ip address negotiated no-default**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the specified interface (only one primary address is allowed). Use the optional **secondary** keyword to define a secondary IPv4 address. Use the **no** form of this command to remove a configured IPv4 address. Variations of this command include:

ip address <*ipv4 address*> <*subnet mask*>
ip address <*ipv4 address*> <*subnet mask*> **secondary**

Syntax Description

<*ipv4 address*>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*subnet mask*>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the specified interface.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IP addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a secondary IPv4 address of **192.22.72.101 /30**:

(config)**#interface ppp 1**
(config-ppp 1)**#ip address 192.22.72.101 /30 secondary**

ip address range *<start ip address> <end ip address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the specified interface. Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#interface ppp 1**
(config-ppp 1)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip crypto map *<name>*

Use the **ip crypto map** command to associate Internet Protocol version 4 (IPv4) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

When you apply a map to an interface, you are applying all crypto maps with the given map name. This allows you to apply multiple crypto maps if you have created maps that share the same name, but have different map index numbers.

Syntax Description

<name>	Specifies the IPv4 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

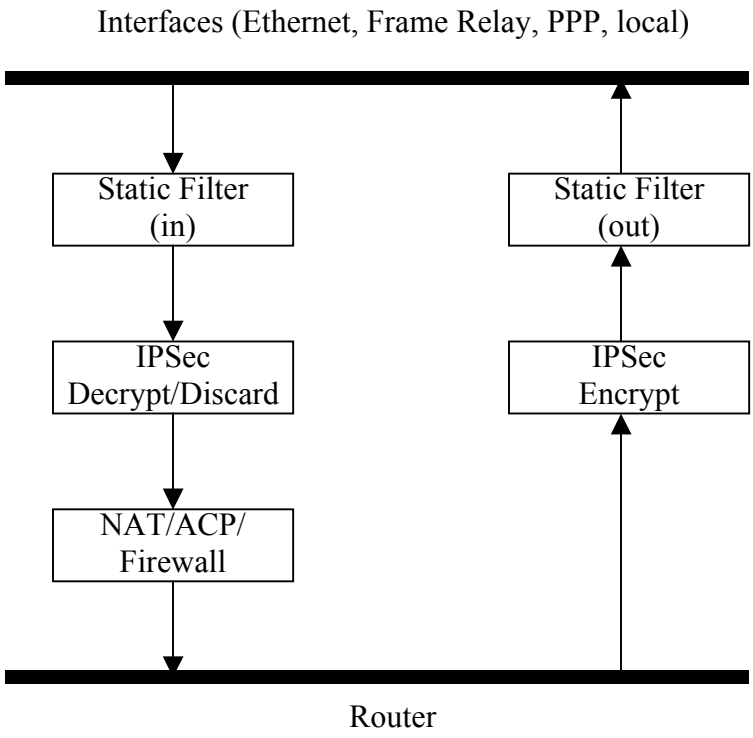
Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 9.1	Command was expanded to include the High-Levell Data Link Control (HDLC) interface.
Release 11.1	Command was expanded to include the demand interface.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.7.0	Command syntax was changed to require the **ip** keyword.

Functional Notes

When configuring a system to use both the stateful inspection firewall and Internet key exchange (IKE) negotiation for VPN, keep the following notes in mind.

When defining the IPv4 policy class and associated access control lists (ACLs) that describe the behavior of the IPv4 firewall, do not forget to include the traffic coming into the system over a VPN tunnel terminated by the system. The firewall should be set up with respect to the unencrypted traffic that is destined to be sent or received over the VPN tunnel. The following diagram represents typical AOS data-flow logic.



As shown in the diagram above, data coming into the product is first processed by the static filter associated with the interface on which the data is received. This access group is a true static filter and is available for use regardless of whether the IPv4 firewall is enabled or disabled. Next (if the data is encrypted), it is sent to the IPSec engine for decryption. The decrypted data is then processed by the stateful inspection firewall. Therefore, given a terminating VPN tunnel, only unencrypted data is processed by the firewall.

The IPv4 ACLs for a crypto map on an interface work in reverse logic to the ACLs for a policy class on an interface. When specifying the ACLs for a crypto map, the source information is the private local side, unencrypted source of the data. The destination information will be the far-end, unencrypted destination of the data. However, ACLs for a policy class work in reverse. The source information for the ACL in a policy class is the far end. The destination information is the local side.

Usage Examples

The following example applies all IPv4 crypto maps with the name **MyMap** to the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ip crypto map MyMap**

ip dhcp relay destination *<ipv4 address>*

Use the **ip dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 4 (IPv4) and to specify the IPv4 address for the DHCPv4 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv4 relay functionality is disabled on the interface.

Syntax Description

<ipv4 address>	Specifies the IPv4 address for the DHCPv4 messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**)..

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.

Usage Examples

The following example enables DHCPv4 relay agent functionality and specifies the destination address as **192.33.4.251**:

(config)**#interface ppp 1**
(config-ppp 1)**#ip dhcp relay destination 192.33.4.251**

ip directed-broadcast

Use the **ip directed-broadcast** command to allow reception/forwarding of directed broadcasts. Use the **no** form of this command to disable this feature. Variations of this command include:

ip directed-broadcast
ip directed-broadcast <*name*>

Syntax Description

<*name*>	Specifies IP access control list (ACL) name.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.

Functional Notes

A directed broadcast is a packet intended for all nodes on a nonlocal network. For example, the broadcast address 255.255.255.255 reaches all nodes on a network; the directed broadcast address 128.1.255.255 is intended for all nodes whose network address is 128.1.0.0. A router not directly attached to 128.1.0.0 simply forwards the directed broadcast packet to the next hop. A router on network 128.1.0.0 that has **ip directed-broadcast** enabled, accepts and forwards the packet to all nodes whose network address is 128.1.0.0. Routers connecting subnets of 128.1.0.0 also accept and forward the packet to the nodes on their respective subnets. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is distributed as a broadcast on the destination subnet. The packet is then sent as a link-layer broadcast.

The **ip directed-broadcast** command controls the distribution of directed broadcasts when they reach their target subnets. Only the final transmission of the directed broadcast on its ultimate destination subnet is affected. It does not affect the transit unicast routing of IP directed broadcasts.

If **ip directed-broadcast** is enabled for this interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which this interface is attached will be forwarded as broadcasts on that subnet. Forwarding of the packets can be limited by specifying an ACL with this command. In this case, only directed broadcasts that are permitted by the specified ACL will be forwarded, and all other directed broadcasts directed to this interface subnet will be dropped.

Disabling the **ip directed-broadcast** command will cause directed broadcasts destined for the subnet to which this interface is attached to be dropped.

This option is a requirement for routers as described in RFC 1812, section 4.2.2.11. Furthermore, it is disabled by default (RFC 2644), with the intended goal of reducing the efficacy of certain types of denial of service (DoS) attacks.

Usage Examples

The following example enables forwarding of directed broadcasts on the interface **ppp 1**:

(config)**#interface ppp 1**
(config-ppp 1)**#ip directed-broadcast**

ip ffe

Use the **ip ffe** command to enable the RapidRoute fast forwarding engine (FFE) on this Internet Protocol version 4 (IPv4) interface with the default number of entries. Use the **no** form of this command to disable this feature. Variations of this command include:

ip ffe
ip ffe max-entries <*value*>

Issuing this command will cause all RapidRoute entries to be cleared from this IPv4 interface.

Syntax Description

max-entries <*value*>	Optional. Specifies the maximum number of entries stored in the flow table. Valid range is from **1** to **500000**.

Default Values

By default, the RapidRoute Engine is enabled. The default number of **max-entries** is **4096**.

Command History

Release 13.1	Command was introduced.
Release 17.6	Command was expanded to include the high level data link control (HDLC) and tunnel interfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.4.0	Maximum number of stored entries was expanded to **500000** and RapidRoute is now enabled by default.

Functional Notes

RapidRoute can be used to help reduce routing overhead, and thus reduce overall routing times. Routing times are reduced by the creation of a flow table on the ingress interface. The maximum number of entries that can be stored in the flow table at any one time may be specified by using the **max-entries** parameters.

Usage Examples

The following example disables RapidRoute on the IPv4 interface:

(config)**#interface ppp 1**
(config-ppp 1)**#no ip ffe**

Technology Review

The RapidRoute system goal is to increase IP packet throughput by moving as much of the packet processing into the engine as possible. Packets are classified into flows based upon the IP protocol (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol (ICMP), etc.), the source and destination IP addresses, IP type of service (ToS), and the protocol-specific information, such as the source and destination port numbers. Flows are defined as the unidirectional representation of a conversation between two IP hosts. Each ingress interface keeps its own flow table, a collection of flow entries.

The first packet in a flow that is forwarded through the unit will build a flow entry. When a flow entry is looked up but no entry is found, a RapidRouteBuilder object is allocated and attached to the packet. As the packet passes through the various processing layers, each subsystem will add processing to the RapidRouteBuilder. When packet is about to be forwarded out of the egress interface, the RapidRouteBuilder will be finalized. That is, the flow entry being built will be checked for completeness and committed to the flow table on the ingress interface. Subsequent flow matches can then bypass the normal processing layers.

ip flow

Use the **ip flow** command to enable integrated traffic monitoring (ITM) for all traffic received or forwarded on an interface. Use the **no** form of this command to disable traffic monitoring. Variations of this command include:

ip flow egress
ip flow egress <*name*>
ip flow ingress
ip flow ingress <*name*>

Syntax Description

egress	Specifies that all outgoing traffic be monitored.
ingress	Specifies that all incoming traffic be monitored.
<*name*>	Optional. Specifies the name of an access control list (ACL) to use for filtering traffic.

Default Values

By default, no traffic monitoring is enabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables traffic monitoring on a Point-to-Point Protocol (**PPP)** interface to monitor **incoming** traffic through an ACL called **myacl**:

(config)**#interface ppp 1**
(config-ppp 1)**#ip flow ingress myacl**

ip helper-address *<ip address>*

Use the **ip helper-address** command to configure AOS to forward User Datagram Protocol (UDP) broadcast packets received on the interface. Use the **no** form of this command to disable forwarding packets.

> NOTE *The **ip helper** command must be used in conjunction with the **ip forward-protocol** command to configure AOS to forward UDP broadcast packets. Refer to ip forward-protocol udp <value> on page 1398 for more information.*

Syntax Description

<ip address>	Specifies the destination IP address for the forwarded UDP packets. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, broadcast UDP packets are not forwarded.

Command History

Release 1.1	Command was introduced.

Functional Notes

When used in conjunction with the **ip forward-protocol** command, the **ip helper-address** feature allows you to customize which broadcast packets are forwarded.

To implement the helper address feature, assign a helper address(es) (specifying the device that needs to receive the broadcast traffic) to the interface closest to the host that transmits the broadcast packets. When broadcast packets (of the specified type forwarded using the **ip forward-protocol** command) are received on the interface, they will be forwarded to the device that needs the information.

Only packets meeting the following criteria are considered eligible by the **ip helper-address** feature:

1. The packet IP protocol is UDP.
2. Any UDP port specified using the **ip forward-protocol** command.
3. The medium access control (MAC) address of the frame is an all-ones broadcast address (ffff.ffff.ffff).
4. The destination IP address is broadcast defined by all ones (255.255.255.255) or a subnet broadcast (for example, 192.33.4.251 for the 192.33.4.248 /30 subnet).

Usage Examples

The following example forwards all domain naming system (DNS) broadcast traffic to the DNS server with IP address **192.33.5.99**:

(config)**#ip forward-protocol udp domain**
(config)**#interface ppp 1**
(config-ppp 1)**#ip helper-address 192.33.5.99**

ip igmp

Use the **ip igmp** command to configure multicasting related functions for the interface. Variations of this command include:

ip igmp immediate-leave
ip igmp last-member-query-interval <*milliseconds*>
ip igmp querier-timeout <*seconds*>
ip igmp query-interval <*seconds*>
ip igmp query-max-response-time <*seconds*>
ip igmp static-group <*address*>
ip igmp version [1 | 2]

Syntax Description

immediate-leave	Specifies that if only one host (or Internet Group Management Protocol (IGMP) snooping switch) is connected to the interface, when a leave is received, multicast of that group is immediately terminated as opposed to sending a group query and timing out the group if no device responds. Works in conjunction with **ip igmp last-member-query-interval**. Applies to all groups when configured. Use the **no** form of this command to disable the **immediate-leave** feature.
last-member-query-interval <*milliseconds*>	Controls the timeout (in milliseconds) used to detect whether any group receivers remain on an interface after a receiver leaves a group. If a receiver sends a leave-group message (IGMP Version 2), the router sends a group-specific query on that interface. After twice the time specified by this command plus as much as one second longer, if no receiver responds, the router removes that interface from the group and stops sending that group's multicast packets to the interface. Range is **100** to **65535** ms. Use the **no** form of this command to return to the default setting.
querier-timeout <*seconds*>	Specifies the interval (in seconds) that the router waits after the current querier's last query before it takes over as querier (IGMP V2). Range is **60** to **300** seconds. Use the **no** form of this command to return to the default setting.
query-interval <*seconds*>	Specifies the interval (in seconds) at which IGMP queries are sent on an interface. Host query messages are addressed to the all-hosts multicast group with an IP time to live (TTL) of 1. The router uses queries to detect whether multicast group members are on the interface and to select an IGMP designated router (DR) for the attached segment (if more than one multicast router exists). Only the DR for the segment sends queries. For IGMP V2, the DR is the router with the lowest IP address on the segment. Range is **0** to **65535** seconds. Use the **no** form of this command to return to the default setting.
query-max-response-time <*seconds*>	Specifies the maximum response time (in seconds) advertised by this interface in queries when using IGMP V2. Hosts are allowed a random time within this period to respond, reducing response bursts. Use the **no** form of this command to return to the default setting.

Syntax Description

static-group <*address*>	Configures the router's interface to be a statically connected member of the specified group. Packets received on the correct reverse path forwarding (RPF) interface are forwarded to this interface regardless of whether any receivers have joined the specified group using IGMP. Use the **no** form of this command to remove a configured static group.
version [1 | 2]	Sets the interface's IGMP version. Use the **no** form of this command to return to the default setting.

Default Values

ip igmp immediate-leave	No default
ip igmp last-member-query-interval	**1000** milliseconds
ip igmp querier-timeout	2x the **query-interval** value
ip igmp query-interval	**60** seconds
ip igmp query-max-response-time	**10** seconds
ip igmp static-group	No default
ip igmp version	Version **1**

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example sets the query message interval on the interface to **200** milliseconds:

(config)**#interface ppp 1**
(config-ppp 1)**#ip igmp last-member-query-interval 200**

ip mcast-stub downstream

Use the **ip mcast-stub downstream** command to enable multicast forwarding and Internet Group Management Protocol (IGMP) (router mode) on an interface and place it in multicast stub downstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub upstream** commands. Downstream interfaces connect to segments with multicast hosts. Multiple interfaces may be configured in downstream mode; however, interfaces connecting to the multicast network (upstream) should not be configured in downstream mode. Interfaces configured as downstream should have the lowest IP address of all IGMP-capable routers on the connected segment in order to be selected as the designated router (DR) and ensure proper forwarding. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub upstream on page 3111* for more information.

Usage Examples

The following example enables multicast forwarding and IGMP on the interface:

```
(config)#interface ppp 1
(config-ppp 1)#ip mcast-stub downstream
```

ip mcast-stub fixed

Use the **ip mcast-stub fixed** command to allow forwarding of multicast traffic on a selected interface after enabling multicast routing. Use the **no** form of this command to disable this mode.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 12.1	Command was introduced.

Functional Notes

Multicast routing must be enabled prior to setting **ip mcast-stub fixed** on the selected interface. Also, use the **ip igmp static-group** <*address*> command (refer to *ip igmp on page 3106*) to receive multicast traffic without host-initiated Internet Group Management Protocol (IGMP) activity on the selected interface. Otherwise, all host-initiated IGMP transactions will enter multicast routes on the router's interface involved with IGMP activities.

Usage Examples

The following example enables multicast traffic forwarding and IGMP on the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ip mcast-stub fixed**

ip mcast-stub helper-enable

Use the **ip mcast-stub helper-enable** command to assign the **ip mcast-stub helper-address** as the Internet Group Management Protocol (IGMP) proxy. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 8.1	Command was introduced.
Release 10.1	Command was expanded to include the Point-to-Point Protocol (PPP) interfaces.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address**, **ip mcast-stub upstream**, and **ip mcast-stub downstream** commands. When enabled, the interface becomes a helper forwarding interface. The IGMP host function is dynamically enabled and the interface becomes the active upstream interface, enabling the unit to perform as an IGMP proxy. Refer to *ip mcast-stub helper-address <ip address> on page 1418*, *ip mcast-stub downstream on page 3108*, and *ip mcast-stub upstream on page 3111* for more information.

Usage Examples

The following example sets the helper address as the IGMP proxy:

(config)**#interface ppp 1**
(config-ppp 1)**#ip mcast-stub helper-enable**

ip mcast-stub upstream

Use the **ip mcast-stub upstream** command to enable multicast forwarding on an interface and place it in multicast stub upstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub downstream** commands. When enabled, the interface becomes a candidate to be a helper forwarding interface. If chosen as the best path toward the helper address by the router's unicast route table, the Internet Group Management Protocol (IGMP) host function is dynamically enabled and the interface becomes the active upstream interface, enabling the router to perform as an Internet Group Management Protocol (IGMP) proxy. Though multiple interfaces may be candidates, no more than one interface will actively serve as the helper forwarding interface. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub downstream on page 3108* for more information.

Usage Examples

The following example enables multicast forwarding on the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ip mcast-stub upstream**

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces	(all types)1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

Open shortest path first (OSPF) will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ip mtu 1200**

ip ospf

Use the **ip ospf** command to customize Open Shortest Path First version 2 (OSPFv2) settings (if needed). Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **area** <*area id*>
ip ospf <*process id*> **authentication-key** <*password*>
ip ospf <*process id*> **cost** <*value*>
ip ospf <*process id*> **dead-interval** <*seconds*>
ip ospf <*process id*> **hello-interval** <*seconds*>
ip ospf <*process id*> **message-digest-key [1 | 2] md5** <*key*>
ip ospf <*process id*> **priority** <*value*>
ip ospf <*process id*> **retransmit-interval** <*seconds*>
ip ospf <*process id*> **shutdown**
ip ospf <*process id*> **transmit-delay** <*seconds*>

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
area <*area id*>	Specifies the ID of the area to which this interface is assigned for the specified OSPFv2 process. Valid range is **0** to **4294967295**.
authentication-key <*password*>	Assigns a simple-text authentication password to be used by other routers using the OSPF simple password authentication.
cost <*value*>	Specifies the OSPF cost of sending a packet on the interface. This value overrides any computed cost value. Range is **1** to **65535**.
dead-interval <*seconds*>	Sets the maximum interval (in seconds) allowed between hello packets. If the maximum is exceeded, neighboring devices will determine that the device is down. Range is **0** to **32767** seconds.
hello-interval <*seconds*>	Specifies the interval (in seconds) between hello packets sent on the interface. Range is **0** to **32767** seconds.
message-digest-key [1 | 2] md5 <*key*>	Configures OSPF message digest 5 (MD5) authentication (16 byte maximum) keys.
priority <*value*>	Sets the OSPF priority. The value set in this field helps determine the designated router (DR) for this network. Range is **0** to **255**.
retransmit-interval <*seconds*>	Specifies the interval (in seconds) between link state advertisements (LSAs). Range is **0** to **32767** seconds.

shutdown	Disables the OSPFv2 process on the interface. When this keyword is used, the OSPFv2 settings remain in place, but logically it appears to the interface as though the process has been removed from the configuration. This parameter can be useful in troubleshooting.
transmit-delay <*seconds*>	Sets the estimated time (in seconds) required to send a link state advertisement (LSA) on the interface. Range is **0** to **32767** seconds.

Default Values

The defaults for this command are:

dead-interval <*seconds*>	40 seconds
hello-interval <*seconds*>	10 seconds: Ethernet, Frame Relay, and Point-to-Point Protocol (PPP)
priority <*value*>	1
retransmit-interval <*seconds*>	5 seconds
transmit-delay <*seconds*>	1 second

Command History

Release 3.1	Command was introduced.
Release R11.3.0	Command was expanded to include the <*process id*>, **area** <*area id*>, and **shutdown** parameters.

Usage Examples

The following example sets the maximum number of seconds allowed between hello packets to **25000**:

(config)**#interface ppp 1**
(config-ppp 1)**#ip ospf 1 dead-interval 25000**

ip ospf <*process id*> authentication

Use the **ip ospf authentication** command to authenticate an interface that is performing open shortest path first (OSPF) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **authentication**
ip ospf <*process id*> **authentication message-digest**
ip ospf <*process id*> **authentication null**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
message-digest	Optional. Selects message digest authentication type.
null	Optional. Specifies that no authentication be used.

Default Values

By default, **ip ospf authentication** is set to **null** (meaning no authentication is used).

Command History

Release 3.1	Command was introduced.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Usage Examples

The following example specifies that no authentication will be used on the Point-to-Point Protocol (PPP) interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ip ospf 1 authentication null**

ip ospf <*process id*> network

Use the **ip ospf network** command to specify the type of network on this interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **network broadcast**
ip ospf <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
broadcast	Sets the network type for broadcast.
point-to-point	Sets the network type for point-to-point.

Default Values

By default, Ethernet defaults to **broadcast**. Point-to-Point Protocol (PPP) and Frame Relay default to **point-to-point**.

Command History

Release 3.1	Command was introduced.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Functional Notes

A point-to-point network will not elect designated routers.

Usage Examples

The following example designates a broadcast network type:

(config)**#interface ppp 1**
(config-ppp 1)**#ip ospf 1 network broadcast**

ip pim sparse-mode

Use the **ip pim sparse-mode** command to enable protocol-independent multicast (PIM) sparse mode for this interface. Use the **no** form of this command to disable PIM sparse mode.

Syntax Description

No subcommands.

Default Values

By default, PIM sparse mode for this interface is disabled.

Command History

Release 11.1	Command was introduced.

Functional Notes

PIM sparse mode is a multicast routing protocol that makes use of the unicast forwarding table. It builds unidirectional shared trees rooted at a rendezvous point (RP) for a multicast group or a shortest-path tree rooted at a specific source for a multicast group.

Usage Examples

The following example enables PIM sparse mode on the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ip pim sparse-mode**

ip pim-sparse dr-priority <*value*>

Use the **ip pim-sparse dr-priority** command to specify the priority for the designated router (DR). This command modifies the router's priority in the DR election process. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the priority of this interface (to be used when determining the DR). Valid range is **1** to **4294967295**.

Default Values

By default, the priority of all protocol-independent multicast (PIM) interfaces is **1**.

Command History

Release 11.1	Command was introduced.

Functional Notes

Interfaces advertise their configured priority values in the hello messages transmitted on the interface. Routers use the priority values to determine the appropriate DR. The router on the network segment with the highest priority is selected as the DR. If a hello message is received on the interface from a router on the network segment and it does not contain a priority, the entire network segment defaults to DR selection based on IP addresses instead of priority. In this instance, the DR is selected as the router on the network segment that has the highest IP address. AOS will always include a priority in all transmitted hello messages. If no priority is specifically designated by the user, the priority is set as the default of 1.

Usage Examples

The following example specifies a priority of **100** on the Point-to-Point Protocol (PPP) 1 interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ip pim-sparse dr-priority 100**

ip pim-sparse hello-timer <*value*>

Use the **ip pim-sparse hello-timer** command to specify protocol-independent multicast (PIM) sparse hello timer period. This is the time interval at which periodic hellos are sent out on all interfaces of a PIM-capable router. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the interval (in seconds) at which periodic hellos are sent out of the interface. Valid range is **10** to **3600** seconds.

Default Values

By default, the hellos are transmitted on PIM interfaces every **60** seconds.

Command History

Release 11.1	Command was introduced.

Functional Notes

Hello messages are used to inform neighbors of a router's presence. Hello messages normally generate a small amount of traffic on an interface. Setting the **hello-timer** to a small interval increases the number of hellos sent (thus increasing the amount of traffic). Set the **hello-timer** to a reasonable value, taking into consideration the bandwidth available on the interface.

Usage Examples

The following example specifies hellos be sent on the Point-to-Point Protocol (PPP) 1 interface every **3600** seconds:

(config)**#interface ppp 1**
(config-ppp 1)**#ip pim-sparse hello-timer 3600**

ip pim-sparse nbr-timeout <*value*>

Use the **ip pim-sparse nbr-timeout** command to specify protocol-independent multicast (PIM) sparse neighbor timeout. This is the time interval after which a PIM-capable router will consider a neighbor not present. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the time interval in seconds after which a neighbor is considered not present. Valid range is **30** to **10800** seconds.

Default Values

By default, the nbr-timeout is set to **105** seconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the nbr-timeout to **300** seconds:

(config)**#interface ppp 1**
(config-ppp 1)**#ip pim-sparse nbr-timeout 300**

ip pim-sparse override-interval <*value*>

Use the **ip pim-sparse override-interval** command to specify the protocol-independent multicast (PIM) sparse join/prune override interval. This delay interval is the period after a join/prune that another router on the local area network (LAN) may override a join/prune. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the delay time in milliseconds. Valid range is **0** to **65535** milliseconds.

Default Values

By default, the override interval is set to **2500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the override interval to **3000** milliseconds:

(config)**#interface ppp 1**
(config-ppp 1)**#ip pim-sparse override-interval 3000**

ip pim-sparse propagation-delay *<value>*

Use the **ip pim-sparse propagation-delay** command to specify the expected propagation delay for join/prune messages. Set the propagation delay (in milliseconds) to estimate the amount of delay found in the local link. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the expected propagation delay in the local link in milliseconds. Valid range is **0** to **32767** milliseconds.

Default Values

By default, the propagation delay is set to **500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the propagation delay to **300** milliseconds:

(config)**#interface ppp 1**
(config-ppp 1)**#ip pim-sparse propagation-delay 300**

ip policy route-map *<name>*

Use the **ip policy route-map** command to assign a policy route map to this interface. Use the **no** form of this command to remove the route-map policy.

Syntax Description

<name>	Specifies the name of the policy route map to assign to this interface.

Default Values

By default, no policy route map is assigned to this interface.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example assigns the policy route map **policy1** to the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ip policy route-map policy1**

ip proxy-arp

Use the **ip proxy-arp** command to enable proxy Address Resolution Protocol (ARP) on the interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, proxy ARP is enabled.

Command History

Release 1.1	Command was introduced.

Functional Notes

In general, the principle of proxy ARP allows a router to insert its IP address in the source IP address field of a packet (if the packet is from a host on one of its subnetworks). This allows hosts to reach devices on other subnetworks without implementing routing or specifying a default gateway.

If proxy ARP is enabled, AOS will respond to all proxy ARP requests with its specified medium access control (MAC) address and forward packets accordingly.

Enabling proxy ARP on an interface may introduce unnecessary ARP traffic on the network.

Usage Examples

The following example enables proxy ARP on the virtual Point-to-Point Protocol (PPP) interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ip proxy-arp**

ip rip receive version

Use the **ip rip receive version** command to configure the Routing Information Protocol (RIP) version the unit accepts in all RIP packets received on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip receive version 1
ip rip receive version 2

Syntax Description

1	Accepts only received RIP version 1 packets on the interface.
2	Accepts only received RIP version 2 packets on the interface.

Default Values

By default, all interfaces implement RIP **version 1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.

Functional Notes

Use the **ip rip receive version** to specify a RIP version that overrides the **version** (in the Router RIP) configuration.

AOS only accepts one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the virtual Point-to-Point Protocol (PPP) interface to accept only RIP **version 2** packets:

(config)**#interface ppp 1**
(config-ppp 1)**#ip rip receive version 2**

ip rip send version

Use the **ip rip send version** command to configure the Routing Information Protocol (RIP) version the unit sends in all RIP packets transmitted on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip send version 1
ip rip send version 2

Syntax Description

1	Transmits only RIP version 1 packets on the interface.
2	Transmits only RIP version 2 packets on the interface.

Default Values

By default, all interfaces transmit RIP **version 1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.

Functional Notes

Use the **ip rip send version** to specify a RIP version that overrides the **version** (in the Router RIP) configuration.

AOS only transmits one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the virtual Point-to-Point Protocol (PPP) interface to transmit only RIP **version 2** packets:

(config)**#interface ppp 1**
(config-ppp 1)**#ip rip send version 2**

ip rip summary-address *<ip address> <subnet mask>*

Use the **ip rip summary-address** command to manually summarize the routes Routing Information Protocol (RIP) will advertise and send out a specified interface. Use the **no** form of this command to disable this mode.

Syntax Description

<ip address>	Specifies the summarized network IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.0**).
<subnet mask>	Specifies the subnet mask that corresponds to the range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no manual summarization is applied by RIP.

Command History

Release 12.1	Command was introduced.

Functional Notes

Unlike the automatic summarization on classful network boundaries, only specific network advertisements are made by RIP using the **ip rip summary-address** command. This command is only effective if RIP version 2 is configured.

Usage Examples

The following example enables manual summarization on the specified IP address:

(config)**#interface ppp 1**
(config-ppp 1)**#ip rip summary-address 10.10.123.0 255.255.255.0**

ip route-cache

Use the **ip route-cache** command to enable Internet Protocol version 4 (IPv4) fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

*Using network address translation (NAT) or the AOS firewall capabilities on an interface requires process switching mode (using the **no ip route-cache** command).*

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Fast switching allows an IPv4 interface to provide optimum performance when processing IPv4 traffic.

Usage Examples

The following example enables IPv4 fast switching on the PPP interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ip route-cache**

ip unnumbered *<interface>*

Use the **ip unnumbered** command to use the IP address assigned to the specified interface for all IP processing on the active interface. Use the **no** form of this command to remove the unnumbered configuration.

Syntax Description

<interface>	Specifies the interface that contains the IP address to use as the source address for all packets transmitted on this interface. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip unnumbered ?** for a list of valid interfaces.

Default Values

By default, all interfaces are configured to use a specified IP address (using the **ip address** command).

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface.

Functional Notes

If **ip unnumbered** is enabled on an interface, all IP traffic from the interface will use a source IP address taken from the specified interface. For example, specifying **ip unnumbered eth 0/1** while in the Point-to-Point Protocol (PPP) Interface Configuration mode configures the PPP interface to use the IP address assigned to the Ethernet interface for all IP processing. In addition, AOS uses the specified interface information when sending route updates over the unnumbered interface. Static routes may either use the interface name (ppp 1) or the far-end address (if it will be discovered).

Usage Examples

The following example configures the PPP interface (labeled **ppp 1**) to use the IP address assigned to the Ethernet interface (**eth 0/1**):

(config)**#interface ppp 1**
(config-ppp 1)**#ip unnumbered eth 0/1**

ip urlfilter <*name*>

Use the **ip urlfilter** command to apply a universal resource locator (URL) filter to the interface for all inbound or outbound traffic. Use the **no** form of this command to remove the URL filter from an interface. Variations of this command include:

ip urlfilter <*name*> **in**
ip urlfilter <*name*> **out**

Syntax Description

<*name*>	Specifies the URL filter name to use on the interface.
in	Applies the filter to the inbound traffic.
out	Applies the filter to the outbound traffic.

Default Values

By default, there are no URL filters applied to any interfaces.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the virtual local area network (VLAN) interfaces.

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be created by using the **ip urlfilter** <*name*> **http** command before applying it to the interface. Refer to *ip urlfilter allowmode on page 1493* for more information on using this command.

Usage Examples

The following example performs URL filtering on all traffic entering through the Point-to-Point Protocol (PPP) interface (labeled **ppp 1**) and matches the URL filter named **MyFilter**:

(config)**#interface ppp 1**
(config-ppp 1)**#ip urlfilter MyFilter in**

ipv6

Use the **ipv6** command to enable Internet Protocol version 6 (IPv6) processing and create a link-local address on an interface. Use the **no** form of this command to disable IPv6 processing and remove all IPv6 configuration on the interface.

Syntax Description

No subcommands.

Default Values

By default, IPv6 is not enabled on the interface.

Command History

Release 18.1	Command was introduced.

Functional Notes

Because AOS uses the dual-stack for IPv6 implementation, IPv6 features must be enabled for the supported IPv6 features to be used. Enabling IPv6 in AOS is completed by using an IPv6 address or using the **ipv6** keyword with specific commands. For example, to enable IPv6 on an interface and cause the interface to join the link scoped all-nodes and all-routers multicast group, enter an IPv6 address on the interface.

Use the **ipv6** command to enable IPv6 processing and create a link-local address on an interface when other unicast IPv6 addresses are not needed on the interface. This command is not necessary nor effectual when any other form of an IPv6 address command is also present on the interface.

Usage Examples

The following example enables IPv6 and creates a link-local IPv6 address on the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6**

ipv6 access-group *<ipv6 acl name>*

Use the **ipv6 access-group** command to apply an Internet Protocol version 6 (IPv6) access control list (ACL) to be used for IPv6 packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ipv6 access-group <*ipv6 acl name*> **in**
ipv6 access-group <*ipv6 acl name*> **out**

Syntax Description

<ipv6 acl name>	Applies the named IPv6 ACL to the interface.
in	Enables access control on IPv6 packets received on the specified interface.
out	Enables access control on IPv6 packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 18.1	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.

Functional Notes

Only one IPv6 ACL can be applied in each traffic direction.

Unlike in IPv4, IPv6 traffic filters include an implicit **permit** for neighbor solicitation and advertisement packets in an ACL before the traditional implicit **deny** at the end of the ACL. This prevents blocking of address resolution and unreachability detection, although this can be overridden by entering explicit **deny** commands in the IPv6 ACL.

Usage Examples

The following example applies the IPv6 ACL **Privatev6** to incoming IPv6 traffic on the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 access-group Privatev6 in**

ipv6 access-policy *<ipv6 acp name>*

Use the **ipv6 access-policy** command to assign a specified Internet Protocol version 6 (IPv6) access control policy (ACP) to an interface. IPv6 ACPs are applied to IPv6 traffic entering an interface. Use the **no** form of this command to remove an ACP association.

Syntax Description

<ipv6 acp name>	Identifies the configured IPv6 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv6 ACPs associated with an interface.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example applies the IPv6 ACP **PRIVATEv6** to the interface:

Enable the AOS security features:
(config)**#ipv6 firewall**

Associate the ACP with the PPP interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 access-policy PRIVATEv6**

ipv6 address *<ipv6 address/prefix-length>*

Use the **ipv6 address** command to assign a unicast Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<ipv6 address/prefix-length>	Specifies the IPv6 unicast address to add to the interface. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

Default Values

By default, no IPv6 address is configured on the interface and IPv6 processing is not enabled on the interface.

Command History

Release 18.1	Command was introduced.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the interface using the command *ipv6 address <ipv6 link-local address> link-local on page 3137*.

The address created by this command is a manually configured IPv6 address, which must have all parts (prefix and host bits) specified.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example adds a unicast IPv6 address to the interface and enables IPv6 processing on the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 address 2001:DB8::/32**

ipv6 address *<ipv6 prefix/prefix-length>* eui-64

Use the **ipv6 address eui-64** command to assign a unicast Internet Protocol version 6 (IPv6) address and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<ipv6 prefix/prefix-length>	Specifies the IPv6 prefix. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
eui-64	Specifies that the IPv6 address is constructed using the specified prefix in the high-order bits and followed by the EUI-64 Interface ID in the lower 64 bits.

Default Values

By default, no IPv6 address is configured on the interface and IPv6 processing is not enabled on the interface.

Command History

Release 18.1	Command was introduced.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the interface using the command *ipv6 address <ipv6 link-local address> link-local on page 3137*.

The address created by this command is an EUI-64 unicast address. For this type of address, the EUI-64 interface ID is automatically placed in the IPv6 address. Any manually configured bits beyond the address's prefix length are set to **0**; however, any manually configured bits within the prefix length that extend into the lower 64 bits take precedence over the Interface ID bits.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example adds a unicast IPv6 address with an EUI-64 Interface ID to the interface and enables IPv6 processing on the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 address 2001:DB8:3F::/48 eui-64**

ipv6 address <*ipv6 link-local address*> link-local

Use the **ipv6 address link-local** command to manually assign a link-local Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<*ipv6 link-local address*>	Specifies the link-local IPv6 address. Link-local addresses are specified in colon hexadecimal notation, and begin with **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since link-local addresses have no prefix, the bits entered form the entire IPv6 address.
link-local	Specifies this is a manually configured link-local address. Manually configured link-local addresses replace automatically configured link-local addresses on the interface.

Default Values

By default, no IPv6 address is configured for the interface and IPv6 processing is not enabled.

Command History

Release 18.1	Command was introduced.

Functional Notes

A single link-local address can be manually configured on an interface. The lower 64 bits of the specified address become the Interface ID for the interface, overriding the default interface ID. Any other address that uses the EUI-64 parameter to automatically place the interface ID in the lower 64 bits of the IPv6 address use the new value for the interface ID.

The <*ipv6 address*> for a link-local IPv6 address is specified in the format **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since this form of address has no prefix, the bits entered form the entire IPv6 address. These bits also become the new interface ID for the interface and can be derived from the interface's medium access control (MAC) address.

The **link-local** parameter specifies this is a manually configured link-local address. Any manually configured link-local address will replace an automatically configured link-local address for the interface.

Using the **no** form of this command with a specified IPv6 address removes that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example manually creates a link-local IPv6 address on the interface and enables IPv6 processing:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 address FE80::220:8FF:FE54:F9D8 link-local**

ipv6 address autoconfig

Use the **ipv6 address autoconfig** command to enable Internet Protocol version 6 (IPv6) processing on the interface, create a local-link IPv6 address for the interface, and allow the interface to automatically configure itself based on advertisements from other routers on the link. Use the **no** form of this command to remove all autoconfigured addresses, prefixes, and any resulting routes from the interface and also causes the interface to cease processing received router advertisements (RAs).Variations of this command include:

ipv6 address autoconfig
ipv6 address autoconfig default
ipv6 address autoconfig default metric <*value*>

Syntax Description

default	Optional. Specifies that the interface maintain a list of advertising routers that are willing to be IPv6 default routers.
metric <*value*>	Optional. Specifies the administrative distance for a default router maintained in the default router list. Range is **1** to **255**. Routes with lower administrative distance are favored.

Default Values

By default, no IPv6 addresses are configured for the interface and IPv6 processing is not enabled. When an IPv6 address is configured automatically, the administrative distance for default routers is **2** by default.

Command History

Release 18.1	Command was introduced.

Functional Notes

When autoconfiguration is enabled, the interface listens for RA messages that tell the interface how it should be configured. The interface then creates addresses for advertised 64-bit prefixes with the A flag in the IPv6 address set using stateless address autoconfiguration (SLAAC). The addresses use the EUI-64 interface ID in the lower 64 bits of the address. A route type of *Connected* is added to the route table if the L flag on the prefix advertisement (on-link flag) is also set.

Usage Examples

The following example enables IPv6 processing on the interface, creates a link-local IPv6 address for the interface, and allows the interface to automatically configure itself for IPv6:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 address autoconfig**

ipv6 address dhcp

Use the **ipv6 address dhcp** command to enable Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) on the interface, place the interface in DHCPv6 client mode, and configure the address parameters of the DHCPv6 client. Use the **no** form of this command to disable the DHCPv6 client on the interface. Variations of this command include:

ipv6 address dhcp
ipv6 address dhcp hostname <*partial fqdn*>
ipv6 address dhcp hostname fqdn <*fqdn*>
ipv6 address dhcp no-domain-name
ipv6 address dhcp no-nameservers
ipv6 address dhcp no-ntp
ipv6 address dhcp no-sntp-server
ipv6 address dhcp rapid-commit

Syntax Description

hostname <*partial fqdn*>	Optional. Specifies the name to be sent to the DHCPv6 server as the host portion of its fully qualified domain name (FQDN). FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
fqdn <*fqdn*>	Optional. Specifies a name to be sent to the DHCPv6 server as the system's FQDN. FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
no-domain-name	Optional. Specifies that no domain names are obtained using this DHCPv6 client.
no-nameservers	Optional. Specifies that no domain naming server (DNS) addresses are obtained through DHCPv6.
no-ntp	Optional. Specifies that no Network Time Protocol (NTP) server values are obtained through this DHCPv6 client.
no-sntp-server	Optional. Specifies that no Simple Network Time Protocol (SNTP) server values are obtained through this DHCPv6 client.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Functional Notes

To enable an interface as a DHCPv6 client, you must first enable IPv6 on the interface using the command *ipv6 on page 3132*.

Enabling the interface as a DHCPv6 client using the **ipv6 address dhcp** command places the interface into DHCPv6 client mode. DHCPv6 modes (**client**, **server**, **relay**) are mutually exclusive at the interface. Any existing mode must be removed before a different mode can be applied. For example, if the interface is configured as a DHCPv6 relay agent, you must first disable the **relay** mode before you can specify the interface is in **client** mode.

Usage Examples

The following example enables the interface as a DHCPv6 client and specifies the client's host name:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 address 2001:DB8:1::1/64**
(config-ppp 1)**#ipv6 address dhcp fqdn client@company.com**

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*

Use the **ipv6 address named-prefix** command to create an Internet Protocol version 6 (IPv6) address for the interface using the values in a named prefix. Use the **no** form of this command to remove the address from the interface. Variations of this command include:

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*
ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>* **eui-64**

Syntax Description

<prefix name>	Specifies the named prefix to use to create the address.
<ipv6 address/prefix-length>	Specifies the address portion appended to the named prefix to create a 128-bit host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
eui-64	Optional. Indicates that the interface ID is to be placed in the lower 64 bits of the address.

Default Values

By default, no IPv6 addresses are specified on the interface.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example creates an IPv6 address on the interface using the named prefix **PREFIX1**:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 address named-prefix PREFIX1 2001:1:0:/48**

Enabling the interface as a DHCPv6 client using the **ipv6 address dhcp** command places the interface into DHCPv6 client mode. DHCPv6 modes (**client**, **server**, **relay**) are mutually exclusive at the interface. Any existing mode must be removed before a different mode can be applied. For example, if the interface is configured as a DHCPv6 relay agent, you must first disable the **relay** mode before you can specify the interface is in **client** mode.

Usage Examples

The following example enables the interface as a DHCPv6 client and specifies the client's host name:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 address 2001:DB8:1::1/64**
(config-ppp 1)**#ipv6 address dhcp fqdn client@company.com**

ipv6 crypto map *<name>*

Use the **ipv6 crypto map** command to associate Internet Protocol version 6 (IPv6) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

Syntax Description

<name>	Specifies the IPv6 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

Command History

Release R10.7.0	Command was introduced.

Functional Notes

Only one IPv6 crypto map can be specified per interface, and the crypto map is applied within the virtual routing and forwarding (VRF) instance to which the interface belongs. To apply the IPv6 crypto map, the interface must have IPv6 enabled. In addition, the interface must have an IPv6 address of appropriate scope to allow connectivity to peer's addresses as specified in the crypto map's entries.

Usage Examples

The following example applies all IPv6 crypto maps with the name **MyMap** to the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6**
(config-ppp 1)**#ipv6 crypto map MyMap**

ipv6 dhcp client information refresh minimum <*seconds*>

Use the **ipv6 dhcp client information refresh minimum** command to specify the minimum value the Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) client on the interface accepts as its information refresh timer. Use the **no** version of this command to return to the default setting.

Syntax Description

<*seconds*>	Specifies the refresh timer in seconds. Valid range is **600** to **3600** seconds.

Default Values

By default, the DHCPv6 client refresh timer is set to **600** seconds.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example specifies the DHCPv6 client refresh timer for the interface is **800** seconds:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 dhcp client information refresh minimum 800**

ipv6 dhcp client pd <*prefix name*>

Use the **ipv6 dhcp client pd** command to enable the Dynamic Control Host Protocol for Internet Protocol version 6 (DHCPv6) client on the interface and specify that the interface acquires an IPv6 prefix for the DHCPv6 client. Use the **no** form of this command to disable this feature. Variations of this command include:

ipv6 dhcp client pd <*prefix name*>
ipv6 dhcp client pd <*prefix name*> **no-aggregate-route**
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*>
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*> **tag** <*value*>
ipv6 dhcp client pd <*prefix name*> **rapid-commit**

Syntax Description

<*prefix name*>	Specifies the variable of the prefix stored on the AOS system. Variables are expressed in ASCII text of up to **80** characters.
no-aggregate-route	Optional. Specifies that a route to the null 0 interface is not injected into the route table for the prefixes assigned.
distance <*distance*>	Optional. Specifies the administrative distance to assign to the injected route. Valid range is **1** to **255** with a default distance of **1**.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.
tag <*value*>	Optional. Specifies a number to use as a tag for labeling and filtering routers. Valid range is **1** to **65535**.

Default Values

By default, the DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Usage Examples

The following example enables the DHCPv6 client on the interface and assigns the prefix **PREFIX1**:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 dhcp client pd PREFIX1**

ipv6 dhcp relay destination <*ipv6 address*>

Use the **ipv6 dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 6 (IPv6) and to specify the IPv6 address for the DHCPv6 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv6 relay functionality is disabled on the interface. Variations of this command include:

ipv6 dhcp relay destination <*ipv6 address*>
ipv6 dhcp relay destination <*ipv6 address*> <*interface*>
ipv6 dhcp relay destination <*ipv6 address*> **mef-ethernet** <*slot/port*>
ipv6 dhcp relay destination <*ipv6 address*> **system-control-evc**
ipv6 dhcp relay destination <*ipv6 address*> **system-management-evc**

Syntax Description

<*ipv6 address*>	Specifies the IPv6 address for the DHCPv6 messages. IPv6 addresses should be specified in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<*interface*>	Optional. Specifies an output interface to use when sending messages to the DHCPv6 server. If no interface is specified, the interface is selected by the routing table. This parameter is only required when the IPv6 address is a link-scoped address. Interfaces are specified in the <*interface type*> <*slot/port* | *interface id*> format. For example, for an Ethernet interface, use **eth 0/1**. Type **ipv6 dhcp relay destination** <*ipv6 address*> **?** to display a list of valid interfaces.
mef-ethernet <*slot/port*>	Specifies the Metro Ethernet Forum (MEF) Ethernet interface.
system-control-evc	Optional. Specifies the system control Ethernet virtual connection (EVC) is used when sending messages to the DHCPv6 server.
system-management-evc	Optional. Specifies the system management EVC is used when sending messages to the DHCPv6 server.

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.
Release R10.5.0	Command was expanded to include the loopback interface.
Release R10.10.0	Command was expanded to include the system control and system management EVCs.
Release R10.11.0	Command was expanded to include the MEF Ethernet interface.

Functional Notes

To configure an interface to function as a DHCPv6 relay agent, you must first enable IPv6 on the interface using the command *ipv6 on page 3132*.

Usage Examples

The following example enables DHCPv6 relay agent functionality and specifies the destination address as **2001:DB8:2::1**:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6**
(config-ppp 1)**#ipv6 dhcp relay destination 2001:DB8:2::1**

Technology Review

DHCPv6, like DHCP in IPv4, is used in IP networks to supply hosts with IP addresses and other networking information. DHCPv6, however, functions slightly differently than DHCPv4 by providing relay agents with the ability to send relay-forward and relay-reply messages. In addition, in DHCPv4, when DHCP messages are sent to a DHCP server whose address is not known, the IPv4 client uses the broadcast address. In DHCPv6, the IPv6 client sends messages using the link-scoped mulitcast address. This address is the All DHCP Relay Agents and Servers link, designated as **FF02::1:2**.

In AOS, DHCPv6 relay agents are used when the DHCP server is not on the same link as the DHCP client. The relay is typically a router on the same link as the client, which acts as an intermediary to help the client's DHCP messages reach the DHCP server. DHCPv6 relay agents operate transparently to the DHCP client, and can be configured in chains, meaning that information about each agent encountered is encapsulated into the relay message. Relay agents add fields to the DHCP message as they send these messages to the server, thus providing a method to properly manage the DHCP client.

For more information about DHCPv6 functionality in AOS, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

ipv6 dhcp server

Use the **ipv6 dhcp server** command to enable Internet Protocol version 6 (IPv6) Dynamic Host Control Protocol (DHCP) on the interface and specify that the interface is functioning as a DHCPv6 server. This command not only enables the DHCPv6 server on the interface, it also configures specific parameters of the DHCPv6 server. Hence, the parameters of this command can be entered multiple times and in any order. Use the **no** form of this command to disable DHCPv6 on the interface. Variations of this command include:

ipv6 dhcp server automatic
ipv6 dhcp server automatic allow-hint
ipv6 dhcp server automatic preference <*number*>
ipv6 dhcp server automatic rapid-commit
ipv6 dhcp server <*pool name*>
ipv6 dhcp server <*pool name*> **allow-hint**
ipv6 dhcp server <*pool name*> **preference** <*number*>
ipv6 dhcp server <*pool name*> **rapid-commit**

Syntax Description

automatic	Enables automatic selection of the DHCPv6 server pool based on information extracted from the DHCPv6 client's request. You must specify the pool selection method before configuring other options for this command.
<*pool name*>	Specifies the DHCPv6 server pool that services this interface. All DHCPV^ requests received on this interface are serviced from this pool. If a pool name is not specified, the server pool is selected automatically. You must specify the pool selection method before configuring the other options for this command.
allow-hint	Optional. Specifies that the DHCPv6 server attempts to honor the DHCPv6 client's request for specific values as hinted in the client's request (if they are valid and not already assigned). If this option is not specified, any hints from the DHCPv6 client are ignored.
preference <*number*>	Optional. Specifies the preference value advertised by the server. This option is sent by the server to a DHCPv6 client to influence the selection of a server when there are multiple servers from which to choose. Valid range is **0** to **255**, with a default value of **0**. When the preference value is set to a non-zero value, the server includes a preference option containing the value. If the preference value is not set, or is set to 0, the option is omitted and the client assumes the value is 0.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 server mode is not enabled on the interface.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

Enabling the interface as a DHCPv6 server using this command places the interface into DHCPv6 server mode. DHCPv6 modes (server or relay) are mutually exclusive at the interface. Any existing mode will be removed if a different mode is specified, and a message will be shown indicating the change in DHCPv6 mode.

Usage Examples

The following example enables the interface as a DHCPv6 server, and specifies that the DHCPv6 server pool **POOL1** is associated with the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 address 2001:DB8:1::1/64**
(config-ppp 1)**#ipv6 dhcp server POOL1**

ipv6 ffe

Use the **ipv6 ffe** command to enable the RapidRoute fast forwarding engine (FFE) on this Internet Protocol version 6 (IPv6) interface with the default number of entries. Use the **no** form of this command to disable this feature. Variations of this command include:

ipv6 ffe
ipv6 ffe max-entries <*value*>

> NOTE *Issuing this command will cause all RapidRoute entries to be cleared from this IPv6 interface.*

Syntax Description

max-entries <*value*>	Optional. Specifies the maximum number of entries stored in the flow table. Valid range is from **1** to **500000**.

Default Values

By default, the RapidRoute Engine is enabled on IPv6-enabled interfaces (using the command *ipv6 on page 2231*). The default number of **max-entries** is **4096**.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

RapidRoute can be used to help reduce routing overhead, and thus reduce overall routing times. Routing times are reduced by the creation of a flow table on the ingress interface. The maximum number of entries that can be stored in the flow table at any one time may be specified by using the **max-entries** parameters.

Usage Examples

The following example disables RapidRoute on the IPv6 interface:

(config)**#interface ppp 1**
(config-ppp 1)**#no ipv6 ffe**

Technology Review

The RapidRoute system goal is to increase IP packet throughput by moving as much of the packet processing into the engine as possible. Packets are classified into flows based upon the IP protocol (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol (ICMP), etc.), the source and destination IP addresses, IP type of service (ToS), and the protocol-specific information, such as the source and destination port numbers. Flows are defined as the unidirectional representation of a conversation between two IP hosts. Each ingress interface keeps its own flow table, a collection of flow entries.

The first packet in a flow that is forwarded through the unit will build a flow entry. When a flow entry is looked up but no entry is found, a RapidRouteBuilder object is allocated and attached to the packet. As the packet passes through the various processing layers, each subsystem will add processing to the RapidRouteBuilder. When packet is about to be forwarded out of the egress interface, the RapidRouteBuilder will be finalized. That is, the flow entry being built will be checked for completeness and committed to the flow table on the ingress interface. Subsequent flow matches can then bypass the normal processing layers.

ipv6 mode host unicast

Use the **ipv6 mode host unicast** command to place the interface in host mode using an Internet Protocol version 6 (IPv6) unicast address. Use the **no** form of this command to disable host mode on the interface.

Syntax Description

No subcommands.

Default Values

By default, host mode is disabled.

Command History

Release R10.9.0	Command was introduced.

Command History

When this command is configured on an interface, the MTU value is learned from received router advertisements. Link MTU value is learned in host mode from the following locations (in decreasing order of priority): the provisioned MTU value in the interface configuration, the router advertisements received on the interface, and the default MTU value (1500).

Usage Examples

The following example places the interface in host mode:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 mode host unicast**

ipv6 mtu *<size>*

Use the **ipv6 mtu** command to specify the maximum transmission unit (MTU) for Internet Protocol version 6 (IPv6) packets on the interface. Use the **no** form of this command to return to the default value.

Syntax Description

<size>	Specifies the MTU value. Valid range is **1280** to **1500** bytes.

Default Values

By default, the MTU of the interface is set to **1280** bytes.

Command History

Release 18.1	Command was introduced.

Functional Notes

In IPv6, the minimum MTU is 1280 octets. Any link that has an MTU less than 1280 octets must use link fragmentation and reassembly that is transparent to IPv6 (for example, the Fragmentation Header). Sources in the IPv6 network are expected to perform path maximum transmission unit (PMTU) discovery to send packets larger than 1280 octets. PMTU works in the following manner: First, the sending node assumes the link MTU of the interface from which the traffic is being forwarded and then sends the IPv6 packet at the link MTU size. If a router on the path is unable to forward the packet, it sends an ICMP *Packet Too Big* message back to the sending node containing the link MTU of the link on which the packet forwarding failed. The sending node then rests the PMTU to the value of the MTU field in the Internet Control Message Protocol version 6 (ICMPv6) *Packet Too Big* message, and the packet is resent.

The MTU for IPv6 packets can be set on a per-interface basis. There are two methods for setting MTUs for interfaces if required: one for Layer 3 interfaces, and one for the underlying Layer 1 and Layer 2 interfaces. For all interface types, use the **ipv6 mtu** *<size>* command to specify the IPv6 MTU in bytes from the interface's configuration mode. The minimum MTU setting for IPv6 is **1280** bytes, and the maximum is **1500** bytes. The IPv6 MTU value is independent of the IPv4 MTU setting (set with the command *ip mtu <size> on page 3112*).

When the interface is forwarding the IPv6 packet as a router, if the packet size exceeds the IPv6 MTU of the egress interface, the packet is dropped and ICMPv6 *Packet Too Big* message is sent to the source. When originating an IPv6 packet from the local IPv6 stack, and the packet is larger than the IPv6 MTU of the egress interface, the packet is fragmented and sent.

Usage Examples

The following example specifies the IPv6 MTU value for the interface:

```
(config)#interface ppp 1
(config-ppp 1)#ipv6 mtu 1350
```

ipv6 nd advertisement-interval

Use the **ipv6 nd advertisement-interval** command to specify that the Advertisement Interval Option is sent in Internet Protocol version 6 (IPv6) router advertisement (RA) messages from the router. This command is effectual only when the interface is in router mode. Use the **no** form of this command to return to the default interval.

Syntax Description

No subcommands.

Default Values

By default, Advertisement Interval Options are not sent in RA messages.

Command History

Release 18.1	Command was introduced.

Functional Notes

Sending the Advertisement Interval Option should be enabled when the router is functioning in a mobile IP environment to aid movement detection by mobile nodes. This option contains the current value of the maximum router advertisement interval configured using the command *ipv6 nd ra interval on page 3162*.

Usage Examples

The following example specifies that the interface include Advertisement Interval Options in RA messages sent from the router:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 nd advertisement-interval**

ipv6 nd dad attempts *<number>*

Use the **ipv6 nd dad attempts** command to specify the number of neighbor solicitation (NS) messages sent by the interface when performing Internet Protocol version 6 (IPv6) duplicate address detection (DAD). This command is effectual when the interface is in either host or router mode. Use the **no** form of this command to return to the default value.

Syntax Description

<number>	Specifies the number of NS messages that will be sent. Range is **0** to **10** messages. A value of **0** disables DAD on the interface.

Default Values

By default, the interface sends **1** NS message.

Command History

Release 18.1	Command was introduced.

Functional Notes

DAD is used by devices to determine if IPv6 addresses are unique before they are applied to interfaces. DAD is used in NS messages to detect duplicate unicast addresses. The Target Address fields in the NS messages are set to the IPv6 address for which duplication is being detected. Destination IPv6 addresses for DAD in NS messages are the solicited-node multicast version of the address being tested. Source IPv6 addresses for DAD are set to the IPv6 unspecified address (::). Once the IPv6 address is determined by DAD to be unique, it can be applied to the IPv6 interface on the node.

DAD in AOS is performed when an interface transitions state from DOWN to UP or when manually configuring an address. When performing DAD because of an interface transition, DAD will happen immediately after the interface transition and again 40 seconds later to cooperate with the port being connected to an Ethernet switch.

Usage Examples

The following example specifies that **3** NS messages are sent by the interface when performing DAD:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 nd dad attempts 3**

ipv6 nd managed-config-flag

Use the **ipv6 nd managed-config-flag** command to specify the M flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. The M flag instructs hosts receiving the RA that they can use stateful Dynamic Host Configuration Protocol version 6 (DHCPv6) to configure addresses and nonaddress information. Use the **no** form of this command to disable the setting of the M flag.

Syntax Description

No subcommands.

Default Values

By default, the M flag is not set in RAs.

Command History

Release 18.1	Command was introduced.

Functional Notes

If you specify that the M flag is set in RA messages, you do not need to set the 0 flag (it becomes redundant).

Usage Examples

The following example sets the M flag for RA messages sent by the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 nd managed-config-flag**

ipv6 nd ns-interval *<value>*

Use the **ipv6 nd ns-interval** command to specify the interval between transmission of certain Internet Protocol version 6 (IPv6) Neighbor Discovery (ND) messages and to control what ND value is advertised in router advertisement (RA) messages. This command is effectual whether the interface is in host or router mode. Use the **no** form of this command to return the interval to the default value.

Syntax Description

<value>	Specifies the time (in milliseconds) between neighbor message transmissions. Valid range is **1000** to **3600000** ms.

Default Values

By default, the interval is set to **1000** ms for internal use by the router and **0** (unspecified) is sent in RA messages.

Command History

Release 18.1	Command was introduced.

Functional Notes

This command controls the spacing of neighbor solicitation (NS) messages for functions such as address resolution, reachability detection, and duplicate address detection (DAD). For DAD it also serves as the amount of time after the last transmission before the detection phase of autoconfiguration terminates. In addition, the command controls the interval between unsolicited neighbor advertisement (NA) messages.

Usage Examples

The following example changes the interval between RA messages sent from the interface to **2000** ms:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 nd ns-interval 2000**

ipv6 nd other-config-flag

Use the **ipv6 nd other-config-flag** command to specify the O flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the interface is in router mode. When the O flag is set, hosts receiving the RA messages are instructed that they may use stateless Dynamic Host Configuration Protocol version 6 (DHCPv6) to receive information that is not IPv6 addressing information, and to use some other method (whether through manual configuration, stateless address autoconfiguration (SLAAC), etc.) for addressing information. Use the **no** form of this command to disable the O flag setting.

Syntax Description

No subcommands.

Default Values

By default, the O flag is not set in RA messages.

Command History

Release 18.1	Command was introduced.

Functional Notes

If the M flag is set for RA messages, you do not need to set the O flag.

Usage Examples

The following example sets the O flag in RA messages from the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 nd other-config-flag**

ipv6 nd prefix

Use the **ipv6 nd prefix** command to specify the Internet Protocol version 6 (IPv6) address prefixes used in router advertisement (RA) messages sent from the interface. Use the **no** form of this command to remove the specified prefix configuration from the interface. Variations of this command include:

ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise] [**<*valid lifetime*> | **infinite]** <*preferred lifetime* | **infinite**>
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite] [no-advertise] [no-autoconfig] [no-rtr-address] [no-onlink] [off-link]**

Syntax Description

named-prefix <*prefix name*>	Optional. Specifies that a named prefix is used in RA messages. When a named prefix is used, the default prefix cannot be used.
<*ipv6 prefix/prefix-length*>	Specifies the IPv6 prefix and length to be advertised. Pv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
default	Specifies the default values for the IPv6 prefix parameters. Refer to the *Functional Notes* below for more information.
<*valid lifetime*>	Optional. Specifies the valid lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
<*preferred lifetime*>	Optional. Specifies the preferred lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
infinite	Optional. Specifies that the the valid and preferred lifetimes of the prefix do not expire.
no-advertise	Optional. Specifies that the prefix is excluded from the RA message.
no-autoconfig	Optional. Sets the A flag in the RA message to **0**, indicating that hosts may not create an address for this prefix using stateless address autoconfiguration (SLAAC). This parameter only affects hosts receiving the RA message, it does not affect the operation of the local router.
no-rtr-address	Optional. Sets the R flag in the RA message to **0** and specifies the full router IPv6 address is not included in the RA message.
no-onlink	Optional. Specifies that the IPv6 prefix in the RA message is not to be used for on-link determination.
off-link	Optional. Sets the L flag value to **0** in RA messages, which indicates the RA makes no statement about the on-link or off-link properties of the IPv6 prefix.

Default Values

By default, all prefixes derived from the interface's configured IPv6 addresses are advertised using the system default values.

By default, the valid lifetime advertised for a prefix is **2592000** seconds and the preferred lifetime advertised is **604800** seconds.

By default, the L flag is set to **1**, the R flag is set to **1**, and the A flag is set to **1**.

Command History

Release 18.1	Command was introduced.
Release R10.9.0	Command was expanded to include the **named-prefix** and *<prefix name>* options.

Functional Notes

This command works for both routers and hosts, but in host implementations it is used to manually add on-link prefixes that do not have an IPv6 address or to make off-link a prefix generated by an IPv6 address command. Hosts do not send RA messages, so the command only adds prefixes to RA messages when the interface is in router mode. This command can also be used to change the defaults used on configured prefixes when all options are not specified.

Changing the prefix defaults will affect prefixes derived from configured IPv6 addresses, as well as prefixes configured using the ***ipv6 nd prefix*** *command.*

Prefixes advertised can be a subset or a superset of the prefixes derived from the IPv6 addresses configured on the interface. Prefixes for IPv6 addresses configured on a router interface are automatically eligible to be advertised on that interface using system or configured default values without having to enter a prefix command. To impose additional controls on those prefixes, an entry must be made using this command with the desired settings.

The **default** parameter is used to change the default settings for the IPv6 prefix parameters. Changing these settings can be useful when multiple prefixes are implemented that will use the same set of parameters. When configuring IPv6 prefixes, the prefix default values are only used if no other parameters are specified after specifying the IPv6 prefix and length (for example, **ipv6 nd prefix 2001:DB8::/64**). If additional parameters are specified, any unspecified parameters use the system default values rather than the configured default values. When the default values are changed, any prefix that uses them will also change. Using this command to change prefix default values also affects prefixes derived from configured IPv6 addresses on the interface.

The optional *<valid lifetime>* parameter specifies the valid lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep this prefix until the valid lifetime expires.

The optional <*preferred lifetime*> parameter specifies the preferred lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep the prefix in the preferred state during this time period. After the preferred time period expires, the prefix transitions to the deprecated state where it remains until the valid lifetime expires and the route is removed. The <*preferred lifetime*> value must be set to be shorter than the <*valid lifetime*> value.

The optional **off-link** parameter sets the L flag (on-link flag) value to **0** in RA messages. When the L flag is set to 0, the advertisement makes no statement about on-link or off-link properties of the prefix. When the L flag is set, the prefix is considered on-link and locally reachable by hosts on the link (meaning a router is not needed). Hosts attached to the link will add on-link prefixes to their prefix list or route table. When off-link is not specified, a connected route is added to the route table of this router for this prefix. When off-link is specified, no route is added to the route table. By default, prefixes are advertised as on-link with the L flag set to 1.

The optional **no-rtr-address** parameter sets the R flag (router flag) of the RA to **0** and does not include the full router address in the advertisement. The router address is typically included in the RA to assist in Mobile IP environments. By default, the R flag is set to 1 and the router address is sent in RA messages.

The optional **no-autoconfig** parameter sets the A flag of the RA to **0**, indicating that hosts may not create an address for this prefix using SLAAC. If the A flag is set to **1** (the default setting), hosts perform SLAAC to generate an address based on the prefix. This parameter only affects hosts receiving the RA, it does not effect the operation of the local router.

The optional **no-advertise** parameter specifies that the prefix is excluded from RA messages. By default, the prefix is included in RA messages. The **no-onlink** parameter informs the router that the prefix is not to be used for on-link determination.

By default, all prefixes derived from the interface's configured IPv6 addresses are advertised using the system default values.

Usage Examples

The following example specifies that the IPv6 prefix **2001:DB8:3F::/48** has an infinite valid and preferred lifetime advertised in RA messages sent from the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 nd prefix 2001:DB8:3F::/48 infinite infinite**

The following example changes the default values and behaviors of prefixes included in RA messages to infinite valid and preferred lifetimes, and specifies that the on- or off-link state of the prefix is not included in the RA and that hosts receiving the RA may not use the prefix for creating an IPv6 address:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 nd prefix default infinite infinite off-link no-autoconfig**

ipv6 nd purge-timer <*value*>

Use the **ipv6 nd purge-timer** command to specify the maximum amount of time an unused Internet Protocol version 6 (IPv6) neighbor entry remains in the neighbor cache. This command applies to interfaces in either host or router mode. Use the **no** form of this command to return the purging interval to the default value.

Syntax Description

<*value*>	Specifies the neighbor cache entry storage time in minutes. Valid range is **10** to **1440** minutes.

Default Values

By default, idle (STALE) neighbor cache entries are cleared after **1440** minutes (24 hours).

Command History

Release 18.1	Command was introduced.

Functional Notes

This command applies to interfaces in either router or host mode. A neighbor entry is typically purged when neighbor unreachability detection (NUD) is invoked and the neighbor is determined to no longer be reachable. However, NUD is not performed on idle (STALE) neighbor entries, so this command provides a method for purging unused entries after a specified amount of time.

Usage Examples

The following example specifies that idle neighbor entries in the neighbor cache are removed after **800** minutes:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 nd purge-timer 800**

ipv6 nd ra interval

Use the **ipv6 nd ra interval** command to specify the interval between transmission of Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the interface is in router mode. Use the **no** form of this command to return to the default value. Variations of this command include:

ipv6 nd ra interval *<max time>*
ipv6 nd ra interval *<max time> <min time>*
ipv6 nd ra interval msec *<max time>*
ipv6 nd ra interval msec *<max time> <min time>*

Syntax Description

<max time>	Specifies the maximum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **4** to **1800** seconds and **70** to **1800000** ms.
<min time>	Optional. Specifies the minimum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **3** seconds to 75 percent of the configured maximum time value in seconds, or **30** ms to 75 percent of the configured maximum time value in ms.
msec	Optional. Specifies that the time values are in milliseconds.

Default Values

By default, the interval is set in seconds and has a maximum interval time of **200** seconds and a minimum interval time of 75 percent of the maximum seconds value, but not less than **3** seconds.

Command History

Release 18.1	Command was introduced.

Functional Notes

If this router is used as a default router, the interval between RA messages should not be set to a larger value than the RA lifetime set by the command *ipv6 nd ra lifetime <value> on page 3163*, which has a default value of **1800** seconds.

Usage Examples

The following example specifies that the maximum interval in seconds between RA message transmissions is **300**:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 nd ra interval 300**

ipv6 nd ra lifetime <*value*>

Use the **ipv6 nd ra lifetime** command to specify the router lifetime advertised in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is effectual when the interface is in router mode. Use the **no** form of this command to return to the default setting. Variations of this command include:

ipv6 nd ra lifetime <*value*>
ipv6 nd ra lifetime default-route

Syntax Description

<*value*>	Specifies the router lifetime in seconds. Range is **0** to **9000** seconds. A value of **0** indicates this is not a default router. A value other than 0 indicates to other nodes that this router can be used as a default router.
default-route	Specifies the RA lifetime is **0** if no default route exists on any IPv6 interface.

Default Values

By default, the router lifetime is set to **1800** seconds.

Command History

Release 18.1	Command was introduced.
Release R11.5.0	Command was expanded to include the **default-route** parameter.

Functional Notes

A value other than **0** for a router lifetime should be larger than the router advertisement interval specified in the command *ipv6 nd ra interval on page 3162*.

Usage Examples

In the following example, the router lifetime advertised in RA messages is **3000** seconds:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 nd ra lifetime 3000**

ipv6 nd ra reachable-time <*value*>

Use the **ipv6 nd ra reachable-time** command to specify the value advertised for reachable time in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command also specifies the internal base reachable time used by the router. This command is effectual for interfaces in either host or router mode. Use the **no** form of this command to return the reachability value to the default setting.

Syntax Description

<*value*>	Specifies the reachability time in milliseconds. Range is **0** to **3600000** ms. A value of **0** indicates the reachable time is unspecified.

Default Values

By default, the router advertises a reachability time of **0** ms and uses an internal value of **30000** ms.

Command History

Release 18.1	Command was introduced.

Functional Notes

This command is effectual for interfaces in either router or host mode. For hosts, this value sets the internal reachable time used by the host if no RAs are received specifying a different value. For routers, the value indicates the amount of time a device is considered reachable after having received a reachability confirmation in neighbor unreachabililty detection (NUD).

Usage Examples

The following example specifies that a reachability time of **50000** ms is advertised in RA messages:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 nd ra reachable-time 50000**

ipv6 nd ra suppress

Use the **ipv6 nd ra suppress** command to specify whether Internet Protocol version 6 (IPv6) router advertisement (RA) messages will be suppressed. This command only applies to interfaces in router mode. Use the **no** form of this command to begin sending RA messages.

Syntax Description

No subcommands.

Default Values

By default, RA messages are not suppressed. When IPv6 routing is not enabled on the router, or when implemented in a host-only mode, the default setting is to suppress advertisements on all interface types.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example suppresses RA messages on the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 nd ra suppress**

ipv6 nd router-preference

Use the **ipv6 nd router-preference** command to specify the default router preference value set in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. Setting this preference helps the receivers of RA messages to determine the preference of one router over another as a default router in environments with multiple routers. Use the **no** form of this command to return the preference to the default setting. Variations of this command include:

ipv6 nd router-preference high
ipv6 nd router-preference low
ipv6 nd router-preference medium

Syntax Description

high	Specifies the preference value is high.
low	Specifies the preference value is low.
medium	Specifies the preference value is medium.

Default Values

By default, the router preference is set to medium.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example specifies that the advertised default router preference is high:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 nd router-preference high**

ipv6 route-cache

Use the **ipv6 route-cache** command to enable Internet Protocol version 6 (IPv6) fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 18.2	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.

Functional Notes

Fast switching allows an IPv6 interface to provide optimum performance when processing IPv6 traffic.

Usage Examples

The following example enables IPv6 fast switching on the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ipv6 route-cache**

keepalive *<value>*

Use the **keepalive** command to enable the transmission of keepalive packets on the interface and specify the time interval in seconds between transmitted packets. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Defines the time interval (in seconds) between transmitted keepalive packets. Valid range is **0** to **32767** seconds.

Default Values

By default, the time interval between transmitted keepalive packets is **10** seconds.

Command History

Release 1.1	Command was introduced.

Functional Notes

If three keepalive packets are sent to an interface with no response, the interface is considered down. To detect interface failures quickly, specify a smaller keepalive time.

Usage Examples

The following example specifies a keepalive time of **5** seconds on the virtual Point-to-Point Protocol (PPP) interface:

(config)**#interface ppp 1**
(config-ppp 1)**#keepalive 5**

lldp receive

Use the **lldp receive** command to allow Link Layer Discovery Protocol (LLDP) packets to be received on this interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, all interfaces are configured to send and receive LLDP packets.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example configures the Point-to-Point Protocol (PPP) interface to receive LLDP packets:

(config)**#interface ppp 1**
(config-ppp 1)**#lldp receive**

lldp send

Use the **lldp send** command to configure this interface to transmit Link Layer Discovery Protocol (LLDP) packets or to control the types of information contained in the LLDP packets transmitted by this interface. Use the **no** form of this command to disable this feature. Variations of this command include:

lldp send management-address
lldp send port-description
lldp send system-capabilities
lldp send system-description
lldp send system-name
lldp send-and-receive

Syntax Description

management-address	Enables transmission of management address information on this interface.
port-description	Enables transmission of port description information on this interface.
system-capabilities	Enables transmission of this device's system capabilities on this interface.
system-description	Enables transmission of this device's system description on this interface.
system-name	Enables transmission of this device's system name on this interface.
and-receive	Configures this interface to both transmit and receive LLDP packets.

Default Values

By default, all interfaces are configured to transmit and receive LLDP packets of all types.

Command History

Release 9.1	Command was introduced.

Functional Notes

Individual LLDP information can be enabled or disabled using the various forms of the **lldp send** command. For example, use the **lldp send-and-receive** command to enable transmit and receive of all LLDP information. Then use the **no lldp send port-description** command to prevent LLDP from transmitting port description information.

Usage Examples

The following example configures the Point-to-Point Protocol (PPP) interface to transmit LLDP packets containing all enabled information types:

(config)**#interface ppp 1**
(config-ppp 1)**#lldp send**

The following example configures the PPP interface to transmit and receive LLDP packets containing all information types:

(config)**#interface ppp 1**
(config-ppp 1)**#lldp send-and-receive**

max-reserved-bandwidth <*value*>

Use the **max-reserved-bandwidth** command to specify the percentage of interface bandwidth reserved for use in user-defined (priority or class-based) queues. The remainder of the interface bandwidth is reserved for system-critical traffic and is not available to user-defined queues. Use the **no** form of this command to restore the default value.

Reserving a portion of the interface bandwidth for system-critical traffic is necessary for proper operation. Specifying the entire interface bandwidth for use in user-defined queues can cause undesirable operation.

Syntax Description

<*value*>	Specifies the maximum percentage of bandwidth to reserve for quality of service (QoS). This setting is configured as a percentage of the total interface speed. Range: **1** to **100** percent.

Default Values

By default, **max-reserved-bandwidth** is set to **75** percent, which reserves 25 percent of the interface bandwidth for system-critical traffic.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example specifies **85** percent of the bandwidth on the Point-to-Point Protocol (PPP) 1 be available for use in user-defined queues:

(config)**#interface ppp 1**
(config-ppp 1)**#max-reserved-bandwidth 85**

media-gateway ip

Use the **media-gateway ip** command to associate an Internet Protocol version 4 (IPv4) address source to use for Realtime Transport Protocol (RTP) traffic. When configuring Voice over Internet Protocol (VoIP), RTP traffic must have an IPv4 address associated with it. However, some interfaces allow dynamic configuration of IPv4 addresses, causing this value to change periodically. Use the **no** form of this command to disable this function. Variations of this command include:

media-gateway ip loopback <*interface id*>
media-gateway ip primary
media-gateway ip primary vrrp <*number*>
media-gateway ip primary vrrpv3 <*number*>
media-gateway ip secondary <*ipv4 address*>
media-gateway ip secondary vrrp <*number*>
media-gateway ip secondary vrrp <*number*> <*ipv4 address*>
media-gateway ip secondary vrrpv3 <*number*>
media-gateway ip secondary vrrpv3 <*number*> <*ipv4 address*>

Syntax Description

loopback <*interface id*>	Specifies an IPv4 address statically defined to a loopback interface for RTP traffic. This is helpful when using a single IPv4 address across multiple wide area network (WAN) interfaces for RTP traffic. The valid range for loopback interface identifiers is **1** to **1024**. The interface ID is used to uniquely identify a loopback interface. The entered value cannot be in use by another loopback interface.
primary	Specifies using this interface's configured primary IPv4 address for RTP traffic. Applies to static, Dynamic Host Configuration Protocol (DHCP), or negotiated addresses.
secondary <*ipv4 address*>	Specifies using this interface's statically defined secondary IPv4 address for RTP traffic. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
vrrp <*number*>	Specifies that the IPv4 address of the Virtual Router Redundancy Protocol version 2 (VRRP) router group's virtual router ID (VRID) is used as the media gateway address on the interface. Valid VRID range is **1** to **255**.
vrrpv3 <*number*>	Specifies that the IPv4 address of the VRRP version 3 (VRRPv3) VRID is used as the media gateway address on the interface. Valid VRID range is **1** to **255**.
<*ipv4 address*>	Optional. Specifies a secondary IPv4 address of the VRRP or VRRPv3 VRID is used as the media gateway address on the interface. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, **media-gateway ip** is disabled.

Command History

Release 10.1	Command was introduced.
Release 17.3	Command was updated with the loopback interface identification option.
Release A4.01	Command was expanded to include the Metro Ethernet forum (MEF) Ethernet interface.
Release R12.2.0	Command was expanded to include the **vrrp** and **vrrpv3** parameters.

Functional Notes

To use VRRP or VRRPv3 addresses as the media gateway on the interface, you must first have configured VRRP or VRRPv3.

Usage Examples

The following example configures the unit to use the primary IPv4 address for RTP traffic:

(config)**#interface ppp 1**
(config-ppp 1)**#media-gateway ip primary**

media-gateway ipv6

Use the **media-gateway ipv6** command to associate an Internet Protocol version 6 (IPv6) address source to use for Realtime Transport Protocol (RTP) traffic. When configuring Voice over Internet Protocol (VoIP), RTP traffic must have an IPv6 address associated with it. However, some interfaces allow dynamic configuration of IPv6 addresses, causing this value to change periodically. Use the **no** form of this command to disable this function. Variations of this command include:

media-gateway ipv6
media-gateway ipv6 <*ipv6 address*>
media-gateway ipv6 loopback <*interface id*>
media-gateway ipv6 vrrpv3 <*number*>
media-gateway ipv6 vrrpv3 <*number*> <*ipv6 address*>

Syntax Description

<*ipv6 address*>	Specifies an IPv6 address to use for the media gateway. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
loopback <*interface id*>	Specifies an IPv6 address statically defined to a loopback interface for RTP traffic. This is helpful when using a single IPv6 address across multiple wide area network (WAN) interfaces for RTP traffic. The valid range for loopback interface identifiers is **1** to **1024**. The interface ID is used to uniquely identify a loopback interface. The entered value cannot be in use by another loopback interface.
vrrpv3 <*number*>	Specifies that all the secondary IPv6 addresses of the Virtual Routing Redundancy Protocol version 3 (VRRPv3) virtual router ID (VRID) are used as media gateway addresses on the interface. Valid VRID range is **1** to **255**.
<*ipv6 address*>	Optional. Specifies a single IPv6 address of the VRRPv3 VRID is used as the media gateway address on the interface. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.

Default Values

By default, **media-gateway ipv6** is disabled.

Command History

Release R10.8.0	Command was introduced.
Release R12.2.0	Command was expanded to include the **vrrpv3** parameters.

Functional Notes

To use VRRPv3 addresses as the media gateway on the interface, you must first have configured VRRPv3.

Usage Examples

The following example configures the unit to use the IPv6 address for RTP traffic:

(config)**#interface ppp 1**
(config-ppp 1)**#media-gateway ipv6**

ospfv3 <*process id*> **area** <*area id*>

Use the **ospfv3 area** command to add an interface to an Open Shortest Path First version 3 (OSPFv3) process, and to configure the OSPFv3 process on the interface. This command places the interface in the specified area for the specified Internet Protocol version 6 (IPv6) OSPFv3 address family, and optionally defines the instance ID that is used to represent this OSPFv3 process in messages on the interface's link. Use the **no** form of this command to remove the OSPFv3 process from the interface. Variations of this command include:

ospfv3 <*process id*> **area** <*area id*> **ipv6**
ospfv3 <*process id*> **area** <*area id*> **ipv6 instance** <*instance id*>

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join, for the specified address family. The process ID is locally significant to the device, and must be unique among all OSPFv3 processes on the device. Valid range is **1** to **65535**.
<*area id*>	Specifies the ID of the area to which this interface is assigned for the given OSPFv3 process. Valid range is **0** to **4294967295**.
ipv6	Identifies the OSPFv3 address family as IPv6.
instance <*instance id*>	Optional. Specifies the value to use in the instance ID field of messages sent or received by this OSPFv3 process on the interface's link. Valid range is **0** to **31**.

Default Values

By default, an OSPFv3 process is not configured on an interface. By default, process IDs, area IDs, and instance IDs are not defined.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

When using this command to enable an OSPFv3 process on an interface, keep the following rules in mind:

- The interface must have the address family enabled on the interface. If the address family is not enabled on the interface, the command is rejected and an error is displayed.
- Only interfaces on the default virtual routing and forwarding (VRF) instance support this command. Interfaces on a nondefault VRF will display an error when you attempt to configure OSPFv3 settings.
- The interface and the specified OSPFv3 process (if defined in the global configuration) must be in the same VRF or the command will fail.
- The address family must match that specified for the OSPFv3 process if the process has been defined in the global configuration or the command will fail.
- If the OSPFv3 process identified by the process ID does not exist in the global configuration, it is automatically created, along with the specified address family, and it is assigned to the VRF of which the interface is a member.

- If the specified OSPFv3 process is already at its maximum limit of processes or address families, the command fails.
- If the specified OSPFv3 process already exists in the global configuration, but its configuration does not include an address family, the specified address family is added to the OSPFv3 router configuration.
- A given OSPFv3 process can only have one address family.
- Multiple OSPFv3 instances per address family, per VRF, can be created and can be assigned to a given interface.
- If the interface's VRF changes, all OSPFv3 assignments are removed.
- To change an OSPFv3 process's VRF, the process must first be removed and then recreated. Removing the process removes all OSPFv3 assignments for that process form all interfaces.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

To add an interface to the OSPFv3 process **5**, in area **10**, with an instance ID of **10**, enter the command as follows:

(config)**#interface ppp 1**
(config-ppp 1)**#ospfv3 5 area 10 ipv6 instance 10**

ospfv3 authentication

Use the **ospfv3 authentication** command to authenticate an interface that is performing Internet Protocol version 6 (IPv6) Open Shortest Path First version 3 (OSPFv3) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ospfv3 authentication ipsec spi <*spi*> **md5** <*key*>
ospfv3 authentication ipsec spi <*spi*> **sha1** <*key*>
ospfv3 authentication null

Syntax Description

ipsec	Specifies that IP security (IPsec) authentication is used.
spi <*spi*>	Specifies the security parameter index (SPI). Valid range is **256** to **4294967295**.
md5 <*key*>	Specifies that MD5 authentication is used. Keys are specified in 32 hexadecimal characters.
sha1 <*key*>	Specifies that SHA-1 authentication is used. Keys are specified in 40 hexadecimal characters.
null	Specifies that no OSPFv3 authentication is used.

Default Values

By default, this is set to **null** (meaning no authentication is used).

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example specifies that no OSPFv3 authentication will be used on the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ospfv3 authentication null**

ospfv3 <*process id*> cost <*cost*>

Use the **ospfv3 cost** command to specify a value that represents the cost of sending an Open Shortest Path First version 3 (OSPFv3) packet over the interface. Use the **no** form of this command to return the cost to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3177*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
cost <*cost*>	Specifies the OSPFv3 cost of the interface. This value overrides any automatically computed cost value (default value). Valid range is **1** to **65535**.

Default Values

By default, the OSPFv3 cost of the interface is automatically computed. The automatic cost computation is the reference bandwidth divided by the interface bandwidth. The reference bandwidth is set by the command *auto-cost reference-bandwidth <value> on page 4150*, and defaults to **100** Mbps.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the OSPFv3 cost of the interface as **10**:

```
(config)#interface ppp 1
(config-ppp 1)#ospfv3 5 cost 10
```

ospfv3 <*process id*> dead-interval <*value*>

Use the **ospfv3 dead-interval** command to specify the maximum interval allowed between Open Shortest Path First version 3 (OSPFv3) Hello packets on the interface. If the maximum interval is exceeded, neighboring devices will assume that the device is down. This value must be the same across all interfaces on a link. Use the **no** form of this command to return the dead interval to the default value.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3177*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
dead-interval <*value*>	Specifies the maximum number of seconds allowed between OSPFv3 Hello packets. It is recommended that this value be **4** times the Hello packet interval (set with the command *ospfv3 <process id> hello-interval <value> on page 3184*). Valid range is **1** to **65535** seconds.

Default Values

By default, the maximum interval allowed between OSPFv3 Hello packets is set to **40** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

To specify the dead interval between OSPFv3 Hello packets on the interface, enter the command as follows:

(config)**#interface ppp 1**
(config-ppp 1)**#ospfv3 5 dead-interval 100**

ospfv3 encryption

Use the **ospfv3 encryption** command to specify a symmetrical, bidirectional Open Shortest Path First version 3 (OSPFv3) security association (SA) that uses encapsulating security payload (ESP) for encryption and authentication of all OSPFv3 messages that are sent or received on the interface. This command allows you to specify OSPFv3 security at the interface level. Use the **no** form of this command to remove IP security (IPsec) protection of OSPFv3 messages on the interface. Variations of this command include:

ospfv3 encryption ipsec spi <*spi*> **esp** <*encryption type*> <*encryption key*> <*authentication type*> <*authentication key*>
ospfv3 encryption ipsec spi <*spi*> **esp null** <*authentication type*> <*authentication key*>
ospfv3 encryption null

Syntax Description

ipsec	Specifies that IPsec encryption is used on the interface for OSPFv3 SAs.
spi <*spi*>	Specifies the security parameter index (SPI) for the SA. The value specified must not be in used by any other IPsec function on the system, or an error message is generated. If the same SPI is already in use in the same OSPFv3 area, entering this command with the same value will overwrite the current configuration. Valid SPI range is **256** to **4294967295**.
esp	Specifies that ESP is used.
null	Specifies that OSPFv3 messages on this interface are not encrypted when used in the **ospfv3 encryption null** format (even when encryption is specified by the OSPFv3 area configuration). When used in the **ospfv3 encryption ipsec spi** <*spi*> **esp null** format, **null** indicates that messages on the interface will not be encrypted, but will be authenticated.
<*encryption type*>	Specifies the type of algorithm used to encrypt OSPFv3 messages. Valid values for encryption are: **3des** uses triple data encryption standard (DES). **aes-cbc** uses advanced encryption standard (AES) with cipher block chaining (CBC). Select from **aes-cbc 128**, **aes-cbc 192**, or **aes-cbc 256**. **des** uses DES.
<*encryption key*>	Specifies the hexadecimal encryption key. The size of the encryption key is determined by the respective encryption algorithm, as follows: **3des** uses a **48** character key size. **aes-cbc 128** uses a **32** character key size. **aes-cbc 192** uses a **48** character key size. **aes-cbc 256** uses a **64** character key size. **des** uses a **16** character key size.
<*authentication type*>	Specifies the algorithm used for authenticating OSPFv3 messages. Valid authentication methods are Message-Digest 5 (**md5**) and Secure-Hash 1 (**sha1**) algorithms.

<authentication key> Specifies the hexadecimal authentication key. The size of the authentication key is determined by the respective authentication algorithm, as follows:

md5 uses a **32** character key size.

sha1 uses a **40** character key size.

Default Values

By default, there is no security for OSPFv3 messages on an interface.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

This commands specifies OSPFv3 security at the interface level. Protection specified with this command overrides any area-level OSPFv3 protection that might apply to the interface.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures OSPFv3 messages with an SPI of **120**, no encryption, and **md5** as the authentication method:

```
(config)#interface ppp 1
(config-ppp 1)#ospfv3 encryption ipsec spi 120 esp null md5
    NeWtStpsswdLoonGpsswDhtThmnWoKEY
```

ospfv3 <*process id*> hello-interval <*value*>

Use the **ospfv3 hello-interval** command to specify the interval between Open Shortest Path First version 3 (OSPFv3) Hello packets sent on the interface. This value must be the same across all interfaces on the link. Use the **no** form of this command to return the Hello packet interval to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3177*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
hello-interval <*value*>	Specifies the number of seconds allowed between OSPFv3 Hello packets. Valid range is **1** to **65535** seconds.

Default Values

By default, the Hello packet interval for OSPFv3 is **10** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the interval between OSPFv3 Hello packets on the interface is **20** seconds:

(config)**#interface ppp 1**
(config-ppp 1)**#ospfv3 5 hello-interval 20**

ospfv3 <*process id*> network

Use the **ospfv3 network** command to specify the network type for Open Shortest Path First version 3 (OSPFv3) enabled interfaces. Use the **no** form of this command to return the interface's network type to the default value. Variations of this command include:

ospfv3 <*process id*> **network broadcast**
ospfv3 <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3177*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
broadcast	Specifies that the OSPFv3 network type for the interface is set to broadcast.
point-to-point	Specifies that the OSPFv3 network type for the interface is set to point-to-point.

Default Values

By default, Ethernet interfaces are set to network type broadcast, and point-to-point (PPP), Frame Relay, and loopback interfaces are set to network type point-to-point.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the network interface as point-to-point:

(config)**#interface ppp 1**
(config-ppp 1)**#ospfv3 5 network point-to-point**

ospfv3 <*process id*> priority <*value*>

Use the **ospfv3 priority** command to specify the Open Shortest Path First version 3 (OSPFv3) priority for the interface. Use the **no** form of this command to return the interface's priority to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3177*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
priority <*value*>	Specifies the OSPFv3 priority for the interface. Valid range is **0** to **255**.

Default Values

By default, the OSPFv3 priority of an interface is set to **1**.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

Priority is used in the election of the designated router and backup designated router on multi-access networks. Interfaces connected to multi-access networks (such as Ethernet interfaces) perform an election for a designated and backup designated router. The router interface with the highest OSPFv3 priority on the link becomes the designated router for that link. The interface with the next highest priority becomes the designated backup router. In the event there is a tie, the router interface with the highest router ID takes precedence. A priority value of **0** indicates the router is ineligible to become either the designated or backup designated router.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example changes the interface's OSPFv3 priority value to **6**:

```
(config)#interface ppp 1
(config-ppp 1)#ospfv3 5 priority 6
```

ospfv3 <*process id*> retransmit-interval <*value*>

Use the **ospfv3 retransmit-interval** command to specify the interval between Open Shortest Path First version 3 (OSPFv3) link-state advertisements (LSAs) sent on the interface. Use the **no** form of this command to return the OSPFv3 LSA interval to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3177*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
retransmit-interval <*value*>	Specifies the number of seconds between OSPFv3 LSAs sent on the interface. Valid range is **1** to **65535** seconds.

Default Values

By default, the LSA retransmit interval is set to **5** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the LSA retransmit interval is **10** seconds:

(config)**#interface ppp 1**
(config-ppp 1)**#ospfv3 5 retransmit-interval 10**

ospfv3 <*process id*> shutdown

Use the **ospfv3 shutdown** command to disable an Open Shortest Path First version 3 (OSPFv3) process on the interface. When this command is used, the OSPFv3 commands remain in place, but logically it appears to the interface as though the OSPFv3 process has been removed from the configuration. This command can be useful in troubleshooting. Use the **no** form of this command to reinstate the OSPFv3 process.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3177*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.

Default Values

No default values are necessary for this command.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example disables OSPFv3 process **5** on the interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ospfv3 5 shutdown**

ospfv3 <*process id*> transmit-delay <*value*>

Use the **ospfv3 transmit-delay** command to specify the estimated time that is required to propagate an Open Shortest Path First version 3 (OSPFv3) link-state advertisement (LSA) on the interface. Use the **no** form of this command to return the transmit delay to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3177*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
transmit-delay <*value*>	Specifies the number of seconds required to send LSAs from the interface. Valid range is **1** to **65535** seconds.

Default Values

By default, the LSA transmit delay is set to **1** second.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example changes the interface's LSA transmit delay to **2** seconds:

(config)**#interface ppp 1**
(config-ppp 1)**#ospfv3 5 transmit-delay 2**

peer default ip address *<ipv4 address>*

Use the **peer default ip address** command to specify the default peer Internet Protocol version 4 (IPv4) address of the remote end of this interface. Use the **no** form of this command to remove an assigned IPv4 address.

Syntax Description

<ipv4 address>	Specifies the default peer IPv4 address for the remote end. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, there is no assigned default peer IPv4 address.

Command History

Release 3.1	Command was introduced.

Functional Notes

This command is useful if the peer does not send the IPv4 address option during Point-to-Point Protocol (PPP) negotiations.

Usage Examples

The following example sets the default peer IPv4 address to **192.22.71.50**:

(config)**#interface ppp 1**
(config-ppp 1)**#peer default ip address 192.22.71.50**

peer default ipv6 interface-id *<interface id>*

Use the **peer default ipv6 interface-id** command to specify the default peer Internet Protocol version 6 (IPv6) interface ID of the remote end of this interface. Use the **no** form of this command to remove an assigned IPv6 interface ID.

Syntax Description

<interface id>	Specifies the default peer IPv6 interface ID for the remote end. IPv6 interface IDs should be expressed in colon hexadecimal notation (**X:X:X:X**). For example, **2AA:FF:FE3F:2A1C**.

Default Values

By default, there is no assigned default peer IPv6 interface ID.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example sets the default peer IPv6 interface ID to **2AA:FF:FE3F:2A1C**:

(config)**#interface ppp 1**
(config-ppp 1)**#peer default ipv6 interface-id 2AA:FF:FE3F:2A1C**

ppp authentication

Use the **ppp authentication** command to specify the authentication protocol on the Point-to-Point Protocol (PPP) virtual interface that the peer should use to authenticate itself. Use the **no** form of this command to disable this feature. Variations of this command include:

ppp authentication chap
ppp authentication pap

Syntax Description

chap	Configures Challenge-Handshake Authentication Protocol (CHAP) on the interface.
pap	Configures Password Authentication Protocol (PAP) on the interface.

Default Values

By default, PPP endpoints have no authentication configured.

Command History

Release 1.1	Command was introduced.

Technology Review

CHAP and PAP are two authentication methods that enjoy widespread support. Both methods are included in AOS and are easily configured.

The authentication method set up on the local router can be different from that on the peer. Also, just because one router requires authentication from its peer does not mean it also has to authenticate itself to the peer.

Defining PAP

PAP is used to verify that the PPP peer is a permitted device by checking a user name and password configured on the peer. The user name and password are both sent unencrypted across the connecting private circuit.

PAP requires two-way message passing. First, the router that is required to be authenticated (for example, the peer) sends an authentication request with its user name and password to the router requiring authentication (for example, the local router). The local router then looks up the user name and password in the user name database within the PPP interface, and if they match sends an authentication acknowledge back to the peer.

The PPP user name and password database is separate and distinct from the global user name password database. For PAP and CHAP, use the database under the PPP interface configuration.

Several example scenarios are given below for clarity.

Configuring PAP Example 1: Only the local router requires the peer to authenticate itself.

On the local router (host name **Local**):

Local(config-ppp 1)**#ppp authentication pap**
Local(config-ppp 1)**#username farend password far**

On the peer (host name **Peer**):

Peer(config-ppp 1)**#ppp pap sent-username farend password far**

The first line of the configuration sets the authentication mode as PAP. This means the peer is required to authenticate itself to the local router via PAP. The second line is the user name and password expected to be sent from the peer. On the peer, the **ppp pap sent-username** command is used to specify the appropriate matching user name and password.

Configuring PAP Example 2: Both routers require the peer to authenticate itself.

On the local router (host name **Local**):

Local(config-ppp 1)**#ppp authentication pap**
Local(config-ppp 1)**#username farend password far**
Local(config-ppp 1)**#ppp pap sent-username nearend password near**

On the peer (host name **Peer**):

Peer(config-ppp 1)**#ppp authentication pap**
Peer(config-ppp 1)**#username nearend password near**
Peer(config-ppp 1)**#ppp pap sent-username farend password far**

Now both routers send the authentication request, verify that the user name and password sent match what is expected in the database, and send an authentication acknowledge.

Defining CHAP

CHAP is a three-way authentication protocol composed of a challenge response and success or failure. The message digest 5 (MD5) protocol is used to protect user names and passwords in the response.

First, the local router (requiring its peer to be authenticated) sends a challenge containing the unencrypted user name of the peer and a random number. The user name of the peer is found in the user name database within the PPP interface of the local router. The peer then looks up the user name in the user name database within the PPP interface, and if found takes the corresponding password and its own host name and sends a response back to the local router. This data is encrypted. The local router verifies that the user name and password are in its own user name database within the PPP interface, and if so sends a success back to the peer.

The PPP user name and password database is separate and distinct from the global user name password database. For PAP and CHAP, use the database under the PPP interface configuration.

Several example scenarios are given below for clarity.

Configuring CHAP Example 1: Only the local router requires the peer to authenticate itself.

On the local router (host name **Local**):

Local(config-ppp 1)**#ppp authentication chap**
Local(config-ppp 1)**#username Peer password same**

On the peer (host name **Peer**):

Peer(config-ppp 1)**#ppp chap password same**

The first line of this configuration sets the authentication mode to CHAP. This means the peer is required to authenticate itself to the local router via CHAP. The second line is the user name and password expected to be sent from the peer. The peer uses its **hostname** and **ppp chap password** commands to send the proper authentication information.

Both ends must have identical passwords.

Configuring CHAP Example 2: Using the ppp chap hostname command as an alternate solution.

On the local router (host name **Local**):

Local(config-ppp 1)**#ppp authentication chap**
Local(config-ppp 1)**#username farend password same**

On the peer (host name **Peer**):

Peer(config-ppp 1)**#ppp chap hostname farend**
Peer(config-ppp 1)**#ppp chap password same**

Notice the local router is expecting user name **farend** even though the peer router's host name is **Peer**. Therefore, the peer router can use the **ppp chap hostname** command to send the correct name in the challenge.

Both ends must have identical passwords.

Configuring CHAP Example 3: Both routers require each other to authenticate themselves using the same shared password.

On the local router (host name **Local**):

Local(config-ppp 1)**#ppp authentication chap**
Local(config-ppp 1)**#username Peer password same**

On the peer (host name **Peer**):

Peer(config-ppp 1)**#ppp authentication chap**
Peer(config-ppp 1)**#username Local password same**

This is basically identical to Example 1 except that both routers will now challenge each other and respond.

Both ends must have identical passwords.

Configuring CHAP Example 4: Both routers require each other to authenticate themselves using two separate shared passwords.

On the local router (host name **Local**):

Local(config-ppp 1)**#ppp authentication chap**
Local(config-ppp 1)**#username Peer password far**
Local(config-ppp 1)**#ppp chap password near**

On the peer (host name **Peer**):

Peer(config-ppp 1)**#ppp authentication chap**
Peer(config-ppp 1)**#username Local password near**
Peer(config-ppp 1)**#ppp chap password far**

This is basically identical to Example 3, except that there are two separate shared passwords.

Notice this example has both ends using different sets of passwords.

Configuring CHAP Example 5: Using the ppp chap hostname command as an alternate solution.

On the local router (host name **Local**):

Local(config-ppp 1)**#ppp authentication chap**
Local(config-ppp 1)**#username farend password far**
Local(config-ppp 1)**#ppp chap hostname nearend**
Local(config-ppp 1)**#ppp chap password near**

On the peer (host name **Peer**):

Peer(config-ppp 1)**#ppp authentication chap**
Peer(config-ppp 1)**#username nearend password near**
Peer(config-ppp 1)**#ppp chap hostname farend**
Peer(config-ppp 1)**#ppp chap password far**

Notice the local router is expecting user name **farend** even though the peer router's host name is **Peer**. Therefore, the peer router can use the **ppp chap hostname** command to send the correct name on the challenge.

Notice this example has both ends using different sets of passwords.

ppp bcp tagged-frame

Use the **ppp bcp tagged-frame** command to allow negotiation of IEEE 802.1Q-tagged packets over Bridging Control Protocol (BCP). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release 14.1	Command was introduced.

Usage Examples

The following example configures Point-to-Point Protocol (PPP) interface 1 to negotiate tagged frames over BCP:

(config)**#interface ppp 1**
(config-ppp 1)**#ppp bcp tagged-frame**

ppp chap hostname *<name>*

Use the **ppp chap hostname** command to configure an alternate host name for Challenge-Handshake Authentication Protocol (CHAP) Point-to-Point Protocol (PPP) authentication. Use the **no** form of this command to remove a configured host name. For more information on Password Authentication Protocol (PAP) and CHAP functionality, refer to the *Technology Review* section for the command *ppp authentication on page 3192*.

Syntax Description

<name>	Specifies a host name using an alphanumeric string up to 80 characters in length.

Default Values

By default, there are no configured PPP CHAP host names.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example specifies a PPP CHAP host name of **my_host**:

(config)**#interface ppp 1**
(config-ppp 1)**#ppp chap hostname my_host**

ppp chap password *<password>*

Use the **ppp chap password** command to configure an alternate password when the peer requires Challenge-Handshake Authentication Protocol (CHAP) Point-to-Point Protocol (PPP) authentication. Use the **no** form of this command to remove a configured password. For more information on Password Authentication Protocol (PAP) and CHAP functionality, refer to the *Technology Review* section for the command *ppp authentication on page 3192*.

Syntax Description

<password>	Specifies a password using an alphanumeric string up to 80 characters in length.

Default Values

By default, there is no defined PPP CHAP password.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example specifies a PPP CHAP password of **my_password**:

(config)**#interface ppp 1**
(config-ppp 1)**#ppp chap password my_password**

ppp mtu *<size>*

Use the **ppp mtu** command to configure the Point-to-Point Protocol (PPP) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<size>	Configures the window size for transmitted packets. The valid range is **64** to **2100** bytes.

Default Values

By default, the PPP MTU on an interface is set to **1500** bytes.

Command History

Release 17.9	Command was introduced.

Usage Examples

The following example specifies a PPP MTU of **1200** on the PPP interface:

(config)**#interface ppp 1**
(config-ppp 1)**#ppp mtu 1200**

ppp multilink

Use the **ppp multilink** command to enable Multilink Point-to-Point Protocol (MLPPP) operation on an existing Point-to-Point Protocol (PPP) interface. Use the **no** form of this command to disable this feature. Variations of this command include:

ppp multilink fragmentation
ppp multilink interleave
ppp multilink maximum <*number*>

Syntax Description

fragmentation	Enables multilink fragmentation operation.
interleave	Enables multilink interleave operation.
maximum <*number*>	Specifies the maximum number of links allowed in a PPP multilink bundle.

Default Values

By default, MLPPP is disabled.

Command History

Release 7.1	Command was introduced.
Release 7.2	Fragmentation and interleave operation were added.
Release 11.1	Command was expanded to include the demand interface.

Functional Notes

When enabled, this interface is capable of the following:

- Combining multiple physical links into one logical link.
- Receiving upper layer protocol data units (PDUs), fragmenting and transmitting over the physical links.
- Receiving fragments over the physical links and reassembling them into PDUs.

The fragmentation and interleave options can be used to enhance the multilink operation. Fragmentation is used to reduce serialization delays of large packets. The fragmentation process evenly divides the data among all links in the bundle with a minimum packet size of 96 bytes. The interleave operation is used with streaming protocols to reduce delay by giving priority to packets identified as high priority. In order delivery is guaranteed with multilink fragmentation, but is not guaranteed with multilink interleave operation.

The multilink bundle will remain active with a minimum of one physical link. Physical links may be dynamically added or removed from the multilink bundle with minor interruption to traffic flow.

Usage Examples

The following example enables MLPPP:

(config)**#interface ppp 1**
(config-ppp 1)**#ppp multilink**

ppp pap sent-username <*username*> password <*password*>

Use the **ppp pap sent-username password** command to configure a user name and password when the peer requires Password Authentication Protocol (PAP) Point-to-Point Protocol (PPP) authentication. Use the **no** form of this command to remove a configured password. For more information on PAP and Challenge-Handshake Authentication Protocol (CHAP) functionality, refer to the *Technology Review* section for the command *ppp authentication on page 3192*.

Syntax Description

<username>	Specifies a user name by alphanumeric string up to 80 characters in length (the user name is case sensitive).
<password>	Specifies a password by alphanumeric string up to 80 characters in length (the password is case sensitive).

Default Values

By default, there is no defined **ppp pap sent-username** and **password**.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example specifies a PPP PAP sent user name of **local** and a password of **my_password**:

(config)**#interface ppp 1**
(config-ppp 1)**#ppp pap sent-username local password my_password**

pppoe ac-name *<name>*

Use the **pppoe ac-name** command to identify the access controller (AC) with which AOS expects to establish a Point-to-Point Protocol over Ethernet (PPPoE) session. Use the **no** form of this command to return to the default setting.

Syntax Description

<name>	Specifies an AC by text string (up to 255 characters) corresponding to the AC-Name Tag under RFC 2516. If this field is not specified, any AC is acceptable. The AC value may be a combination of trademark, model, and serial ID information (or simply the medium access control (MAC) address of the unit).

Default Values

By default, no AC is specified.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example identifies the AC with which AOS expects to establish a PPPoE session:

(config)**#interface ppp 1**
(config-ppp 1)**#pppoe ac-name Access_Controller_Name**

pppoe service-name <*name*>

Use the **pppoe service-name** command to use this tag value to filter Point-to-Point Protocol over Ethernet (PPPoE) session offers from PPPoE servers. Use the **no** form of this command to return to the default setting.

Syntax Description

<*name*>	Specifies a service name by text string (up to 255 characters) corresponding to the Service-Name Tags under RFC 2516. This string indicates an Internet service provider (ISP) name (or a class of service (CoS) or quality of service (QoS)). If this field is not specified, any service is acceptable.

Default Values

By default, no names are specified.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example defines a service type that is not to be accepted by AOS:

(config)**#interface ppp 1**
(config-ppp 1)**#pppoe service-name Service_Name**

qos-policy

Use the **qos-policy** command to apply a previously configured quality of service (QoS) map to incoming or outgoing packets on an interface. Use the **no** form of this command to remove the map from the interface. Variations of this command include:

qos-policy in *<name>*
qos-policy out *<name>*

Syntax Description

<name>	Specifies the name of a previously created QoS map (refer to *qos map <name> <number> on page 1673* for more information).
in	Assigns a QoS map to this interface's input.
out	Assigns a QoS map to this interface's output.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.
Release 15.1	Command was expanded to include the **in** parameter.

Functional Notes

When a QoS policy is applied to an interface, it may be disabled if the interface bandwidth is not adequate to support the requested bandwidth on the map set. Once the bandwidth problem is resolved, the map will work again. The bandwidth will be rechecked on any of the following changes:

1. A priority or class-based entry is added to, deleted from, or changed in a QoS map set.
2. The interface bandwidth is changed by the **bandwidth** command on the interface.
3. A QoS policy is applied to an interface.
4. A cross connect is created that includes an interface with a QoS policy.
5. The interface queuing method is changed to fair-queue to use weighted fair queuing (WFQ).
6. The interface operational status changes.
7. The interface bandwidth changes for other reasons (e.g., when asymmetric digital subscriber line (ADSL) finishes training).

In order to prevent the map from being disabled in cases of temporary inadequate bandwidth (e.g., a single link goes down in a dual T1 multilink configuration where the map requests more than one T1's worth of bandwidth), the QoS map uses the maximum theoretical bandwidth on an interface, not the actual bandwidth at that time. This actually helps QoS keep higher priority class-based traffic working better than best-effort traffic when the bandwidth drops.

Usage Examples

The following example applies the QoS map **VOICEMAP** to the Point-to-Point Protocol (PPP) 1 interface:

(config)**#interface ppp 1**
(config-ppp 1)**#qos-policy out VOICEMAP**

rtp quality-monitoring

Use the **rtp quality-monitoring** command to enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets on this interface. If the global command (**ip rtp quality-monitoring**) is disabled when this command is issued, the system will return the following warning: "Applied but not used, you must globally enable **ip rtp quality-monitoring** to use VQM." Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, VQM is enabled on all wide area network (WAN) and local area network (LAN) interfaces.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables RTP quality monitoring on the virtual Point-to-Point Protocol (PPP) interface:

(config)**#interface ppp 1**
(config-ppp 1)**#rtp quality-monitoring**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release 17.2	Command was expanded to the cellular interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the virtual Point-to-Point Protocol (PPP) interface:

(config)**#interface ppp 1**
(config-ppp 1)**#no snmp trap link-status**

username *<username>* **password** *<password>*

Use the **username password** command to configure the user name and password of the peer to use for Point-to-Point Protocol (PPP) authentication. Use the **no** form of this command to remove a configured user name and password.

Syntax Description

<username>	Specifies a user name by alphanumerical string up to 30 characters in length (the user name is case sensitive).
<password>	Specifies a password by alphanumerical string up to 30 characters in length (the password is case sensitive).

Default Values

By default, there is no established user name and password.

Command History

Release 1.1	Command was introduced.

Functional Notes

Password Authentication Protocol (PAP) uses this entry to check received information from the peer. Challenge-Handshake Authentication Protocol (CHAP) uses this entry to check the received peer host name and a common password.

Usage Examples

The following example creates a user name of **Adtran** with password **Adtran** for the PPP link labeled 5:

(config)**#interface ppp 5**
(config-ppp 5)**#username Adtran password Adtran**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an interface to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the interface from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an interface's VRF association will clear all IP-related settings on that interface.

Syntax Description

<name>	Specifies the name of the VRF to which to assign the interface.

Default Values

By default, interfaces are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release 17.8	The keyword **ip** was removed from this command.

Functional Notes

VRF instances must be created first before an interface can be assigned. An interface can only be assigned to one VRF, but multiple interfaces can be assigned to the same VRF.

An interface will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the Point-to-Point Protocol (PPP) 1 interface to the VRF instance named **RED**:

(config)**#interface ppp 1**
(config-ppp 1)**#vrf forwarding RED**

TUNNEL INTERFACE COMMAND SET

There are three different types of tunnel interfaces that can be configured in AOS. Generic routing encapsulation (GRE) tunnel interfaces, multipoint GRE (mGRE) tunnel interfaces, and virtual extensible local area network (VxLAN) interfaces.

The GRE tunnel interface creates a virtual point-to-point link between routers in an Internet Protocol (IP) network by encapsulating the IP packets first in a GRE packet (by adding a GRE header), then in an IP version 4 (IPv4) packet (by adding an IPv4 header). When the packets reach the terminating endpoint router, they are stripped of the IPv4 and GRE headers to reveal the packet payload.

This encapsulation process allows network routers to tunnel IPv4 traffic over an IPv4 network and IPv6 traffic over an IPv4 Internet connection (IPv6 over IPv4 GRE). For example, a host on an IPv6 network cannot normally communicate with a host on another IPv6 network using an IPv4 Internet connection. However, when using the GRE tunnel interface, the IPv6 packet is first encapsulated into a GRE packet, and the GRE traffic is then encapsulated into an IPv4 packet between the two tunnel endpoints. The terminating tunnel endpoint then removes the IPv4 and GRE headers, revealing the original IPv6 packet before sending it on to the destination host.

MGRE tunnel interfaces create a virtual multipoint link between routers in a Dynamic Multipoint Virtual Private Network (DMVPN), much the same way as GRE tunnel interfaces operate in an IP network. When you create a tunnel interface, you must specify whether the tunnel is a GRE tunnel or an mGRE tunnel.

VxLAN tunnel interfaces are used to expand Layer 2 network segments beyond physical network boundaries, utilizing Layer 3 as a underlay network. For example, to share computer resources, virtual machines (VMs) residing on physical servers in two separate locations must be able to transparently see a single Layer 2 network segment between each other.

VxLAN tunnel implementation is point-to-point only since AOS does not currently support multicast VxLAN tunnels. VxLAN tunnel support is limited to IPv4 for underlay networks. However, IPv6 overlay networks can be created over IPv4 underlay networks.

*Not all platforms have mGRE or VxLAN tunnel interfaces available. To see if your unit has this capability, type **show interfaces** at the enable prompt.*

To activate the GRE Tunnel Interface Configuration mode, enter the **interface tunnel** <*interface id*> **gre ip** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface tunnel 1 gre ip
(config-tunnel 1)#
```

To activate the mGRE Tunnel Interface Configuration mode, enter the **interface tunnel** <*interface id*> **multipoint-gre ip** command at the Global Configuration mode prompt. For example:

>enable
#configure terminal
(config)**#interface tunnel 1 multipoint-gre ip**
(config-tunnel 1)**#**

To activate the VxLAN Tunnel Interface Configuration mode, enter the **interface tunnel** <*interface id*> **vxlan** command at the Global Configuration mode prompt. For example:

>enable
#configure terminal
(config)**#interface tunnel 1 vxlan**
(config-tunnel 1)**#**

*Not all tunnel interface commands apply to all tunnel interface types. Use the **?** command to display a list of valid commands. For example:*

*>**enable***
*Password:**xxxxx***
#config term
*(config)#**interface tunnel 1 gre ip***
*(config-tunnel 1)#**?***
alias - A text name assigned by an SNMP NMS
bandwidth - Set bandwidth parameter
etc.

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

bandwidth <value> on page 3214
dial-backup commands begin on page 3215
dynamic-dns on page 3232
encapsulate-inner-vlan on page 3234
ip commands begin on page 3235
ipv6 commands begin on page 3284

bandwidth <*value*>

Use the **bandwidth** command to provide the bandwidth value of an interface to the higher level protocols. This value is used in cost calculations. Use the **no** form of this command to restore the default value.

Syntax Description

<*value*>	Specifies bandwidth in kbps. Range is **1** to **4294967295** kbps.

Default Values

To view the default values, use the **show interfaces** command.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 9.1	Command was expanded to include the tunnel interfaces.

Functional Notes

The **bandwidth** command is an informational value that is communicated to the higher level protocols to be used in cost calculations. While this is a routing parameter that does not affect the physical interface, it does affect the amount of bandwidth available for use in Quality of Service (QoS) configurations.

It is important to note that there is an order of precedence in determining the interface bandwidth reported by the router for QoS. Under normal circumstances, the Layer 1 bandwidth is reported based on the interface type. For example, a T1 interface will report the available bandwidth as 1.536 Mbps. This can be misleading in QoS configurations if the **bandwidth** command has been applied to the IP interface for routing purposes because the command overrides the reported available bandwidth that can be utilized for QoS. Using the **bandwidth** command can severely disrupt the configuration of QoS on the interface.

Usage Examples

The following example sets bandwidth of the tunnel 1 interface to **10** Mbps:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#bandwidth 10000**

dial-backup auto-backup

Use the **dial-backup auto-backup** command to configure the interface to automatically attempt a dial backup upon failure. Use the **no** form of this command to disable this feature. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 3218*.

Syntax Description

No subcommands.

Default Values

By default, all backup endpoints will automatically attempt dial backup upon a failure.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example enables automatic dial backup on the endpoint:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup auto-backup**

dial-backup auto-restore

Use the **dial-backup auto-restore** command to configure the interface to automatically discontinue dial backup when all network conditions are operational. Use the **no** form of this command to disable the auto-restore feature. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 3218*.

Syntax Description

No subcommands.

Default Values

By default, all backup endpoints will automatically restore the primary connection when the failure condition clears.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to automatically restore the primary connection when the failure condition clears:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup auto-restore**

dial-backup backup-delay *<value>*

Use the **dial-backup backup-delay** command to configure the amount of time the router will wait after the failure condition is recognized before attempting to backup the link. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 3218*.

Syntax Description

<value>	Specifies the delay period (in seconds) a failure must be active before AOS will enter backup operation on the interface. Range is **10** to **86400** seconds.

Default Values

By default, the **dial-backup backup-delay** period is set to **10** seconds.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to wait **60** seconds (on an endpoint with an active alarm condition) before attempting dial-backup operation:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup backup-delay 60**

dial-backup call-mode

Use the **dial-backup call-mode** command to specify whether the configured backup interface answers or originates (or a combination of both) backup calls. Use the **no** form of this command to return to the default value. Variations of this command include:

dial-backup call-mode answer
dial-backup call-mode answer-always
dial-backup call-mode originate
dial-backup call-mode originate-answer
dial-backup call-mode originate-answer-always

Syntax Description

answer	Answers and backs up primary link on failure.
answer-always	Answers and backs up regardless of primary link state.
originate	Originates backup call on primary link failure.
originate-answer	Originates or answers call on primary link failure.
originate-answer-always	Originates on failure; answers and backs up always.

Default Values

By default, the **dial-backup call-mode** is set to **originate-answer**.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Functional Notes

The majority of the configuration for AOS dial-backup implementation is configured via the dial-backup PPP interface configuration commands. However, the numbers dialed are configured in the primary interface. Full sample configurations follow:

Sample configuration for remote router (dialing out)

```
hostname “Remote3200”
enable password adtran
!
interface eth 0/1
 ip address 192.168.1.254 255.255.255.0
 no shutdown
!
interface modem 1/3
 no shutdown
!
interface t1 1/1
```

```
 coding b8zs
 framing esf
 clock source line
 tdm-group 1 timeslots 1-24
 no shutdown
!
interface fr 1 point-to-point
 frame-relay lmi-type ansi
 no shutdown
 cross-connect 1 t1 1/1 1 fr 1
!
interface fr 1.16 point-to-point
 frame-relay interface-dlci 16
 ip address 10.1.1.2 255.255.255.252
 dial-backup call-mode originate
 dial-backup number 5551111 analog ppp1
 dial-backup number 5552222 analog ppp1
no shutdown
!
interface ppp 1
 ip address 172.22.56.1 255.255.255.252
 ppp authentication chap
 username remoterouter password remotepass
 ppp chap hostname localrouter
 ppp chap password adtran
 no shutdown
!
ip route 192.168.2.0 255.255.255.0 172.22.56.2 255.255.255.252
!
line telnet 0 4
 password password
```

Sample configuration for central router (dialing in)

```
hostname “Central3200”
enable password adtran
!
interface eth 0/1
 ip address 192.168.100.254 255.255.255.0
 no shutdown
!
interface modem 1/3
 no shutdown
!
interface t1 1/1
 coding b8zs
 framing esf
 clock source line
```

```
 tdm-group 1 timeslots 1-24
 no shutdown
!
interface fr 1 point-to-point
 frame-relay lmi-type ansi
 no shutdown
 cross-connect 1 t1 1/1 1 fr 1
!
interface fr 1.100 point-to-point
 frame-relay interface-dlci 100
 ip address 10.1.1.1 255.255.255.252
 dial-backup call-mode answer
 dial-backup number 555-8888 analog ppp 1
!
interface ppp 1
 ip address 172.22.56.2 255.255.255.252
 ppp authentication chap
 username localrouter password adtran
 ppp chap hostname remoterouter
 ppp chap password remotepass
 no shutdown
!
ip route 192.168.1.0 255.255.255.0 172.22.56.1 255.255.255.252

line telnet 0 4
 password password
```

Usage Examples

The following example configures AOS to generate backup calls for this endpoint using an analog modem interface (to phone number 555 1111), but never answer calls and specifies **ppp 2** as the backup interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup call-mode originate**
(config-tunnel 1)**#dial-backup number 555 1111 analog ppp 2**

Technology Review

This technology review provides information regarding specific dial-backup router behavior (i.e., when the router will perform dial backup, where in the configuration AOS accesses specific routing information, etc.):

Dialing Out

1. AOS determines to place an outbound call when either the Layer 1 or Layer 2 has a failure.
2. When placing outbound calls, AOS matches the number dialed to a PPP interface. This is accomplished with an addition to the **dial-backup number** command (refer to *dial-backup number on page 3225*).
3. When placing the call, AOS uses the configuration of the related PPP interface for authentication and IP negotiation.
4. If the call fails to connect on the first number dialed, AOS places a call to the second number (if a second number is configured). The second number to be dialed references a separate PPP interface.

Dialing In

1. AOS receives an inbound call on a physical interface.
2. Caller ID is used to match the **dial-backup number** command to the configured PPP interface.
3. If a match is found, the call connects and AOS pulls down the primary connection if it is not already in a down state.
4. If no match is found from caller ID, the call is terminated.

dial-backup connect-timeout <*value*>

Use the **dial-backup connect-timeout** command to specify the number of seconds to wait for a connection after a call is attempted before trying to call again or dialing a different number. It is recommended this number be greater than 60. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 3218*.

Syntax Description

<*value*>	Selects the amount of time (in seconds) that the router will wait for a connection before attempting another call. Valid range is **10** to **300** seconds.

Default Values

By default, the **dial-backup connect-timeout** period is set to **60** seconds.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to wait **120** seconds before retrying a failed dial-backup call:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup connect-timeout 120**

dial-backup force

Use the **dial-backup force** command to manually override the automatic dial-backup feature. This can be used to force a link into backup to allow maintenance to be performed on the primary link without disrupting data. Use the **no** form of this command to return to the normal dial-backup operation state. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 3218*. Variations of this command include:

dial-backup force backup
dial-backup force primary

Syntax Description

backup	Force backup regardless of primary link state.
primary	Force primary link regardless of its state.

Default Values

By default, this feature is disabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to force this interface into dial backup:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup force backup**

dial-backup maximum-retry <*value*>

Use the **dial-backup maximum-retry** command to select the number of calls the router will make when attempting to backup a link. Use the **no** form of this command to return to the default state. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of *dial-backup call-mode on page 3218*.

Syntax Description

<*value*>	Selects the number of call retry attempts that will be made after a link failure. Valid range is **0** to **15** attempts. Setting this value to 0 will allow unlimited retries during the time the network is failed.

Default Values

By default, **dial-backup maximum-retry** is set to **0** attempts.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to retry a dial-backup call **four** times before considering backup operation not available:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup maximum-retry 4**

dial-backup number

Use the **dial-backup number** command to configure the phone number and the call type the router will dial upon network failure. Multiple entries can be made for an interface to allow alternate sites to be dialed. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3218*. Variations of this command include:

dial-backup number <*number*> **analog ppp** <*interface*>
dial-backup number <*number*> **digital-56k** <*isdn min chan*> <*isdn max chan*> **ppp** <*interface*>
dial-backup number <*number*> **digital-64k** <*isdn min chan*> <*isdn max chan*> **ppp** <*interface*>

Syntax Description

<*number*>	Specifies the phone numbers to call when the backup is initiated.
analog	Indicates the number connects to an analog modem.
digital-56k	Indicates the number belongs to a digital 56 kbps per DS0 connection.
digital-64k	Indicates the number belongs to a digital 64 kbps per DS0 connection.
<*isdn min chan*>	Specifies the minimum number of DS0s required for a digital 56 or 64 kbps connection. Range is **1** to **24**.
<*isdn max chan*>	Specifies the maximum number of DS0s desired for a digital 56 or 64 kbps connection. Range is **1** to **24**.
ppp <*interface*>	Specifies the Point-to-Point Protocol (PPP) interface to use as the backup for this interface.

Default Values

By default, there are no configured dial-backup numbers.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the PPP interface.
Release 17.2	Command was expanded to include the cellular connections.
Release 17.3	Cellular connections were removed from this command.

Usage Examples

The following example configures AOS to dial **704-555-1212** (digital 64 kbps connection) to initiate dial-backup operation on this endpoint using interface **ppp 1** backup interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup number 7045551212 digital-64k 1 1 ppp 1**

dial-backup priority <*value*>

Use the **dial-backup priority** command to select the backup priority for this interface. This allows the user to establish the highest priority backup link and ensure that link will override backups attempted by lower priority links. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3218*.

Syntax Description

<*value*>	Sets the relative priority of this link. Valid range is **0** to **100**. A value of 100 designates the highest priority.

Default Values

By default, **dial-backup priority** is set to **50**.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example assigns the highest priority to this endpoint:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup priority 100**

dial-backup randomize-timers

Use the **dial-backup randomize-timers** command to randomize the call timers to minimize potential contention for resources. Use the **no** form of this command to return to the default value. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3218*.

Syntax Description

No subcommands.

Default Values

By default, AOS does not randomize the dial-backup call timers.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to randomize the dial-backup timers associated with this endpoint:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup randomize-timers**

dial-backup redial-delay <*value*>

Use the **dial-backup redial-delay** command to configure the delay after an unsuccessful call until the call will be re-tried. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3218*.

Syntax Description

<*value*>	Specifies the delay in seconds between attempting to redial a failed backup attempt. Range is **10** to **3600** seconds.

Default Values

By default, **dial-backup redial-delay** is set to **10** seconds.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures a redial delay of **25** seconds on this endpoint:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup redial-delay 25**

dial-backup restore-delay *<value>*

Use the **dial-backup restore-delay** command to configure the amount of time the router will wait after the network is restored before disconnecting the backup link and reverting to the primary. This setting is used to prevent disconnecting the backup link if the primary link is bouncing in and out of alarm. Use the **no** form of this command to return to the default setting. For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3218*.

Syntax Description

<value>	Specifies the number of seconds AOS will wait (after a primary link is restored) before disconnecting dial-backup operation. Range is **10** to **86400** seconds.

Default Values

By default, **dial-backup restore-delay** is set to **10** seconds.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example configures AOS to wait **30** seconds before disconnecting dial-backup operation and restoring the primary connection for this endpoint:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup restore-delay 30**

dial-backup schedule

Use the **dial-backup schedule** command to set the time of day that backup will be enabled. Use this command if backup is desired only during normal business hours and on specific days of the week. Use the **no** form of this command to disable dial backup (as specified). For more detailed information on dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3218*. Variations of this command include:

dial-backup schedule day <*name*>
dial-backup schedule enable-time <*value*>
dial-backup schedule disable-time <*value*>

Syntax Description

day <*name*>	Sets the days to allow backup. Valid range is Monday through Sunday.
enable-time <*value*>	Sets the time of day to enable backup. Time is entered in a 24-hour format (00:00).
disable-time <*value*>	Sets the time of day to disable backup. Time is entered in a 24-hour format (00:00).

Default Values

By default, dial backup is enabled for all days and times if the **dial-backup auto-backup** command has been issued and the dial-backup schedule has not been entered.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Point-to-Point Protocol (PPP) interface.

Usage Examples

The following example enables dial backup Monday through Friday 8:00 a.m. to 7:00 p.m.:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup schedule enable-time 08:00**
(config-tunnel 1)**#dial-backup schedule disable-time 19:00**
(config-tunnel 1)**#no dial-backup schedule day Saturday**
(config-tunnel 1)**#no dial-backup schedule day Sunday**

dial-backup shutdown

Use the **dial-backup shutdown** command to deactivate all dial-backup functionality in the unit. Dial-backup configuration parameters are kept intact, but the unit will not initiate (or respond) to dial-backup sequences in the event of a network outage. Use the **no** form of this command to reactivate the dial-backup interface. For more detailed information on Point-to-Point Protocol (PPP) dial-backup functionality, refer to the *Functional Notes* and *Technology Review* sections of the command *dial-backup call-mode on page 3218*.

Syntax Description

No subcommands.

Default Values

By default, all AOS interfaces are **disabled**.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the PPP interface.

Usage Examples

The following example deactivates the configured dial-backup interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dial-backup shutdown**

dynamic-dns

Use the **dynamic-dns** command to configure Dynamic DNS service provided by Dynamic Network Services, Inc. (www.dyndns.org). Use the **no** form of this command to disable this feature. Variations of this command include:

dynamic-dns custom <*hostname*> <*minutes*>
dynamic-dns dyndns <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-custom <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-static <*hostname*> <*username*> <*password*>

Syntax Description

<*hostname*>	Specifies the host name for the server that updates the dynamic domain naming system (DNS).
<*minutes*>	Specifies the intervals in minutes to update the server with information (updates also occur when the interface's IP address changes regardless of the update intervals).
<*username*>	Specifies a user name using an alphanumerical string up to 30 characters in length (the user name is case sensitive).
<*password*>	Specifies a password using an alphanumerical string up to 30 characters in length (the password is case sensitive). Refer to *Functional Notes* below for additional argument descriptions.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.
Release 12.1	Command was expanded.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

custom - Constanttime.com's Custom Dynamic DNS^{SM} service allows you complete access and management control over your domain name regardless of where you purchased/registered it. This allows you to manage IP address mappings (A records), domain aliases (CNAME records), and mail servers (mail exchange (MX) records).

dyndns - The Dynamic DNS^{SM} offered by Dynamic Network Services, Inc. (DynDNS.org) allows you to alias a dynamic IP address to a static host name in various domains. This allows your unit to be more easily accessed from various locations on the Internet. This service is provided for up to five host names.

dyndns-custom - DynDNS.org's Custom DNS^{SM} service provides a full DNS solution, giving you complete control over an entire domain name. A Web-based interface provides two levels of control over your domain, catering to average or advanced users. Five globally redundant DNS servers ensure that your domain will always resolve.

A choice of two interfaces is available. The basic interface is designed for most users. It comes preconfigured for most common configurations and allows for easy creation of most common record types. The advanced interface is designed for system administrators with a solid DNS background and provides layout and functionality similar to a BIND zone file, allowing for the creation of nearly any record type.

Custom DNS^{SM} can be used with both static and dynamic IPs, and has the same automatic update capability through Custom DNS-aware clients as Dynamic DNS.

dyndns-static - The Static DNS service is similar to DynDNS.org's Dynamic DNS^{SM} service in that it allows a host name, such as yourname.dyndns.org, to point to your IP address. Unlike a Dynamic DNS host, a Static DNS host does not expire after 35 days without updates; however, updates take longer to propagate through the DNS system. This service is provided for up to five host names.

If your IP address does not change often or at all, but you still want an easy name to remember it by (without having to purchase your own domain name), Static DNS service is ideal for you.

If you would like to use your own domain name (such as yourname.com), you need Custom DNS service that also provides full dynamic and static IP address support.

Usage Examples

The following example sets the Dynamic DNS to **dyndns-custom** with host name **host**, user name **user**, and password **pass**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#dynamic-dns dyndns-custom host user pass**

encapsulate-inner-vlan

Use the **encapsulate-inner-vlan** command to configure a virtual extensible local area network (VxLAN) interface to preserve the VLAN tag in Layer 2 frames transmitted via the VxLAN tunnel. Use the **no** form of this command to return to the default value.

Syntax Description

No subcommands.

Default Values

By default, the VxLAN tunnel strips the VLAN tag off of Layer 2 frames.

Command History

Release 13.1.0	Command was introduced.

Usage Examples

The following example enables preservation of the VLAN tag for VxLAN tunnel interface 1:

(config)**#interface tunnel 1 vxlan**
(config-tunnel 1)**#encapsulate-inner-vlan**

ip access-group *<ipv4 acl name>*

Use the **ip access-group** command to create an Internet Protocol version 4 (IPv4) access control list (ACL) to be used for packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ip access-group *<ipv4 acl name>* **in**
ip access-group *<ipv4 acl name>* **out**

Syntax Description

<ipv4 acl name>	Assigns an IPv4 ACL name.
in	Enables access control on packets received on the specified interface.
out	Enables access control on packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 3.1	Command was introduced.
Release 9.1	Command was expanded to include the tunnel interfaces.

Functional Notes

When this command is enabled, the IPv4 destination address of each packet must be validated before being passed through. If the packet is not acceptable per these settings, it is dropped.

Usage Examples

The following example sets up the unit to only allow Telnet traffic (as defined in the user-configured **TelnetOnly** IP ACL) into the tunnel interface:

(config)**#ip access-list extended TelnetOnly**
(config-ext-nacl)**#permit tcp any any eq telnet**
(config-ext-nacl)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip access-group TelnetOnly in**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to an interface. IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

> NOTE *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an interface.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the Ethernet interface 0/1:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip access-policy PRIVATE**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the specified interface. Use the optional **secondary** keyword to define a secondary IPv4 address. Use the **no** form of this command to remove a configured IPv4 address. Variations of this command include:

ip address <*ipv4 address*> <*subnet mask*>
ip address <*ipv4 address*> <*subnet mask*> **secondary**

Syntax Description

<*ipv4 address*>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*subnet mask*>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the specified interface.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 5.1	Command was introduced.
Release 9.1	Command was expanded to include the tunnel interfaces.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures an IPv4 address of **192.22.72.101 255.255.255.252**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip address 192.22.72.101 255.255.255.252**

ip address range *<start ip address> <end ip address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the specified interface. Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip crypto map *<name>*

Use the **ip crypto map** command to associate Internet Protocol version 4 (IPv4) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

When you apply a map to an interface, you are applying all crypto maps with the given map name. This allows you to apply multiple crypto maps if you have created maps that share the same name, but have different map index numbers.

Syntax Description

<name>	Specifies the IPv4 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

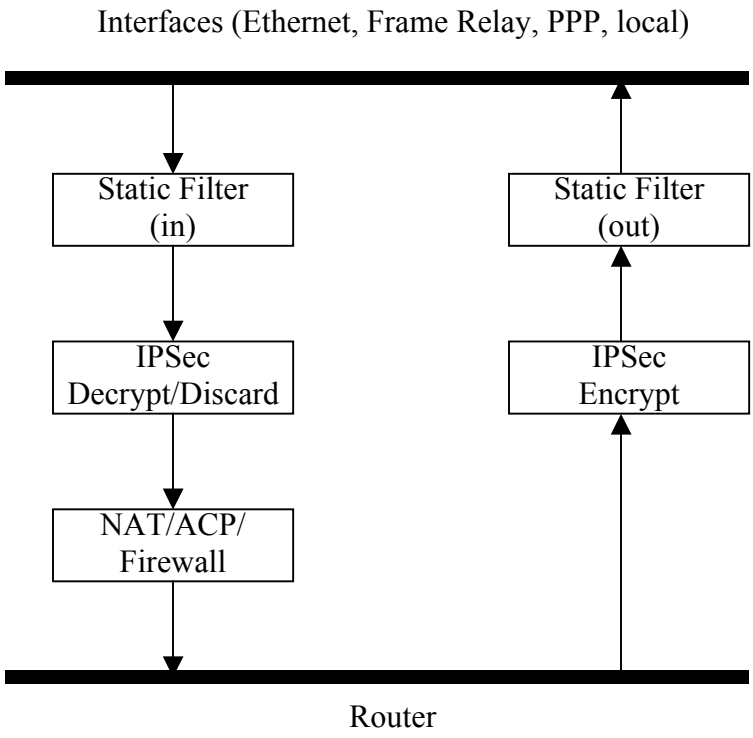
Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 9.1	Command was expanded to include the High-Levell Data Link Control (HDLC) interface.
Release 11.1	Command was expanded to include the demand interface.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.7.0	Command syntax was changed to require the **ip** keyword.

Functional Notes

When configuring a system to use both the stateful inspection firewall and Internet key exchange (IKE) negotiation for VPN, keep the following notes in mind.

When defining the IPv4 policy class and associated access control lists (ACLs) that describe the behavior of the IPv4 firewall, do not forget to include the traffic coming into the system over a VPN tunnel terminated by the system. The firewall should be set up with respect to the unencrypted traffic that is destined to be sent or received over the VPN tunnel. The following diagram represents typical AOS data-flow logic.



As shown in the diagram above, data coming into the product is first processed by the static filter associated with the interface on which the data is received. This access group is a true static filter and is available for use regardless of whether the IPv4 firewall is enabled or disabled. Next (if the data is encrypted), it is sent to the IPSec engine for decryption. The decrypted data is then processed by the stateful inspection firewall. Therefore, given a terminating VPN tunnel, only unencrypted data is processed by the firewall.

The IPv4 ACLs for a crypto map on an interface work in reverse logic to the ACLs for a policy class on an interface. When specifying the ACLs for a crypto map, the source information is the private local side, unencrypted source of the data. The destination information will be the far-end, unencrypted destination of the data. However, ACLs for a policy class work in reverse. The source information for the ACL in a policy class is the far end. The destination information is the local side.

Usage Examples

The following example applies all IPv4 crypto maps with the name **MyMap** to the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip crypto map MyMap**

ip dhcp relay destination *<ipv4 address>*

Use the **ip dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 4 (IPv4) and to specify the IPv4 address for the DHCPv4 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv4 relay functionality is disabled on the interface.

Syntax Description

<ipv4 address>	Specifies the IPv4 address for the DHCPv4 messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.1.0	Command was expanded to include the VLAN, PPP, HDLC, BVI, demand, and loopback interfaces as well as the Ethernet, Frame Relay, and ATM subinterfaces.

Usage Examples

The following example enables DHCPv4 relay agent functionality and specifies the destination address as **192.33.4.251**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip dhcp relay destination 192.33.4.251**

ip directed-broadcast

Use the **ip directed-broadcast** command to allow reception/forwarding of directed broadcasts. Use the **no** form of this command to disable this feature. Variations of this command include:

ip directed-broadcast
ip directed-broadcast <*name*>

Syntax Description

<*name*>	Specifies IP access control list (ACL) name.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.

Functional Notes

A directed broadcast is a packet intended for all nodes on a nonlocal network. For example, the broadcast address 255.255.255.255 reaches all nodes on a network; the directed broadcast address 128.1.255.255 is intended for all nodes whose network address is 128.1.0.0. A router not directly attached to 128.1.0.0 simply forwards the directed broadcast packet to the next hop. A router on network 128.1.0.0 that has **ip directed-broadcast** enabled, accepts and forwards the packet to all nodes whose network address is 128.1.0.0. Routers connecting subnets of 128.1.0.0 also accept and forward the packet to the nodes on their respective subnets. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is distributed as a broadcast on the destination subnet. The packet is then sent as a link-layer broadcast.

The **ip directed-broadcast** command controls the distribution of directed broadcasts when they reach their target subnets. Only the final transmission of the directed broadcast on its ultimate destination subnet is affected. It does not affect the transit unicast routing of IP directed broadcasts.

If **ip directed-broadcast** is enabled for this interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which this interface is attached will be forwarded as broadcasts on that subnet. Forwarding of the packets can be limited by specifying an ACL with this command. In this case, only directed broadcasts that are permitted by the specified ACL will be forwarded, and all other directed broadcasts directed to this interface subnet will be dropped.

Disabling the **ip directed-broadcast** command will cause directed broadcasts destined for the subnet to which this interface is attached to be dropped.

This option is a requirement for routers as described in RFC 1812, section 4.2.2.11. Furthermore, it is disabled by default (RFC 2644) with the intended goal of reducing the efficacy of certain types of denial of service (DoS) attacks.

Usage Examples

The following example enables forwarding of directed broadcasts on the interface **tunnel 1**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip directed-broadcast**

ip ffe

Use the **ip ffe** command to enable the RapidRoute fast forwarding engine (FFE) on this Internet Protocol version 4 (IPv4) interface with the default number of entries. Use the **no** form of this command to disable this feature. Variations of this command include:

ip ffe
ip ffe max-entries <*value*>

Issuing this command will cause all RapidRoute entries to be cleared from this IPv4 interface.

Syntax Description

max-entries <*value*>	Optional. Specifies the maximum number of entries stored in the flow table. Valid range is from **1** to **500000**.

Default Values

By default, the RapidRoute Engine is enabled. The default number of **max-entries** is **4096**.

Command History

Release 13.1	Command was introduced.
Release 17.6	Command was expanded to include the high level data link control (HDLC) and tunnel interfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.4.0	Maximum number of stored entries was expanded to **500000** and RapidRoute is now enabled by default.

Functional Notes

RapidRoute can be used to help reduce routing overhead, and thus reduce overall routing times. Routing times are reduced by the creation of a flow table on the ingress interface. The maximum number of entries that can be stored in the flow table at any one time may be specified by using the **max-entries** parameters.

Usage Examples

The following example disables RapidRoute on the IPv4 interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#no ip ffe**

Technology Review

The RapidRoute system goal is to increase IP packet throughput by moving as much of the packet processing into the engine as possible. Packets are classified into flows based upon the IP protocol (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol (ICMP), etc.), the source and destination IP addresses, IP type of service (ToS), and the protocol-specific information, such as the source and destination port numbers. Flows are defined as the unidirectional representation of a conversation between two IP hosts. Each ingress interface keeps its own flow table, a collection of flow entries.

The first packet in a flow that is forwarded through the unit will build a flow entry. When a flow entry is looked up but no entry is found, a RapidRouteBuilder object is allocated and attached to the packet. As the packet passes through the various processing layers, each subsystem will add processing to the RapidRouteBuilder. When packet is about to be forwarded out of the egress interface, the RapidRouteBuilder will be finalized. That is, the flow entry being built will be checked for completeness and committed to the flow table on the ingress interface. Subsequent flow matches can then bypass the normal processing layers.

ip flow

Use the **ip flow** command to enable integrated traffic monitoring (ITM) for all traffic received or forwarded on an interface. Use the **no** form of this command to disable traffic monitoring. Variations of this command include:

ip flow egress
ip flow egress <*name*>
ip flow ingress
ip flow ingress <*name*>

Syntax Description

egress	Specifies that all outgoing traffic be monitored.
ingress	Specifies that all incoming traffic be monitored.
<*name*>	Optional. Specifies the name of an access control list (ACL) to use for filtering traffic.

Default Values

By default, no traffic monitoring is enabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables traffic monitoring on a **tunnel** interface to monitor **incoming** traffic through an ACL called **myacl**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip flow ingress myacl**

ip helper-address *<ip address>*

Use the **ip helper-address** command to configure AOS to forward User Datagram Protocol (UDP) broadcast packets received on the interface. Use the **no** form of this command to disable forwarding packets.

> NOTE *The **ip helper-address** command must be used in conjunction with the **ip forward-protocol** command to configure AOS to forward UDP broadcast packets. Refer to ip forward-protocol udp <value> on page 1398 for more information.*

Syntax Description

<ip address>	Specifies the destination IP address for the forwarded UDP packets. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, broadcast UDP packets are not forwarded.

Command History

Release 1.1	Command was introduced.
Release 9.1	Command was expanded to include the tunnel interfaces.

Functional Notes

When used in conjunction with the **ip forward-protocol** command, the **ip helper-address** feature allows you to customize which broadcast packets are forwarded.

To implement the helper address feature, assign helper address(es) (specifying the device that needs to receive the broadcast traffic) to the interface closest to the host that transmits the broadcast packets. When broadcast packets (of the specified type forwarded using the **ip forward-protocol** command) are received on the interface, they will be forwarded to the device that needs the information.

Only packets meeting the following criteria are considered eligible by the **ip helper-address** feature:

1. The packet IP protocol is UDP.
2. Any UDP port specified using the **ip forward-protocol** command.
3. The medium access control (MAC) address of the frame is an all-ones broadcast address (ffff.ffff.ffff).
4. The destination IP address is broadcast defined by all ones (255.255.255.255) or a subnet broadcast (for example, 192.33.4.251 for the 192.33.4.248 /30 subnet).

Usage Examples

The following example forwards all DNS broadcast traffic to the DNS server with IP address **192.33.5.99**:

(config)**#ip forward-protocol udp domain**
(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip helper-address 192.33.5.99**

ip igmp

Use the **ip igmp** command to configure multicasting related functions for the interface. Variations of this command include:

ip igmp immediate-leave
ip igmp last-member-query-interval <*milliseconds*>
ip igmp querier-timeout <*seconds*>
ip igmp query-interval <*seconds*>
ip igmp query-max-response-time <*seconds*>
ip igmp static-group <*address*>
ip igmp version [1 | 2]

Syntax Description

immediate-leave	Specifies that if only one host (or Internet Group Management Protocol (IGMP) snooping switch) is connected to the interface, when a leave is received, multicast of that group is immediately terminated as opposed to sending a group query and timing out the group if no device responds. Works in conjunction with **ip igmp last-member-query-interval**. Applies to all groups when configured. Use the **no** form of this command to disable the **immediate-leave** feature.
last-member-query-interval <*milliseconds*>	Controls the timeout (in milliseconds) used to detect whether any group receivers remain on an interface after a receiver leaves a group. If a receiver sends a leave-group message (IGMP Version 2), the router sends a group-specific query on that interface. After twice the time specified by this command plus as much as one second longer, if no receiver responds, the router removes that interface from the group and stops sending that group's multicast packets to the interface. Range is **100** to **65535** ms. Use the **no** form of this command to return to the default setting.
querier-timeout <*seconds*>	Specifies the interval (in seconds) that the router waits after the current querier's last query before it takes over as querier (IGMP V2). Range is **60** to **300** seconds. Use the **no** form of this command to return to the default setting.

Syntax Description

query-interval <*seconds*>	Specifies the interval (in seconds) at which IGMP queries are sent on an interface. Host query messages are addressed to the all-hosts multicast group with an IP time to live (TTL) of 1. The router uses queries to detect whether multicast group members are on the interface and to select an IGMP designated router (DR) for the attached segment (if more than one multicast router exists). Only the DR for the segment sends queries. For IGMP V2, the DR is the router with the lowest IP address on the segment. Range is **0** to **65535** seconds. Use the **no** form of this command to return to the default setting.
query-max-response-time <*seconds*>	Specifies the maximum response time (in seconds) advertised by this interface in queries when using IGMP V2. Hosts are allowed a random time within this period to respond, reducing response bursts. Use the **no** form of this command to return to the default setting.
static-group <*address*>	Configures the router's interface to be a statically connected member of the specified group. Packets received on the correct reverse path forwarding (RPF) interface are forwarded to this interface regardless of whether any receivers have joined the specified group using IGMP. Use the **no** form of this command to remove a configured static group.
version [1 | 2]	Sets the interface's IGMP version. Use the **no** form of this command to return to the default setting.

Default Values

ip igmp immediate-leave	No default
ip igmp last-member-query-interval	**1000** milliseconds
ip igmp querier-timeout	2x the **query-interval** value
ip igmp query-interval	**60** seconds
ip igmp query-max-response-time	**10** seconds
ip igmp static-group	No default
ip igmp version	Version **1**

Command History

Release 7.1	Command was introduced.
Release 8.1	Asynchronous transfer mode (ATM) subinterface was added.
Release 9.1	tunnel subinterface was added.

Usage Examples

The following example sets the query message interval on the interface to **200** milliseconds:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip igmp last-member-query-interval 200**

ip mcast-stub downstream

Use the **ip mcast-stub downstream** command to enable multicast forwarding and Internet Group Management Protocol (IGMP) (router mode) on an interface and to place it in multicast stub downstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.
Release 9.1	Command was expanded to include the tunnel interfaces.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub upstream** commands. Downstream interfaces connect to segments with multicast hosts. Multiple interfaces may be configured in downstream mode; however, interfaces connecting to the multicast network (upstream) should not be configured in downstream mode. Interfaces configured as downstream should have the lowest IP address of all IGMP-capable routers on the connected segment in order to be selected as the designated router (DR) and ensure proper forwarding. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub upstream on page 3256* for more information.

Usage Examples

The following example enables multicast forwarding and IGMP on the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip mcast-stub downstream**

ip mcast-stub fixed

Use the **ip mcast-stub fixed** command to allow forwarding of multicast traffic on a selected interface after enabling multicast routing. Use the **no** form of this command to disable this mode.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 12.1	Command was introduced.

Functional Notes

Multicast routing must be enabled prior to setting **ip mcast-stub fixed** on the selected interface. Also, use the command **ip igmp static-group** <*address*> (refer to *ip igmp on page 3250*) to receive multicast traffic without host-initiated Internet Group Management Protocol (IGMP) activity on the selected interface. Otherwise, all host-initiated IGMP transactions will enter multicast routes on the router's interface involved with IGMP activities.

Usage Examples

The following example enables multicast traffic forwarding and IGMP on the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip mcast-stub fixed**

ip mcast-stub helper-enable

Use the **ip mcast-stub helper-enable** command to assign the **ip mcast-stub helper-address** as the Internet Group Management Protocol (IGMP) proxy. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 8.1	Command was introduced.
Release 9.1	Command was expanded to include the tunnel interfaces.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address**, **ip mcast-stub upstream**, and **ip mcast-stub downstream** commands. When enabled, the interface becomes a helper forwarding interface. The IGMP host function is dynamically enabled, and the interface becomes the active upstream interface, enabling the unit to perform as an IGMP proxy. Refer to *ip mcast-stub helper-address <ip address> on page 1418*, *ip mcast-stub downstream on page 3253*, and *ip mcast-stub upstream on page 3256* for more information.

Usage Examples

The following example sets the helper address as the IGMP proxy:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip mcast-stub helper-enable**

ip mcast-stub upstream

Use the **ip mcast-stub upstream** command to enable multicast forwarding on an interface and place it in multicast stub upstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.
Release 9.1	Command was expanded to include the tunnel interfaces.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub downstream** commands. When enabled, the interface becomes a candidate to be a helper forwarding interface. If chosen as the best path toward the helper address by the router's unicast route table, the Internet Group Management Protocol (IGMP) host function is dynamically enabled, and the interface becomes the active upstream interface, enabling the router to perform as an IGMP proxy. Though multiple interfaces may be candidates, no more than one interface will actively serve as the helper forwarding interface. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub downstream on page 3253* for more information.

Usage Examples

The following example enables multicast forwarding on the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip mcast-stub upstream**

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces	(all types)1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

Open shortest path first (OSPF) will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip mtu 1200**

ip nhrp authentication <*string*>

Use the **ip nhrp authentication** command to specify the authentication string used on the router for Next Hop Resolution Protocol (NHRP) communication in a Dynamic Multipoint Virtual Private Network (DMVPN) network. Use the **no** form of this command to disable NHRP authentication.

Syntax Description

<*string*>	Specifies a text string used for NHRP authentication. Strings should be no longer than **8** characters.

Default Values

By default, NHRP authentication is disabled.

Command History

Release R11.7.0	Command was introduced.

Functional Notes

The NHRP authentication string is used for NHRP communication and all routers communicating with NHRP must be configured with the same authentication string. The string is not encrypted.

Usage Examples

The following example configures an NHRP authentication string on tunnel interface **1**:

(config)**#tunnel interface 1 gre ip**
(config-tunnel 1)**#ip nhrp authentication STRINGX**

ip nhrp holdtime <*value*>

Use the **ip nhrp holdtime** command to specify how often the router sends Next Hop Resolution Protocol (NHRP) registration requests to the next-hop server (NHS). Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the time, in seconds, between sending registration requests. Valid range is **1** to **65535** seconds.

Default Values

By default, the hold time is set to **7200** seconds. In addition, by default, the NHRP registration requests are sent at intervals of one third the hold time value; for example, if the hold time is set to 7200 seconds (default), then the registration requests are sent every 2400 seconds.

Command History

Release R11.7.0	Command was introduced.

Usage Examples

The following example specifies a hold time of **800** seconds on tunnel interface **1**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip nhrp holdtime 800**

ip nhrp map *<destination ipv4 address> <nbma address>*

Use the **ip nhrp map** command to statically create a Next Hop Resolution Protocol (NHRP) mapping between the Internet Protocol version 4 (IPv4) address and the nonbroadcast multiaccess (NBMA) address of the next hop server (NHS). Use the **no** form of this command to remove the mapping.

Syntax Description

<destination IPv4 address>	Specifies the destination IPv4 address to map to the NBMA address. Express IPv4 addresses in dotted decimal notation; for example, **10.10.10.1**.
<nbma address>	Specifies the NBMA address to map to the destination IPv4 address. Express the NBMA address in dotted decimal notation; for example, **192.168.1.101**.

Default Values

By default, no mapping is configured.

Command History

Release R11.9.0	Command was introduced.

Functional Notes

In Dynamic Multipoint Virtual Private Networking (DMVPN), the destination IPv4 address is typically the private tunnel address, and the NBMA address is the tunnel's public facing address.

Usage Examples

The following example statically maps between the IPv4 destination address **10.10.10.1** and the NBMA address **192.168.1.101** on the unit:

(config)**#interface tunnel 1 multipoint-gre ip**
(config-tunnel 1)**#ip nhrp map 10.10.10.1 192.168.1.101**

ip nhrp map multicast *<nbma address>*

Use the **ip nhrp map multicast** command to statically add a Next Hop Resolution Protocol (NHRP) mapping for multicast and broadcast traffic to a nonbroadcast multiaccess (NMBA) address. The next-hop server (NHS) is typically used as the NBMA address. Use the **no** form of this command to remove the mapping.

Syntax Description

<nbma address>	Specifies the NBMA address that will receive multicast and broadcast traffic. This address is typically the NHS. Express NBMA addresses in dotted decimal notation; for example, **192.168.1.101**.

Default Values

By default, the NBMA address is not mapped.

Command History

Release R11.9.0	Command was introduced.

Functional Notes

In Dynamic Multipoint Virtual Private Networking (DMVPN), the NBMA address is the tunnel's public facing address.

Usage Examples

The following example enables multicast and broadcast traffic to the NMBA address **192.168.1.101**:

(config)**#interface tunnel 1 multicast-gre ip**
(config-tunnel 1)**#ip nhrp map multicast 192.168.1.101**

ip nhrp nhs *<ip address>*

Use the **ip nhrp nhs** command to specify the address used by the router acting as a next-hop client (NHC) to communicate with the next-hop server (NHS) in a Dynamic Multipoint Virtual Private Network (DMVPN) configuration using Next Hop Resolution Protocol (NHRP). This address is the private tunnel address used in a Generic Routing Encapsulation (GRE) tunnel between the spoke (NHC) and the hub (NHS). Use the **no** form of this command to remove the address from the tunnel's configuration.

Syntax Description

<ip address>	Specifies the private tunnel IP address on the NHS. Specify IP addresses in dotted decimal notation (**10.10.10.1**).

Default Values

By default, no NHS address is configured.

Command History

Release R11.7.0	Command was introduced.

Functional Notes

Only a single address can be configured for a point-to-point GRE tunnel.

Usage Examples

The following example specifies an NHS address of **10.10.10.1** on tunnel interface **1**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip nhrp nhs 10.10.10.1**

ip nhrp record

Use the **ip nhrp record** command to specify whether Next Hop Resolution Protocol (NHRP) requests and replies should include forward and backward record extensions. Use the **no** form of this command to disable the addition of these extensions.

Syntax Description

No subcommands.

Default Values

By default, both forward and backward record extensions are included in NHRP requests and replies.

Command History

Release R11.9.0	Command was introduced.

Usage Examples

The following example disables the addition of forward and backward record extensions for NHRP messages:

(config)**#interface tunnel 1 multicast-gre ip**
(config-tunnel 1)**#no ip nhrp record**

ip nhrp registration non-unique

Use the **ip nhrp registration non-unique** command to specify whether the Unique flag is set in the Next Hop Resolution Protocol (NHRP) registration packet. Use the **no** form of this command to remove the Unique flag.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release R11.9.0	Command was introduced.

Functional Notes

The Generic Routing Encapsulation (GRE) tunnel source is used in NHRP registration events. When the source IP address changes, a new registration with the next hop server (NHS) occurs. Adtran recommends enabling the **ip nhrp registration non-unique** feature on interfaces where the IP addresses can change.

Usage Examples

The following example enables the Unique flag for NHRP registration packets on the interface:

(config)**#interface tunnel 1 multicast-gre ip**
(config-tunnel 1)**#ip nhrp registration non-unique**

ip nhrp registration timeout <*value*>

Use the **ip nhrp registration timeout** command to specify how often the router sends Next Hop Resolution Protocol (NHRP) registration requests to the next-hop server (NHS) independent of the NHRP hold time setting (refer to the command *ip nhrp holdtime <value> on page 3260*). Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the time, in seconds, between NHRP registration requests. Valid range is **1** to **65535** seconds.

Default Values

By default, this option is not configured and the registration requests are sent at intervals of one third the hold time value (refer to the command *ip nhrp holdtime <value> on page 3260*).

Command History

Release R11.7.0	Command was introduced.

Functional Notes

The timeout value must be set to less than or equal to the value set with **ip nhrp holdtime** command.

Usage Examples

The following example specifies that NHRP registration requests are sent independently from the hold time value every **300** seconds:

(config)**#tunnel interface 1 gre ip**
(config-tunnel 1)**#ip nhrp registration timeout 300**

ip ospf

Use the **ip ospf** command to customize Open Shortest Path First version 2 (OSPFv2) settings (if needed). Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **area** <*area id*>
ip ospf <*process id*> **authentication-key** <*password*>
ip ospf <*process id*> **cost** <*value*>
ip ospf <*process id*> **dead-interval** <*seconds*>
ip ospf <*process id*> **hello-interval** <*seconds*>
ip ospf <*process id*> **message-digest-key [1 | 2] md5** <*key*>
ip ospf <*process id*> **priority** <*value*>
ip ospf <*process id*> **retransmit-interval** <*seconds*>
ip ospf <*process id*> **shutdown**
ip ospf <*process id*> **transmit-delay** <*seconds*>

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
area <*area id*>	Specifies the ID of the area to which this interface is assigned for the specified OSPFv2 process. Valid range is **0** to **4294967295**.
authentication-key <*password*>	Assigns a simple-text authentication password to be used by other routers using the OSPF simple password authentication.
cost <*value*>	Specifies the OSPF cost of sending a packet on the interface. This value overrides any computed cost value. Range is **1** to **65535**.
dead-interval <*seconds*>	Sets the maximum interval (in seconds) allowed between hello packets. If the maximum is exceeded, neighboring devices will determine that the device is down. Range is **0** to **32767** seconds.
hello-interval <*seconds*>	Specifies the interval (in seconds) between hello packets sent on the interface. Range is **0** to **32767** seconds.
message-digest-key [1 | 2] md5 <*key*>	Configures OSPF message digest 5 (MD5) authentication (16 byte maximum) keys.
priority <*value*>	Sets the OSPF priority. The value set in this field helps determine the designated router (DR) for this network. Range is **0** to **255**.
retransmit-interval <*seconds*>	Specifies the interval (in seconds) between link state advertisements (LSAs). Range is **0** to **32767** seconds.

shutdown	Disables the OSPFv2 process on the interface. When this keyword is used, the OSPFv2 settings remain in place, but logically it appears to the interface as though the process has been removed from the configuration. This parameter can be useful in troubleshooting.
transmit-delay <*seconds*>	Sets the estimated time (in seconds) required to send a link state advertisement (LSA) on the interface. Range is **0** to **32767** seconds.

Default Values

The defaults for this command are:

dead-interval <*seconds*>	40 seconds
hello-interval <*seconds*>	10 seconds: Ethernet, Frame Relay, and Point-to-Point Protocol (PPP)
priority <*value*>	1
retransmit-interval <*seconds*>	5 seconds
transmit-delay <*seconds*>	1 second

Command History

Release 3.1	Command was introduced.
Release 9.1	Command was expanded to include the tunnel interfaces.
Release R11.3.0	Command was expanded to include the <*process id*>, **area** <*area id*>, and **shutdown** parameters.

Usage Examples

The following example sets the maximum number of seconds allowed between hello packets to **25000**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip ospf 1 dead-interval 25000**

ip ospf <*process id*> authentication

Use the **ip ospf authentication** command to authenticate an interface that is performing open shortest path first (OSPF) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **authentication**
ip ospf <*process id*> **authentication message-digest**
ip ospf <*process id*> **authentication null**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
message-digest	Optional. Selects message digest authentication type.
null	Optional. Specifies that no authentication be used.

Default Values

By default, **ip ospf authentication** is set to **null** (meaning no authentication is used).

Command History

Release 3.1	Command was introduced.
Release 9.1	Command was expanded to include the tunnel interfaces.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Usage Examples

The following example specifies that no authentication will be used on the tunnel interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip ospf 1 authentication null**

ip ospf <*process id*> network

Use the **ip ospf network** command to specify the type of network on this interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **network broadcast**
ip ospf <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
broadcast	Sets the network type for broadcast.
point-to-point	Sets the network type for point-to-point.

Default Values

By default, Ethernet defaults to **broadcast**. Point-to-Point Protocol (PPP) and Frame Relay default to **point-to-point**.

Command History

Release 3.1	Command was introduced.
Release 9.1	Command was expanded to include the tunnel interfaces.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Functional Notes

A point-to-point network will not elect designated routers.

Usage Examples

The following example designates a broadcast network type:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip ospf 1 network broadcast**

ip pim sparse-mode

Use the **ip pim sparse-mode** command to enable protocol-independent multicast (PIM) sparse mode for this interface. Use the **no** form of this command to disable PIM sparse mode.

Syntax Description

No subcommands.

Default Values

By default, PIM sparse mode for this interface is disabled.

Command History

Release 11.1	Command was introduced.

Functional Notes

PIM sparse mode is a multicast routing protocol that makes use of the unicast forwarding table. It builds unidirectional shared trees rooted at a rendezvous point (RP) for a multicast group or a shortest-path tree rooted at a specific source for a multicast group.

Usage Examples

The following example enables PIM sparse mode on the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip pim sparse-mode**

ip pim-sparse dr-priority <*value*>

Use the **ip pim-sparse dr-priority** command to specify the priority for the designated router (DR). This command modifies the router's priority in the DR election process. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the priority of this interface (to be used when determining the DR). Valid range is **1** to **4294967295**.

Default Values

By default, the priority of all protocol-independent multicast (PIM) interfaces is **1**.

Command History

Release 11.1	Command was introduced.

Functional Notes

Interfaces advertise their configured priority values in the hello messages transmitted on the interface. Routers use the priority values to determine the appropriate DR. The router on the network segment with the highest priority is selected as the DR. If a hello message is received on the interface from a router on the network segment and it does not contain a priority, the entire network segment defaults to DR selection based on IP addresses instead of priority. In this instance, the DR is selected as the router on the network segment that has the highest IP address. AOS will always include a priority in all transmitted hello messages. If no priority is specifically designated by the user, the priority is set as the default of 1.

Usage Examples

The following example specifies a priority of **100** on the tunnel 1 interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip pim-sparse dr-priority 100**

ip pim-sparse hello-timer <*value*>

Use the **ip pim-sparse hello-timer** command to specify protocol-independent multicast (PIM) sparse hello timer period. This is the time interval at which periodic hellos are sent out on all interfaces of a PIM-capable router. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the interval (in seconds) at which periodic hellos are sent out of the interface. Valid range is **10** to **3600** seconds.

Default Values

By default, the hellos are transmitted on PIM interfaces every **60** seconds.

Command History

Release 11.1	Command was introduced.

Functional Notes

Hello messages are used to inform neighbors of a router's presence. Hello messages normally generate a small amount of traffic on an interface. Setting the **hello-timer** to a small interval increases the number of hellos sent (thus increasing the amount of traffic). Set the **hello-timer** to a reasonable value, taking into consideration the bandwidth available on the interface.

Usage Examples

The following example specifies hellos be sent on the tunnel 1 interface every **3600** seconds:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip pim-sparse hello-timer 3600**

ip pim-sparse nbr-timeout <*value*>

Use the **ip pim-sparse nbr-timeout** command to specify protocol-independent multicast (PIM) sparse neighbor timeout. This is the time interval after which a PIM-capable router will consider a neighbor not present. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the time interval in seconds after which a neighbor is considered not present. Valid range is **30** to **10800** seconds.

Default Values

By default, the nbr-timeout is set to **105** seconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the neighbor timeout to **300** seconds:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip pim-sparse nbr-timeout 300**

ip pim-sparse override-interval <*value*>

Use the **ip pim-sparse override-interval** command to specify the protocol-independent multicast (PIM) sparse join/prune override interval. This delay interval is the period after a join/prune that another router on the local area network (LAN) may override a join/prune. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the delay time in milliseconds. Valid range is **0** to **65535** milliseconds.

Default Values

By default, the override interval is set to **2500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the override interval to **3000** milliseconds:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip pim-sparse override-interval 3000**

ip pim-sparse propagation-delay *<value>*

Use the **ip pim-sparse propagation-delay** command to specify the expected propagation delay for join/prune messages. Set the propagation delay (in milliseconds) to estimate the amount of delay found in the local link. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the expected propagation delay in the local link in milliseconds. Valid range is **0** to **32767** milliseconds.

Default Values

By default, the propagation delay is set to **500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the propagation delay to **300** milliseconds:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip pim-sparse propagation-delay 300**

ip policy route-map *<name>*

Use the **ip policy route-map** command to assign a policy route map to this interface. Use the **no** form of this command to remove the route-map policy.

Syntax Description

<name>	Specifies the name of the policy route map to assign to this interface.

Default Values

By default, no policy route map is assigned to this interface.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example assigns the policy route map **policy1** to the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip policy route-map policy1**

ip proxy-arp

Use the **ip proxy-arp** command to enable proxy Address Resolution Protocol (ARP) on the interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, proxy ARP is enabled.

Command History

Release 9.1	Command was introduced.

Functional Notes

In general, the principle of proxy ARP allows a router to insert its IP address in the source IP address field of a packet (if the packet is from a host on one of its subnetworks). This allows hosts to reach devices on other subnetworks without implementing routing or specifying a default gateway.

If proxy ARP is enabled, AOS will respond to all proxy ARP requests with its specified medium access control (MAC) address and forward packets accordingly.

Enabling proxy ARP on an interface may introduce unnecessary ARP traffic on the network.

Usage Examples

The following example enables proxy ARP on the tunnel interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip proxy-arp**

ip rip receive version

Use the **ip rip receive version** command to configure the Routing Information Protocol (RIP) version the unit accepts in all RIP packets received on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip receive version 1
ip rip receive version 2

Syntax Description

1	Accepts only received RIP version 1 packets on the interface.
2	Accepts only received RIP version 2 packets on the interface.

Default Values

By default, all interfaces implement RIP **version 1** (the default value for the **version** command).

Command History

Release 9.1	Command was introduced.

Functional Notes

Use the **ip rip receive version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only accepts one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the tunnel interface to accept only RIP version 2 packets:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip rip receive version 2**

ip rip send version

Use the **ip rip send version** command to configure the Routing Information Protocol (RIP) version the unit sends in all RIP packets transmitted on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip send version 1
ip rip send version 2

Syntax Description

1	Transmits only RIP version 1 packets on the interface.
2	Transmits only RIP version 2 packets on the interface.

Default Values

By default, all interfaces transmit RIP **version 1** (the default value for the **version** command).

Command History

Release 9.1	Command was introduced.

Functional Notes

Use the **ip rip send version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only transmits one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the tunnel interface to transmit only RIP version 2 packets:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip rip send version 2**

ip rip summary-address *<ip address> <subnet mask>*

Use the **ip rip summary-address** command to manually summarize the routes Routing Information Protocol (RIP) will advertise and send out a specified interface. Use the **no** form of this command to disable this mode.

Syntax Description

<ip address>	Specifies the summarized network IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.0**).
<subnet mask>	Specifies the subnet mask that corresponds to the range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no manual summarization is applied by RIP.

Command History

Release 12.1	Command was introduced.

Functional Notes

Unlike the automatic summarization on classful network boundaries, only specific network advertisements are made by RIP using the **ip rip summary-address** command. This command is only effective if RIP version 2 is configured.

Usage Examples

The following example enables manual summarization on the specified IP address:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip rip summary-address 10.10.123.0 255.255.255.0**

ip route-cache

Use the **ip route-cache** command to enable fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

*Using network address translation (NAT) or the AOS firewall capabilities on an interface requires process switching mode (using the **no ip route-cache** command).*

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 9.1	Command was introduced.

Functional Notes

Fast switching allows an IP interface to provide optimum performance when processing IP traffic.

Usage Examples

The following example enables fast switching on the tunnel interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip route-cache**

ip urlfilter <*name*>

Use the **ip urlfilter** command to apply a universal resource locator (URL) filter to the interface for all inbound or outbound traffic. Use the **no** form of this command to remove the URL filter from an interface. Variations of this command include:

ip urlfilter <*name*> **in**
ip urlfilter <*name*> **out**

Syntax Description

<*name*>	Specifies the URL filter name to use on the interface.
in	Applies the filter to the inbound traffic.
out	Applies the filter to the outbound traffic.

Default Values

By default, there are no URL filters applied to any interfaces.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the virtual local area network (VLAN) interfaces.

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be created by using the **ip urlfilter** <*name*> **http** command before applying it to the interface. Refer to *ip urlfilter allowmode on page 1493* for more information on using this command.

Usage Examples

The following example performs URL filtering on all traffic entering through the tunnel interface and matches the URL filter named **MyFilter**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ip urlfilter MyFilter in**

ipv6

Use the **ipv6** command to enable Internet Protocol version 6 (IPv6) processing and create a link-local address on an interface. Use the **no** form of this command to disable IPv6 processing and remove all IPv6 configuration on the interface.

Syntax Description

No subcommands.

Default Values

By default, IPv6 is not enabled on the interface.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

Because AOS uses the dual-stack for IPv6 implementation, IPv6 features must be enabled for the supported IPv6 features to be used. Enabling IPv6 in AOS is completed by using an IPv6 address or using the **ipv6** keyword with specific commands. For example, to enable IPv6 on an interface and cause the interface to join the link scoped all-nodes and all-routers multicast group, enter an IPv6 address on the interface.

Use the **ipv6** command to enable IPv6 processing and create a link-local address on an interface when other unicast IPv6 addresses are not needed on the interface. This command is not necessary nor effectual when any other form of an IPv6 address command is also present on the interface.

Usage Examples

The following example enables IPv6 and creates a link-local IPv6 address on the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6**

ipv6 access-group *<ipv6 acl name>*

Use the **ipv6 access-group** command to apply an Internet Protocol version 6 (IPv6) access control list (ACL) to be used for IPv6 packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ipv6 access-group <*ipv6 acl name*> **in**
ipv6 access-group <*ipv6 acl name*> **out**

Syntax Description

<ipv6 acl name>	Applies the named IPv6 ACL to the interface.
in	Enables access control on IPv6 packets received on the specified interface.
out	Enables access control on IPv6 packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 18.1	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.

Functional Notes

Only one IPv6 ACL can be applied in each traffic direction.

Unlike in IPv4, IPv6 traffic filters include an implicit **permit** for neighbor solicitation and advertisement packets in an ACL before the traditional implicit **deny** at the end of the ACL. This prevents blocking of address resolution and unreachability detection, although this can be overridden by entering explicit **deny** commands in the IPv6 ACL.

Usage Examples

The following example applies the IPv6 ACL **Privatev6** to incoming IPv6 traffic on the interface:

(config)**#tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 access-group Privatev6 in**

ipv6 address *<ipv6 address/prefix-length>*

Use the **ipv6 address** command to assign a unicast Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<ipv6 address/prefix-length>	Specifies the IPv6 unicast address to add to the interface. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

Default Values

By default, no IPv6 address is configured on the interface and IPv6 processing is not enabled on the interface.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the interface using the command *ipv6 address <ipv6 link-local address> link-local on page 3288*.

The address created by this command is a manually configured IPv6 address, which must have all parts (prefix and host bits) specified.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example adds a unicast IPv6 address to the interface and enables IPv6 processing on the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 address 2001:DB8::/32**

ipv6 address *<ipv6 prefix/prefix-length>* eui-64

Use the **ipv6 address eui-64** command to assign a unicast Internet Protocol version 6 (IPv6) address and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<ipv6 prefix/prefix-length>	Specifies the IPv6 prefix. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
eui-64	Specifies that the IPv6 address is constructed using the specified prefix in the high-order bits and followed by the EUI-64 Interface ID in the lower 64 bits.

Default Values

By default, no IPv6 address is configured on the interface and IPv6 processing is not enabled on the interface.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the interface using the command *ipv6 address <ipv6 link-local address> link-local on page 3288*.

The address created by this command is an EUI-64 unicast address. For this type of address, the EUI-64 interface ID is automatically placed in the IPv6 address. Any manually configured bits beyond the address's prefix length are set to **0**; however, any manually configured bits within the prefix length that extend into the lower 64 bits take precedence over the Interface ID bits.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example adds a unicast IPv6 address with an EUI-64 Interface ID to the interface and enables IPv6 processing on the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 address 2001:DB8:3F::/48 eui-64**

ipv6 address <*ipv6 link-local address*> link-local

Use the **ipv6 address link-local** command to manually assign a link-local Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<*ipv6 link-local address*>	Specifies the link-local IPv6 address. Link-local addresses are specified in colon hexadecimal notation, and begin with **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since link-local addresses have no prefix, the bits entered form the entire IPv6 address.
link-local	Specifies this is a manually configured link-local address. Manually configured link-local addresses replace automatically configured link-local addresses on the interface.

Default Values

By default, no IPv6 address is configured for the interface and IPv6 processing is not enabled.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

A single link-local address can be manually configured on an interface. The lower 64 bits of the specified address become the Interface ID for the interface, overriding the default interface ID. Any other address that uses the EUI-64 parameter to automatically place the interface ID in the lower 64 bits of the IPv6 address use the new value for the interface ID.

The <*ipv6 address*> for a link-local IPv6 address is specified in the format **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since this form of address has no prefix, the bits entered form the entire IPv6 address. These bits also become the new interface ID for the interface and can be derived from the interface's medium access control (MAC) address.

The **link-local** parameter specifies this is a manually configured link-local address. Any manually configured link-local address will replace an automatically configured link-local address for the interface.

Using the **no** form of this command with a specified IPv6 address removes that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example manually creates a link-local IPv6 address on the interface and enables IPv6 processing:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 address FE80::220:8FF:FE54:F9D8 link-local**

ipv6 address autoconfig

Use the **ipv6 address autoconfig** command to enable Internet Protocol version 6 (IPv6) processing on the interface, create a local-link IPv6 address for the interface, and allow the interface to automatically configure itself based on advertisements from other routers on the link. Use the **no** form of this command to remove all autoconfigured addresses, prefixes, and any resulting routes from the interface and also causes the interface to cease processing received router advertisements (RAs).Variations of this command include:

ipv6 address autoconfig
ipv6 address autoconfig default
ipv6 address autoconfig default metric <*value*>

Syntax Description

default	Optional. Specifies that the interface maintain a list of advertising routers that are willing to be IPv6 default routers.
metric <*value*>	Optional. Specifies the administrative distance for a default router maintained in the default router list. Range is **1** to **255**. Routes with lower administrative distance are favored.

Default Values

By default, no IPv6 addresses are configured for the interface and IPv6 processing is not enabled. When an IPv6 address is configured automatically, the administrative distance for default routers is **2** by default.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

When autoconfiguration is enabled, the interface listens for RA messages that tell the interface how it should be configured. The interface then creates addresses for advertised 64-bit prefixes with the A flag in the IPv6 address set using stateless address autoconfiguration (SLAAC). The addresses use the EUI-64 interface ID in the lower 64 bits of the address. A route type of *Connected* is added to the route table if the L flag on the prefix advertisement (on-link flag) is also set.

Usage Examples

The following example enables IPv6 processing on the interface, creates a link-local IPv6 address for the interface, and allows the interface to automatically configure itself for IPv6:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 address autoconfig**

ipv6 address dhcp

Use the **ipv6 address dhcp** command to enable Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) on the interface, place the interface in DHCPv6 client mode, and configure the address parameters of the DHCPv6 client. Use the **no** form of this command to disable the DHCPv6 client on the interface. Variations of this command include:

ipv6 address dhcp
ipv6 address dhcp hostname <*partial fqdn*>
ipv6 address dhcp hostname fqdn <*fqdn*>
ipv6 address dhcp no-domain-name
ipv6 address dhcp no-nameservers
ipv6 address dhcp no-ntp
ipv6 address dhcp no-sntp-server
ipv6 address dhcp rapid-commit

Syntax Description

hostname <*partial fqdn*>	Optional. Specifies the name to be sent to the DHCPv6 server as the host portion of its fully qualified domain name (FQDN). FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
fqdn <*fqdn*>	Optional. Specifies a name to be sent to the DHCPv6 server as the system's FQDN. FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
no-domain-name	Optional. Specifies that no domain names are obtained using this DHCPv6 client.
no-nameservers	Optional. Specifies that no domain naming server (DNS) addresses are obtained through DHCPv6.
no-ntp	Optional. Specifies that no Network Time Protocol (NTP) server values are obtained through this DHCPv6 client.
no-sntp-server	Optional. Specifies that no Simple Network Time Protocol (SNTP) server values are obtained through this DHCPv6 client.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Functional Notes

To enable an interface as a DHCPv6 client, you must first enable IPv6 on the interface using the command *ipv6 on page 3284*.

Enabling the interface as a DHCPv6 client using the **ipv6 address dhcp** command places the interface into DHCPv6 client mode. DHCPv6 modes (**client**, **server**, **relay**) are mutually exclusive at the interface. Any existing mode must be removed before a different mode can be applied. For example, if the interface is configured as a DHCPv6 relay agent, you must first disable the **relay** mode before you can specify the interface is in **client** mode.

Usage Examples

The following example enables the interface as a DHCPv6 client and specifies the client's host name:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 address 2001:DB8:1::1/64**
(config-tunnel 1)**#ipv6 address dhcp fqdn client@company.com**

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*

Use the **ipv6 address named-prefix** command to create an Internet Protocol version 6 (IPv6) address for the interface using the values in a named prefix. Use the **no** form of this command to remove the address from the interface. Variations of this command include:

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*
ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>* **eui-64**

Syntax Description

<prefix name>	Specifies the named prefix to use to create the address.
<ipv6 address/prefix-length>	Specifies the address portion appended to the named prefix to create a 128-bit host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
eui-64	Optional. Indicates that the interface ID is to be placed in the lower 64 bits of the address.

Default Values

By default, no IPv6 addresses are specified on the interface.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example creates an IPv6 address on the interface using the named prefix **PREFIX1**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 address named-prefix PREFIX1 2001:1:0:/48**

ipv6 crypto map *<name>*

Use the **ipv6 crypto map** command to associate Internet Protocol version 6 (IPv6) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

Syntax Description

<name>	Specifies the IPv6 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

Command History

Release R10.7.0	Command was introduced.

Functional Notes

Only one IPv6 crypto map can be specified per interface, and the crypto map is applied within the virtual routing and forwarding (VRF) instance to which the interface belongs. To apply the IPv6 crypto map, the interface must have IPv6 enabled. In addition, the interface must have an IPv6 address of appropriate scope to allow connectivity to peer's addresses as specified in the crypto map's entries.

Usage Examples

The following example applies all IPv6 crypto maps with the name **MyMap** to the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6**
(config-tunnel 1)**#ipv6 crypto map MyMap**

ipv6 dhcp client information refresh minimum <*seconds*>

Use the **ipv6 dhcp client information refresh minimum** command to specify the minimum value the Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) client on the interface accepts as its information refresh timer. Use the **no** version of this command to return to the default setting.

Syntax Description

<*seconds*>	Specifies the refresh timer in seconds. Valid range is **600** to **3600** seconds.

Default Values

By default, the DHCPv6 client refresh timer is set to **600** seconds.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example specifies the DHCPv6 client refresh timer for the interface is **800** seconds:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 dhcp client information refresh minimum 800**

ipv6 dhcp client pd <*prefix name*>

Use the **ipv6 dhcp client pd** command to enable the Dynamic Control Host Protocol for Internet Protocol version 6 (DHCPv6) client on the interface and specify that the interface acquires an IPv6 prefix for the DHCPv6 client. Use the **no** form of this command to disable this feature. Variations of this command include:

ipv6 dhcp client pd <*prefix name*>
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*>
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*> **tag** <*value*>
ipv6 dhcp client pd <*prefix name*> **no-aggregate-route**
ipv6 dhcp client pd <*prefix name*> **rapid-commit**

Syntax Description

<*prefix name*>	Specifies the variable of the prefix stored on the AOS system. Variables are expressed in ASCII text of up to **80** characters.
distance <*distance*>	Optional. Specifies the administrative distance to assign to the injected route. Valid range is **1** to **255** with a default distance of **1**.
no-aggregate-route	Optional. Specifies that a route to the null 0 interface is not injected into the route table for the prefixes assigned.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.
tag <*value*>	Optional. Specifies a number to use as a tag for labeling and filtering routers. Valid range is **1** to **65535**.

Default Values

By default, the DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Usage Examples

The following example enables the DHCPv6 client on the interface and assigns the prefix **PREFIX1**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 dhcp client pd PREFIX1**

ipv6 dhcp relay destination <*ipv6 address*>

Use the **ipv6 dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 6 (IPv6) and to specify the IPv6 address for the DHCPv6 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv6 relay functionality is disabled on the interface. Variations of this command include:

ipv6 dhcp relay destination <*ipv6 address*>
ipv6 dhcp relay destination <*ipv6 address*> <*interface*>
ipv6 dhcp relay destination <*ipv6 address*> **mef-ethernet** <*slot/port*>
ipv6 dhcp relay destination <*ipv6 address*> **system-control-evc**
ipv6 dhcp relay destination <*ipv6 address*> **system-management-evc**

Syntax Description

<*ipv6 address*>	Specifies the IPv6 address for the DHCPv6 messages. IPv6 addresses should be specified in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<*interface*>	Optional. Specifies an output interface to use when sending messages to the DHCPv6 server. If no interface is specified, the interface is selected by the routing table. This parameter is only required when the IPv6 address is a link-scoped address. Interfaces are specified in the <*interface type*> <*slot/port* | *interface id*> format. For example, for an Ethernet interface, use **eth 0/1**. Type **ipv6 dhcp relay destination** <*ipv6 address*> **?** to display a list of valid interfaces.
mef-ethernet <*slot/port*>	Specifies the Metro Ethernet Forum (MEF) Ethernet interface.
system-control-evc	Optional. Specifies the system control Ethernet virtual connection (EVC) is used when sending messages to the DHCPv6 server.
system-management-evc	Optional. Specifies the system management EVC is used when sending messages to the DHCPv6 server.

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.
Release R10.5.0	Command was expanded to include the loopback interface.
Release R10.10.0	Command was expanded to include the system control and system management EVCs.
Release R10.11.0	Command was expanded to include the MEF Ethernet interface.

Functional Notes

To configure an interface to function as a DHCPv6 relay agent, you must first enable IPv6 on the interface using the command *ipv6 on page 3284*.

Usage Examples

The following example enables DHCPv6 relay agent functionality and specifies the destination address as **2001:DB8:2::1**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6**
(config-tunnel 1)**#ipv6 dhcp relay destination 2001:DB8:2::1**

Technology Review

DHCPv6, like DHCP in IPv4, is used in IP networks to supply hosts with IP addresses and other networking information. DHCPv6, however, functions slightly differently than DHCPv4 by providing relay agents with the ability to send relay-forward and relay-reply messages. In addition, in DHCPv4, when DHCP messages are sent to a DHCP server whose address is not known, the IPv4 client uses the broadcast address. In DHCPv6, the IPv6 client sends messages using the link-scoped mulitcast address. This address is the All DHCP Relay Agents and Servers link, designated as **FF02::1:2**.

In AOS, DHCPv6 relay agents are used when the DHCP server is not on the same link as the DHCP client. The relay is typically a router on the same link as the client, which acts as an intermediary to help the client's DHCP messages reach the DHCP server. DHCPv6 relay agents operate transparently to the DHCP client, and can be configured in chains, meaning that information about each agent encountered is encapsulated into the relay message. Relay agents add fields to the DHCP message as they send these messages to the server, thus providing a method to properly manage the DHCP client.

For more information about DHCPv6 functionality in AOS, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

ipv6 dhcp server

Use the **ipv6 dhcp server** command to enable Internet Protocol version 6 (IPv6) Dynamic Host Control Protocol (DHCP) on the interface and specify that the interface is functioning as a DHCPv6 server. This command not only enables the DHCPv6 server on the interface, it also configures specific parameters of the DHCPv6 server. Hence, the parameters of this command can be entered multiple times and in any order. Use the **no** form of this command to disable DHCPv6 on the interface. Variations of this command include:

ipv6 dhcp server automatic
ipv6 dhcp server automatic allow-hint
ipv6 dhcp server automatic preference <*number*>
ipv6 dhcp server automatic rapid-commit
ipv6 dhcp server <*pool name*>
ipv6 dhcp server <*pool name*> **allow-hint**
ipv6 dhcp server <*pool name*> **preference** <*number*>
ipv6 dhcp server <*pool name*> **rapid-commit**

Syntax Description

automatic	Enables automatic selection of the DHCPv6 server pool based on information extracted from the DHCPv6 client's request. You must specify the pool selection method before configuring other options for this command.
<*pool name*>	Specifies the DHCPv6 server pool that services this interface. All DHCPV^ requests received on this interface are serviced from this pool. If a pool name is not specified, the server pool is selected automatically. You must specify the pool selection method before configuring the other options for this command.
allow-hint	Optional. Specifies that the DHCPv6 server attempts to honor the DHCPv6 client's request for specific values as hinted in the client's request (if they are valid and not already assigned). If this option is not specified, any hints from the DHCPv6 client are ignored.
preference <*number*>	Optional. Specifies the preference value advertised by the server. This option is sent by the server to a DHCPv6 client to influence the selection of a server when there are multiple servers from which to choose. Valid range is **0** to **255**, with a default value of **0**. When the preference value is set to a non-zero value, the server includes a preference option containing the value. If the preference value is not set, or is set to 0, the option is omitted and the client assumes the value is 0.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 server mode is not enabled on the interface.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

Enabling the interface as a DHCPv6 server using this command places the interface into DHCPv6 server mode. DHCPv6 modes (server or relay) are mutually exclusive at the interface. Any existing mode will be removed if a different mode is specified, and a message will be shown indicating the change in DHCPv6 mode.

Usage Examples

The following example enables the interface as a DHCPv6 server, and specifies that the DHCPv6 server pool **POOL1** is associated with the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 address 2001:DB8:1::1/64**
(config-tunnel 1)**#ipv6 dhcp server POOL1**

ipv6 ffe

Use the **ipv6 ffe** command to enable the RapidRoute fast forwarding engine (FFE) on this Internet Protocol version 6 (IPv6) interface with the default number of entries. Use the **no** form of this command to disable this feature. Variations of this command include:

ipv6 ffe
ipv6 ffe max-entries <*value*>

Issuing this command will cause all RapidRoute entries to be cleared from this IPv6 interface.

Syntax Description

max-entries <*value*>	Optional. Specifies the maximum number of entries stored in the flow table. Valid range is from **1** to **500000**.

Default Values

By default, the RapidRoute Engine is enabled on IPv6-enabled interfaces (using the command *ipv6 on page 2231*). The default number of **max-entries** is **4096**.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

RapidRoute can be used to help reduce routing overhead, and thus reduce overall routing times. Routing times are reduced by the creation of a flow table on the ingress interface. The maximum number of entries that can be stored in the flow table at any one time may be specified by using the **max-entries** parameters.

Usage Examples

The following example disables RapidRoute on the IPv6 interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#no ipv6 ffe**

Technology Review

The RapidRoute system goal is to increase IP packet throughput by moving as much of the packet processing into the engine as possible. Packets are classified into flows based upon the IP protocol (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol (ICMP), etc.), the source and destination IP addresses, IP type of service (ToS), and the protocol-specific information, such as the source and destination port numbers. Flows are defined as the unidirectional representation of a conversation between two IP hosts. Each ingress interface keeps its own flow table, a collection of flow entries.

The first packet in a flow that is forwarded through the unit will build a flow entry. When a flow entry is looked up but no entry is found, a RapidRouteBuilder object is allocated and attached to the packet. As the packet passes through the various processing layers, each subsystem will add processing to the RapidRouteBuilder. When packet is about to be forwarded out of the egress interface, the RapidRouteBuilder will be finalized. That is, the flow entry being built will be checked for completeness and committed to the flow table on the ingress interface. Subsequent flow matches can then bypass the normal processing layers.

ipv6 mode host unicast

Use the **ipv6 mode host unicast** command to place the interface in host mode using an Internet Protocol version 6 (IPv6) unicast address. Use the **no** form of this command to disable host mode on the interface.

Syntax Description

No subcommands.

Default Values

By default, host mode is disabled.

Command History

Release R10.9.0	Command was introduced.

Command History

When this command is configured on an interface, the MTU value is learned from received router advertisements. Link MTU value is learned in host mode from the following locations (in decreasing order of priority): the provisioned MTU value in the interface configuration, the router advertisements received on the interface, and the default MTU value (1500).

Usage Examples

The following example places the interface in host mode:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 mode host unicast**

ipv6 mtu *<size>*

Use the **ipv6 mtu** command to specify the maximum transmission unit (MTU) for Internet Protocol version 6 (IPv6) packets on the interface. Use the **no** form of this command to return to the default value.

Syntax Description

<size>	Specifies the MTU value. Valid range is **1280** to **1500** bytes.

Default Values

By default, the MTU of the interface is set to **1280** bytes.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

In IPv6, the minimum MTU is 1280 octets. Any link that has an MTU less than 1280 octets must use link fragmentation and reassembly that is transparent to IPv6 (for example, the Fragmentation Header). Sources in the IPv6 network are expected to perform path maximum transmission unit (PMTU) discovery to send packets larger than 1280 octets. PMTU works in the following manner: First, the sending node assumes the link MTU of the interface from which the traffic is being forwarded and then sends the IPv6 packet at the link MTU size. If a router on the path is unable to forward the packet, it sends an ICMP *Packet Too Big* message back to the sending node containing the link MTU of the link on which the packet forwarding failed. The sending node then rests the PMTU to the value of the MTU field in the Internet Control Message Protocol version 6 (ICMPv6) *Packet Too Big* message, and the packet is resent.

The MTU for IPv6 packets can be set on a per-interface basis. There are two methods for setting MTUs for interfaces if required: one for Layer 3 interfaces, and one for the underlying Layer 1 and Layer 2 interfaces. For all interface types, use the **ipv6 mtu** *<size>* command to specify the IPv6 MTU in bytes from the interface's configuration mode. The minimum MTU setting for IPv6 is **1280** bytes, and the maximum is **1500** bytes. The IPv6 MTU value is independent of the IPv4 MTU setting (set with the command *ip mtu <size> on page 3257*).

When the interface is forwarding the IPv6 packet as a router, if the packet size exceeds the IPv6 MTU of the egress interface, the packet is dropped and ICMPv6 *Packet Too Big* message is sent to the source. When originating an IPv6 packet from the local IPv6 stack, and the packet is larger than the IPv6 MTU of the egress interface, the packet is fragmented and sent.

Usage Examples

The following example specifies the IPv6 MTU value for the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 mtu 1350**

ipv6 nd advertisement-interval

Use the **ipv6 nd advertisement-interval** command to specify that the Advertisement Interval Option is sent in Internet Protocol version 6 (IPv6) router advertisement (RA) messages from the router. This command is effectual only when the interface is in router mode. Use the **no** form of this command to return to the default interval.

Syntax Description

No subcommands.

Default Values

By default, Advertisement Interval Options are not sent in RA messages.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

Sending the Advertisement Interval Option should be enabled when the router is functioning in a mobile IP environment to aid movement detection by mobile nodes. This option contains the current value of the maximum router advertisement interval configured using the command *ipv6 nd ra interval on page 3314*.

Usage Examples

The following example specifies that the interface include Advertisement Interval Options in RA messages sent from the router:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 nd advertisement-interval**

ipv6 nd cache max-incomplete <*number*>

Use the **ipv6 nd cache max-incomplete** command to specify the maximum number of incomplete entries the Neighbor Discovery (ND) cache retains. Use the **no** form of this command to return to the default value.

Syntax Description

<*number*>	Specifies the number of incomplete ND entries to retain in the cache. Valid range is **1** to **321**.

Default Values

By default, the incomplete ND entries can take at maximum one-third of the possible ND cache entries (varies by product).

Command History

Release R11.10.0	Command was introduced.

Usage Examples

The following example specifies that the interface stores **150** incomplete entries in the ND cache:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 nd cache max-incomplete 150**

ipv6 nd dad attempts *<number>*

Use the **ipv6 nd dad attempts** command to specify the number of neighbor solicitation (NS) messages sent by the interface when performing Internet Protocol version 6 (IPv6) duplicate address detection (DAD). This command is effectual when the interface is in either host or router mode. Use the **no** form of this command to return to the default value.

Syntax Description

<number>	Specifies the number of NS messages that will be sent. Range is **0** to **10** messages. A value of **0** disables DAD on the interface.

Default Values

By default, the interface sends **1** NS message.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

DAD is used by devices to determine if IPv6 addresses are unique before they are applied to interfaces. DAD is used in NS messages to detect duplicate unicast addresses. The Target Address fields in the NS messages are set to the IPv6 address for which duplication is being detected. Destination IPv6 addresses for DAD in NS messages are the solicited-node multicast version of the address being tested. Source IPv6 addresses for DAD are set to the IPv6 unspecified address (::). Once the IPv6 address is determined by DAD to be unique, it can be applied to the IPv6 interface on the node.

DAD in AOS is performed when an interface transitions state from DOWN to UP or when manually configuring an address. When performing DAD because of an interface transition, DAD will happen immediately after the interface transition and again 40 seconds later to cooperate with the port being connected to an Ethernet switch.

Usage Examples

The following example specifies that **3** NS messages are sent by the interface when performing DAD:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 nd dad attempts 3**

ipv6 nd managed-config-flag

Use the **ipv6 nd managed-config-flag** command to specify the M flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. The M flag instructs hosts receiving the RA that they can use stateful Dynamic Host Configuration Protocol version 6 (DHCPv6) to configure addresses and nonaddress information. Use the **no** form of this command to disable the setting of the M flag.

Syntax Description

No subcommands.

Default Values

By default, the M flag is not set in RAs.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

If you specify that the M flag is set in RA messages, you do not need to set the 0 flag (it becomes redundant).

Usage Examples

The following example sets the M flag for RA messages sent by the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 nd managed-config-flag**

ipv6 nd ns-interval *<value>*

Use the **ipv6 nd ns-interval** command to specify the interval between transmission of certain Internet Protocol version 6 (IPv6) Neighbor Discovery (ND) messages and to control what ND value is advertised in router advertisement (RA) messages. This command is effectual whether the interface is in host or router mode. Use the **no** form of this command to return the interval to the default value.

Syntax Description

<value>	Specifies the time (in milliseconds) between neighbor message transmissions. Valid range is **1000** to **3600000** ms.

Default Values

By default, the interval is set to **1000** ms for internal use by the router and **0** (unspecified) is sent in RA messages.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

This command controls the spacing of NS messages for functions such as address resolution, reachability detection, and DAD. For DAD it also serves as the amount of time after the last transmission before the detection phase of autoconfiguration terminates. In addition, the command controls the interval between unsolicited NA messages.

Usage Examples

The following example changes the interval between RA messages sent from the interface to **2000** ms:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 nd ns-interval 2000**

ipv6 nd other-config-flag

Use the **ipv6 nd other-config-flag** command to specify the O flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the interface is in router mode. When the O flag is set, hosts receiving the RA messages are instructed that they may use stateless Dynamic Host Configuration Protocol version 6 (DHCPv6) to receive information that is not IPv6 addressing information, and to use some other method (whether through manual configuration, stateless address autoconfiguration (SLAAC), etc.) for addressing information. Use the **no** form of this command to disable the O flag setting.

Syntax Description

No subcommands.

Default Values

By default, the O flag is not set in RA messages.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

If the M flag is set for RA messages, you do not need to set the O flag.

Usage Examples

The following example sets the O flag in RA messages from the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 nd other-config-flag**

ipv6 nd prefix

Use the **ipv6 nd prefix** command to specify the Internet Protocol version 6 (IPv6) address prefixes used in router advertisement (RA) messages sent from the interface. Use the **no** form of this command to remove the specified prefix configuration from the interface. Variations of this command include:

ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise] [**<*valid lifetime*> | **infinite]** <*preferred lifetime* | **infinite**>
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite] [no-advertise] [no-autoconfig] [no-rtr-address] [no-onlink] [off-link]**

Syntax Description

named-prefix <*prefix name*>	Optional. Specifies that a named prefix is used in RA messages. When a named prefix is used, the default prefix cannot be used.
<*ipv6 prefix/prefix-length*>	Specifies the IPv6 prefix and length to be advertised. Pv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
default	Specifies the default values for the IPv6 prefix parameters. Refer to the *Functional Notes* below for more information.
<*valid lifetime*>	Optional. Specifies the valid lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
<*preferred lifetime*>	Optional. Specifies the preferred lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
infinite	Optional. Specifies that the the valid and preferred lifetimes of the prefix do not expire.
no-advertise	Optional. Specifies that the prefix is excluded from the RA message.
no-autoconfig	Optional. Sets the A flag in the RA message to **0**, indicating that hosts may not create an address for this prefix using stateless address autoconfiguration (SLAAC). This parameter only affects hosts receiving the RA message, it does not affect the operation of the local router.
no-rtr-address	Optional. Sets the R flag in the RA message to **0** and specifies the full router IPv6 address is not included in the RA message.
no-onlink	Optional. Specifies that the IPv6 prefix in the RA message is not to be used for on-link determination.
off-link	Optional. Sets the L flag value to **0** in RA messages, which indicates the RA makes no statement about the on-link or off-link properties of the IPv6 prefix.

Default Values

By default, all prefixes derived from the interface's configured IPv6 addresses are advertised using the system default values.

By default, the valid lifetime advertised for a prefix is **2592000** seconds and the preferred lifetime advertised is **604800** seconds.

By default, the L flag is set to **1**, the R flag is set to **1**, and the A flag is set to **1**.

Command History

Release 18.1	Command was introduced.
Release R10.9.0	Command was expanded to include the **named-prefix** and *<prefix name>* options.

Functional Notes

This command works for both routers and hosts, but in host implementations it is used to manually add on-link prefixes that do not have an IPv6 address or to make off-link a prefix generated by an IPv6 address command. Hosts do not send RA messages, so the command only adds prefixes to RA messages when the interface is in router mode. This command can also be used to change the defaults used on configured prefixes when all options are not specified.

Changing the prefix defaults will affect prefixes derived from configured IPv6 addresses, as well as prefixes configured using the ***ipv6 nd prefix*** *command.*

Prefixes advertised can be a subset or a superset of the prefixes derived from the IPv6 addresses configured on the interface. Prefixes for IPv6 addresses configured on a router interface are automatically eligible to be advertised on that interface using system or configured default values without having to enter a prefix command. To impose additional controls on those prefixes, an entry must be made using this command with the desired settings.

The **default** parameter is used to change the default settings for the IPv6 prefix parameters. Changing these settings can be useful when multiple prefixes are implemented that will use the same set of parameters. When configuring IPv6 prefixes, the prefix default values are only used if no other parameters are specified after specifying the IPv6 prefix and length (for example, **ipv6 nd prefix 2001:DB8::/64**). If additional parameters are specified, any unspecified parameters use the system default values rather than the configured default values. When the default values are changed, any prefix that uses them will also change. Using this command to change prefix default values also affects prefixes derived from configured IPv6 addresses on the interface.

The optional *<valid lifetime>* parameter specifies the valid lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep this prefix until the valid lifetime expires.

The optional <*preferred lifetime*> parameter specifies the preferred lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep the prefix in the preferred state during this time period. After the preferred time period expires, the prefix transitions to the deprecated state where it remains until the valid lifetime expires and the route is removed. The <*preferred lifetime*> value must be set to be shorter than the <*valid lifetime*> value.

The optional **off-link** parameter sets the L flag (on-link flag) value to **0** in RA messages. When the L flag is set to 0, the advertisement makes no statement about on-link or off-link properties of the prefix. When the L flag is set, the prefix is considered on-link and locally reachable by hosts on the link (meaning a router is not needed). Hosts attached to the link will add on-link prefixes to their prefix list or route table. When off-link is not specified, a connected route is added to the route table of this router for this prefix. When off-link is specified, no route is added to the route table. By default, prefixes are advertised as on-link with the L flag set to 1.

The optional **no-rtr-address** parameter sets the R flag (router flag) of the RA to **0** and does not include the full router address in the advertisement. The router address is typically included in the RA to assist in Mobile IP environments. By default, the R flag is set to 1 and the router address is sent in RA messages.

The optional **no-autoconfig** parameter sets the A flag of the RA to **0**, indicating that hosts may not create an address for this prefix using SLAAC. If the A flag is set to **1** (the default setting), hosts perform SLAAC to generate an address based on the prefix. This parameter only affects hosts receiving the RA, it does not effect the operation of the local router.

The optional **no-advertise** parameter specifies that the prefix is excluded from RA messages. By default, the prefix is included in RA messages. The **no-onlink** parameter informs the router that the prefix is not to be used for on-link determination.

By default, all prefixes derived from the interface's configured IPv6 addresses are advertised using the system default values.

Usage Examples

The following example specifies that the IPv6 prefix **2001:DB8:3F::/48** has an infinite valid and preferred lifetime advertised in RA messages sent from the interface:

(config)**#interface tunnel 1**
(config-tunnel 1)**#ipv6 nd prefix 2001:DB8:3F::/48 infinite infinite**

The following example changes the default values and behaviors of prefixes included in RA messages to infinite valid and preferred lifetimes, and specifies that the on- or off-link state of the prefix is not included in the RA and that hosts receiving the RA may not use the prefix for creating an IPv6 address:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 nd prefix default infinite infinite off-link no-autoconfig**

ipv6 nd purge-timer <*value*>

Use the **ipv6 nd purge-timer** command to specify the maximum amount of time an unused Internet Protocol version 6 (IPv6) neighbor entry remains in the neighbor cache. This command applies to interfaces in either host or router mode. Use the **no** form of this command to return the purging interval to the default value.

Syntax Description

<*value*>	Specifies the neighbor cache entry storage time in minutes. Valid range is **10** to **1440** minutes.

Default Values

By default, idle (STALE) neighbor cache entries are cleared after **1440** minutes (24 hours).

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

This command applies to interfaces in either router or host mode. A neighbor entry is typically purged when neighbor unreachability detection (NUD) is invoked and the neighbor is determined to no longer be reachable. However, NUD is not performed on idle (STALE) neighbor entries, so this command provides a method for purging unused entries after a specified amount of time.

Usage Examples

The following example specifies that idle neighbor entries in the neighbor cache are removed after **800** minutes:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 nd purge-timer 800**

ipv6 nd ra interval

Use the **ipv6 nd ra interval** command to specify the interval between transmission of Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the interface is in router mode. Use the **no** form of this command to return to the default value. Variations of this command include:

ipv6 nd ra interval *<max time>*
ipv6 nd ra interval *<max time> <min time>*
ipv6 nd ra interval msec *<max time>*
ipv6 nd ra interval msec *<max time> <min time>*

Syntax Description

<max time>	Specifies the maximum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **4** to **1800** seconds and **70** to **1800000** ms.
<min time>	Optional. Specifies the minimum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **3** seconds to 75 percent of the configured maximum time value in seconds, or **30** ms to 75 percent of the configured maximum time value in ms.
msec	Optional. Specifies that the time values are in milliseconds.

Default Values

By default, the interval is set in seconds and has a maximum interval time of **200** seconds and a minimum interval time of 75 percent of the maximum seconds value, but not less than **3** seconds.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

If this router is used as a default router, the interval between RA messages should not be set to a larger value than the RA lifetime set by the command *ipv6 nd ra lifetime <value> on page 3315*, which has a default value of **1800** seconds.

Usage Examples

The following example specifies that the maximum interval in seconds between RA message transmissions is **300**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 nd ra interval 300**

ipv6 nd ra lifetime <*value*>

Use the **ipv6 nd ra lifetime** command to specify the router lifetime advertised in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is effectual when the interface is in router mode. Use the **no** form of this command to return to the default setting. Variations of this command include:

ipv6 nd ra lifetime <*value*>
ipv6 nd ra lifetime default-route

Syntax Description

<*value*>	Specifies the router lifetime in seconds. Range is **0** to **9000** seconds. A value of **0** indicates this is not a default router. A value other than 0 indicates to other nodes that this router can be used as a default router.
default-route	Specifies the RA lifetime is **0** if no default route exists on any IPv6 interface.

Default Values

By default, the router lifetime is set to **1800** seconds.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.
Release R11.5.0	Command was expanded to include the **default-route** parameter.

Functional Notes

A value other than **0** for a router lifetime should be larger than the router advertisement interval specified in the command *ipv6 nd ra interval on page 3314*.

Usage Examples

In the following example, the router lifetime advertised in RA messages is **3000** seconds:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 nd ra lifetime 3000**

ipv6 nd ra reachable-time <*value*>

Use the **ipv6 nd ra reachable-time** command to specify the value advertised for reachable time in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command also specifies the internal base reachable time used by the router. This command is effectual for interfaces in either host or router mode. Use the **no** form of this command to return the reachability value to the default setting.

Syntax Description

<*value*>	Specifies the reachability time in milliseconds. Range is **0** to **3600000** ms. A value of **0** indicates the reachable time is unspecified.

Default Values

By default, the router advertises a reachability time of **0** ms and uses an internal value of **30000** ms.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Functional Notes

This command is effectual for interfaces in either router or host mode. For hosts, this value sets the internal reachable time used by the host if no RAs are received specifying a different value. For routers, the value indicates the amount of time a device is considered reachable after having received a reachability confirmation in neighbor unreachabililty detection (NUD).

Usage Examples

The following example specifies that a reachability time of **50000** ms is advertised in RA messages:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 nd ra reachable-time 50000**

ipv6 nd ra suppress

Use the **ipv6 nd ra suppress** command to specify whether Internet Protocol version 6 (IPv6) router advertisement (RA) messages will be suppressed. This command only applies to interfaces in router mode. Use the **no** form of this command to begin sending RA messages.

Syntax Description

No subcommands.

Default Values

By default, RA messages are not suppressed. When IPv6 routing is not enabled on the router, or when implemented in a host-only mode, the default setting is to suppress advertisements on all interface types.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Usage Examples

The following example suppresses RA messages on the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 nd ra suppress**

ipv6 nd router-preference

Use the **ipv6 nd router-preference** command to specify the default router preference value set in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. Setting this preference helps the receivers of RA messages to determine the preference of one router over another as a default router in environments with multiple routers. Use the **no** form of this command to return the preference to the default setting. Variations of this command include:

ipv6 nd router-preference high
ipv6 nd router-preference low
ipv6 nd router-preference medium

Syntax Description

high	Specifies the preference value is high.
low	Specifies the preference value is low.
medium	Specifies the preference value is medium.

Default Values

By default, the router preference is set to medium.

Command History

Release 18.1	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.

Usage Examples

The following example specifies that the advertised default router preference is high:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ipv6 nd router-preference high**

ipv6 route-cache

Use the **ipv6 route-cache** command to enable Internet Protocol version 6 (IPv6) fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 18.2	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.

Functional Notes

Fast switching allows an IPv6 interface to provide optimum performance when processing IPv6 traffic.

Usage Examples

The following example enables IPv6 fast switching on the interface:

(config)**#tunnel 1gre ip**
(config-tunnel 1)**#ipv6 route-cache**

keepalive

Use the **keepalive** command to periodically send keepalive packets to verify the integrity of the tunnel from end to end. Use the **no** form of this command to disable keepalives. Variations of this command include:

keepalive
keepalive <*value*>
keepalive <*value*> <*number*>

Syntax Description

<*value*>	Defines the time interval (in seconds) between transmitted keepalive packets. Valid range is **1** to **32767** seconds.
<*number*>	Defines the number of times to retry after failed keepalives before determining that the tunnel endpoint is down. Valid range is **1** to **255** times.

Default Values

By default, keepalives are disabled. When enabled, the keepalive period defaults to **10** seconds and the retry count defaults to **3** times.

Command History

Release 9.1	Command was introduced.

Functional Notes

Keepalives do not have to be configured on both ends of the tunnel in order to work. A tunnel is not aware of incoming keepalive packets.

Usage Examples

The following example enables **keepalive** with a period of **30** seconds and a retry count of **5** times:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#keepalive 30 5**

lldp receive

Use the **lldp receive** command to allow Link Layer Discovery Protocol (LLDP) packets to be received on this interface. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, all interfaces are configured to send and receive LLDP packets.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example configures the tunnel interface to receive LLDP packets:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#lldp receive**

lldp send

Use the **lldp send** command to configure this interface to transmit Link Layer Discovery Protocol (LLDP) packets or to control the types of information contained in the LLDP packets transmitted by this interface. Use the **no** form of this command to disable this feature. Variations of this command include:

lldp send
lldp send management-address
lldp send port-description
lldp send system-capabilities
lldp send system-description
lldp send system-name
lldp send-and-receive

Syntax Description

management-address	Enables transmission of management address information on this interface.
port-description	Enables transmission of port description information on this interface.
system-capabilities	Enables transmission of this device's system capabilities on this interface.
system-description	Enables transmission of this device's system description on this interface.
system-name	Enables transmission of this device's system name on this interface.
and-receive	Configures this interface to both transmit and receive LLDP packets.

Default Values

By default, all interfaces are configured to transmit and receive LLDP packets of all types.

Command History

Release 9.1	Command was introduced.

Functional Notes

Individual LLDP information can be enabled or disabled using the various forms of the **lldp send** command. For example, use the **lldp send-and-receive** command to enable transmit and receive of all LLDP information. Then use the **no lldp send port-description** command to prevent LLDP from transmitting port description information.

Usage Examples

The following example configures the tunnel interface to transmit LLDP packets containing all enabled information types:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#lldp send**

The following example configures the tunnel interface to transmit and receive LLDP packets containing all information types:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#lldp send-and-receive**

media-gateway ip

Use the **media-gateway ip** command to associate an Internet Protocol version 4 (IPv4) address source to use for Realtime Transport Protocol (RTP) traffic. When configuring Voice over Internet Protocol (VoIP), RTP traffic must have an IPv4 address associated with it. However, some interfaces allow dynamic configuration of IPv4 addresses, causing this value to change periodically. Use the **no** form of this command to disable this function. Variations of this command include:

media-gateway ip loopback <*interface id*>
media-gateway ip primary
media-gateway ip primary vrrp <*number*>
media-gateway ip primary vrrpv3 <*number*>
media-gateway ip secondary <*ipv4 address*>
media-gateway ip secondary vrrp <*number*>
media-gateway ip secondary vrrp <*number*> <*ipv4 address*>
media-gateway ip secondary vrrpv3 <*number*>
media-gateway ip secondary vrrpv3 <*number*> <*ipv4 address*>

Syntax Description

loopback <*interface id*>	Specifies an IPv4 address statically defined to a loopback interface for RTP traffic. This is helpful when using a single IPv4 address across multiple wide area network (WAN) interfaces for RTP traffic. The valid range for loopback interface identifiers is **1** to **1024**. The interface ID is used to uniquely identify a loopback interface. The entered value cannot be in use by another loopback interface.
primary	Specifies using this interface's configured primary IPv4 address for RTP traffic. Applies to static, Dynamic Host Configuration Protocol (DHCP), or negotiated addresses.
secondary <*ipv4 address*>	Specifies using this interface's statically defined secondary IPv4 address for RTP traffic. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
vrrp <*number*>	Specifies that the IPv4 address of the Virtual Router Redundancy Protocol version 2 (VRRP) router group's virtual router ID (VRID) is used as the media gateway address on the interface. Valid VRID range is **1** to **255**.
vrrpv3 <*number*>	Specifies that the IPv4 address of the VRRP version 3 (VRRPv3) VRID is used as the media gateway address on the interface. Valid VRID range is **1** to **255**.
<*ipv4 address*>	Optional. Specifies a secondary IPv4 address of the VRRP or VRRPv3 VRID is used as the media gateway address on the interface. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, **media-gateway ip** is disabled.

Command History

Release 10.1	Command was introduced.
Release 17.3	Command was updated with the loopback interface identification option.
Release A4.01	Command was expanded to include the Metro Ethernet forum (MEF) Ethernet interface.
Release R12.2.0	Command was expanded to include the **vrrp** and **vrrpv3** parameters.

Functional Notes

To use VRRP or VRRPv3 addresses as the media gateway on the interface, you must first have configured VRRP or VRRPv3.

Usage Examples

The following example configures the unit to use the primary IPv4 address for RTP traffic:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#media-gateway ip primary**

media-gateway ipv6

Use the **media-gateway ipv6** command to associate an Internet Protocol version 6 (IPv6) address source to use for Realtime Transport Protocol (RTP) traffic. When configuring Voice over Internet Protocol (VoIP), RTP traffic must have an IPv6 address associated with it. However, some interfaces allow dynamic configuration of IPv6 addresses, causing this value to change periodically. Use the **no** form of this command to disable this function. Variations of this command include:

media-gateway ipv6
media-gateway ipv6 <*ipv6 address*>
media-gateway ipv6 loopback <*interface id*>
media-gateway ipv6 vrrpv3 <*number*>
media-gateway ipv6 vrrpv3 <*number*> <*ipv6 address*>

Syntax Description

<*ipv6 address*>	Specifies an IPv6 address to use for the media gateway. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
loopback <*interface id*>	Specifies an IPv6 address statically defined to a loopback interface for RTP traffic. This is helpful when using a single IPv6 address across multiple wide area network (WAN) interfaces for RTP traffic. The valid range for loopback interface identifiers is **1** to **1024**. The interface ID is used to uniquely identify a loopback interface. The entered value cannot be in use by another loopback interface.
vrrpv3 <*number*>	Specifies that all the secondary IPv6 addresses of the Virtual Routing Redundancy Protocol version 3 (VRRPv3) virtual router ID (VRID) are used as media gateway addresses on the interface. Valid VRID range is **1** to **255**.
<*ipv6 address*>	Optional. Specifies a single IPv6 address of the VRRPv3 VRID is used as the media gateway address on the interface. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.

Default Values

By default, **media-gateway ipv6** is disabled.

Command History

Release R10.8.0	Command was introduced.
Release R12.2.0	Command was expanded to include the **vrrpv3** parameters.

Functional Notes

To use VRRPv3 addresses as the media gateway on the interface, you must first have configured VRRPv3.

Usage Examples

The following example configures the unit to use the IPv6 address for RTP traffic:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#media-gateway ipv6**

mtu <*size*>

Use the **mtu** command to specify the maximum transmission unit (MTU) for a virtual extensible local area network (VxLAN) tunnel interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Specifies the MTU value. Valid range is **64** to **1464** bytes.

Default Values

By default, the MTU of the interface is set to 1464 bytes.

Command History

Release 13.1.0	Command was introduced.

Functional Notes

A VxLAN tunnel interface has two MTUs associated with it, one that is dynamically configured based on the outgoing IPv4 Ethernet interface (refer to the MTU specified by the *ip mtu <size> on page 3257*). The minimum value of these two MTUs is used when transmitting a packet from this tunnel interface. If an IP security (IPSec) profile has been applied to the tunnel, the MTU size may need to be reduced to accommodate a larger packet header.

Usage Examples

The following example specifies the MTU value for the VxLAN tunnel interface:

(config)**#interface tunnel 1 vxlan**
(config-tunnel 1)**#mtu 1350**

ospfv3 <*process id*> **area** <*area id*>

Use the **ospfv3 area** command to add an interface to an Open Shortest Path First version 3 (OSPFv3) process, and to configure the OSPFv3 process on the interface. This command places the interface in the specified area for the specified Internet Protocol version 6 (IPv6) OSPFv3 address family, and optionally defines the instance ID that is used to represent this OSPFv3 process in messages on the interface's link. Use the **no** form of this command to remove the OSPFv3 process from the interface. Variations of this command include:

ospfv3 <*process id*> **area** <*area id*> **ipv6**
ospfv3 <*process id*> **area** <*area id*> **ipv6 instance** <*instance id*>

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join, for the specified address family. The process ID is locally significant to the device, and must be unique among all OSPFv3 processes on the device. Valid range is **1** to **65535**.
<*area id*>	Specifies the ID of the area to which this interface is assigned for the given OSPFv3 process. Valid range is **0** to **4294967295**.
ipv6	Identifies the OSPFv3 address family as IPv6.
instance <*instance id*>	Optional. Specifies the value to use in the instance ID field of messages sent or received by this OSPFv3 process on the interface's link. Valid range is **0** to **31**.

Default Values

By default, an OSPFv3 process is not configured on an interface. By default, process IDs, area IDs, and instance IDs are not defined.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

When using this command to enable an OSPFv3 process on an interface, keep the following rules in mind:

- The interface must have the address family enabled on the interface. If the address family is not enabled on the interface, the command is rejected and an error is displayed.
- Only interfaces on the default virtual routing and forwarding (VRF) instance support this command. Interfaces on a nondefault VRF will display an error when you attempt to configure OSPFv3 settings.
- The interface and the specified OSPFv3 process (if defined in the global configuration) must be in the same VRF or the command will fail.
- The address family must match that specified for the OSPFv3 process if the process has been defined in the global configuration or the command will fail.
- If the OSPFv3 process identified by the process ID does not exist in the global configuration, it is automatically created, along with the specified address family, and it is assigned to the VRF of which the interface is a member.

- If the specified OSPFv3 process is already at its maximum limit of processes or address families, the command fails.
- If the specified OSPFv3 process already exists in the global configuration, but its configuration does not include an address family, the specified address family is added to the OSPFv3 router configuration.
- A given OSPFv3 process can only have one address family.
- Multiple OSPFv3 instances per address family, per VRF, can be created and can be assigned to a given interface.
- If the interface's VRF changes, all OSPFv3 assignments are removed.
- To change an OSPFv3 process's VRF, the process must first be removed and then recreated. Removing the process removes all OSPFv3 assignments for that process form all interfaces.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

To add an interface to the OSPFv3 process **5**, in area **10**, with an instance ID of **10**, enter the command as follows:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ospfv3 5 area 10 ipv6 instance 10**

ospfv3 authentication

Use the **ospfv3 authentication** command to authenticate an interface that is performing Internet Protocol version 6 (IPv6) Open Shortest Path First version 3 (OSPFv3) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ospfv3 authentication ipsec spi <*spi*> **md5** <*key*>
ospfv3 authentication ipsec spi <*spi*> **sha1** <*key*>
ospfv3 authentication null

Syntax Description

ipsec	Specifies that IP security (IPsec) authentication is used.
spi <*spi*>	Specifies the security parameter index (SPI). Valid range is **256** to **4294967295**.
md5 <*key*>	Specifies that MD5 authentication is used. Keys are specified in 32 hexadecimal characters.
sha1 <*key*>	Specifies that SHA-1 authentication is used. Keys are specified in 40 hexadecimal characters.
null	Specifies that no OSPFv3 authentication is used.

Default Values

By default, this is set to **null** (meaning no authentication is used).

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example specifies that no OSPFv3 authentication will be used on the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ospfv3 authentication null**

ospfv3 *<process id>* **cost** *<cost>*

Use the **ospfv3 cost** command to specify a value that represents the cost of sending an Open Shortest Path First version 3 (OSPFv3) packet over the interface. Use the **no** form of this command to return the cost to the default value.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3329*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
cost *<cost>*	Specifies the OSPFv3 cost of the interface. This value overrides any automatically computed cost value (default value). Valid range is **1** to **65535**.

Default Values

By default, the OSPFv3 cost of the interface is automatically computed. The automatic cost computation is the reference bandwidth divided by the interface bandwidth. The reference bandwidth is set by the command *auto-cost reference-bandwidth <value> on page 4150*, and defaults to **100** Mbps.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the OSPFv3 cost of the interface as **10**:

```
(config)#interface tunnel 1 gre ip
(config-tunnel 1)#ospfv3 5 cost 10
```

ospfv3 <*process id*> dead-interval <*value*>

Use the **ospfv3 dead-interval** command to specify the maximum interval allowed between Open Shortest Path First version 3 (OSPFv3) Hello packets on the interface. If the maximum interval is exceeded, neighboring devices will assume that the device is down. This value must be the same across all interfaces on a link. Use the **no** form of this command to return the dead interval to the default value.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3329*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
dead-interval <*value*>	Specifies the maximum number of seconds allowed between OSPFv3 Hello packets. It is recommended that this value be **4** times the Hello packet interval (set with the command *ospfv3 <process id> hello-interval <value> on page 3336*). Valid range is **1** to **65535** seconds.

Default Values

By default, the maximum interval allowed between OSPFv3 Hello packets is set to **40** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

To specify the dead interval between OSPFv3 Hello packets on the interface, enter the command as follows:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ospfv3 5 dead-interval 100**

ospfv3 encryption

Use the **ospfv3 encryption** command to specify a symmetrical, bidirectional Open Shortest Path First version 3 (OSPFv3) security association (SA) that uses encapsulating security payload (ESP) for encryption and authentication of all OSPFv3 messages that are sent or received on the interface. This command allows you to specify OSPFv3 security at the interface level. Use the **no** form of this command to remove IP security (IPsec) protection of OSPFv3 messages on the interface. Variations of this command include:

ospfv3 encryption ipsec spi <*spi*> **esp** <*encryption type*> <*encryption key*> <*authentication type*> <*authentication key*>
ospfv3 encryption ipsec spi <*spi*> **esp null** <*authentication type*> <*authentication key*>
ospfv3 encryption null

Syntax Description

ipsec	Specifies that IPsec encryption is used on the interface for OSPFv3 SAs.
spi <*spi*>	Specifies the security parameter index (SPI) for the SA. The value specified must not be in used by any other IPsec function on the system, or an error message is generated. If the same SPI is already in use in the same OSPFv3 area, entering this command with the same value will overwrite the current configuration. Valid SPI range is **256** to **4294967295**.
esp	Specifies that ESP is used.
null	Specifies that OSPFv3 messages on this interface are not encrypted when used in the **ospfv3 encryption null** format (even when encryption is specified by the OSPFv3 area configuration). When used in the **ospfv3 encryption ipsec spi** <*spi*> **esp null** format, **null** indicates that messages on the interface will not be encrypted, but will be authenticated.
<*encryption type*>	Specifies the type of algorithm used to encrypt OSPFv3 messages. Valid values for encryption are: **3des** uses triple data encryption standard (DES). **aes-cbc** uses advanced encryption standard (AES) with cipher block chaining (CBC). Select from **aes-cbc 128**, **aes-cbc 192**, or **aes-cbc 256**. **des** uses DES.
<*encryption key*>	Specifies the hexadecimal encryption key. The size of the encryption key is determined by the respective encryption algorithm, as follows: **3des** uses a **48** character key size. **aes-cbc 128** uses a **32** character key size. **aes-cbc 192** uses a **48** character key size. **aes-cbc 256** uses a **64** character key size. **des** uses a **16** character key size.
<*authentication type*>	Specifies the algorithm used for authenticating OSPFv3 messages. Valid authentication methods are Message-Digest 5 (**md5**) and Secure-Hash 1 (**sha1**) algorithms.

<authentication key> Specifies the hexadecimal authentication key. The size of the authentication key is determined by the respective authentication algorithm, as follows:

md5 uses a **32** character key size.

sha1 uses a **40** character key size.

Default Values

By default, there is no security for OSPFv3 messages on an interface.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

This commands specifies OSPFv3 security at the interface level. Protection specified with this command overrides any area-level OSPFv3 protection that might apply to the interface.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures OSPFv3 messages with an SPI of **120**, no encryption, and **md5** as the authentication method:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ospfv3 encryption ipsec spi 120 esp null md5**
NeWtStpsswdLoonGpsswDhtThmnWoKEY

ospfv3 <*process id*> **hello-interval** <*value*>

Use the **ospfv3 hello-interval** command to specify the interval between Open Shortest Path First version 3 (OSPFv3) Hello packets sent on the interface. This value must be the same across all interfaces on the link. Use the **no** form of this command to return the Hello packet interval to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3329*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
hello-interval <*value*>	Specifies the number of seconds allowed between OSPFv3 Hello packets. Valid range is **1** to **65535** seconds.

Default Values

By default, the Hello packet interval for OSPFv3 is **10** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the interval between OSPFv3 Hello packets on the interface is **20** seconds:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ospfv3 5 hello-interval 20**

ospfv3 <*process id*> network

Use the **ospfv3 network** command to specify the network type for Open Shortest Path First version 3 (OSPFv3) enabled interfaces. Use the **no** form of this command to return the interface's network type to the default value. Variations of this command include:

ospfv3 <*process id*> **network broadcast**
ospfv3 <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3329*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
broadcast	Specifies that the OSPFv3 network type for the interface is set to broadcast.
point-to-point	Specifies that the OSPFv3 network type for the interface is set to point-to-point.

Default Values

By default, Ethernet interfaces are set to network type broadcast, and point-to-point (PPP), Frame Relay, and loopback interfaces are set to network type point-to-point.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the network interface as point-to-point:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ospfv3 5 network point-to-point**

ospfv3 *<process id>* **priority** *<value>*

Use the **ospfv3 priority** command to specify the Open Shortest Path First version 3 (OSPFv3) priority for the interface. Use the **no** form of this command to return the interface's priority to the default value.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3329*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
priority *<value>*	Specifies the OSPFv3 priority for the interface. Valid range is **0** to **255**.

Default Values

By default, the OSPFv3 priority of an interface is set to **1**.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

Priority is used in the election of the designated router and backup designated router on multi-access networks. Interfaces connected to multi-access networks (such as Ethernet interfaces) perform an election for a designated and backup designated router. The router interface with the highest OSPFv3 priority on the link becomes the designated router for that link. The interface with the next highest priority becomes the designated backup router. In the event there is a tie, the router interface with the highest router ID takes precedence. A priority value of **0** indicates the router is ineligible to become either the designated or backup designated router.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example changes the interface's OSPFv3 priority value to **6**:

```
(config)#interface tunnel 1 gre ip
(config-tunnel 1)#ospfv3 5 priority 6
```

ospfv3 <*process id*> retransmit-interval <*value*>

Use the **ospfv3 retransmit-interval** command to specify the interval between Open Shortest Path First version 3 (OSPFv3) link-state advertisements (LSAs) sent on the interface. Use the **no** form of this command to return the OSPFv3 LSA interval to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3329*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
retransmit-interval <*value*>	Specifies the number of seconds between OSPFv3 LSAs sent on the interface. Valid range is **1** to **65535** seconds.

Default Values

By default, the LSA retransmit interval is set to **5** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the LSA retransmit interval is **10** seconds:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ospfv3 5 retransmit-interval 10**

ospfv3 <*process id*> shutdown

Use the **ospfv3 shutdown** command to disable an Open Shortest Path First version 3 (OSPFv3) process on the interface. When this command is used, the OSPFv3 commands remain in place, but logically it appears to the interface as though the OSPFv3 process has been removed from the configuration. This command can be useful in troubleshooting. Use the **no** form of this command to reinstate the OSPFv3 process.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3329*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.

Default Values

No default values are necessary for this command.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example disables OSPFv3 process **5** on the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ospfv3 5 shutdown**

ospfv3 <*process id*> transmit-delay <*value*>

Use the **ospfv3 transmit-delay** command to specify the estimated time that is required to propagate an Open Shortest Path First version 3 (OSPFv3) link-state advertisement (LSA) on the interface. Use the **no** form of this command to return the transmit delay to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3329*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
transmit-delay <*value*>	Specifies the number of seconds required to send LSAs from the interface. Valid range is **1** to **65535** seconds.

Default Values

By default, the LSA transmit delay is set to **1** second.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example changes the interface's LSA transmit delay to **2** seconds:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#ospfv3 5 transmit-delay 2**

packet-capture <*name*>

Use the **packet-capture** command to apply a previously configured packet capture instance to the interface. Use the **no** form of this command to remove the packet capture instance.

Syntax Description

<*name*>	Specifies the name of the packet capture instance to apply to the interface.

Default Values

By default, no packet capture instances are configured or applied to the interface.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

The AOS packet capture feature is used with network monitoring to effectively capture data packets as they traverse the network. For more information about packet capturing, its uses, and its implementation in AOS, refer to the configuration guide *Configuring Packet Capture in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example applies the previously configured packet capture **1CAPTURE** to the interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#packet-capture 1CAPTURE**

qos-policy

Use the **qos-policy** command to apply a previously configured quality of service (QoS) map to police incoming or outgoing packets on the tunnel interface. Use the **no** form of this command to remove the map from the interface. Variations of this command include:

qos-policy in *<name>*
qos-policy out *<name>*

Syntax Description

<name>	Specifies the name of a previously created QoS map (refer to *qos map <name> <number> on page 1673* for more information).
in	Assigns a QoS map to this interface's input.
out	Assigns a QoS map to this interface's output.

Default Values

No default values are necessary for this command.

Command History

Release 9.1	Command was introduced.
Release 15.1	Command was expanded to include the **in** parameter.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the system control Ethernet virtual connection (EVC) and system management EVC.
Release R11.9.0	Command was expanded to include the tunnel interface for policing QoS maps.

Functional Notes

When a QoS policy is applied to a tunnel interface, it is used to police the inbound or outbound traffic on the interface. QoS maps configured with information other than the traffic police rates and traffic matching criteria (set using the commands *match on page 4469* and *police cir <rate> on page 4479*) cannot be associated with the tunnel interface. Instead, the association between the QoS map and the tunnel interface is rejected.

Usage Examples

The following example applies the QoS map **QOSPOLICE1** to outbound traffic on the Tunnel interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#qos-policy out QOSPOLICE1**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.

Usage Examples

The following example enables SNMP on the tunnel interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release 17.2	Command was expanded to the cellular interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the tunnel interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#no snmp trap link-status**

tunnel checksum

Use the **tunnel checksum** command to verify the checksum of incoming generic routing encapsulation (GRE) packets and to include a checksum on outgoing packets. Use the **no** form of this command to disable checksum.

Syntax Description

No subcommands.

Default Values

By default, **tunnel checksum** is disabled.

Command History

Release 9.1	Command was introduced.

Functional Notes

Both ends of the tunnel must have **tunnel checksum** enabled in order for a meaningful configuration. When both endpoints have **tunnel checksum** enabled, a packet with an incorrect checksum will be dropped. If the endpoints differ in their checksum configuration, all packets will still flow without any checksum verification.

Usage Examples

The following example enables checksum on the tunnel 1 interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#tunnel checksum**

Technology Review

When enabled, the **tunnel checksum** will be calculated for each outgoing GRE packet with the result stored in the GRE header. The checksum present bit will also be set in the header.

tunnel destination *<ip address>*

Use the **tunnel destination** command to specify the IP address to use as the destination address for all packets transmitted on this interface. Use the **no** form of this command to clear the **tunnel destination** address.

Syntax Description

<ip address>	Specifies the IP address to use as the destination address for all packets transmitted on this interface. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no tunnel destinations are defined.

Command History

Release 9.1	Command was introduced.

Functional Notes

Until a tunnel interface has a destination IP address defined, it is not operational.

The tunnel destination IP address will be the value put into the destination field of the outer IP header after generic routing encapsulation (GRE) of the original packet. A route must be defined for the destination address. Be certain there are no recursive routes by ensuring that a tunnel's destination address will be routed out a physical interface. There is a possibility of creating a routing loop when tunnel interface traffic gets routed back to the same tunnel interface or to another tunnel interface, which in turn, does not have a route out of a physical interface. In either case, the tunnel will go down for a period of one minute, after which it will come back up to determine if the recursive routes have been resolved. This allows time for routing protocols to converge on a valid route. If a static route has caused the recursive routing loop, the tunnel status may oscillate until the route is changed.

Usage Examples

The following example sets the tunnel destination IP address to **192.22.73.101**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#tunnel destination 192.22.73.101**

tunnel key *<value>*

Use the **tunnel key** command to specify a value shared by both endpoints of the tunnel that will provide minimal security and delineate between tunnels with the same source and destination addresses. Use the **no** form of this command to disable the key.

Syntax Description

<value>	Defines the key value for this tunnel. Valid range is **1** to **4294967294**.

Default Values

By default, a key is not configured.

Command History

Release 9.1	Command was introduced.

Functional Notes

When enabled, the key will be stored in the generic routing encapsulation (GRE) header and the key present bit will be set. If tunnel keys are used, a matching key value must be defined on both endpoints of the tunnel or packets will be discarded.

Usage Examples

The following example sets the key on a tunnel interface to a value of **1234**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#tunnel key 1234**

tunnel protection ipsec profile *<name>*

Use the **tunnel protection ipsec profile** command to apply the IPsec profile to traffic egressing the tunnel. Use the **no** form of this command to remove the IPsec profile from the tunnel.

Syntax Description

<name>	Specifies the name of the IPsec profile to apply to the tunnel.

Default Values

By default, no IPsec profile is configured.

Command History

Release R11.9.0	Command was introduced.

Functional Notes

The IPsec profile must be created before attempting to apply it to the tunnel. Refer to the command *ip crypto ipsec profile <name> on page 1351*. If the **tunnel protection ipsec profile** command is entered, and the profile has not been created, an error is returned.

If a crypto map is already configured on the tunnel interface, an error is returned if the **tunnel protection ipsec profile** command is entered.

Usage Examples

The following example applies the IPsec profile **PROFILE1** to the tunnel **1** interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#tunnel protection ipsec profile PROFILE1**

tunnel sequence-datagrams

Use the **tunnel sequence-datagrams** command to enable sequence number checking on incoming generic routing encapsulation (GRE) packets, to drop packets arriving out of order, and to include a sequence number in outgoing packets. Use the **no** form of this command to disable sequence number checking.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 9.1	Command was introduced.

Functional Notes

Both ends of the tunnel must have sequence numbering enabled. When both endpoints have sequence numbering enabled, a packet arriving with a sequence number less than the current expected value will be dropped. If the endpoints differ in their sequence numbering configuration, all packets will still flow without any sequence number verification. Be careful enabling sequence number verification on a tunnel. The tunnel can easily become out of sequence due to network conditions outside of the tunnel endpoints. It may be difficult to establish a successful traffic flow after an out of sequence condition occurs.

Usage Examples

The following example enables sequence number processing on the tunnel interface:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#tunnel sequence-datagrams**

Technology Review

When enabled, the next valid sequence number will be placed in the GRE header of each outgoing packet, and the sequence number present bit will be set.

tunnel source

Use the **tunnel source** command to specify the IP address or name of a physical interface to use as the source address for all packets transmitted on this interface. Use the **no** form of this command to clear the tunnel source address. Variations of this command include:

tunnel source <*ip address*>
tunnel source <*ip address*> <*interface*>

Syntax Description

<*ip address*>	Specifies the IP address in dotted decimal notation to use as the source address for all packets transmitted on this interface. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*interface*>	Specifies the interface that contains the IP address to use as the source address for all packets transmitted on this interface. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **tunnel source ?** for a complete list of valid interfaces.

Default Values

By default, a tunnel source is not defined.

Command History

Release 9.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface.

Functional Notes

Until a tunnel interface has a source IP address defined and the physical interface used as the source is operational, the tunnel is not operational.

The tunnel source IP address will be the value put into the source field of the outer IP header after generic routing encapsulation (GRE) of the original packet.

Usage Examples

The following example sets the tunnel source IP address to **192.22.73.101**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#tunnel source 192.22.73.101**

The following example sets the tunnel source IP address to the address of the Ethernet interface labeled **0/1**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#tunnel source eth 0/1**

tunnel vrf <*name*>

Use the **tunnel vrf** command to specify the virtual routing and forwarding (VRF) to use in order to reach the tunnel source and the tunnel destination. Use the **no** form of this command to use the default VRF.

VRF on an AOS product allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the abovementioned commands without specifying a VRF will affect the default unnamed VRF.

Syntax Description

<*name*>	Optional. Specifies the name of the VRF.

Default Values

By default, the default VRF is used.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example sets the VRF instance to use to reach the tunnel source as VRF **RED**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#tunnel vrf RED**
(config-tunnel 1)**#tunnel source 10.10.10.254**
(config-tunnel 1)**#tunnel destination 10.10.10.1**

udp destination-port <*value*>

Use the **udp destination-port** command to specify a value for the virtual extensible local area network (VxLAN) user datagram protocol (UDP) destination port. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the UDP destination port for a VxLAN tunnel interface. Valid range is **1** to **65535**.

Default Values

By default, the VxLAN UDP destination port is set to **4789**.

Command History

Release R13.1.0	Command was introduced.

Usage Examples

The following example sets the VxLAN UDP destination port to 1525:

(config)**#interface tunnel 1 vxlan**
(config-tunnel 1)**#udp destination-port 1525**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an interface to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the interface from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an interface's VRF association will clear all IP-related settings on that interface.

Syntax Description

<name>	Specifies the name of the VRF to which to assign the interface.

Default Values

By default, interfaces are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release 17.8	The keyword **ip** was removed from this command.

Functional Notes

VRF instances must be created first before an interface can be assigned. An interface can only be assigned to one VRF, but multiple interfaces can be assigned to the same VRF.

An interface will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the tunnel interface to the VRF instance named **RED**:

(config)**#interface tunnel 1 gre ip**
(config-tunnel 1)**#vrf forwarding RED**

VLAN COMMAND SET

To activate the Virtual Local Area Network (VLAN) Configuration mode, enter the **vlan** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#vlan 1
(config-vlan 1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

ip flow on page 3357
media ethernet on page 3358
name <name> on page 3359
state on page 3360

ip flow

Use the **ip flow** command to enable integrated traffic monitoring (ITM) for all traffic received or forwarded on an interface. Use the **no** form of this command to disable traffic monitoring. Variations of this command include:

ip flow egress
ip flow egress <*name*>
ip flow ingress
ip flow ingress <*name*>

Syntax Description

egress	Specifies that all outgoing traffic be monitored.
ingress	Specifies that all incoming traffic be monitored.
<*name*>	Optional. Specifies the name of an access control list (ACL) to use for filtering traffic.

Default Values

By default, no traffic monitoring is enabled.

Command History

Release 16.1	Command was introduced.

Usage Examples

The following example enables traffic monitoring on a virtual local area network (VLAN) interface to monitor **incoming** traffic through an ACL called **myacl**:

(config)**#interface vlan 2**
(config-vlan 2)**#ip flow ingress myacl**

media ethernet

Use the **media ethernet** command to set the virtual local area network (VLAN) media type to Ethernet. The only media type currently supported is Ethernet. Use the **no** form of this command to reset to the default setting.

Syntax Description

No subcommands.

Default Values

By default, media is set to **Ethernet**.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example sets the media type to Ethernet for VLAN 2:

```
(config)#vlan 2
(config-vlan 2)#media ethernet
```

name <*name*>

Use the **name** command to assign a name to the virtual local area network (VLAN). Use the **no** form of this command to remove a name given to a VLAN.

Syntax Description

<*name*>	Assigns a name to the VLAN using **1** to **32** characters.

Default Values

By default, the name is set to VLANxxxx, where xxxx represents four numeric digits (including leading zeroes) equal to the VLAN ID number.

Command History

Release 5.1	Command was introduced.

Functional Notes

The name is limited to 32 characters and must be unique throughout.

Usage Examples

The following example sets the name of VLAN 2 to **Accounting**:

(config)**#vlan 2**
(config-vlan 2)**#name Accounting**

state

Use the **state** command to change the state of the virtual local area network (VLAN). Variations of this command include:

state active
state suspend

Syntax Description

active	Changes the VLAN state to active.
suspend	Changes the VLAN state to suspended.

Default Values

The default setting is **active** (once the VLAN has been created).

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example sets the VLAN **state** to suspended:

(config)**#vlan 2**
(config-vlan 2)**#state suspend**

VLAN DATABASE COMMAND SET

To activate the Virtual Local Area Network (VLAN) Database Configuration mode, enter the **vlan database** command at the Enable security mode prompt. For example:

```
>enable
#configure terminal
(config)#vlan database
(vlan)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

abort on page 3362
apply on page 3363
reset on page 3364
show on page 3365
vlan <vlan id> on page 3366
vlan <vlan id> media ethernet on page 3367
vlan <vlan id> name <name> on page 3368
vlan <vlan id> state on page 3369

abort

Use the **abort** command to exit the virtual local area network (VLAN) database without saving any changes made.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this setting.

Command History

Release 5.1	Command was introduced.

Functional Notes

The **abort** command discards all configuration changes made since you entered the VLAN Database Configuration mode (or since the last time you issued the **apply** command). The system then exits out of this mode, returning to the enable (**#**) command prompt. Refer to the command *apply on page 3363* for more information.

Usage Examples

The following example exits the VLAN database without saving the changes made:

```
(config)#vlan database
(vlan)#abort
Discarding all changes and exiting.
#
```

apply

Use the **apply** command to apply changes without exiting the virtual local area network (VLAN) database.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this setting.

Command History

Release 5.1	Command was introduced.

Functional Notes

Applies changes to the VLAN database configuration in the running configuration.

Usage Examples

The following example applies changes made, remaining in the VLAN database:

```
(config)#vlan database
(vlan)#apply
Changes applied.
(vlan)#
```

reset

Use the **reset** command to discard all changes made and revert to the previous configuration. The prompt remains in the virtual local area network (VLAN) database.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this setting.

Command History

Release 5.1	Command was introduced.

Functional Notes

The **reset** command discards all changes to the VLAN configuration. The configuration remains the same as it was prior to entering the VLAN Database Configuration mode (or since the last time you issued the **apply** command). The VLAN database reverts to the same state it had upon entry. Refer to the command *apply on page 3363* for more information.

Usage Examples

The following example resets the unit to the previous configuration (i.e., the last configuration saved using the **apply** or the **exit** command):

```
(config)#vlan database
(vlan)#reset
VLAN configuration has been reset.
(vlan)#
```

show

Use the **show** command to display different aspects of the virtual local area network (VLAN) configuration. Variations of this command include:

show changes
show changes <*vlan id*>
show current
show current <*vlan id*>
show proposed
show proposed <*vlan id*>

Syntax Description

<*vlan id*>	Specifies a VLAN ID to display only information for a specific VLAN. Valid VLAN interface ID range is from **1** to **4094**.
changes	Displays the proposed changes to the VLAN configuration.
current	Displays the current VLAN configuration.
proposed	Displays the proposed VLAN database. The proposed version is not part of the running configuration until it is applied (using the **apply** command or the **exit** command).

Default Values

No default values are necessary for this setting.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example shows the proposed VLAN database configuration that will take effect if an **apply** or **exit** command is issued:

(config)**#vlan database**
(vlan)**#show proposed**

vlan <*vlan id*>

Use the **vlan** command to create a virtual local area network (VLAN) within the VLAN database. Use the **no** form of this command to delete a previously created VLAN from the database.

Syntax Description

<*vlan id*>	Specifies a valid VLAN interface ID. Range is **1** to **4094**.

Default Values

No default values are necessary for this setting.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example creates VLAN 2 only within the VLAN database. This VLAN is not added to the running configuration until an **exit** or **apply** command is issued:

```
(vlan)#vlan 2
VLAN 2 created.
Name = VLAN0002
(vlan)#
```

The following example removes VLAN 2 from the VLAN database. This VLAN is not removed from the running configuration until an **exit** or **apply** command is issued:

```
(config)#vlan database
(vlan)#no vlan 2
```

vlan <*vlan id*> media ethernet

Use the **vlan media ethernet** command to set the virtual local area network (VLAN) media type to Ethernet. Use the **no** form of this command to reset to the default setting.

Syntax Description

<*vlan id*>	Specifies a valid VLAN interface ID. Valid range is **1** to **4094**.

Default Values

By default, **vlan media** is set to **Ethernet**.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example sets the media type of VLAN 2 to Ethernet:

(config)**#vlan database**
(vlan)**#vlan 2 media ethernet**

vlan <*vlan id*> **name** <*name*>

Use the **vlan name** command to assign a name to the virtual local area network (VLAN). Use the **no** form of this command to remove an assigned name.

Syntax Description

<*vlan id*>	Specifies a valid VLAN interface ID. Valid range is **1** to **4094**.
<*name*>	Assigns a name to the VLAN using **1** to **32** characters.

Default Values

By default, the assigned name is VLANxxxx; where xxxx represents four numeric digits (including leading zeroes) equal to the VLAN ID number.

Command History

Release 5.1	Command was introduced.

Functional Notes

The name is limited to 32 characters and must be unique throughout the network.

Usage Examples

The following example sets the name of VLAN 2 to **Accounting**:

(config)**#vlan database**
(vlan)**#vlan 2 name Accounting**

vlan <*vlan id*> state

Use the **vlan state** command to change the state of the virtual local area network (VLAN). Use the **no** form of this command to return to the default setting. Variations of this command include:

vlan <*vlan id*> **state active**
vlan <*vlan id*> **state suspend**

Syntax Description

<*vlan id*>	Specifies a valid VLAN interface ID. Valid VLAN ID range is **1** to **4094**.
active	Changes the VLAN state to active.
suspend	Changes the VLAN state to suspended.

Default Values

The default setting is **active** (once the VLAN has been created).

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example sets the VLAN state to suspended:

(config)**#vlan database**
(vlan)**#vlan 2 state suspend**

VLAN INTERFACE COMMAND SET

To create a virtual local area network (VLAN) interface and/or activate the VLAN Interface Configuration mode, enter the **interface vlan** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface vlan 1
(config-interface-vlan 1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

arp arpa on page 3372
awcp on page 3373
bandwidth <value> on page 3374
bridge-group <number> on page 3376
dynamic-dns on page 3377
ip commands begin on page 3379
ipv6 commands begin on page 3423
mac-address <mac address> on page 3460
max-reserved-bandwidth <value> on page 3461
media-gateway ip on page 3462
media-gateway ipv6 on page 3464
no shutdown track <name> on page 3466
ospfv3 commands begin on page 3467
packet-capture <name> on page 3480
qos-policy on page 3481
rtp quality-monitoring on page 3483
snmp trap on page 3484
snmp trap link-status on page 3485
traffic-shape rate <value> on page 3486

arp arpa

Use the **arp arpa** command to set ARPA as the standard Address Resolution Protocol (ARP) on this interface. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, the ARP is set to **ARPA**.

Command History

Release 5.1	Command was introduced.
Release 6.1	Command was extended to include the NetVanta 2000 Series units.

Usage Examples

The following example enables standard ARP for the virtual local area network (VLAN) interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#arp arpa**

awcp

Use the **awcp** command to enable Adtran Wireless Control Protocol (AWCP) on this interface. The AWCP is an Adtran proprietary protocol used by an access controller (AC) to communicate with an access point (AP). Use the **no** form of this command to disable AWCP for this interface.

Syntax Description

No subcommands.

Default Values

By default, AWCP is enabled on the interface.

Command History

Release 15.1	Command was introduced.

Functional Notes

When the global-level command **dot11ap access-point-controller** (refer to *dot11ap access-point-control on page 1268* for more information) is enabled, the AWCP function can be disabled on a specific interface by using the **no** form of this command from the desired interface. When the global-level command **dot11ap access-point-controller** is disabled, it overrides the **awcp** command setting for the interface.

Usage Examples

The following example disables AWCP on virtual local area network (VLAN) 1:

```
(config)#interface vlan 1
(config-interface-vlan 1)#no awcp
```

bandwidth <*value*>

Use the **bandwidth** command to provide the bandwidth value of an interface to the higher level protocols. This value is used in cost calculations. Use the **no** form of this command to restore the default value.

Syntax Description

<*value*>	Specifies bandwidth in kbps. Range is **1** to **4294967295** kbps.

Default Values

To view the default values, use the **show interfaces** command.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.

Functional Notes

The **bandwidth** command is an informational value that is communicated to the higher level protocols to be used in cost calculations. While this is a routing parameter that does not affect the physical interface, it does affect the amount of bandwidth available for use in Quality of Service (QoS) configurations.

It is important to note that there is an order of precedence in determining the interface bandwidth reported by the router for QoS. Under normal circumstances, the Layer 1 bandwidth is reported based on the interface type. For example, a T1 interface will report the available bandwidth as 1.536 Mbps. This can be misleading in QoS configurations if the **bandwidth** command has been applied to the IP interface for routing purposes because the command overrides the reported available bandwidth that can be utilized for QoS. Using the **bandwidth** command can severely disrupt the configuration of QoS on the interface, therefore, use the **max-reserved-bandwidth** command (*page 3461*) to adjust the bandwidth appropriately for QoS configurations.

When configuring QoS for an Ethernet or VLAN interface, the interface **traffic-shape rate** command can be used to configure traffic shaping without applying a QoS map. If traffic shaping is applied to the same interface that will also have a QoS map applied to it, the amount of bandwidth available for the QoS policy is reduced to the value set with the **traffic-shape rate** command (*page 3486*). This value should be set to match the upload speed of the circuit. For example, under normal circumstances, an Ethernet interface can negotiate to 100 Mbps. However, the throughput of the upstream equipment is usually significantly less than the negotiated rate. The **traffic-shape rate** command is used to define the limit of when QoS policies containing the commands *bandwidth on page 4466* or *priority on page 4481* should be enforced according to the upload speed of the circuit. If the **bandwidth** <*value*> command is also entered on the same IP interface as the **traffic-shape rate** command, it will overwrite the value of the **traffic-shape rate** command for QoS purposes. It is not recommended to use the **bandwidth** <*value*> command for QoS. Instead, use the **max-reserved-bandwidth** command (*page 3461*) to adjust the bandwidth appropriately because the **traffic-shape rate** command is required for QoS to function properly on VLAN and Ethernet WAN IP interfaces.

Usage Examples

The following example sets bandwidth of the VLAN 1 interface to 10 Mbps:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#bandwidth 10000**

bridge-group *<number>*

Use the **bridge-group** command to assign an interface to the specified bridge group. Use the **no** form of this command to remove the interface from the bridge group.

Syntax Description

<number>	Specifies a bridge group number. Range is **1** to **255**.

Default Values

By default, there are no configured bridge groups.

Command History

Release 1.1	Command was introduced.

Functional Notes

A bridged network can provide excellent traffic management to reduce collisions and limit the amount of bandwidth wasted with unnecessary transmissions when routing is not necessary. Any two interfaces can be bridged (e.g., Ethernet to T1 bridge, Ethernet to Frame Relay subinterface).

Usage Examples

The following example assigns the virtual local area network (VLAN) interface to bridge group 17:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#bridge-group 17**

dynamic-dns

Use the **dynamic-dns** command to configure Dynamic DNS service provided by Dynamic Network Services, Inc. (www.dyndns.org). Use the **no** form of this command to disable this feature. Variations of this command include:

dynamic-dns custom <*hostname*> <*minutes*>
dynamic-dns dyndns <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-custom <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-static <*hostname*> <*username*> <*password*>

Syntax Description

<*hostname*>	Specifies the host name for the server that updates the dynamic domain naming system (DNS).
<*minutes*>	Specifies the intervals in minutes to update the server with information (updates also occur when the interface's IP address changes regardless of the update intervals).
<*username*>	Specifies a user name using an alphanumerical string up to 30 characters in length (the user name is case sensitive).
<*password*>	Specifies a password using an alphanumerical string up to 30 characters in length (the password is case sensitive). Refer to *Functional Notes* below for additional argument descriptions.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.
Release 12.1	Command was expanded.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).

Functional Notes

custom - Constanttime.com's Custom Dynamic DNS^{SM} service allows you complete access and management control over your domain name regardless of where you purchased/registered it. This allows you to manage IP address mappings (A records), domain aliases (CNAME records), and mail servers (mail exchange (MX) records).

dyndns - The Dynamic DNS^{SM} offered by Dynamic Network Services Inc., (DynDNS.org) allows you to alias a dynamic IP address to a static host name in various domains. This allows your unit to be more easily accessed from various locations on the Internet. This service is provided for up to five host names.

dyndns-custom - DynDNS.org's Custom DNS^{SM} service provides a full DNS solution, giving you complete control over an entire domain name. A Web-based interface provides two levels of control over your domain, catering to average or advanced users. Five globally redundant DNS servers ensure that your domain will always resolve.

A choice of two interfaces is available. The basic interface is designed for most users. It comes preconfigured for most common configurations and allows for easy creation of most common record types. The advanced interface is designed for system administrators with a solid DNS background, and provides layout and functionality similar to a BIND zone file allowing for the creation of nearly any record type.

Custom DNS^{SM} can be used with both static and dynamic IPs, and has the same automatic update capability through Custom DNS-aware clients as Dynamic DNS.

dyndns-static - The Static DNS service is similar to DynDNS.org's Dynamic DNS^{SM} service in that it allows a host name, such as yourname.dyndns.org, to point to your IP address. Unlike a Dynamic DNS host, a Static DNS host does not expire after 35 days without updates, but updates take longer to propagate through the DNS system. This service is provided for up to five host names.

If your IP address does not change often or at all, but you still want an easy name to remember it by (without having to purchase your own domain name), Static DNS service is ideal for you.

If you would like to use your own domain name (such as yourname.com), you need Custom DNS service that also provides full dynamic and static IP address support.

Usage Examples

The following example sets the Dynamic DNS to **dyndns-custom** with host name **host**, user name **user**, and password **pass**:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#dynamic-dns dyndns-custom host user pass**

ip access-group *<ipv4 acl name>*

Use the **ip access-group** command to apply an Internet Protocol version 4 (IPv4) access control list (ACL) to be used for IPv4 packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ip access-group *<ipv4 acl name>* **in**
ip access-group *<ipv4 acl name>* **out**

Syntax Description

<ipv4 acl name>	Applies the named IPv4 ACL to the interface.
in	Enables access control on IPv4 packets received on the specified interface.
out	Enables access control on IPv4 packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

When this command is enabled, the IPv4 destination address of each packet must be validated before being passed through. If the packet is not acceptable per these settings, it is dropped.

Usage Examples

The following example configures the router to only allow IPv4 Telnet traffic (as defined in the user-configured **TelnetOnly** ACL) into the VLAN interface:

(config)**#ip access-list extended TelnetOnly**
(config-ext-nacl)**#permit tcp any any eq telnet**
(config-ext-nacl)**#interface vlan 1**
(config-vlan 1)**#ip access-group TelnetOnly in**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to an interface. IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

> NOTE *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an interface.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the Ethernet interface 0/1:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the interface:

(config)**#interface vlan 1**
(config-vlan 1)**#ip access-policy PRIVATE**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the specified interface (only one primary address is allowed). Use the optional **secondary** keyword to define a secondary IPv4 address. Use the **no** form of this command to remove a configured IPv4 address. Variations of this command include:

ip address <*ipv4 address*> <*subnet mask*>
ip address <*ipv4 address*> <*subnet mask*> **secondary**

Syntax Description

<*ipv4 address*>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*subnet mask*>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the specified interface.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IP addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a secondary IPv4 address of **192.22.72.101 /30**:

(config)**#interface vlan 1**
(config-vlan 1)**#ip address 192.22.72.101 /30 secondary**

ip address range *<start ip address> <end ip address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the specified interface. Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip address dhcp

Use the **ip address dhcp** command to use Dynamic Host Configuration Protocol (DHCP) to obtain an address on the interface. Use the **no** form of this command to remove a configured IP address (using DHCP) and disable DHCP operation on the interface. Variables that may be used with this command to further define the DHCP configuration include:

ip address dhcp class-id [ascii *<string>* **| hex** *<value>***] [client-id [***<interface>* **|** *<identifier>***]] [hostname** *<"string">***] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp client-id [*<interface>* **|** *<identifier>***] [hostname** *<"string">***] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp hostname *"<string>"* **[no-default-route | no-domain-name | no-nameservers] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp [no-default-route | no-domain-name | no-nameservers] [track *<name>***] [***<administrative distance>***]**
ip address dhcp track *<name>* **[***<administrative distance>***]**

Syntax Description

<administrative distance>	Optional. Specifies the administrative distance to use when adding the DHCP gateway into the route table. It is used to determine the best route when multiple routes to the same destination exist. The lower the administrative distance, the more reliable the route. Range is **1** to **255**.
class-id	Optional. Specifies the vendor class identifier for the interface.
ascii *<string>*	Specifies the vendor class identifier in an ASCII string of up to **255** bytes.
hex *<value>*	Specfies the vendor class identifier in hexadecimal format. Valid range is up to **510** hexadecimal numbers. An even number of digits is required.
client-id	Optional. Specifies the client identifier used when obtaining an IP address from a DHCP server.
<interface>	Specifies an interface, thus defining the client identifier as the hexadecimal medium access control (MAC) address of the specified interface (including a hexadecimal number added to the front of the MAC address to identify the media type). For example, specifying the **client-id ethernet 0/1** (where the Ethernet interface has a MAC address of d217.0491.1150) defines the client identifier as **01:d2:17:04:91:11:50** (where 01 defines the media type as Ethernet). Refer to *hardware-address on page 4344* for a detailed listing of media types.
<identifier>	Specifies a custom client-identifier using a text string (that is converted to a hexadecimal equivalent) or 7 to 28 hexadecimal numbers (with colon delimiters). For example, a custom client identifier of **0f:ff:ff:ff:ff:51:04:99:a1** may be entered using the *<identifier>* option.
hostname *<"string">*	Optional. Specifies a text string (to override the global router name) to use as the name in the DHCP option 12 field. The string is enclosed in quotation marks and can consist of up to 35 characters.

no-default-route Optional. Specifies that no default route is obtained via DHCP.

no-domain-name Optional. Specifies that no domain name is obtained via DHCP.

no-nameservers Optional. Specifies that no domain naming system (DNS) servers are obtained via DHCP.

track *<name>* Optional. Attaches a network monitoring track to the DHCP client. The DHCP gateway route for this client will only reside in the route table while the track is in the pass state. For more information on configuring track objects, refer to *track <name> on page 1886*.

Default Values

<administrative distance> By default, the administrative distance value is 1.

class-id Optional. By default, no vendor class identifier is configured.

client-id Optional. By default, the client identifier is populated using the following formula:

TYPE: INTERFACE SPECIFIC INFO : MAC ADDRESS

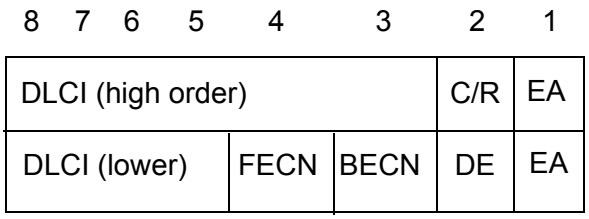
Where TYPE specifies the media type in the form of one hexadecimal byte (refer to *hardware-address on page 4344* for a detailed listing of media types), and the MAC ADDRESS is the medium access control (MAC) address assigned to the first Ethernet interface in the unit in the form of six hexadecimal bytes. (For units with a single Ethernet interface, the MAC ADDRESS assigned to Ethernet 0/1 is used in this field.)

INTERFACE SPECIFIC INFO is only used for Frame Relay interfaces and can be determined using the following:

FR_PORT#: Q.922 ADDRESS

Where the FR_PORT# specifies the label assigned to the virtual Frame Relay interface using four hexadecimal bytes. For example, a virtual Frame Relay interface labeled 1 would have a FR_PORT# of 00:00:00:01.

The Q.922 ADDRESS field is populated using the following:



Where the FECN, BECN, C/R, DE, and high order extended address (EA) bits are assumed to be 0 and the lower order EA bit is set to 1.

The following list provides a few example DLCIs and associated Q.922 address:

DLCI (decimal) / Q.922 address (hex)

16 / 0x0401
50 / 0x0C21
60 / 0x0CC1
70 / 0x1061
80 / 0x1401

hostname *“<string>”* By default, the host name is the name configured using the Global Configuration **hostname** command.

Command History

Release 2.1	Command was introduced.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 13.1	Command was expanded to include the track and administrative distance.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.10.0	Command was expanded to include the **class-id** parameter in support of DHCP Option 60.

Functional Notes

DHCP allows interfaces to acquire a dynamically assigned IP address from a configured DHCP server on the network. Many service providers require the use of DHCP when connecting to their services. Using DHCP reduces the number of dedicated IP addresses the ISP must obtain. Consult your ISP to determine the proper values for the **client-id** and **hostname** fields.

The vendor class identifier is sent to the DHCP server in DHCP discover and request messages via DHCP Option 60. This option gives the DHCP server details regarding DHCP client configuration and also allows the server to send any vendor-specific information to the client in DHCP offer messages via Option 43.

Usage Examples

The following example enables DHCP operation on the interface:

(config)**#interface vlan 2**
(config-intf-vlan 2)**#ip address dhcp**

The following example enables DHCP operation on the interface utilizing host name **adtran** and does not allow obtaining a default route, domain name, or name servers. It also sets the administrative distance as **5**:

(config)**#interface vlan 2**
(config-intf-vlan 2)**#ip address dhcp hostname “adtran” no-default-route no-domain-name no-nameservers 5**

ip crypto map *<name>*

Use the **ip crypto map** command to associate Internet Protocol version 4 (IPv4) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

When you apply a map to an interface, you are applying all crypto maps with the given map name. This allows you to apply multiple crypto maps if you have created maps that share the same name, but have different map index numbers.

Syntax Description

<name>	Specifies the IPv4 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

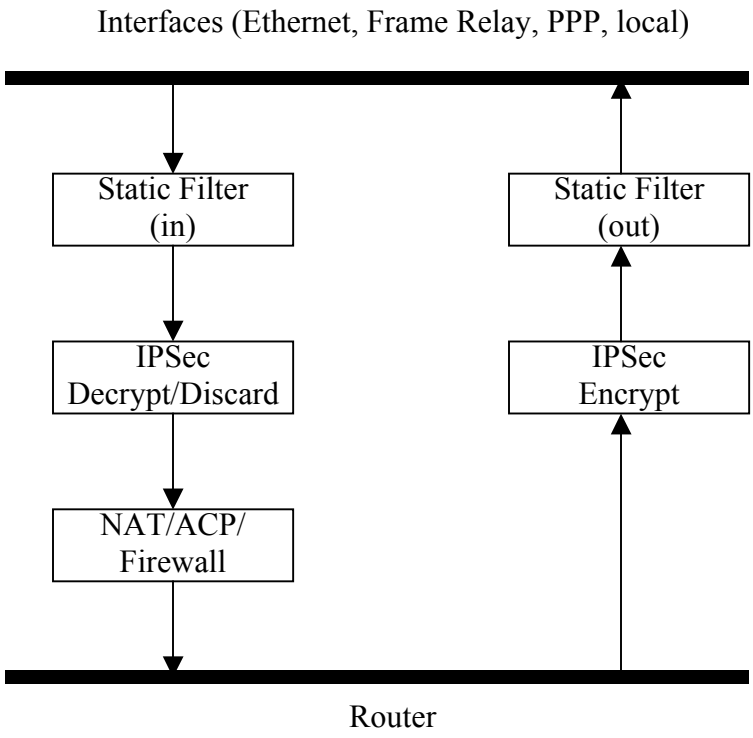
Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 9.1	Command was expanded to include the High-Levell Data Link Control (HDLC) interface.
Release 11.1	Command was expanded to include the demand interface.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.7.0	Command syntax was changed to require the **ip** keyword.

Functional Notes

When configuring a system to use both the stateful inspection firewall and Internet key exchange (IKE) negotiation for VPN, keep the following notes in mind.

When defining the IPv4 policy class and associated access control lists (ACLs) that describe the behavior of the IPv4 firewall, do not forget to include the traffic coming into the system over a VPN tunnel terminated by the system. The firewall should be set up with respect to the unencrypted traffic that is destined to be sent or received over the VPN tunnel. The following diagram represents typical AOS data-flow logic.



As shown in the diagram above, data coming into the product is first processed by the static filter associated with the interface on which the data is received. This access group is a true static filter and is available for use regardless of whether the IPv4 firewall is enabled or disabled. Next (if the data is encrypted), it is sent to the IPSec engine for decryption. The decrypted data is then processed by the stateful inspection firewall. Therefore, given a terminating VPN tunnel, only unencrypted data is processed by the firewall.

The IPv4 ACLs for a crypto map on an interface work in reverse logic to the ACLs for a policy class on an interface. When specifying the ACLs for a crypto map, the source information is the private local side, unencrypted source of the data. The destination information will be the far-end, unencrypted destination of the data. However, ACLs for a policy class work in reverse. The source information for the ACL in a policy class is the far end. The destination information is the local side.

Usage Examples

The following example applies all IPv4 crypto maps with the name **MyMap** to the interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip crypto map MyMap**

ip dhcp

Use the **ip dhcp** command to release or renew the Dynamic Host Configuration Protocol (DHCP) Internet Protocol version 4 (IPv4) address. This command is only applicable when using DHCP for IP address assignment. Variations of this command include:

ip dhcp release
ip dhcp renew

Syntax Description

release	Releases the DHCP IPv4 address.
renew	Renews the DHCP IPv4 address.

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.
Release 8.1	Command was added to the asynchronous transfer mode (ATM) subinterface.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release R10.1.0	Command was added to the bridged virtual interface (BVI).

Usage Examples

The following example releases the IPv4 DHCP address for the virtual local area network (VLAN) interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip dhcp release**

ip dhcp relay destination *<ipv4 address>*

Use the **ip dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 4 (IPv4) and to specify the IPv4 address for the DHCPv4 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv4 relay functionality is disabled on the interface.

Syntax Description

<ipv4 address>	Specifies the IPv4 address for the DHCPv4 messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**)..

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.

Usage Examples

The following example enables DHCPv4 relay agent functionality and specifies the destination address as **192.33.4.251**:

(config)**#interface vlan 1**
(config-vlan 1)**#ip dhcp relay destination 192.33.4.251**

ip directed-broadcast

Use the **ip directed-broadcast** command to allow reception/forwarding of directed broadcasts. Use the **no** form of this command to disable this feature. Variations of this command include:

ip directed-broadcast
ip directed-broadcast <*name*>

Syntax Description

<*name*>	Specifies IP access control list (ACL) name.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.

Functional Notes

A directed broadcast is a packet intended for all nodes on a nonlocal network. For example, the broadcast address 255.255.255.255 reaches all nodes on a network; the directed broadcast address 128.1.255.255 is intended for all nodes whose network address is 128.1.0.0. A router not directly attached to 128.1.0.0 simply forwards the directed broadcast packet to the next hop. A router on network 128.1.0.0 that has **ip directed-broadcast** enabled, accepts and forwards the packet to all nodes whose network address is 128.1.0.0. Routers connecting subnets of 128.1.0.0 also accept and forward the packet to the nodes on their respective subnets. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is distributed as a broadcast on the destination subnet. The packet is then sent as a link-layer broadcast.

The **ip directed-broadcast** command controls the distribution of directed broadcasts when they reach their target subnets. Only the final transmission of the directed broadcast on its ultimate destination subnet is affected. It does not affect the transit unicast routing of IP directed broadcasts.

If **ip directed-broadcast** is enabled for this interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which this interface is attached will be forwarded as broadcasts on that subnet. Forwarding of the packets can be limited by specifying an ACL with this command. In this case, only directed broadcasts that are permitted by the specified ACL will be forwarded, and all other directed broadcasts directed to this interface subnet will be dropped.

Disabling the **ip directed-broadcast** command will cause directed broadcasts destined for the subnet to which this interface is attached to be dropped.

This option is a requirement for routers as described in RFC 1812, section 4.2.2.11. Furthermore, it is disabled by default (RFC 2644), with the intended goal of reducing the efficacy of certain types of denial of service (DoS) attacks.

Usage Examples

The following example enables forwarding of directed broadcasts on the interface **vlan 1**:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip directed-broadcast**

ip ffe

Use the **ip ffe** command to enable the RapidRoute fast forwarding engine (FFE) on this Internet Protocol version 4 (IPv4) interface with the default number of entries. Use the **no** form of this command to disable this feature. Variations of this command include:

ip ffe
ip ffe max-entries <*value*>

Issuing this command will cause all RapidRoute entries to be cleared from this IPv4 interface.

Syntax Description

max-entries <*value*>	Optional. Specifies the maximum number of entries stored in the flow table. Valid range is from **1** to **500000**.

Default Values

By default, the RapidRoute Engine is enabled. The default number of **max-entries** is **4096**.

Command History

Release 13.1	Command was introduced.
Release 17.6	Command was expanded to include the high level data link control (HDLC) and tunnel interfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.4.0	Maximum number of stored entries was expanded to **500000** and RapidRoute is now enabled by default.

Functional Notes

RapidRoute can be used to help reduce routing overhead, and thus reduce overall routing times. Routing times are reduced by the creation of a flow table on the ingress interface. The maximum number of entries that can be stored in the flow table at any one time may be specified by using the **max-entries** parameters.

Usage Examples

The following example disables RapidRoute on the IPv4 interface:

(config)**#interface vlan 1**
(config-vlan 1)**#no ip ffe**

Technology Review

The RapidRoute system goal is to increase IP packet throughput by moving as much of the packet processing into the engine as possible. Packets are classified into flows based upon the IP protocol (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol (ICMP), etc.), the source and destination IP addresses, IP type of service (ToS), and the protocol-specific information, such as the source and destination port numbers. Flows are defined as the unidirectional representation of a conversation between two IP hosts. Each ingress interface keeps its own flow table, a collection of flow entries.

The first packet in a flow that is forwarded through the unit will build a flow entry. When a flow entry is looked up but no entry is found, a RapidRouteBuilder object is allocated and attached to the packet. As the packet passes through the various processing layers, each subsystem will add processing to the RapidRouteBuilder. When packet is about to be forwarded out of the egress interface, the RapidRouteBuilder will be finalized. That is, the flow entry being built will be checked for completeness and committed to the flow table on the ingress interface. Subsequent flow matches can then bypass the normal processing layers.

ip helper-address *<ip address>*

Use the **ip helper-address** command to configure AOS to forward User Datagram Protocol (UDP) broadcast packets received on the interface. Use the **no** form of this command to disable forwarding packets.

> NOTE *The **ip helper-address** command must be used in conjunction with the **ip forward-protocol** command to configure AOS to forward UDP broadcast packets. Refer to ip forward-protocol udp <value> on page 1398 for more information.*

Syntax Description

<ip address>	Specifies the destination IP address for the forwarded UDP packets. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, broadcast UDP packets are not forwarded.

Command History

Release 1.1	Command was introduced.

Functional Notes

When used in conjunction with the **ip forward-protocol** command, the **ip helper-address** feature allows you to customize which broadcast packets are forwarded.

To implement the helper address feature, assign helper address(es) (specifying the device that needs to receive the broadcast traffic) to the interface closest to the host that transmits the broadcast packets. When broadcast packets (of the specified type forwarded using the **ip forward-protocol** command) are received on the interface, they will be forwarded to the device that needs the information.

Only packets meeting the following criteria are considered eligible by the **ip helper-address** feature:

1. The packet IP protocol is UDP.
2. Any UDP port specified using the **ip forward-protocol** command.
3. The medium access control (MAC) address of the frame is an all-ones broadcast address (ffff.ffff.ffff).
4. The destination IP address is broadcast defined by all ones (**255.255.255.255**) or a subnet broadcast (for example, **192.33.4.251** for the **192.33.4.248 /30** subnet).

Usage Examples

The following example forwards all DNS broadcast traffic to the DNS server with IP address **192.33.5.99**:

(config)**#ip forward-protocol udp domain**
(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip helper-address 192.33.5.99**

ip igmp

Use the **ip igmp** command to configure multicasting related functions for the interface. Variations of this command include:

ip igmp immediate-leave
ip igmp last-member-query-interval <*milliseconds*>
ip igmp querier-timeout <*seconds*>
ip igmp query-interval <*seconds*>
ip igmp query-max-response-time <*seconds*>
ip igmp static-group <*address*>
ip igmp version [1 | 2]

Syntax Description

immediate-leave	Specifies that if only one host (or Internet Group Management Protocol (IGMP) snooping switch) is connected to the interface, when a leave is received, multicast of that group is immediately terminated as opposed to sending a group query and timing out the group if no device responds. Works in conjunction with **ip igmp last-member-query-interval**. Applies to all groups when configured. Use the **no** form of this command to disable the **immediate-leave** feature.
last-member-query-interval <*milliseconds*>	Controls the timeout (in milliseconds) used to detect whether any group receivers remain on an interface after a receiver leaves a group. If a receiver sends a leave-group message (IGMP Version 2), the router sends a group-specific query on that interface. After twice the time specified by this command plus as much as one second longer, if no receiver responds, the router removes that interface from the group and stops sending that group's multicast packets to the interface. Range is **100** to **65535** ms. Use the **no** form of this command to return to the default setting.
querier-timeout <*seconds*>	Specifies the interval (in seconds) that the router waits after the current querier's last query before it takes over as querier (IGMP V2). Range is **60** to **300** seconds. Use the **no** form of this command to return to the default setting.

Syntax Description

query-interval <*seconds*>	Specifies the interval (in seconds) at which IGMP queries are sent on an interface. Host query messages are addressed to the all-hosts multicast group with an IP time to live (TTL) of 1. The router uses queries to detect whether multicast group members are on the interface and to select an IGMP designated router (DR) for the attached segment (if more than one multicast router exists). Only the DR for the segment sends queries. For IGMP V2, the DR is the router with the lowest IP address on the segment. Range is **0** to **65535** seconds. Use the **no** form of this command to return to the default setting.
query-max-response-time <*seconds*>	Specifies the maximum response time (in seconds) advertised by this interface in queries when using IGMP V2. Hosts are allowed a random time within this period to respond, reducing response bursts. Use the **no** form of this command to return to the default setting.
static-group <*address*>	Configures the router's interface to be a statically connected member of the specified group. Packets received on the correct reverse path forwarding (RPF) interface are forwarded to this interface regardless of whether any receivers have joined the specified group using IGMP. Use the **no** form of this command to remove a configured static group.
version [1 | 2]	Sets the interface's IGMP version. Use the **no** form of this command to return to the default setting.

Default Values

ip igmp immediate-leave	No default
ip igmp last-member-query-interval	**1000** milliseconds
ip igmp querier-timeout	2x the **query-interval** value
ip igmp query-interval	**60** seconds
ip igmp query-max-response-time	**10** seconds
ip igmp static-group	No default
ip igmp version	Version **1**

Command History

Release 7.1	Command was introduced.

Usage Examples

The following example sets the query message interval on the interface to **200** milliseconds:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip igmp last-member-query-interval 200**

ip mcast-stub downstream

Use the **ip mcast-stub downstream** command to enable multicast forwarding and Internet Group Management Protocol (IGMP) (router mode) on an interface, and to place it in multicast stub downstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub upstream** commands. Downstream interfaces connect to segments with multicast hosts. Multiple interfaces may be configured in downstream mode; however, interfaces connecting to the multicast network (upstream) should not be configured in downstream mode. Interfaces configured as downstream should have the lowest IP address of all IGMP-capable routers on the connected segment in order to be selected as the designated router (DR) and ensure proper forwarding. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub upstream on page 3402* for more information.

Usage Examples

The following example enables multicast forwarding and IGMP on the interface:

```
(config)#interface vlan 1
(config-interface-vlan 1)#ip mcast-stub downstream
```

ip mcast-stub fixed

Use the **ip mcast-stub fixed** command to allow forwarding of multicast traffic on a selected interface after enabling multicast routing. Use the **no** form of this command to disable this mode.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 12.1	Command was introduced.

Functional Notes

Multicast routing must be enabled prior to setting **ip mcast-stub fixed** on the selected interface. Also, use the **ip igmp static-group** <*ip address*> command to receive multicast traffic without host-initiated Internet Group Management Protocol (IGMP) activity on the selected interface. Otherwise, all host-initiated IGMP transactions will enter multicast routes on the router's interface involved with IGMP activities.

Usage Examples

The following example enables multicast traffic forwarding and IGMP on the interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip mcast-stub fixed**

ip mcast-stub helper-enable

Use the **ip mcast-stub helper-enable** command to assign the **ip mcast-stub helper-address** as the Internet Group Management Protocol (IGMP) proxy. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 8.1	Command was introduced.
Release 10.1	Command was expanded to include the virtual local area network (VLAN) interfaces.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address**, **ip mcast-stub upstream**, and **ip mcast-stub downstream** commands. When enabled, the interface becomes a helper forwarding interface. The IGMP host function is dynamically enabled and the interface becomes the active upstream interface, enabling the unit to perform as an IGMP proxy. Refer to *ip mcast-stub helper-address <ip address> on page 1418*, *ip mcast-stub downstream on page 3399*, and *ip mcast-stub upstream on page 3402* for more information.

Usage Examples

The following example sets the helper address as the IGMP proxy:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip mcast-stub helper-enable**

ip mcast-stub upstream

Use the **ip mcast-stub upstream** command to enable multicast forwarding on an interface and place it in multicast stub upstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub downstream** commands. When enabled, the interface becomes a candidate to be a helper forwarding interface. If chosen as the best path toward the helper address by the router's unicast route table, the Internet Group Management Protocol (IGMP) host function is dynamically enabled and the interface becomes the active upstream interface, enabling the router to perform as an IGMP proxy. Though multiple interfaces may be candidates, no more than one interface will actively serve as the helper forwarding interface. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub downstream on page 3399* for more information.

Usage Examples

The following example enables multicast forwarding on the interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip mcast-stub upstream**

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces	(all types)1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

Open shortest path first (OSPF) will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the interface:

((config)**#interface vlan 1**
(config-vlan 1)**#ip mtu 1200**

ip ospf

Use the **ip ospf** command to customize Open Shortest Path First version 2 (OSPFv2) settings (if needed). Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **area** <*area id*>
ip ospf <*process id*> **authentication-key** <*password*>
ip ospf <*process id*> **cost** <*value*>
ip ospf <*process id*> **dead-interval** <*seconds*>
ip ospf <*process id*> **hello-interval** <*seconds*>
ip ospf <*process id*> **message-digest-key [1 | 2] md5** <*key*>
ip ospf <*process id*> **priority** <*value*>
ip ospf <*process id*> **retransmit-interval** <*seconds*>
ip ospf <*process id*> **shutdown**
ip ospf <*process id*> **transmit-delay** <*seconds*>

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
area <*area id*>	Specifies the ID of the area to which this interface is assigned for the specified OSPFv2 process. Valid range is **0** to **4294967295**.
authentication-key <*password*>	Assigns a simple-text authentication password to be used by other routers using the OSPF simple password authentication.
cost <*value*>	Specifies the OSPF cost of sending a packet on the interface. This value overrides any computed cost value. Range is **1** to **65535**.
dead-interval <*seconds*>	Sets the maximum interval (in seconds) allowed between hello packets. If the maximum is exceeded, neighboring devices will determine that the device is down. Range is **0** to **32767** seconds.
hello-interval <*seconds*>	Specifies the interval (in seconds) between hello packets sent on the interface. Range is **0** to **32767** seconds.
message-digest-key [1 | 2] md5 <*key*>	Configures OSPF message digest 5 (MD5) authentication (16 byte maximum) keys.
priority <*value*>	Sets the OSPF priority. The value set in this field helps determine the designated router (DR) for this network. Range is **0** to **255**.
retransmit-interval <*seconds*>	Specifies the interval (in seconds) between link state advertisements (LSAs). Range is **0** to **32767** seconds.

shutdown	Disables the OSPFv2 process on the interface. When this keyword is used, the OSPFv2 settings remain in place, but logically it appears to the interface as though the process has been removed from the configuration. This parameter can be useful in troubleshooting.
transmit-delay <*seconds*>	Sets the estimated time (in seconds) required to send a link state advertisement (LSA) on the interface. Range is **0** to **32767** seconds.

Default Values

The defaults for this command are:

dead-interval <*seconds*>	40 seconds
hello-interval <*seconds*>	10 seconds: Ethernet, Frame Relay, and Point-to-Point Protocol (PPP)
priority <*value*>	1
retransmit-interval <*seconds*>	5 seconds
transmit-delay <*seconds*>	1 second

Command History

Release 3.1	Command was introduced.
Release R11.3.0	Command was expanded to include the <*process id*>, **area** <*area id*>, and **shutdown** parameters.

Usage Examples

The following example sets the maximum number of seconds allowed between hello packets to **25000**:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip ospf 1 dead-interval 25000**

ip ospf <*process id*> authentication

Use the **ip ospf authentication** command to authenticate an interface that is performing open shortest path first (OSPF) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **authentication**
ip ospf <*process id*> **authentication message-digest**
ip ospf <*process id*> **authentication null**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
message-digest	Optional. Selects message digest authentication type.
null	Optional. Specifies that no authentication be used.

Default Values

By default, **ip ospf authentication** is set to **null** (meaning no authentication is used).

Command History

Release 3.1	Command was introduced.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Usage Examples

The following example specifies that no authentication will be used on the virtual local area network (VLAN) interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip ospf 1 authentication null**

ip ospf <*process id*> network

Use the **ip ospf network** command to specify the type of network on this interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf <*process id*> **network broadcast**
ip ospf <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv2 routing process this interface is to join. The process ID is locally significant to the device, and must be unique among all OSPFv2 processes on the device. Valid range is **1** to **65535**.
broadcast	Sets the network type for broadcast.
point-to-point	Sets the network type for point-to-point.

Default Values

By default, Ethernet defaults to **broadcast**. Point-to-Point Protocol (PPP) and Frame Relay default to **point-to-point**.

Command History

Release 3.1	Command was introduced.
Release R11.3.0	Command was expanded to include the <*process id*> parameter.

Functional Notes

A point-to-point network will not elect designated routers.

Usage Examples

The following example designates a broadcast network type:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip ospf 1 network broadcast**

ip pim sparse-mode

Use the **ip pim sparse-mode** command to enable protocol-independent multicast (PIM) sparse mode for this interface. Use the **no** form of this command to disable PIM sparse mode.

Syntax Description

No subcommands.

Default Values

By default, PIM sparse mode for this interface is disabled.

Command History

Release 11.1	Command was introduced.

Functional Notes

PIM sparse mode is a multicast routing protocol that makes use of the unicast forwarding table. It builds unidirectional shared trees rooted at a rendezvous point (RP) for a multicast group or a shortest-path tree rooted at a specific source for a multicast group.

Usage Examples

The following example enables PIM sparse mode on the interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip pim sparse-mode**

ip pim-sparse dr-priority <*value*>

Use the **ip pim-sparse dr-priority** command to specify the priority for the designated router (DR). This command modifies the router's priority in the DR election process. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the priority of this interface (to be used when determining the DR). Valid range is **1** to **4294967295**.

Default Values

By default, the priority of all protocol-independent multicast (PIM) interfaces is **1**.

Command History

Release 11.1	Command was introduced.

Functional Notes

Interfaces advertise their configured priority values in the hello messages transmitted on the interface. Routers use the priority values to determine the appropriate DR. The router on the network segment with the highest priority is selected as the DR. If a hello message is received on the interface from a router on the network segment and it does not contain a priority, the entire network segment defaults to DR selection based on IP addresses instead of priority. In this instance, the DR is selected as the router on the network segment that has the highest IP address. AOS will always include a priority in all transmitted hello messages. If no priority is specifically designated by the user, the priority is set as the default of 1.

Usage Examples

The following example specifies a priority of **100** on the virtual local area network (VLAN) 1 interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip pim-sparse dr-priority 100**

ip pim-sparse hello-timer <*value*>

Use the **ip pim-sparse hello-timer** command to specify protocol-independent multicast (PIM) sparse hello timer period. This is the time interval at which periodic hellos are sent out on all interfaces of a PIM-capable router. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the interval (in seconds) at which periodic hellos are sent out of the interface. Valid range is **10** to **3600** seconds.

Default Values

By default, the hellos are transmitted on PIM interfaces every **60** seconds.

Command History

Release 11.1	Command was introduced.

Functional Notes

Hello messages are used to inform neighbors of a router's presence. Hello messages normally generate a small amount of traffic on an interface. Setting the **hello-timer** to a small interval increases the number of hellos sent (thus increasing the amount of traffic). Set the **hello-timer** to a reasonable value, taking into consideration the bandwidth available on the interface.

Usage Examples

The following example specifies hellos be sent on the virtual local area network (VLAN) 1 interface every **3600** seconds:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip pim-sparse hello-timer 3600**

ip pim-sparse nbr-timeout <*value*>

Use the **ip pim-sparse nbr-timeout** command to specify protocol-independent multicast (PIM) sparse neighbor timeout. This is the time interval after which a PIM-capable router will consider a neighbor not present. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the time interval in seconds after which a neighbor is considered not present. Valid range is **30** to **10800** seconds.

Default Values

By default, the nbr-timeout is set to **105** seconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the nbr-timeout to **300** seconds:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip pim-sparse nbr-timeout 300**

ip pim-sparse override-interval <*value*>

Use the **ip pim-sparse override-interval** command to specify the protocol-independent multicast (PIM) sparse join/prune override interval. This delay interval is the period after a join/prune that another router on the local area network (LAN) may override a join/prune. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the delay time in milliseconds. Valid range is **0** to **65535** milliseconds.

Default Values

By default, the override interval is set to **2500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the override interval to **3000** milliseconds:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip pim-sparse override-interval 3000**

ip pim-sparse propagation-delay *<value>*

Use the **ip pim-sparse propagation-delay** command to specify the expected propagation delay for join/prune messages. Set the propagation delay (in milliseconds) to estimate the amount of delay found in the local link. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the expected propagation delay in the local link in milliseconds. Valid range is **0** to **32767** milliseconds.

Default Values

By default, the propagation delay is set to **500** milliseconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the propagation delay to **300** milliseconds:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip pim-sparse propagation-delay 300**

ip proxy-arp

Use the **ip proxy-arp** command to enable proxy Address Resolution Protocol (ARP) on the interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, proxy ARP is enabled.

Command History

Release 1.1	Command was introduced.

Functional Notes

In general, the principle of proxy ARP allows a router to insert its IP address in the source IP address field of a packet (if the packet is from a host on one of its subnetworks). This allows hosts to reach devices on other subnetworks without implementing routing or specifying a default gateway.

If proxy ARP is enabled, AOS will respond to all proxy ARP requests with its specified medium access control (MAC) address and forward packets accordingly.

Enabling proxy ARP on an interface may introduce unnecessary ARP traffic on the network.

Usage Examples

The following example enables proxy ARP on the virtual local area network (VLAN) interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip proxy-arp**

ip rip receive version

Use the **ip rip receive version** command to configure the Routing Information Protocol (RIP) version the unit accepts in all RIP packets received on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip receive version 1
ip rip receive version 2

Syntax Description

1	Accepts only RIP version 1 packets received on the interface.
2	Accepts only RIP version 2 packets received on the interface.

Default Values

By default, all interfaces implement RIP **version 1** (the default value for the version command).

Command History

Release 1.1	Command was introduced.

Functional Notes

Use the **ip rip receive version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only accepts one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the virtual local area network (VLAN) interface to accept only RIP **version 2** packets:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip rip receive version 2**

ip rip send version

Use the **ip rip send version** command to configure the Routing Information Protocol (RIP) version the unit sends in all RIP packets transmitted on the interface. Use the **no** form of this command to restore the default value. Variations of this command include:

ip rip send version 1
ip rip send version 2

Syntax Description

1	Transmits only RIP version 1 packets on the interface.
2	Transmits only RIP version 2 packets on the interface.

Default Values

By default, all interfaces transmit RIP **version 1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.

Functional Notes

Use the **ip rip send version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only transmits one version (either 1 or 2) on a given interface.

Usage Examples

The following example configures the virtual local area network (VLAN) interface to transmit only RIP **version 2** packets:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip rip send version 2**

ip rip summary-address *<ip address> <subnet mask>*

Use the **ip rip summary-address** command to manually summarize the routes Routing Information Protocol (RIP) will advertise and send out a specified interface. Use the **no** form of this command to disable this mode.

Syntax Description

<ip address>	Specifies the summarized network IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.0**).
<subnet mask>	Specifies the subnet mask that corresponds to the range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no manual summarization is applied by RIP.

Command History

Release 12.1	Command was introduced.

Functional Notes

Unlike the automatic summarization on classful network boundaries, only specific network advertisements are made by RIP using the **ip rip summary-address** command. This command is only effective if RIP version 2 is configured.

Usage Examples

The following example enables manual summarization on the specified IP address:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip rip summary-address 10.10.123.0 255.255.255.0**

ip route-cache

Use the **ip route-cache** command to enable Internet Protocol version 4 (IPv4) fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

*Using network address translation (NAT) or the AOS firewall capabilities on an interface requires process switching mode (using the **no ip route-cache** command).*

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.

Functional Notes

Fast switching allows an IPv4 interface to provide optimum performance when processing IPv4 traffic.

Usage Examples

The following example enables IPv4 fast switching on the VLAN interface:

(config)**#interface vlan 1**
(config-vlan 1)**#ip route-cache**

ip route-cache express

Use the **ip route-cache express** command to enable Layer 3 switching on the virtual local area network (VLAN) interface. Use the **no** form of this command to disable Layer 3 switching on the interface.

Syntax Description

No subcommands.

Default Values

Layer 3 switching is disabled by default, except on the NetVanta 1544. Layer 3 switching is enabled by default on the NetVanta 1544.

Functional Notes

Layer 3 switching cannot be disabled on the NetVanta 1544.

Enabling or disabling Layer 3 switching on the VLAN interfaces overrides the global Layer 3 switching configuration.

For more information about Layer 3 switching, refer to the *Layer 3 Switching in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Command History

Release 17.5	Command was introduced.

Usage Examples

The following example enables Layer 3 switching on VLAN **200**:

```
(config)#interface vlan 200
(config-intf-vlan 200)#ip route-cache express
```

ip unnumbered *<interface>*

Use the **ip unnumbered** command to use the IP address assigned to the specified interface for all IP processing on the active interface. Use the **no** form of this command to remove the unnumbered configuration.

Syntax Description

<interface>	Specifies the interface that contains the IP address to use as the source address for all packets transmitted on this interface. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **ip unnumbered ?** for a list of valid interfaces.

Default Values

By default, all interfaces are configured to use a specified IP address (using the **ip address** command).

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interfaces.

Functional Notes

If **ip unnumbered** is enabled on an interface, all IP traffic from the interface will use a source IP address taken from the specified interface. For example, specifying **ip unnumbered eth 0/1** while in the Frame Relay Subinterface Configuration mode configures the Frame Relay subinterface to use the IP address assigned to the Ethernet interface for all IP processing. In addition, AOS uses the specified interface information when sending route updates over the unnumbered interface.

Usage Examples

The following example configures the virtual local area network (VLAN) interface (labeled **vlan 1**) to use the IP address assigned to the Ethernet interface (**eth 0/1**):

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip unnumbered eth 0/1**

ip urlfilter <*name*>

Use the **ip urlfilter** command to apply a universal resource locator (URL) filter to the interface for all inbound or outbound traffic. Use the **no** form of this command to remove the URL filter from an interface. Variations of this command include:

ip urlfilter <*name*> **in**
ip urlfilter <*name*> **out**

Syntax Description

<*name*>	Specifies the URL filter name to use on the interface.
in	Applies the filter to the inbound traffic.
out	Applies the filter to the outbound traffic.

Default Values

By default, there are no URL filters applied to any interfaces.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the virtual local area network (VLAN) interfaces.

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be created by using the **ip urlfilter** <*name*> **http** command before applying it to the interface. Refer to *ip urlfilter allowmode on page 1493* for more information on using this command.

Usage Examples

The following example performs URL filtering on all traffic entering through the VLAN interface and matches the URL filter named **MyFilter**:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ip urlfilter MyFilter in**

ipv6

Use the **ipv6** command to enable Internet Protocol version 6 (IPv6) processing and create a link-local address on an interface. Use the **no** form of this command to disable IPv6 processing and remove all IPv6 configuration on the interface.

Syntax Description

No subcommands.

Default Values

By default, IPv6 is not enabled on the interface.

Command History

Release 18.1	Command was introduced.

Functional Notes

Because AOS uses the dual-stack for IPv6 implementation, IPv6 features must be enabled for the supported IPv6 features to be used. Enabling IPv6 in AOS is completed by using an IPv6 address or using the **ipv6** keyword with specific commands. For example, to enable IPv6 on an interface and cause the interface to join the link scoped all-nodes and all-routers multicast group, enter an IPv6 address on the interface.

Use the **ipv6** command to enable IPv6 processing and create a link-local address on an interface when other unicast IPv6 addresses are not needed on the interface. This command is not necessary nor effectual when any other form of an IPv6 address command is also present on the interface.

Usage Examples

The following example enables IPv6 and creates a link-local IPv6 address on the interface:

```
(config)#interface vlan 1
(config-vlan 1)#ipv6
```

ipv6 access-group *<ipv6 acl name>*

Use the **ipv6 access-group** command to apply an Internet Protocol version 6 (IPv6) access control list (ACL) to be used for IPv6 packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ipv6 access-group <*ipv6 acl name*> **in**
ipv6 access-group <*ipv6 acl name*> **out**

Syntax Description

<ipv6 acl name>	Applies the named IPv6 ACL to the interface.
in	Enables access control on IPv6 packets received on the specified interface.
out	Enables access control on IPv6 packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 18.1	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.

Functional Notes

Only one IPv6 ACL can be applied in each traffic direction.

Unlike in IPv4, IPv6 traffic filters include an implicit **permit** for neighbor solicitation and advertisement packets in an ACL before the traditional implicit **deny** at the end of the ACL. This prevents blocking of address resolution and unreachability detection, although this can be overridden by entering explicit **deny** commands in the IPv6 ACL.

Usage Examples

The following example applies the IPv6 ACL **Privatev6** to incoming IPv6 traffic on the interface:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 access-group Privatev6 in**

ipv6 access-policy *<ipv6 acp name>*

Use the **ipv6 access-policy** command to assign a specified Internet Protocol version 6 (IPv6) access control policy (ACP) to an interface. IPv6 ACPs are applied to IPv6 traffic entering an interface. Use the **no** form of this command to remove an ACP association.

Syntax Description

<ipv6 acp name>	Identifies the configured IPv6 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv6 ACPs associated with an interface.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example applies the IPv6 ACP **PRIVATEv6** to the interface:

Enable the AOS security features:
(config)**#ipv6 firewall**

Associate the ACP with the VLAN interface:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 access-policy PRIVATEv6**

ipv6 address *<ipv6 address/prefix-length>*

Use the **ipv6 address** command to assign a unicast Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<ipv6 address/prefix-length>	Specifies the IPv6 unicast address to add to the interface. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

Default Values

By default, no IPv6 address is configured on the interface and IPv6 processing is not enabled on the interface.

Command History

Release 18.1	Command was introduced.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the interface using the command *ipv6 address <ipv6 link-local address> link-local on page 3428*.

The address created by this command is a manually configured IPv6 address, which must have all parts (prefix and host bits) specified.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example adds a unicast IPv6 address to the interface and enables IPv6 processing on the interface:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 address 2001:DB8::/32**

ipv6 address *<ipv6 prefix/prefix-length>* eui-64

Use the **ipv6 address eui-64** command to assign a unicast Internet Protocol version 6 (IPv6) address and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<ipv6 prefix/prefix-length>	Specifies the IPv6 prefix. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
eui-64	Specifies that the IPv6 address is constructed using the specified prefix in the high-order bits and followed by the EUI-64 Interface ID in the lower 64 bits.

Default Values

By default, no IPv6 address is configured on the interface and IPv6 processing is not enabled on the interface.

Command History

Release 18.1	Command was introduced.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the interface using the command *ipv6 address <ipv6 link-local address> link-local on page 3428*.

The address created by this command is an EUI-64 unicast address. For this type of address, the EUI-64 interface ID is automatically placed in the IPv6 address. Any manually configured bits beyond the address's prefix length are set to **0**; however, any manually configured bits within the prefix length that extend into the lower 64 bits take precedence over the Interface ID bits.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example adds a unicast IPv6 address with an EUI-64 Interface ID to the interface and enables IPv6 processing on the interface:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 address 2001:DB8:3F::/48 eui-64**

ipv6 address <*ipv6 link-local address*> link-local

Use the **ipv6 address link-local** command to manually assign a link-local Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the interface. Use the **no** form of this command to remove the IPv6 address from the interface.

Syntax Description

<*ipv6 link-local address*>	Specifies the link-local IPv6 address. Link-local addresses are specified in colon hexadecimal notation, and begin with **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since link-local addresses have no prefix, the bits entered form the entire IPv6 address.
link-local	Specifies this is a manually configured link-local address. Manually configured link-local addresses replace automatically configured link-local addresses on the interface.

Default Values

By default, no IPv6 address is configured for the interface and IPv6 processing is not enabled.

Command History

Release 18.1	Command was introduced.

Functional Notes

A single link-local address can be manually configured on an interface. The lower 64 bits of the specified address become the Interface ID for the interface, overriding the default interface ID. Any other address that uses the EUI-64 parameter to automatically place the interface ID in the lower 64 bits of the IPv6 address use the new value for the interface ID.

The <*ipv6 address*> for a link-local IPv6 address is specified in the format **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since this form of address has no prefix, the bits entered form the entire IPv6 address. These bits also become the new interface ID for the interface and can be derived from the interface's medium access control (MAC) address.

The **link-local** parameter specifies this is a manually configured link-local address. Any manually configured link-local address will replace an automatically configured link-local address for the interface.

Using the **no** form of this command with a specified IPv6 address removes that IPv6 address from the interface. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the interface.

Usage Examples

The following example manually creates a link-local IPv6 address on the interface and enables IPv6 processing:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 address FE80::220:8FF:FE54:F9D8 link-local**

ipv6 address autoconfig

Use the **ipv6 address autoconfig** command to enable Internet Protocol version 6 (IPv6) processing on the interface, create a local-link IPv6 address for the interface, and allow the interface to automatically configure itself based on advertisements from other routers on the link. Use the **no** form of this command to remove all autoconfigured addresses, prefixes, and any resulting routes from the interface and also causes the interface to cease processing received router advertisements (RAs).Variations of this command include:

ipv6 address autoconfig
ipv6 address autoconfig default
ipv6 address autoconfig default metric <*value*>

Syntax Description

default	Optional. Specifies that the interface maintain a list of advertising routers that are willing to be IPv6 default routers.
metric <*value*>	Optional. Specifies the administrative distance for a default router maintained in the default router list. Range is **1** to **255**. Routes with lower administrative distance are favored.

Default Values

By default, no IPv6 addresses are configured for the interface and IPv6 processing is not enabled. When an IPv6 address is configured automatically, the administrative distance for default routers is **2** by default.

Command History

Release 18.1	Command was introduced.

Functional Notes

When autoconfiguration is enabled, the interface listens for RA messages that tell the interface how it should be configured. The interface then creates addresses for advertised 64-bit prefixes with the A flag in the IPv6 address set using stateless address autoconfiguration (SLAAC). The addresses use the EUI-64 interface ID in the lower 64 bits of the address. A route type of *Connected* is added to the route table if the L flag on the prefix advertisement (on-link flag) is also set.

Usage Examples

The following example enables IPv6 processing on the interface, creates a link-local IPv6 address for the interface, and allows the interface to automatically configure itself for IPv6:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 address autoconfig**

ipv6 address dhcp

Use the **ipv6 address dhcp** command to enable Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) on the interface, place the interface in DHCPv6 client mode, and configure the address parameters of the DHCPv6 client. Use the **no** form of this command to disable the DHCPv6 client on the interface. Variations of this command include:

ipv6 address dhcp
ipv6 address dhcp hostname <*partial fqdn*>
ipv6 address dhcp hostname fqdn <*fqdn*>
ipv6 address dhcp no-domain-name
ipv6 address dhcp no-nameservers
ipv6 address dhcp no-ntp
ipv6 address dhcp no-sntp-server
ipv6 address dhcp rapid-commit

Syntax Description

hostname <*partial fqdn*>	Optional. Specifies the name to be sent to the DHCPv6 server as the host portion of its fully qualified domain name (FQDN). FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
fqdn <*fqdn*>	Optional. Specifies a name to be sent to the DHCPv6 server as the system's FQDN. FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
no-domain-name	Optional. Specifies that no domain names are obtained using this DHCPv6 client.
no-nameservers	Optional. Specifies that no domain naming server (DNS) addresses are obtained through DHCPv6.
no-ntp	Optional. Specifies that no Network Time Protocol (NTP) server values are obtained through this DHCPv6 client.
no-sntp-server	Optional. Specifies that no Simple Network Time Protocol (SNTP) server values are obtained through this DHCPv6 client.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Functional Notes

To enable an interface as a DHCPv6 client, you must first enable IPv6 on the interface using the command *ipv6 on page 3423*.

Enabling the interface as a DHCPv6 client using the **ipv6 address dhcp** command places the interface into DHCPv6 client mode. DHCPv6 modes (**client**, **server**, **relay**) are mutually exclusive at the interface. Any existing mode must be removed before a different mode can be applied. For example, if the interface is configured as a DHCPv6 relay agent, you must first disable the **relay** mode before you can specify the interface is in **client** mode.

Usage Examples

The following example enables the interface as a DHCPv6 client and specifies the client's host name:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 address 2001:DB8:1::1/64**
(config-vlan 1)**#ipv6 address dhcp fqdn client@company.com**

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*

Use the **ipv6 address named-prefix** command to create an Internet Protocol version 6 (IPv6) address for the interface using the values in a named prefix. Use the **no** form of this command to remove the address from the interface. Variations of this command include:

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*
ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>* **eui-64**

Syntax Description

<prefix name>	Specifies the named prefix to use to create the address.
<ipv6 address/prefix-length>	Specifies the address portion appended to the named prefix to create a 128-bit host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
eui-64	Optional. Indicates that the interface ID is to be placed in the lower 64 bits of the address.

Default Values

By default, no IPv6 addresses are specified on the interface.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example creates an IPv6 address on the interface using the named prefix **PREFIX1**:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 address named-prefix PREFIX1 2001:1:0:/48**

ipv6 crypto map *<name>*

Use the **ipv6 crypto map** command to associate Internet Protocol version 6 (IPv6) crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

Syntax Description

<name>	Specifies the IPv6 crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

Command History

Release R10.7.0	Command was introduced.

Functional Notes

Only one IPv6 crypto map can be specified per interface, and the crypto map is applied within the virtual routing and forwarding (VRF) instance to which the interface belongs. To apply the IPv6 crypto map, the interface must have IPv6 enabled. In addition, the interface must have an IPv6 address of appropriate scope to allow connectivity to peer's addresses as specified in the crypto map's entries.

Usage Examples

The following example applies all IPv6 crypto maps with the name **MyMap** to the interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ipv6**
(config-interface-vlan 1)**#ipv6 crypto map MyMap**

ipv6 dhcp client information refresh minimum <*seconds*>

Use the **ipv6 dhcp client information refresh minimum** command to specify the minimum value the Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) client on the interface accepts as its information refresh timer. Use the **no** version of this command to return to the default setting.

Syntax Description

<*seconds*>	Specifies the refresh timer in seconds. Valid range is **600** to **3600** seconds.

Default Values

By default, the DHCPv6 client refresh timer is set to **600** seconds.

Command History

Release R10.9.0	Command was introduced.

Usage Examples

The following example specifies the DHCPv6 client refresh timer for the interface is **800** seconds:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 dhcp client information refresh minimum 800**

ipv6 dhcp client pd <*prefix name*>

Use the **ipv6 dhcp client pd** command to enable the Dynamic Control Host Protocol for Internet Protocol version 6 (DHCPv6) client on the interface and specify that the interface acquires an IPv6 prefix for the DHCPv6 client. Use the **no** form of this command to disable this feature. Variations of this command include:

ipv6 dhcp client pd <*prefix name*>
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*>
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*> **tag** <*value*>
ipv6 dhcp client pd <*prefix name*> **no-aggregate-route**
ipv6 dhcp client pd <*prefix name*> **rapid-commit**

Syntax Description

<*prefix name*>	Specifies the variable of the prefix stored on the AOS system. Variables are expressed in ASCII text of up to **80** characters.
distance <*distance*>	Optional. Specifies the administrative distance to assign to the injected route. Valid range is **1** to **255** with a default distance of **1**.
no-aggregate-route	Optional. Specifies that a route to the null 0 interface is not injected into the route table for the prefixes assigned.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.
tag <*value*>	Optional. Specifies a number to use as a tag for labeling and filtering routers. Valid range is **1** to **65535**.

Default Values

By default, the DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Usage Examples

The following example enables the DHCPv6 client on the interface and assigns the prefix **PREFIX1**:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 dhcp client pd PREFIX1**

ipv6 dhcp relay destination *<ipv6 address>*

Use the **ipv6 dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 6 (IPv6) and to specify the IPv6 address for the DHCPv6 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv6 relay functionality is disabled on the interface. Variations of this command include:

ipv6 dhcp relay destination *<ipv6 address>*
ipv6 dhcp relay destination *<ipv6 address> <interface>*

Syntax Description

<ipv6 address>	Specifies the IPv6 address for the DHCPv6 messages. IPv6 addresses should be specified in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<interface>	Optional. Specifies an output interface to use when sending messages to the DHCPv6 server. If no interface is specified, the interface is selected by the routing table. This parameter is only required when the IPv6 address is a link-scoped address. Interfaces are specified in the *<interface type> <slot/port | interface id>* format. For example, for an Ethernet interface, use **eth 0/1**. Type **ipv6 dhcp relay destination** *<ipv6 address>* **?** to display a list of valid interfaces.

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.
Release R10.5.0	Command was expanded to include the loopback interface.
Release R13.7.0	Command was expanded to include the Gigabit Ethernet interface.

Functional Notes

To configure an interface to function as a DHCPv6 relay agent, you must first enable IPv6 on the interface using the command *ipv6 on page 3423*.

Usage Examples

The following example enables DHCPv6 relay agent functionality and specifies the destination address as **2001:DB8:2::1**:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ipv6**
(config-interface vlan 1)**#ipv6 dhcp relay destination 2001:DB8:2::1**

Technology Review

DHCPv6, like DHCP in IPv4, is used in IP networks to supply hosts with IP addresses and other networking information. DHCPv6, however, functions slightly differently than DHCPv4 by providing relay agents with the ability to send relay-forward and relay-reply messages. In addition, in DHCPv4, when DHCP messages are sent to a DHCP server whose address is not known, the IPv4 client uses the broadcast address. In DHCPv6, the IPv6 client sends messages using the link-scoped mulitcast address. This address is the All DHCP Relay Agents and Servers link, designated as **FF02::1:2**.

In AOS, DHCPv6 relay agents are used when the DHCP server is not on the same link as the DHCP client. The relay is typically a router on the same link as the client, which acts as an intermediary to help the client's DHCP messages reach the DHCP server. DHCPv6 relay agents operate transparently to the DHCP client, and can be configured in chains, meaning that information about each agent encountered is encapsulated into the relay message. Relay agents add fields to the DHCP message as they send these messages to the server, thus providing a method to properly manage the DHCP client.

For more information about DHCPv6 functionality in AOS, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

ipv6 dhcp server

Use the **ipv6 dhcp server** command to enable Internet Protocol version 6 (IPv6) Dynamic Host Control Protocol (DHCP) on the interface and specify that the interface is functioning as a DHCPv6 server. This command not only enables the DHCPv6 server on the interface, it also configures specific parameters of the DHCPv6 server. Hence, the parameters of this command can be entered multiple times and in any order. Use the **no** form of this command to disable DHCPv6 on the interface. Variations of this command include:

ipv6 dhcp server automatic
ipv6 dhcp server automatic allow-hint
ipv6 dhcp server automatic preference <*number*>
ipv6 dhcp server automatic rapid-commit
ipv6 dhcp server <*pool name*>
ipv6 dhcp server <*pool name*> **allow-hint**
ipv6 dhcp server <*pool name*> **preference** <*number*>
ipv6 dhcp server <*pool name*> **rapid-commit**

Syntax Description

automatic	Enables automatic selection of the DHCPv6 server pool based on information extracted from the DHCPv6 client's request. You must specify the pool selection method before configuring other options for this command.
<*pool name*>	Specifies the DHCPv6 server pool that services this interface. All DHCPV^ requests received on this interface are serviced from this pool. If a pool name is not specified, the server pool is selected automatically. You must specify the pool selection method before configuring the other options for this command.
allow-hint	Optional. Specifies that the DHCPv6 server attempts to honor the DHCPv6 client's request for specific values as hinted in the client's request (if they are valid and not already assigned). If this option is not specified, any hints from the DHCPv6 client are ignored.
preference <*number*>	Optional. Specifies the preference value advertised by the server. This option is sent by the server to a DHCPv6 client to influence the selection of a server when there are multiple servers from which to choose. Valid range is **0** to **255**, with a default value of **0**. When the preference value is set to a non-zero value, the server includes a preference option containing the value. If the preference value is not set, or is set to 0, the option is omitted and the client assumes the value is 0.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 server mode is not enabled on the interface.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

Enabling the interface as a DHCPv6 server using this command places the interface into DHCPv6 server mode. DHCPv6 modes (server or relay) are mutually exclusive at the interface. Any existing mode will be removed if a different mode is specified, and a message will be shown indicating the change in DHCPv6 mode.

Usage Examples

The following example enables the interface as a DHCPv6 server, and specifies that the DHCPv6 server pool **POOL1** is associated with the interface:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 address 2001:DB8:1::1/64**
(config-vlan 1)**#ipv6 dhcp server POOL1**

ipv6 ffe

Use the **ipv6 ffe** command to enable the RapidRoute fast forwarding engine (FFE) on this Internet Protocol version 6 (IPv6) interface with the default number of entries. Use the **no** form of this command to disable this feature. Variations of this command include:

ipv6 ffe
ipv6 ffe max-entries <*value*>

> NOTE *Issuing this command will cause all RapidRoute entries to be cleared from this IPv6 interface.*

Syntax Description

max-entries <*value*>	Optional. Specifies the maximum number of entries stored in the flow table. Valid range is from **1** to **500000**.

Default Values

By default, the RapidRoute Engine is enabled on IPv6-enabled interfaces (using the command *ipv6 on page 2231*). The default number of **max-entries** is **4096**.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

RapidRoute can be used to help reduce routing overhead, and thus reduce overall routing times. Routing times are reduced by the creation of a flow table on the ingress interface. The maximum number of entries that can be stored in the flow table at any one time may be specified by using the **max-entries** parameters.

Usage Examples

The following example disables RapidRoute on the IPv6 interface:

(config)**#interface vlan 1**
(config-vlan 1)**#no ipv6 ffe**

Technology Review

The RapidRoute system goal is to increase IP packet throughput by moving as much of the packet processing into the engine as possible. Packets are classified into flows based upon the IP protocol (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol (ICMP), etc.), the source and destination IP addresses, IP type of service (ToS), and the protocol-specific information, such as the source and destination port numbers. Flows are defined as the unidirectional representation of a conversation between two IP hosts. Each ingress interface keeps its own flow table, a collection of flow entries.

The first packet in a flow that is forwarded through the unit will build a flow entry. When a flow entry is looked up but no entry is found, a RapidRouteBuilder object is allocated and attached to the packet. As the packet passes through the various processing layers, each subsystem will add processing to the RapidRouteBuilder. When packet is about to be forwarded out of the egress interface, the RapidRouteBuilder will be finalized. That is, the flow entry being built will be checked for completeness and committed to the flow table on the ingress interface. Subsequent flow matches can then bypass the normal processing layers.

ipv6 mode host unicast

Use the **ipv6 mode host unicast** command to place the interface in host mode using an Internet Protocol version 6 (IPv6) unicast address. Use the **no** form of this command to disable host mode on the interface.

Syntax Description

No subcommands.

Default Values

By default, host mode is disabled.

Command History

Release R10.9.0	Command was introduced.

Command History

When this command is configured on an interface, the MTU value is learned from received router advertisements. Link MTU value is learned in host mode from the following locations (in decreasing order of priority): the provisioned MTU value in the interface configuration, the router advertisements received on the interface, and the default MTU value (1500).

Usage Examples

The following example places the interface in host mode:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 mode host unicast**

ipv6 mtu *<size>*

Use the **ipv6 mtu** command to specify the maximum transmission unit (MTU) for Internet Protocol version 6 (IPv6) packets on the interface. Use the **no** form of this command to return to the default value.

Syntax Description

<size>	Specifies the MTU value. Valid range is **1280** to **1500** bytes.

Default Values

By default, the MTU of the interface is set to **1280** bytes.

Command History

Release 18.1	Command was introduced.

Functional Notes

In IPv6, the minimum MTU is 1280 octets. Any link that has an MTU less than 1280 octets must use link fragmentation and reassembly that is transparent to IPv6 (for example, the Fragmentation Header). Sources in the IPv6 network are expected to perform path maximum transmission unit (PMTU) discovery to send packets larger than 1280 octets. PMTU works in the following manner: First, the sending node assumes the link MTU of the interface from which the traffic is being forwarded and then sends the IPv6 packet at the link MTU size. If a router on the path is unable to forward the packet, it sends an ICMP *Packet Too Big* message back to the sending node containing the link MTU of the link on which the packet forwarding failed. The sending node then rests the PMTU to the value of the MTU field in the Internet Control Message Protocol version 6 (ICMPv6) *Packet Too Big* message, and the packet is resent.

The MTU for IPv6 packets can be set on a per-interface basis. There are two methods for setting MTUs for interfaces if required: one for Layer 3 interfaces, and one for the underlying Layer 1 and Layer 2 interfaces. For all interface types, use the **ipv6 mtu** *<size>* command to specify the IPv6 MTU in bytes from the interface's configuration mode. The minimum MTU setting for IPv6 is **1280** bytes, and the maximum is **1500** bytes. The IPv6 MTU value is independent of the IPv4 MTU setting (set with the command *ip mtu <size> on page 3403*).

When the interface is forwarding the IPv6 packet as a router, if the packet size exceeds the IPv6 MTU of the egress interface, the packet is dropped and ICMPv6 *Packet Too Big* message is sent to the source. When originating an IPv6 packet from the local IPv6 stack, and the packet is larger than the IPv6 MTU of the egress interface, the packet is fragmented and sent.

Usage Examples

The following example specifies the IPv6 MTU value for the interface:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 mtu 1350**

ipv6 nd advertisement-interval

Use the **ipv6 nd advertisement-interval** command to specify that the Advertisement Interval Option is sent in Internet Protocol version 6 (IPv6) router advertisement (RA) messages from the router. This command is effectual only when the interface is in router mode. Use the **no** form of this command to return to the default interval.

Syntax Description

No subcommands.

Default Values

By default, Advertisement Interval Options are not sent in RA messages.

Command History

Release 18.1	Command was introduced.

Functional Notes

Sending the Advertisement Interval Option should be enabled when the router is functioning in a mobile IP environment to aid movement detection by mobile nodes. This option contains the current value of the maximum router advertisement interval configured using the command *ipv6 nd ra interval on page 3454*.

Usage Examples

The following example specifies that the interface include Advertisement Interval Options in RA messages sent from the router:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 nd advertisement-interval**

ipv6 nd cache max-incomplete <*number*>

Use the **ipv6 nd cache max-incomplete** command to specify the maximum number of incomplete entries the Neighbor Discovery (ND) cache retains. Use the **no** form of this command to return to the default value.

Syntax Description

<*number*>	Specifies the number of incomplete ND entries to retain in the cache. Valid range is **1** to **321**.

Default Values

By default, the incomplete ND entries can take at maximum one-third of the possible ND cache entries (varies by product).

Command History

Release R11.10.0	Command was introduced.

Usage Examples

The following example specifies that the interface stores **150** incomplete entries in the ND cache:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 nd cache max-incomplete 150**

ipv6 nd dad attempts <*number*>

Use the **ipv6 nd dad attempts** command to specify the number of neighbor solicitation (NS) messages sent by the interface when performing Internet Protocol version 6 (IPv6) duplicate address detection (DAD). This command is effectual when the interface is in either host or router mode. Use the **no** form of this command to return to the default value.

Syntax Description

<*number*>	Specifies the number of NS messages that will be sent. Range is **0** to **10** messages. A value of **0** disables DAD on the interface.

Default Values

By default, the interface sends **1** NS message.

Command History

Release 18.1	Command was introduced.

Functional Notes

DAD is used by devices to determine if IPv6 addresses are unique before they are applied to interfaces. DAD is used in NS messages to detect duplicate unicast addresses. The Target Address fields in the NS messages are set to the IPv6 address for which duplication is being detected. Destination IPv6 addresses for DAD in NS messages are the solicited-node multicast version of the address being tested. Source IPv6 addresses for DAD are set to the IPv6 unspecified address (::). Once the IPv6 address is determined by DAD to be unique, it can be applied to the IPv6 interface on the node.

DAD in AOS is performed when an interface transitions state from DOWN to UP or when manually configuring an address. When performing DAD because of an interface transition, DAD will happen immediately after the interface transition and again 40 seconds later to cooperate with the port being connected to an Ethernet switch.

Usage Examples

The following example specifies that **3** NS messages are sent by the interface when performing DAD:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 nd dad attempts 3**

ipv6 nd managed-config-flag

Use the **ipv6 nd managed-config-flag** command to specify the M flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. The M flag instructs hosts receiving the RA that they can use stateful Dynamic Host Configuration Protocol version 6 (DHCPv6) to configure addresses and nonaddress information. Use the **no** form of this command to disable the setting of the M flag.

Syntax Description

No subcommands.

Default Values

By default, the M flag is not set in RAs.

Command History

Release 18.1	Command was introduced.

Functional Notes

If you specify that the M flag is set in RA messages, you do not need to set the 0 flag (it becomes redundant).

Usage Examples

The following example sets the M flag for RA messages sent by the interface:

```
(config)#interface vlan 1
(config-vlan 1)#ipv6 nd managed-config-flag
```

ipv6 nd ns-interval *<value>*

Use the **ipv6 nd ns-interval** command to specify the interval between transmission of certain Internet Protocol version 6 (IPv6) Neighbor Discovery (ND) messages and to control what ND value is advertised in router advertisement (RA) messages. This command is effectual whether the interface is in host or router mode. Use the **no** form of this command to return the interval to the default value.

Syntax Description

<value>	Specifies the time (in milliseconds) between neighbor message transmissions. Valid range is **1000** to **3600000** ms.

Default Values

By default, the interval is set to **1000** ms for internal use by the router and **0** (unspecified) is sent in RA messages.

Command History

Release 18.1	Command was introduced.

Functional Notes

This command controls the spacing of neighbor solicitation (NS) messages for functions such as address resolution, reachability detection, and duplicate address detection (DAD). For DAD it also serves as the amount of time after the last transmission before the detection phase of autoconfiguration terminates. In addition, the command controls the interval between unsolicited neighbor advertisement (NA) messages.

Usage Examples

The following example changes the interval between RA messages sent from the interface to **2000** ms:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 nd ns-interval 2000**

ipv6 nd other-config-flag

Use the **ipv6 nd other-config-flag** command to specify the O flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the interface is in router mode. When the O flag is set, hosts receiving the RA messages are instructed that they may use stateless Dynamic Host Configuration Protocol version 6 (DHCPv6) to receive information that is not IPv6 addressing information, and to use some other method (whether through manual configuration, stateless address autoconfiguration (SLAAC), etc.) for addressing information. Use the **no** form of this command to disable the O flag setting.

Syntax Description

No subcommands.

Default Values

By default, the O flag is not set in RA messages.

Command History

Release 18.1	Command was introduced.

Functional Notes

If the M flag is set for RA messages, you do not need to set the O flag.

Usage Examples

The following example sets the O flag in RA messages from the interface:

```
(config)#interface vlan 1
(config-vlan 1)#ipv6 nd other-config-flag
```

ipv6 nd prefix

Use the **ipv6 nd prefix** command to specify the Internet Protocol version 6 (IPv6) address prefixes used in router advertisement (RA) messages sent from the interface. Use the **no** form of this command to remove the specified prefix configuration from the interface. Variations of this command include:

ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise] [**<*valid lifetime*> | **infinite]** <*preferred lifetime* | **infinite**>
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite] [no-advertise] [no-autoconfig] [no-rtr-address] [no-onlink] [off-link]**

Syntax Description

named-prefix <*prefix name*>	Optional. Specifies that a named prefix is used in RA messages. When a named prefix is used, the default prefix cannot be used.
<*ipv6 prefix/prefix-length*>	Specifies the IPv6 prefix and length to be advertised. Pv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
default	Specifies the default values for the IPv6 prefix parameters. Refer to the *Functional Notes* below for more information.
<*valid lifetime*>	Optional. Specifies the valid lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
<*preferred lifetime*>	Optional. Specifies the preferred lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
infinite	Optional. Specifies that the the valid and preferred lifetimes of the prefix do not expire.
no-advertise	Optional. Specifies that the prefix is excluded from the RA message.
no-autoconfig	Optional. Sets the A flag in the RA message to **0**, indicating that hosts may not create an address for this prefix using stateless address autoconfiguration (SLAAC). This parameter only affects hosts receiving the RA message, it does not affect the operation of the local router.
no-rtr-address	Optional. Sets the R flag in the RA message to **0** and specifies the full router IPv6 address is not included in the RA message.
no-onlink	Optional. Specifies that the IPv6 prefix in the RA message is not to be used for on-link determination.
off-link	Optional. Sets the L flag value to **0** in RA messages, which indicates the RA makes no statement about the on-link or off-link properties of the IPv6 prefix.

Default Values

By default, all prefixes derived from the interface's configured IPv6 addresses are advertised using the system default values.

By default, the valid lifetime advertised for a prefix is **2592000** seconds and the preferred lifetime advertised is **604800** seconds.

By default, the L flag is set to **1**, the R flag is set to **1**, and the A flag is set to **1**.

Command History

Release 18.1	Command was introduced.
Release R10.9.0	Command was expanded to include the **named-prefix** and *<prefix name>* options.

Functional Notes

This command works for both routers and hosts, but in host implementations it is used to manually add on-link prefixes that do not have an IPv6 address or to make off-link a prefix generated by an IPv6 address command. Hosts do not send RA messages, so the command only adds prefixes to RA messages when the interface is in router mode. This command can also be used to change the defaults used on configured prefixes when all options are not specified.

Changing the prefix defaults will affect prefixes derived from configured IPv6 addresses, as well as prefixes configured using the ***ipv6 nd prefix*** *command.*

Prefixes advertised can be a subset or a superset of the prefixes derived from the IPv6 addresses configured on the interface. Prefixes for IPv6 addresses configured on a router interface are automatically eligible to be advertised on that interface using system or configured default values without having to enter a prefix command. To impose additional controls on those prefixes, an entry must be made using this command with the desired settings.

The **default** parameter is used to change the default settings for the IPv6 prefix parameters. Changing these settings can be useful when multiple prefixes are implemented that will use the same set of parameters. When configuring IPv6 prefixes, the prefix default values are only used if no other parameters are specified after specifying the IPv6 prefix and length (for example, **ipv6 nd prefix 2001:DB8::/64**). If additional parameters are specified, any unspecified parameters use the system default values rather than the configured default values. When the default values are changed, any prefix that uses them will also change. Using this command to change prefix default values also affects prefixes derived from configured IPv6 addresses on the interface.

The optional *<valid lifetime>* parameter specifies the valid lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep this prefix until the valid lifetime expires.

The optional <*preferred lifetime*> parameter specifies the preferred lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep the prefix in the preferred state during this time period. After the preferred time period expires, the prefix transitions to the deprecated state where it remains until the valid lifetime expires and the route is removed. The <*preferred lifetime*> value must be set to be shorter than the <*valid lifetime*> value.

The optional **off-link** parameter sets the L flag (on-link flag) value to **0** in RA messages. When the L flag is set to 0, the advertisement makes no statement about on-link or off-link properties of the prefix. When the L flag is set, the prefix is considered on-link and locally reachable by hosts on the link (meaning a router is not needed). Hosts attached to the link will add on-link prefixes to their prefix list or route table. When off-link is not specified, a connected route is added to the route table of this router for this prefix. When off-link is specified, no route is added to the route table. By default, prefixes are advertised as on-link with the L flag set to 1.

The optional **no-rtr-address** parameter sets the R flag (router flag) of the RA to **0** and does not include the full router address in the advertisement. The router address is typically included in the RA to assist in Mobile IP environments. By default, the R flag is set to 1 and the router address is sent in RA messages.

The optional **no-autoconfig** parameter sets the A flag of the RA to **0**, indicating that hosts may not create an address for this prefix using SLAAC. If the A flag is set to **1** (the default setting), hosts perform SLAAC to generate an address based on the prefix. This parameter only affects hosts receiving the RA, it does not effect the operation of the local router.

The optional **no-advertise** parameter specifies that the prefix is excluded from RA messages. By default, the prefix is included in RA messages. The **no-onlink** parameter informs the router that the prefix is not to be used for on-link determination.

By default, all prefixes derived from the interface's configured IPv6 addresses are advertised using the system default values.

Usage Examples

The following example specifies that the IPv6 prefix **2001:DB8:3F::/48** has an infinite valid and preferred lifetime advertised in RA messages sent from the interface:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 nd prefix 2001:DB8:3F::/48 infinite infinite**

The following example changes the default values and behaviors of prefixes included in RA messages to infinite valid and preferred lifetimes, and specifies that the on- or off-link state of the prefix is not included in the RA and that hosts receiving the RA may not use the prefix for creating an IPv6 address:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 nd prefix default infinite infinite off-link no-autoconfig**

ipv6 nd purge-timer <*value*>

Use the **ipv6 nd purge-timer** command to specify the maximum amount of time an unused Internet Protocol version 6 (IPv6) neighbor entry remains in the neighbor cache. This command applies to interfaces in either host or router mode. Use the **no** form of this command to return the purging interval to the default value.

Syntax Description

<*value*>	Specifies the neighbor cache entry storage time in minutes. Valid range is **10** to **1440** minutes.

Default Values

By default, idle (STALE) neighbor cache entries are cleared after **1440** minutes (24 hours).

Command History

Release 18.1	Command was introduced.

Functional Notes

This command applies to interfaces in either router or host mode. A neighbor entry is typically purged when neighbor unreachability detection (NUD) is invoked and the neighbor is determined to no longer be reachable. However, NUD is not performed on idle (STALE) neighbor entries, so this command provides a method for purging unused entries after a specified amount of time.

Usage Examples

The following example specifies that idle neighbor entries in the neighbor cache are removed after **800** minutes:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 nd purge-timer 800**

ipv6 nd ra interval

Use the **ipv6 nd ra interval** command to specify the interval between transmission of Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the interface is in router mode. Use the **no** form of this command to return to the default value. Variations of this command include:

ipv6 nd ra interval *<max time>*
ipv6 nd ra interval *<max time> <min time>*
ipv6 nd ra interval msec *<max time>*
ipv6 nd ra interval msec *<max time> <min time>*

Syntax Description

<max time>	Specifies the maximum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **4** to **1800** seconds and **70** to **1800000** ms.
<min time>	Optional. Specifies the minimum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **3** seconds to 75 percent of the configured maximum time value in seconds, or **30** ms to 75 percent of the configured maximum time value in ms.
msec	Optional. Specifies that the time values are in milliseconds.

Default Values

By default, the interval is set in seconds and has a maximum interval time of **200** seconds and a minimum interval time of 75 percent of the maximum seconds value, but not less than **3** seconds.

Command History

Release 18.1	Command was introduced.

Functional Notes

If this router is used as a default router, the interval between RA messages should not be set to a larger value than the RA lifetime set by the command *ipv6 nd ra lifetime <value> on page 3455*, which has a default value of **1800** seconds.

Usage Examples

The following example specifies that the maximum interval in seconds between RA message transmissions is **300**:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 nd ra interval 300**

ipv6 nd ra lifetime <*value*>

Use the **ipv6 nd ra lifetime** command to specify the router lifetime advertised in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is effectual when the interface is in router mode. Use the **no** form of this command to return to the default setting. Variations of this command include:

ipv6 nd ra lifetime <*value*>
ipv6 nd ra lifetime default-route

Syntax Description

<*value*>	Specifies the router lifetime in seconds. Range is **0** to **9000** seconds. A value of **0** indicates this is not a default router. A value other than 0 indicates to other nodes that this router can be used as a default router.
default-route	Specifies the RA lifetime is **0** if no default route exists on any IPv6 interface.

Default Values

By default, the router lifetime is set to **1800** seconds.

Command History

Release 18.1	Command was introduced.
Release R11.5.0	Command was expanded to include the **default-route** parameter.

Functional Notes

A value other than **0** for a router lifetime should be larger than the router advertisement interval specified in the command *ipv6 nd ra interval on page 3454*.

Usage Examples

In the following example, the router lifetime advertised in RA messages is **3000** seconds:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 nd ra lifetime 3000**

ipv6 nd ra reachable-time <*value*>

Use the **ipv6 nd ra reachable-time** command to specify the value advertised for reachable time in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command also specifies the internal base reachable time used by the router. This command is effectual for interfaces in either host or router mode. Use the **no** form of this command to return the reachability value to the default setting.

Syntax Description

<*value*>	Specifies the reachability time in milliseconds. Range is **0** to **3600000** ms. A value of **0** indicates the reachable time is unspecified.

Default Values

By default, the router advertises a reachability time of **0** ms and uses an internal value of **30000** ms.

Command History

Release 18.1	Command was introduced.

Functional Notes

This command is effectual for interfaces in either router or host mode. For hosts, this value sets the internal reachable time used by the host if no RAs are received specifying a different value. For routers, the value indicates the amount of time a device is considered reachable after having received a reachability confirmation in neighbor unreachabililty detection (NUD).

Usage Examples

The following example specifies that a reachability time of **50000** ms is advertised in RA messages:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 nd ra reachable-time 50000**

ipv6 nd ra suppress

Use the **ipv6 nd ra suppress** command to specify whether Internet Protocol version 6 (IPv6) router advertisement (RA) messages will be suppressed. This command only applies to interfaces in router mode. Use the **no** form of this command to begin sending RA messages.

Syntax Description

No subcommands.

Default Values

By default, RA messages are not suppressed. When IPv6 routing is not enabled on the router, or when implemented in a host-only mode, the default setting is to suppress advertisements on all interface types.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example suppresses RA messages on the interface:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 nd ra suppress**

ipv6 nd router-preference

Use the **ipv6 nd router-preference** command to specify the default router preference value set in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. Setting this preference helps the receivers of RA messages to determine the preference of one router over another as a default router in environments with multiple routers. Use the **no** form of this command to return the preference to the default setting. Variations of this command include:

ipv6 nd router-preference high
ipv6 nd router-preference low
ipv6 nd router-preference medium

Syntax Description

high	Specifies the preference value is high.
low	Specifies the preference value is low.
medium	Specifies the preference value is medium.

Default Values

By default, the router preference is set to medium.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example specifies that the advertised default router preference is high:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 nd router-preference high**

ipv6 route-cache

Use the **ipv6 route-cache** command to enable Internet Protocol version 6 (IPv6) fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 18.2	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.

Functional Notes

Fast switching allows an IPv6 interface to provide optimum performance when processing IPv6 traffic.

Usage Examples

The following example enables IPv6 fast switching on the interface:

(config)**#interface vlan 1**
(config-vlan 1)**#ipv6 route-cache**

mac-address *<mac address>*

Use the **mac-address** command to specify the medium access control (MAC) address of the virtual local area network (VLAN) interface. Only the last three values of the MAC address can be modified. The first three values contain the Adtran reserved number (00:0A:C8) by default. Use the **no** form of this command to return to the default MAC address programmed by Adtran.

Syntax Description

<mac address>	Specifies a valid 48-bit MAC address. MAC addresses should be expressed in the following format xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).

Default Values

A unique default MAC address is programmed in each unit shipped by Adtran.

Command History

Release 5.1	Command was introduced.

Usage Examples

The following example configures a MAC address of **00:0A:C8:5F:00:D2**:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#mac-address 00:0A:C8:5F:00:D2**

max-reserved-bandwidth <*value*>

Use the **max-reserved-bandwidth** command to specify the percentage of interface bandwidth reserved for use in user-defined (priority or class-based) queues. The remainder of the interface bandwidth is reserved for system-critical traffic and is not available to user-defined queues. Use the **no** form of this command to restore the default value.

Reserving a portion of the interface bandwidth for system-critical traffic is necessary for proper operation. Specifying the entire interface bandwidth for use in user-defined queues can cause undesirable operation.

Syntax Description

<*value*>	Specifies the maximum percentage of bandwidth to reserve for quality of service (QoS). This setting is configured as a percentage of the total interface speed. Range is **1** to **100** percent.

Default Values

By default, **max-reserved-bandwidth** is set to **75** percent, which reserves 25 percent of the interface bandwidth for system-critical traffic.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example specifies **85** percent of the bandwidth on the virtual local area network (VLAN) 1 interface be available for use in user-defined queues:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#max-reserved-bandwidth 85**

media-gateway ip

Use the **media-gateway ip** command to associate an Internet Protocol version 4 (IPv4) address source to use for Realtime Transport Protocol (RTP) traffic. When configuring Voice over Internet Protocol (VoIP), RTP traffic must have an IPv4 address associated with it. However, some interfaces allow dynamic configuration of IPv4 addresses, causing this value to change periodically. Use the **no** form of this command to disable this function. Variations of this command include:

media-gateway ip loopback <*interface id*>
media-gateway ip primary
media-gateway ip primary vrrp <*number*>
media-gateway ip primary vrrpv3 <*number*>
media-gateway ip secondary <*ipv4 address*>
media-gateway ip secondary vrrp <*number*>
media-gateway ip secondary vrrp <*number*> <*ipv4 address*>
media-gateway ip secondary vrrpv3 <*number*>
media-gateway ip secondary vrrpv3 <*number*> <*ipv4 address*>

Syntax Description

loopback <*interface id*>	Specifies an IPv4 address statically defined to a loopback interface for RTP traffic. This is helpful when using a single IPv4 address across multiple wide area network (WAN) interfaces for RTP traffic. The valid range for loopback interface identifiers is **1** to **1024**. The interface ID is used to uniquely identify a loopback interface. The entered value cannot be in use by another loopback interface.
primary	Specifies using this interface's configured primary IPv4 address for RTP traffic. Applies to static, Dynamic Host Configuration Protocol (DHCP), or negotiated addresses.
secondary <*ipv4 address*>	Specifies using this interface's statically defined secondary IPv4 address for RTP traffic. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
vrrp <*number*>	Specifies that the IPv4 address of the Virtual Router Redundancy Protocol version 2 (VRRP) router group's virtual router ID (VRID) is used as the media gateway address on the interface. Valid VRID range is **1** to **255**.
vrrpv3 <*number*>	Specifies that the IPv4 address of the VRRP version 3 (VRRPv3) VRID is used as the media gateway address on the interface. Valid VRID range is **1** to **255**.
<*ipv4 address*>	Optional. Specifies a secondary IPv4 address of the VRRP or VRRPv3 VRID is used as the media gateway address on the interface. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, **media-gateway ip** is disabled.

Command History

Release 10.1	Command was introduced.
Release 17.3	Command was updated with the loopback interface identification option.
Release A4.01	Command was expanded to include the Metro Ethernet forum (MEF) Ethernet interface.
Release R12.2.0	Command was expanded to include the **vrrp** and **vrrpv3** parameters.

Functional Notes

To use VRRP or VRRPv3 addresses as the media gateway on the interface, you must first have configured VRRP or VRRPv3.

Usage Examples

The following example configures the unit to use the primary IPv4 address for RTP traffic:

(config)**#interface vlan 1**
(config-vlan 1)**#media-gateway ip primary**

media-gateway ipv6

Use the **media-gateway ipv6** command to associate an Internet Protocol version 6 (IPv6) address source to use for Realtime Transport Protocol (RTP) traffic. When configuring Voice over Internet Protocol (VoIP), RTP traffic must have an IPv6 address associated with it. However, some interfaces allow dynamic configuration of IPv6 addresses, causing this value to change periodically. Use the **no** form of this command to disable this function. Variations of this command include:

media-gateway ipv6
media-gateway ipv6 <*ipv6 address*>
media-gateway ipv6 loopback <*interface id*>
media-gateway ipv6 vrrpv3 <*number*>
media-gateway ipv6 vrrpv3 <*number*> <*ipv6 address*>

Syntax Description

<*ipv6 address*>	Specifies an IPv6 address to use for the media gateway. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
loopback <*interface id*>	Specifies an IPv6 address statically defined to a loopback interface for RTP traffic. This is helpful when using a single IPv6 address across multiple wide area network (WAN) interfaces for RTP traffic. The valid range for loopback interface identifiers is **1** to **1024**. The interface ID is used to uniquely identify a loopback interface. The entered value cannot be in use by another loopback interface.
vrrpv3 <*number*>	Specifies that all the secondary IPv6 addresses of the Virtual Routing Redundancy Protocol version 3 (VRRPv3) virtual router ID (VRID) are used as media gateway addresses on the interface. Valid VRID range is **1** to **255**.
<*ipv6 address*>	Optional. Specifies a single IPv6 address of the VRRPv3 VRID is used as the media gateway address on the interface. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.

Default Values

By default, **media-gateway ipv6** is disabled.

Command History

Release R10.8.0	Command was introduced.
Release R12.2.0	Command was expanded to include the **vrrpv3** parameters.

Functional Notes

To use VRRPv3 addresses as the media gateway on the interface, you must first have configured VRRPv3.

Usage Examples

The following example configures the unit to use the IPv6 address for RTP traffic:

(config)**#interface vlan 1**
(config-vlan 1)**#media-gateway ipv6**

no shutdown track *<name>*

Use the **no shutdown track** command to restore the VLAN interface when the specified track passes. For more information about tracks, refer to *track <name> on page 1886* and the *Network Monitor Track Command Set on page 4098*.

Syntax Description

<name>	Specifies the name of the track to associate with the activation of the interface.

Default Values

By default, this command is not configured.

Command History

Release 17.5	Command was introduced.
Release R11.5.0	Command was expanded to include the virtual local area network (VLAN) interfaces.

Usage Examples

The following example enables the interface based on the specified track:

(config)**#interface vlan 1**
(config-vlan 1)**#no shutdown track work-hours**

ospfv3 <*process id*> **area** <*area id*>

Use the **ospfv3 area** command to add an interface to an Open Shortest Path First version 3 (OSPFv3) process, and to configure the OSPFv3 process on the interface. This command places the interface in the specified area for the specified Internet Protocol version 6 (IPv6) OSPFv3 address family, and optionally defines the instance ID that is used to represent this OSPFv3 process in messages on the interface's link. Use the **no** form of this command to remove the OSPFv3 process from the interface. Variations of this command include:

ospfv3 <*process id*> **area** <*area id*> **ipv6**
ospfv3 <*process id*> **area** <*area id*> **ipv6 instance** <*instance id*>

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join, for the specified address family. The process ID is locally significant to the device, and must be unique among all OSPFv3 processes on the device. Valid range is **1** to **65535**.
<*area id*>	Specifies the ID of the area to which this interface is assigned for the given OSPFv3 process. Valid range is **0** to **4294967295**.
ipv6	Identifies the OSPFv3 address family as IPv6.
instance <*instance id*>	Optional. Specifies the value to use in the instance ID field of messages sent or received by this OSPFv3 process on the interface's link. Valid range is **0** to **31**.

Default Values

By default, an OSPFv3 process is not configured on an interface. By default, process IDs, area IDs, and instance IDs are not defined.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

When using this command to enable an OSPFv3 process on an interface, keep the following rules in mind:

- The interface must have the address family enabled on the interface. If the address family is not enabled on the interface, the command is rejected and an error is displayed.
- Only interfaces on the default virtual routing and forwarding (VRF) instance support this command. Interfaces on a nondefault VRF will display an error when you attempt to configure OSPFv3 settings.
- The interface and the specified OSPFv3 process (if defined in the global configuration) must be in the same VRF or the command will fail.
- The address family must match that specified for the OSPFv3 process if the process has been defined in the global configuration or the command will fail.
- If the OSPFv3 process identified by the process ID does not exist in the global configuration, it is automatically created, along with the specified address family, and it is assigned to the VRF of which the interface is a member.

- If the specified OSPFv3 process is already at its maximum limit of processes or address families, the command fails.
- If the specified OSPFv3 process already exists in the global configuration, but its configuration does not include an address family, the specified address family is added to the OSPFv3 router configuration.
- A given OSPFv3 process can only have one address family.
- Multiple OSPFv3 instances per address family, per VRF, can be created and can be assigned to a given interface.
- If the interface's VRF changes, all OSPFv3 assignments are removed.
- To change an OSPFv3 process's VRF, the process must first be removed and then recreated. Removing the process removes all OSPFv3 assignments for that process form all interfaces.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

To add an interface to the OSPFv3 process **5**, in area **10**, with an instance ID of **10**, enter the command as follows:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ospfv3 5 area 10 ipv6 instance 10**

ospfv3 authentication

Use the **ospfv3 authentication** command to authenticate an interface that is performing Internet Protocol version 6 (IPv6) Open Shortest Path First version 3 (OSPFv3) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ospfv3 authentication ipsec spi <*spi*> **md5** <*key*>
ospfv3 authentication ipsec spi <*spi*> **sha1** <*key*>
ospfv3 authentication null

Syntax Description

ipsec	Specifies that IP security (IPsec) authentication is used.
spi <*spi*>	Specifies the security parameter index (SPI). Valid range is **256** to **4294967295**.
md5 <*key*>	Specifies that MD5 authentication is used. Keys are specified in 32 hexadecimal characters.
sha1 <*key*>	Specifies that SHA-1 authentication is used. Keys are specified in 40 hexadecimal characters.
null	Specifies that no OSPFv3 authentication is used.

Default Values

By default, this is set to **null** (meaning no authentication is used).

Command History

Release R10.7.0	Command was introduced.

Usage Examples

The following example specifies that no OSPFv3 authentication will be used on the interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ospfv3 authentication null**

ospfv3 *<process id>* **cost** *<cost>*

Use the **ospfv3 cost** command to specify a value that represents the cost of sending an Open Shortest Path First version 3 (OSPFv3) packet over the interface. Use the **no** form of this command to return the cost to the default value.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3467*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
cost *<cost>*	Specifies the OSPFv3 cost of the interface. This value overrides any automatically computed cost value (default value). Valid range is **1** to **65535**.

Default Values

By default, the OSPFv3 cost of the interface is automatically computed. The automatic cost computation is the reference bandwidth divided by the interface bandwidth. The reference bandwidth is set by the command *auto-cost reference-bandwidth <value> on page 4150*, and defaults to **100** Mbps.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the OSPFv3 cost of the interface as **10**:

```
(config)#interface vlan 1
(config-interface-vlan 1)#ospfv3 5 cost 10
```

ospfv3 <*process id*> dead-interval <*value*>

Use the **ospfv3 dead-interval** command to specify the maximum interval allowed between Open Shortest Path First version 3 (OSPFv3) Hello packets on the interface. If the maximum interval is exceeded, neighboring devices will assume that the device is down. This value must be the same across all interfaces on a link. Use the **no** form of this command to return the dead interval to the default value.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3467*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
dead-interval <*value*>	Specifies the maximum number of seconds allowed between OSPFv3 Hello packets. It is recommended that this value be **4** times the Hello packet interval (set with the command *ospfv3 <process id> hello-interval <value> on page 3474*). Valid range is **1** to **65535** seconds.

Default Values

By default, the maximum interval allowed between OSPFv3 Hello packets is set to **40** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

To specify the dead interval between OSPFv3 Hello packets on the interface, enter the command as follows:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ospfv3 5 dead-interval 100**

ospfv3 encryption

Use the **ospfv3 encryption** command to specify a symmetrical, bidirectional Open Shortest Path First version 3 (OSPFv3) security association (SA) that uses encapsulating security payload (ESP) for encryption and authentication of all OSPFv3 messages that are sent or received on the interface. This command allows you to specify OSPFv3 security at the interface level. Use the **no** form of this command to remove IP security (IPsec) protection of OSPFv3 messages on the interface. Variations of this command include:

ospfv3 encryption ipsec spi <*spi*> **esp** <*encryption type*> <*encryption key*> <*authentication type*> <*authentication key*>
ospfv3 encryption ipsec spi <*spi*> **esp null** <*authentication type*> <*authentication key*>
ospfv3 encryption null

Syntax Description

ipsec	Specifies that IPsec encryption is used on the interface for OSPFv3 SAs.
spi <*spi*>	Specifies the security parameter index (SPI) for the SA. The value specified must not be in used by any other IPsec function on the system, or an error message is generated. If the same SPI is already in use in the same OSPFv3 area, entering this command with the same value will overwrite the current configuration. Valid SPI range is **256** to **4294967295**.
esp	Specifies that ESP is used.
null	Specifies that OSPFv3 messages on this interface are not encrypted when used in the **ospfv3 encryption null** format (even when encryption is specified by the OSPFv3 area configuration). When used in the **ospfv3 encryption ipsec spi** <*spi*> **esp null** format, **null** indicates that messages on the interface will not be encrypted, but will be authenticated.
<*encryption type*>	Specifies the type of algorithm used to encrypt OSPFv3 messages. Valid values for encryption are: **3des** uses triple data encryption standard (DES). **aes-cbc** uses advanced encryption standard (AES) with cipher block chaining (CBC). Select from **aes-cbc 128**, **aes-cbc 192**, or **aes-cbc 256**. **des** uses DES.
<*encryption key*>	Specifies the hexadecimal encryption key. The size of the encryption key is determined by the respective encryption algorithm, as follows: **3des** uses a **48** character key size. **aes-cbc 128** uses a **32** character key size. **aes-cbc 192** uses a **48** character key size. **aes-cbc 256** uses a **64** character key size. **des** uses a **16** character key size.
<*authentication type*>	Specifies the algorithm used for authenticating OSPFv3 messages. Valid authentication methods are Message-Digest 5 (**md5**) and Secure-Hash 1 (**sha1**) algorithms.

<authentication key> Specifies the hexadecimal authentication key. The size of the authentication key is determined by the respective authentication algorithm, as follows:

md5 uses a **32** character key size.

sha1 uses a **40** character key size.

Default Values

By default, there is no security for OSPFv3 messages on an interface.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

This commands specifies OSPFv3 security at the interface level. Protection specified with this command overrides any area-level OSPFv3 protection that might apply to the interface.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures OSPFv3 messages with an SPI of **120**, no encryption, and **md5** as the authentication method:

```
(config)#interface vlan 1
(config-interface-vlan 1)#ospfv3 encryption ipsec spi 120 esp null md5
    NeWtStpsswdLoonGpsswDhtThmnWoKEY
```

ospfv3 <*process id*> hello-interval <*value*>

Use the **ospfv3 hello-interval** command to specify the interval between Open Shortest Path First version 3 (OSPFv3) Hello packets sent on the interface. This value must be the same across all interfaces on the link. Use the **no** form of this command to return the Hello packet interval to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3467*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
hello-interval <*value*>	Specifies the number of seconds allowed between OSPFv3 Hello packets. Valid range is **1** to **65535** seconds.

Default Values

By default, the Hello packet interval for OSPFv3 is **10** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the interval between OSPFv3 Hello packets on the interface is **20** seconds:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ospfv3 5 hello-interval 20**

ospfv3 <*process id*> network

Use the **ospfv3 network** command to specify the network type for Open Shortest Path First version 3 (OSPFv3) enabled interfaces. Use the **no** form of this command to return the interface's network type to the default value. Variations of this command include:

ospfv3 <*process id*> **network broadcast**
ospfv3 <*process id*> **network point-to-point**

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3467*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
broadcast	Specifies that the OSPFv3 network type for the interface is set to broadcast.
point-to-point	Specifies that the OSPFv3 network type for the interface is set to point-to-point.

Default Values

By default, Ethernet interfaces are set to network type broadcast, and point-to-point (PPP), Frame Relay, and loopback interfaces are set to network type point-to-point.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the network interface as point-to-point:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ospfv3 5 network point-to-point**

ospfv3 <*process id*> priority <*value*>

Use the **ospfv3 priority** command to specify the Open Shortest Path First version 3 (OSPFv3) priority for the interface. Use the **no** form of this command to return the interface's priority to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3467*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
priority <*value*>	Specifies the OSPFv3 priority for the interface. Valid range is **0** to **255**.

Default Values

By default, the OSPFv3 priority of an interface is set to **1**.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

Priority is used in the election of the designated router and backup designated router on multi-access networks. Interfaces connected to multi-access networks (such as Ethernet interfaces) perform an election for a designated and backup designated router. The router interface with the highest OSPFv3 priority on the link becomes the designated router for that link. The interface with the next highest priority becomes the designated backup router. In the event there is a tie, the router interface with the highest router ID takes precedence. A priority value of **0** indicates the router is ineligible to become either the designated or backup designated router.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example changes the interface's OSPFv3 priority value to **6**:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ospfv3 5 priority 6**

ospfv3 <*process id*> retransmit-interval <*value*>

Use the **ospfv3 retransmit-interval** command to specify the interval between Open Shortest Path First version 3 (OSPFv3) link-state advertisements (LSAs) sent on the interface. Use the **no** form of this command to return the OSPFv3 LSA interval to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3467*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
retransmit-interval <*value*>	Specifies the number of seconds between OSPFv3 LSAs sent on the interface. Valid range is **1** to **65535** seconds.

Default Values

By default, the LSA retransmit interval is set to **5** seconds.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies the LSA retransmit interval is **10** seconds:

```
(config)#interface vlan 1
(config-interface-vlan 1)#ospfv3 5 retransmit-interval 10
```

ospfv3 <*process id*> shutdown

Use the **ospfv3 shutdown** command to disable an Open Shortest Path First version 3 (OSPFv3) process on the interface. When this command is used, the OSPFv3 commands remain in place, but logically it appears to the interface as though the OSPFv3 process has been removed from the configuration. This command can be useful in troubleshooting. Use the **no** form of this command to reinstate the OSPFv3 process.

Syntax Description

<process id>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3467*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.

Default Values

No default values are necessary for this command.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example disables OSPFv3 process **5** on the interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ospfv3 5 shutdown**

ospfv3 <*process id*> transmit-delay <*value*>

Use the **ospfv3 transmit-delay** command to specify the estimated time that is required to propagate an Open Shortest Path First version 3 (OSPFv3) link-state advertisement (LSA) on the interface. Use the **no** form of this command to return the transmit delay to the default value.

Syntax Description

<*process id*>	Specifies the OSPFv3 routing process this interface is to join. Valid process ID range is **1** to **65535**. If the process ID has not already been created (using the command *ospfv3 <process id> area <area id> on page 3467*), entering this command will not create the ID. Only one OSPFv3 process can be configured at a time; if another OSPFv3 process exists, an error is reported.
transmit-delay <*value*>	Specifies the number of seconds required to send LSAs from the interface. Valid range is **1** to **65535** seconds.

Default Values

By default, the LSA transmit delay is set to **1** second.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example changes the interface's LSA transmit delay to **2** seconds:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#ospfv3 5 transmit-delay 2**

packet-capture <*name*>

Use the **packet-capture** command to apply a previously configured packet capture instance to the interface. Use the **no** form of this command to remove the packet capture instance.

Syntax Description

<*name*>	Specifies the name of the packet capture instance to apply to the interface.

Default Values

By default, no packet capture instances are configured or applied to the interface.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

The AOS packet capture feature is used with network monitoring to effectively capture data packets as they traverse the network. For more information about packet capturing, its uses, and its implementation in AOS, refer to the configuration guide *Configuring Packet Capture in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example applies the previously configured packet capture **1CAPTURE** to the interface:

(config)**#interface vlan 1**
(config-vlan 1)**#packet-capture 1CAPTURE**

qos-policy

Use the **qos-policy** command to apply a previously configured quality of service (QoS) map to incoming or outgoing packets on an interface. Use the **no** form of this command to remove the map from the interface. Variations of this command include:

qos-policy in *<name>*
qos-policy out *<name>*

Syntax Description

<name>	Specifies the name of a previously created QoS map (refer to *qos map <name> <number> on page 1673* for more information).
in	Assigns a QoS map to this interface's input.
out	Assigns a QoS map to this interface's output.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.
Release 15.1	Command was expanded to include the **in** parameter.

Functional Notes

When a QoS policy is applied to an interface, it may be disabled if the interface bandwidth is not adequate to support the requested bandwidth on the map set. Once the bandwidth problem is resolved, the map will work again. The bandwidth will be rechecked on any of the following changes:

1. A priority or class-based entry is added to, deleted from, or changed in a QoS map set.
2. The interface bandwidth is changed by the **bandwidth** command on the interface.
3. A QoS policy is applied to an interface.
4. A cross connect is created that includes an interface with a QoS policy.
5. The interface queuing method is changed to fair-queue to use weighted fair queuing (WFQ).
6. The interface operational status changes.
7. The interface bandwidth changes for other reasons (e.g., when asymmetric digital subscriber line (ADSL) finishes training).

In order to prevent the map from being disabled in cases of temporary inadequate bandwidth (e.g., a single link goes down in a dual T1 multilink configuration where the map requests more than one T1's worth of bandwidth), the QoS map uses the maximum theoretical bandwidth on an interface, not the actual bandwidth at that time. This actually helps QoS keep higher priority class-based traffic working better than best-effort traffic when the bandwidth drops.

Usage Examples

The following example applies the QoS map **VOICEMAP** to the virtual local area network (VLAN) interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#qos-policy out VOICEMAP**

rtp quality-monitoring

Use the **rtp quality-monitoring** command to enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets on this interface. If the global command (**ip rtp quality-monitoring**) is disabled when this command is issued, the system will return the following warning: "Applied but not used, you must globally enable **ip rtp quality-monitoring** to use VQM." Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, VQM is enabled on all wide area network (WAN) and local area network (LAN) interfaces.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables RTP quality monitoring on the virtual local area network (VLAN) interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#rtp quality-monitoring**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.

Usage Examples

The following example enables SNMP capability on the VLAN interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is set to enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release 17.2	Command was expanded to the cellular interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the VLAN interface:

(config)**#interface vlan 1**
(config-interface-vlan 1)**#no snmp trap link-status**

traffic-shape rate <*value*>

Use the **traffic-shape rate** command to specify and enforce an output bandwidth for the virtual local area network (VLAN) interface. Use the **no** form of this command to disable this feature. Variations of this command include:

traffic-shape rate <*value*>
traffic-shape rate <*value*> **count-eth-overhead**
traffic-shape rate <*value*> <*burst*>
traffic-shape rate <*value*> <*burst*> **count-eth-overhead**

Syntax Description

<*value*>	Specifies the rate (in bits per second) at which the interface should be shaped.
<*burst*>	Optional. Specifies the allowed burst in bytes. By default, the burst is specified as the rate divided by 5 and represents the number of bytes that would flow within 200 ms.
count-eth-overhead	Optional. Indicates to include the Ethernet header overhead bytes when determining packet size.

Default Values

By default, **traffic-shape rate** is disabled.

Command History

Release 10.1	Command was introduced.
Release R11.1.0	Command was expanded to include the **count-eth-overhead** parameter, system management Ethernet virtual connection (EVC) and the system control EVC.

Functional Notes

Traffic shaping can be used to limit the VLAN interface to a particular rate or to specify use of quality of service (QoS).

Usage Examples

The following example sets the outbound rate of **vlan 1** to 128 kbps and applies a QoS policy that gives all Realtime Transport Protocol (RTP) traffic priority over all other traffic:

(config)**#qos map voip 1**
(config-qos-map)**#match ip rtp 10000 10500 all**
(config-qos-map)**#priority unlimited**
(config-qos-map)**#interface vlan 1**
(config-interface-vlan 1)**#traffic-shape rate 128000**
(config-interface-vlan 1)**#qos-policy out voip**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an interface to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the interface from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an interface's VRF association will clear all IP-related settings on that interface.

Syntax Description

<name>	Specifies the name of the VRF to which to assign the interface.

Default Values

By default, interfaces are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release 17.8	The keyword **ip** was removed from this command.

Functional Notes

VRF instances must be created first before an interface can be assigned. An interface can only be assigned to one VRF, but multiple interfaces can be assigned to the same VRF.

An interface will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the VLAN interface to the VRF instance named **RED**:

(config)**#interface vlan 1**
(config-vlan1)**#vrf forwarding RED**

vrrp <*number*>

Use the **vrrp** command to configure Internet Protocol version 4 (IPv4) Virtual Router Redundancy Protocol version 2 (VRRPv2) routers within a router group. Use the **no** form of this command to remove the VRRP router's configurations. Variations of this command include:

vrrp <*number*> **description** <*text*>
vrrp <*number*> **ip** <*ipv4 address*>
vrrp <*number*> **ip** <*ipv4 address*> **secondary**
vrrp <*number*> **preempt**
vrrp <*number*> **preempt delay minimum** <*time*>
vrrp <*number*> **priority** <*level*>
vrrp <*number*> **shutdown**
vrrp <*number*> **startup-delay** <*delay*>
vrrp <*number*> **timers advertise** <*interval*>
vrrp <*number*> **timers learn**
vrrp <*number*> **track** <*name*>
vrrp <*number*> **track** <*name*> **decrement** <*value*>

Syntax Description

<*number*>	Specifies the VRRP router group's virtual router ID (VRID) number. Range is **1** to **255**.
description <*text*>	Specifies the textual description of the VRRP router within the group.
ip <*ipv4 address*>	Specifies the IPv4 address to be used by the VRRP router. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
secondary	Optional. Specifies the entry of an additional VRRP router supported IPv4 address.
preempt	Allows a VRRP router to preempt the current master router if its priority level is higher than the current master's.
delay minimum <*time*>	Optional. Specifies a delay (in seconds) before the specified router will attempt to preempt the current master router. Range is **0** to **255** seconds.
priority <*level*>	Specifies the configured priority level of the VRRP router. Range is **1** to **254**.
shutdown	Disables the VRRP router.
startup-delay <*delay*>	Specifies a time delay (in seconds) before a VRRP router becomes active. Range is **0** to **255** seconds.
timers	Specifies the configuration of the VRRP timers.
advertise <*interval*>	Specifies the time (in seconds) between advertisements sent by the master router. Range is **1** to **255** seconds.
learn	Specifies that the backup VRRP router learns the advertisement interval of the master router.
track <*name*>	Specifies a change in priority level of the VRRP router based upon the specified track.
decrement <*value*>	Optional. Specifies the numerical amount to decrement the VRRP's priority level if the track transitions to a FAIL state. Range is **1** to **254**.

Default Values

By default, VRRP is enabled.

By default, a VRRP router will preempt with no additional delay.

The default configured priority for a VRRP router that is either a backup router or not the IP address owner is **100**. The default actual priority of a VRRP router that is the IP address owner is **255**.

By default, startup-delay is enabled with a default value of **35** seconds.

By default, the advertisement interval is **1** second.

By default, the default decrement value is **10**.

Command History

Release 16.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet subinterface.

Functional Notes

A VRRP router may be part of more than one virtual router group. Although VRRP group VRIDs can be numbered between 1 and 255, only two VRRP routers per interface are supported.

Adtran recommends that the **timers advertise** setting is kept at the default value. If it is necessary to change this setting, ensure that all VRRP routers are configured with the new value, as all VRRP routers in the virtual group must have the same advertisement interval value. It is also recommended that if the **timers learn** function is enabled on one router in a virtual router group, then the **timers learn** function should be enabled on all routers in the group.

When the virtual router's specified IPv4 address is independent of the IPv4 addresses assigned to real interfaces on the VRRP routers, there is no IPv4 address owner. This addressing method is preferred if object tracking will be used to monitor the network connection. The IPv4 address used for the virtual router must be on the same subnet as either the primary or secondary IPv4 addresses assigned to the VRRP router's real interface.

A track must be created before the **vrrp track** command can be issued. Refer to the *Network Monitor Track Command Set on page 4098* for more information on creating tracks. If a VRRP router owns the virtual router IP address, then the VRRP router's priority level cannot be decremented as a result of the track command. If object tracking will be used, it is important that no VRRP router own the virtual router IP address.

Usage Examples

The following example describes a VRRP router within virtual router group **1** as the **Default Master Router**:

(config)**#interface vlan 1**
(config-interface-vlan 1))**#vrrp 1 description Default Master Router**

The following example specifies an IPv4 address of **10.0.0.1** for a VRRP router within virtual router group **1**:

(config)**#interface vlan 1**
(config-interface-vlan 1))**#vrrp 1 ip 10.0.0.1**

The following example specifies that the VRRP router within virtual router group **1** preempts the current master router after a **30** second delay:

(config)**#interface vlan 1**
(config-interface-vlan 1))**#vrrp 1 preempt delay minimum 30**

The following example specifies the configured priority for the VRRP router within virtual router group **1** is **254**:

(config)**#interface vlan 1**
(config-interface-vlan 1))**#vrrp 1 priority 254**

The following example disables the VRRP router within virtual router group **1**:

(config)**#interface vlan 1**
(config-interface-vlan 1))**#vrrp 1 shutdown**

The following example configures a VRRP router on group **1** to delay **45** seconds before becoming active:

(config)**#interface vlan 1**
(config-interface-vlan 1))#vrrp 1 startup-delay 45

vrrpv3 <*vrid*> address-family

Use the **vrrpv3 address-family** command to configure Virtual Router Redundancy Protocol version 3 (VRRPv3) routers on the interface. This command enables VRRPv3, creates a virtual router ID (VRID), and specifies whether you are using Internet Protocol version 4 (IPv4) or IP version 6 (IPv6) VRRPv3. Use the **no** form of this command to remove the VRRPv3 router configuration. Variations of this command include:

vrrpv3 <*vrid*> **address-family ipv4**
vrrpv3 <*vrid*> **address-family ipv6**

Syntax Description

<*vrid*>	Specifies the VRID for the virtual router instance. This value is advertised by VRRPv3 and is used to generate the virtual router medium access control (MAC) address. Valid range is **1** to **255**.
ipv4	Specifies that IPv4 is used with VRRPv3, and enters the virtual router instance's configuration mode.
ipv6	Specifies that IPv6 is used with VRRPv3, and enters the virtual router instance's configuration mode.

Default Values

By default, VRRPv3 is not configured.

Command History

Release R10.11.0	Command was introduced. This command replaces **vrrpv3** <*vrid*> on the interface.

Functional Notes

VRID values must be the same on all routers that are part of the virtual router group. VRID numbering is independent between VRRPv3 IPv4 and IPv6 address families. Once the VRRPv3 VRID is created and the address family is specified, the virtual router instance's configuration mode is entered. Only two VRIDs per interface per IP version are supported. For more information about configuring the VRRPv3 instance, refer to *VRRPv3 Command Set on page 4221*.

Usage Examples

The following example enables IPv4 VRRPv3, creates a VRID of **15** for the instance, and enters the virtual router instance's configuration mode:

(config)**#interface vlan 1**
(config-vlan 1)**#vrrpv3 15 address-family ipv4**
(config-if-vrrpv3 15)#

The following example enables IPv6 VRRPv3, creates a VRID of **6** for the instance, and enters the virtual router instance's configuration mode:

(config)**#interface vlan 1**
(config-vlan 1)**#vrrpv3 6 address-family ipv6**
(config-if-vrrpv3 6)#

WIRELESS INTERFACE COMMAND SETS

This section includes the following command sets:

NETVANTA 150 AP INTERFACE COMMAND SET

The NetVanta 150 Access Point Interface Configuration command set is used to configure wireless access points (APs) connecting to an AOS platform running the Adtran Wireless Control Protocol (AWCP). The AP is either a physical standalone unit (such as the NetVanta 150) or integrated within an AOS platform via a module, also known as an embedded access point module (EAPM).

Enter the **interface dot11ap** *<ap | ap/radio | ap/radio.vap>* **ap-type nv150** command at the Global Configuration mode prompt to activate the NetVanta 150 AP Interface Configuration mode. For example:

```
>enable
#configure terminal
(config)#interface dot11ap 1 ap-type nv150
(config-dot11ap 1)#
```

Additional steps must be performed before the NetVanta 150 AP is ready for connectivity. The radio-level settings are configured using the NetVanta 150 Radio Interface Command Set on page 3510. The virtual access point (VAP) settings are configured using the NetVanta 150 VAP Interface Command Set on page 3533.

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

access-point controller-standby on page 3495
access-point mac-address <mac address> on page 3496
association access-list <name> on page 3497
country-region on page 3498
encapsulation 802.1q on page 3500
ethernet-speed on page 3502
event-history on page 3503
full-duplex on page 3504
half-duplex on page 3505
ip address <ipv4 address> <subnet mask> on page 3506
ip default-gateway <ipv4 address> on page 3507
location <name> on page 3508
name <name> on page 3509

access-point controller-standby

Use the **access-point controller-standby** command to release wireless access controller (AC) control of the NetVanta 150 wireless access point (AP). This command will cause the AC to stop responding to echo requests from the AP, releasing control of the AP. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, controller-standby mode is disabled.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Usage Examples

The following example enables controller-standby mode for this AP interface:

(config)**#interface dot11ap 1 ap-type nv150**
(config-dot11ap 1)**#access-point controller-standby**

access-point mac-address *<mac address>*

Use the **access-point mac-address** command to specify the medium access control (MAC) address of the NetVanta 150 wireless access point (AP) physical Ethernet interface. Use the **no** form of this command to delete the MAC address of the AP.

Syntax Description

<mac address>	Specifies a valid 48-bit MAC address. MAC addresses should be expressed in the following format xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).

Default Values

No default values are necessary for this command.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Functional Notes

This command binds the wireless access controller (AC) to the AP. Without specifying the MAC address, the AC cannot control the AP.

Usage Examples

The following example configures an AP MAC address of **00:0A:C8:5F:00:D2**:

(config)**#interface dot11ap 1 ap-type nv150**
(config-dot11ap 1)**#access-point mac-address 00:0A:C8:5F:00:D2**

association access-list <*name*>

Use the **association access-list** command to specify a medium access control (MAC) address filter. This filter will only allow access to specific wireless clients. A MAC access control list (ACL) must be created before it can be associated with this NetVanta 150 wireless access point (AP). Refer to *mac access-list standard <name> on page 1606* for more information. Use the **no** form of this command to remove an associated MAC ACL from this AP.

Syntax Description

<name>	Specifies the name of the previously created MAC ACL.

Default Values

By default, no MAC ACLs are associated with an AP.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Usage Examples

The following example configures the AP to use the MAC ACL named **ALLOWLIST** as a filter for allowing access:

(config)**#interface dot11ap 1 ap-type nv150**
(config-dot11ap 1)**#association access-list ALLOWLIST**

country-region

Use the **country-region** command to specify the country region or domain where the NetVanta 150 wireless access point (AP) is being used so that the radio can modify its settings to conform to that country's regulations. Use the **no** form of this command to return to the default value. Variations of this command include:

country-region Asia
country-region Australia
country-region Canada
country-region Denmark
country-region Europe
country-region Finland
country-region France
country-region Germany
country-region Ireland
country-region Italy
country-region Japan
country-region Mexico
country-region Netherlands
country-region New_Zealand
country-region Norway
country-region Puerto_Rico
country-region South_America
country-region Spain
country-region Sweden
country-region Switzerland
country-region UK
country-region USA

Syntax Description

Asia	Specifies Asia configuration.
Australia	Specifies Australia configuration.
Canada	Specifies Canada configuration.
Denmark	Specifies Denmark configuration.
Europe	Specifies Europe configuration.
Finland	Specifies Finland configuration.
France	Specifies France configuration.
Germany	Specifies Germany configuration.
Ireland	Specifies Ireland configuration.
Italy	Specifies Italy configuration.
Japan	Specifies Japan configuration.
Mexico	Specifies Mexico configuration.
Netherlands	Specifies Netherlands configuration.

New_Zealand	Specifies New Zealand configuration.
Norway	Specifies Norway configuration.
Puerto_Rico	Specifies Puerto Rico configuration.
South_America	Specifies South America configuration.
Spain	Specifies Spain configuration.
Sweden	Specifies Sweden configuration.
Switzerland	Specifies Switzerland configuration.
UK	Specifies UK configuration.
USA	Specifies USA configuration.

Default Values

By default, the country-region is set to **USA**.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Usage Examples

The following example sets the country of operation to **Norway**:

(config)**#interface dot11ap 1 ap-type nv150**
(config-dot11ap 1)**#country-region Norway**

encapsulation 802.1q

Use the **encapsulation 802.1q** command to set the NetVanta 150 wireless access point (AP) for virtual local area network (VLAN) encapsulation 802.1q mode. This will apply VLAN tags to the user traffic. Use the **no** form of this command to disable VLAN encapsulation. Variations of this command include:

encapsulation 802.1q
encapsulation 802.1q awcp-vlan <*vlan id*> **native**
encapsulation 802.1q awcp-vlan <*vlan id*> **native priority** <*level*>

Syntax Description

awcp-vlan <*vlan id*>	Optional. Specifies an existing VLAN to be used for Adtran Wireless Control Protocol (AWCP) connection. Valid range is **1** to **4096**. For more information on creating a VLAN, refer to *VLAN Interface Command Set on page 3370*.
native	Enables native mode for the specified VLAN. Packets from this VLAN leaving the interface will not be tagged with the VLAN number. Any untagged packets received by the interface are considered a part of the native VLAN ID. Only one VLAN may be set to **native**. To change where the native VLAN resides, the current native must be disabled using the **no** form of this command before a new one is set.
priority <*level*>	Optional. Specifies the 802.1q priority level for AWCP packets generated by this AP when VLAN tags are applied. Valid range is **1** to **7**, with 1 being the highest priority.

Default Values

By default, **encapsulation 802.1q** is disabled on the AP.

Command History

Release 6.1	Command was introduced.
Release 15.1	Command was expanded to include the access point (AP) interface.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Functional Notes

Settings (including encapsulation, VLAN, and native VLAN) for the AP's Ethernet interface must be coordinated with the physical interface to which the AP is connected.

Since all functions on an AP use the same Ethernet interface, there should be only one VLAN ID set to **native** on the entire AP. It is possible that a VLAN can be used on a virtual access point (VAP) and for the AWCP protocol on the AP’s Ethernet, but this is not typical. Typically, the control protocol will use the native VLAN and the VAP’s data will all be tagged on the Ethernet.

This means that one VLAN on one radio's VAP may be set to **native** or the control protocol (AWCP) VLAN may be set to **native**, but not both unless they both use the same VLAN ID. Typically, the control protocol will use the native VLAN.

If the control protocol and a VAP share the same VLAN ID, control protocol packets will be intercepted by the AP while noncontrol protocol packets will be forwarded to the VAP.

If the AP is to be in trunk mode and the AWCP VLAN is not the native VLAN for the trunk, care must be exercised in transitioning the AP and switchport from access port (nontrunk) mode. The AP should be configured first, then the switchport set to match. When transitioning the AP, set its AWCP VLAN first, then enable trunking mode (encapsulation 802.1q). If the AWCP VLAN is the native VLAN on the AP and switch, AWCP communication will not be lost no matter what combination of trunk mode settings is applied.

Usage Examples

The following example enables encapsulation 802.1q on this AP and makes VLAN 1 the native VLAN:

(config)**#interface dot11ap 1 ap-type nv150**
(config-dot11ap 1)**#encapsulation 802.1q awcp-vlan 1 native**

ethernet-speed

Use the **ethernet-speed** command to configure the speed of the NetVanta 150 wireless access point's (AP) Ethernet interface. Use the **no** form of this command to return to the default value. Variations of this command include:

ethernet-speed 10
ethernet-speed 100
ethernet-speed auto

This command is not available for the embedded access point module (EAPM). For the EAPM, the Ethernet speed is fixed at 100 Mbps.

Syntax Description

10	Configures the AP's Ethernet speed for 10 Mbps.
100	Configures the AP's Ethernet speed for 100 Mbps.
auto	Configures the AP's Ethernet speed for auto negotiation.

Default Values

By default, the **ethernet-speed** is set to **auto**.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example sets the AP's Ethernet speed to 10 Mbps:

(config)**#interface dot11ap 1 ap-type nv150**
(config-dot11ap 1)**#ethernet-speed 10**

event-history

Use the **event-history** command to configure the NetVanta 150 wireless access point (AP) to transmit log messages to the wireless access controller (AC) via the control protocol. The AC will then integrate these messages into the AC's event subsystem for local display, history, or syslog forwarding. Use the **no** form of this command to terminate log messages. Variations of this command include:

event-history on
event-history priority <*level*>

Syntax Description

on	Enables the AP to send log messages to the AC.
priority <*level*>	Sets the minimum priority level of messages sent to the AC. This setting is provided on a per-AP basis so that the user can control the level of logging traffic that will occur on their network. The levels are: 1 (Alert), 2 (Critical), 3 (Error), 4 (Warning), 5 (Notice), 6 (Informational).

Default Values

By default, event history transmission is disabled and the priority level is **3**. This means that messages with levels 1 through 3 will be sent, and messages with level 4 through 6 will not be sent.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example changes the minimum priority level of the log messages sent to the AC to **6**. This will send all log messages to the AC:

(config)**#interface dot11ap 1 ap-type nv150**
(config-dot11ap 1)**#event-history priority 6**

full-duplex

Use the **full-duplex** command to configure the NetVanta 150 wireless access point (AP) Ethernet interface for full-duplex operation. This allows the interface to send and receive simultaneously. Use the **no** form of this command to return to the default **half-duplex** operation.

This command is not available for the embedded access point module (EAPM). The EAPM is fixed at full-duplex operation.

Syntax Description

No subcommands.

Default Values

By default, all AP Ethernet interfaces are configured for **half-duplex** operation.

Command History

Release 15.1	Command was introduced for the AP interface.

Functional Notes

Full-duplex Ethernet is a variety of Ethernet technology currently being standardized by the IEEE. Because there is no official standard, vendors are free to implement their independent versions of full-duplex operation. Therefore, it is not safe to assume that one vendor's equipment will work with another.

Devices at each end of a full-duplex link have the ability to send and receive data simultaneously over the link. Theoretically, this simultaneous action can provide twice the bandwidth of normal (half-duplex) Ethernet. To deploy full-duplex Ethernet, each end of the link must only connect to a single device. With only two devices on a full-duplex link, there is no need to use the medium access control mechanism (to share the signal channel with multiple stations) and listen for other transmissions or collisions before sending data.

Usage Examples

The following example configures the AP's Ethernet interface for **full-duplex** operation:

(config)**#interface dot11ap 1 ap-type nv1500**
(config-dot11ap 1)**#full-duplex**

half-duplex

Use the **half-duplex** command to configure the NetVanta 150 wireless access point's (AP) Ethernet interface for half-duplex operation. This setting allows the Ethernet interface to either send or receive at any given moment, but not simultaneously. Use the **no** form of this command to disable half-duplex operation.

This command is not available for the embedded access point module (EAPM). The EAPM is fixed at full-duplex operation.

Syntax Description

No subcommands.

Default Values

By default, all Ethernet interfaces are configured for **half-duplex** operation.

Command History

Release 15.1	Command was introduced for the AP interface.

Functional Notes

Half-duplex Ethernet is the traditional form of Ethernet that employs the carrier sense multiple access/collision detect (CSMA/CD) protocol to allow two or more hosts to share a common transmission medium while providing mechanisms to avoid collisions. A host on a half-duplex link must listen on the link, and only transmit when there is an idle period. Packets transmitted on the link are broadcast (so it will be heard by all hosts on the network). In the event of a collision (two hosts transmitting at once), a message is sent to inform all hosts of the collision and a backoff algorithm is implemented. The backoff algorithm requires the station to remain silent for a random period of time before attempting another transmission. This sequence is repeated until a successful data transmission occurs.

Usage Examples

The following example configures the AP Ethernet interface for **half-duplex** operation:

(config)**#interface dot11ap 1 ap-type nv150**
(config-dot11ap 1)**#half-duplex**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address for the NetVanta 150 access point (AP) Ethernet interface. Use the **no** form of this command to remove a configured IPv4 address.

Syntax Description

<ipv4 address>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**).

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 15.1	Command was introduced for the AP interface.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Functional Notes

The IPv4 address and subnet mask are only needed on the AP interface if the user wants to use remote authentication dial-in user service (RADIUS) authentication with the wireless clients. A default gateway may also need to be specified.

Usage Examples

The following example configures an IPv4 address of **192.22.72.101** and a subnet mask of **255.255.255.252**:

(config)**#interface dot11ap 1 ap-type nv150**
(config-dot11ap 1)**#ip address 192.22.72.101 255.255.255.252**

ip default-gateway *<ipv4 address>*

Use the **ip default-gateway** command to assign a default gateway to the NetVanta 150 wireless access point (AP). This allows the AP to communicate with Internet Protocol version 4 (IPv4) devices on other IPv4 subnets. Use the **no** form of this command to remove the default gateway.

Syntax Description

<ipv4 address>	Specifies the default gateway IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, there is no configured default gateway.

Command History

Release 15.1	Command was introduced for the AP interface.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Usage Examples

The following example assigns the AP a default gateway for **10.10.10.1**:

(config)**#interface dot11ap 1 ap-type nv150**
(config-dot11ap 1)**#ip default-gateway 10.10.10.1**

location *<name>*

Use the **location** command to specify the location of the NetVanta 150 wireless access point (AP). Use the **no** form of this command to remove the specified location.

Syntax Description

<name>	Specifies the name of the location of the AP. The location name may be up to 32 characters.

Default Values

No default values are necessary for this command.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Usage Examples

The following example assigns the name **FLOOR5** as the location of AP 1:

(config)**#interface dot11ap 1 ap-type nv150**
(config-dot11ap 1)**#location FLOOR5**

name <*name*>

Use the **name** command to specify a name for this NetVanta 150 wireless access point (AP). Use the **no** form of this command to remove the assigned name.

Syntax Description

<*name*>	Specifies the name of the AP. The name may be up to 32 characters in length.

Default Values

By default, the name of the AP will be ADTN plus the last three bytes of the AP medium access control (MAC) address (all uppercase).

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Usage Examples

The following example assigns the name **ACCOUNTING1** to AP 1:

(config)**#interface dot11ap 1 ap-type nv150**
(config-dot11ap 1)**#name ACCOUNTING1**

NETVANTA 150 RADIO INTERFACE COMMAND SET

A NetVanta 150 radio interface is a virtual interface that can be programmed into an AOS platform running the Adtran Wireless Control Protocol (AWCP). This interface is used to configure radio-level commands for an 802.11 wireless access point (AP). The AP is either a physical standalone unit (such as the NetVanta 150) or integrated within the AOS platform via a module, also known as an embedded access point module (EAPM).

The associated AP interface must be configured before access to the Radio Interface Configuration mode is possible. For more information on configuring the AP, refer to *NetVanta 150 AP Interface Command Set on page 3494*. Upon creation, each radio will have one default virtual access point (VAP) configured. More detailed information on configuring the VAP interface is provided in *NetVanta 150 VAP Interface Command Set on page 3533*.

There are only two radio types: 802.11a and 802.11bg. Radio 802.11bg defaults to **interface dot11ap** <*ap*/**1**> and radio 802.11a defaults to **interface dot11ap** <*ap*/**2**>. The only changes that can be made to the radio types is to specify the radio mode of the 802.11bg radio as type b, g, or bg using the command *radio-mode on page 3523*.

The parent (AP) interface must be created before access to the Radio Interface Configuration mode is possible. Execute the ***interface dot11ap*** *<ap> command to create an AP interface.*

To activate Radio Interface Configuration mode for an 802.11b or g radio, enter the commands at the Global Configuration mode prompt as shown below:

```
>enable
#configure terminal
(config)#interface dot11ap 1/1
(config-dot11ap 1/1-bg)#
```

To activate Radio Interface Configuration mode for an 802.11a radio, enter the commands at the Global Configuration mode prompt as shown below:

```
>enable
#configure terminal
(config)#interface dot11ap 1/2
(config-dot11ap 1/2-a)#
```

By default, ***interface dot11ap*** *<ap/**1**> is radio type 802.11bg and* ***interface dot11ap*** *<ap/**2**> is radio type 802.11a.*

*Not all radio interface commands apply to both radio types.Use the **?** command to display a list of valid commands.*

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

antenna

Use the **antenna** command to select the desired antenna mode. Use the **no** form of this command to return to the default value. Variations of this command include the following:

antenna 1
antenna 2
antenna diversity

Syntax Description

1	Sets the antenna mode to transmit or receive on antenna 1.
2	Sets the antenna mode to transmit or receive on antenna 2.
diversity	Sets the mode to transmit or receive on antenna with best signal.

Default Values

By default, the antenna is set to **diversity**.

Command History

Release 15.1	Command was introduced.

Functional Notes

Diversity antennas are two separate antennas that are attached to a single wireless radio. These antennas are designed to reduce the effects of multi-path radio distortion. Each antenna samples the radio signal around the access point (AP). The antenna receiving the best signal is chosen to transmit and receive information. Only one diversity antenna is in use at any given time.

Usage Examples

The following example sets the antenna mode to transmit or receive on antenna 1 on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#antenna 1**

beacon period *<time>*

Use the **beacon period** command to set the time between beacons. Use the **no** form of this command to return to the default value.

Syntax Description

<time>	Specifies the number of 802.11 time units (TUs) between beacons. One TU is 1024 microseconds. Range is **20** to **1000** TU.

Default Values

By default, the beacon period is **100** TU.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Functional Notes

A beacon is a type of management frame used in 802.11 wireless networks. Beacon frames carry important information, such as the basic service set, parameter sets, and capability. The beacon frame is sent to the broadcast medium access control (MAC) address, which means that all clients must be able to receive and process beacons.

Beacon frames are associated with some overhead, which decreases the throughput of the wireless network. The higher the beacon period, the fewer number of beacons sent, thus reducing overhead and increasing throughput on the network. However, fewer beacons can cause a delay in the association process because stations scanning for available access points (APs) may miss the beacons.

Usage Examples

The following example sets the beacon period to 500 TU on an 802.11 bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#beacon period 500**

channel <*number*>

Use the **channel** command to manually select a channel for the wireless radio or to scan for the best channel available. Use the **no** form of this command to return to the default value. Variations of this command include the following:

channel <*number*>
channel least-congested

Syntax Description

<*number*>	Specifies the Institute of Electrical and Electronics Engineers, Inc. (IEEE) channel number. The range of channels is dependent on the radio type and country setting
least-congested	Sets the radio to scan for the best channel available.

Default Values

By default, the radio scans for the least-congested channel available.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Functional Note

*Type **channel ?** to display a list of valid channels from which to choose. The list of channels displayed is based on the selected radio type (refer to the command radio-mode on page 3523) and country setting (refer to the command country-region on page 3498).*

Usage Examples

The following example manually sets an 802.11bg wireless radio to channel 6 in the United States:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#channel 6**

The following example manually sets an 802.11a wireless radio to channel 149 in the United States:

(config)**#interface dot11ap 1/2 radio-type 802.11a**
(config-dot11ap 1/1-a)**#channel 149**

fragment-threshold *<length>*

Use the **fragment-threshold** command to set the packet length threshold. Packets larger than the value set in this command will be fragmented when transmitted on the wireless link. Use the **no** form of this command to return to the default value.

Syntax Description

<length>	Specifies the maximum packet length allowed before fragmentation will occur. Range is **256** to **2346** bytes.

Default Values

By default, the fragment threshold is set at **2346** bytes.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Functional Notes

The fragment threshold can be set to a lower number to prevent retransmission of large packets, but the overhead will increase. If the threshold is large, the overhead is relatively small but large packets will be retransmitted, lowering efficiency.

Usage Examples

The following example sets the fragment threshold at **572** bytes on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#fragment-threshold 572**

inactivity-timeout max <*value*>

Use the **inactivity-timeout max** command to set the maximum length of inactivity allowed between an access point (AP) and its clients. If no response is seen from the client within the timeout, the client will be disassociated. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the maximum length of time a connection between an AP and a client is allowed to remain inactive. Range is **1** to **99** minutes.

Default Values

By default, the maximum inactivity timeout is **5** minutes.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Usage Examples

The following example sets the maximum inactivity timeout to **2** minutes on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#inactivity-timeout max 2**

power local

Use the **power local** command to select the radio's transmit power level. The range of the power level is relative to the country region currently specified for the radio. Use the **no** form of this command to return to the default value. Variations of this command include:

power local eighth
power local half
power local maximum
power local minimum
power local quarter

Syntax Description

eighth	Sets the power local level to one-eighth of the maximum output power setting.
half	Sets the power local level to one-half of the maximum output power setting.
maximum	Sets the power local level to the maximum output power setting.
minimum	Sets the power local level to the minimum output power setting.
quarter	Sets the power local level to one-fourth of the maximum output power setting.

Default Values

By default, the power local setting is **maximum**.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Functional Notes

Radio cell size and interference between cells can be reduced by lowering the radio's transmit power level.

Usage Examples

The following example sets the radio's transmit power to one-half maximum power on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#power local half**

preamble-short

Use the **preamble-short** command to enable short preamble mode on an 802.11bg radio. The preamble is information at the beginning of a packet that is used by the access point (AP), as well as its clients. Use the **no** form of this command to return to the default value.

Syntax Description

No subcommands.

Default Values

By default, short preamble mode is enabled.

Command History

Release 15.1	Command was introduced.

Functional Notes

When short preamble mode is enabled, clients may request short or long preambles according to need. Disabling short preamble mode means that clients must request long preambles only.

Short preamble mode is not supported on the 5 GHz 802.11a radio.

Usage Examples

The following example enables short preamble mode on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#preamble-short**

protection-mode

Use the **protection-mode** command to configure the protection mode, type, and rate for an 802.11bg radio. Use the **no** form of this command to return to the default value. Variations of this command include the following:

protection-mode always
protection-mode always type cts-only
protection-mode always type cts-only rate 1
protection-mode always type cts-only rate 2
protection-mode always type cts-only rate 5.5
protection-mode always type cts-only rate 11
protection-mode always type rts-cts
protection-mode always type rts-cts rate 1
protection-mode always type rts-cts rate 2
protection-mode always type rts-cts rate 5.5
protection-mode always type rts-cts rate 11
protection-mode auto
protection-mode auto type cts-only
protection-mode auto type cts-only rate 1
protection-mode auto type cts-only rate 2
protection-mode auto type cts-only rate 5.5
protection-mode auto type cts-only rate 11
protection-mode auto type rts-cts
protection-mode auto type rts-cts rate 1
protection-mode auto type rts-cts rate 2
protection-mode auto type rts-cts rate 5.5
protection-mode auto type rts-cts rate 11

This command is only available on the 802.11bg radio interface.

Syntax Description

always	Protection mode is always on regardless of the presence of 802.11b clients.
auto	Protection mode is automatically activated when an 802.11b client associates with an 802.11g access point (AP).
type	
cts-only	Specifies clear to send-only (CTS-only) protection mode.
rts-cts	Specifies request to send-clear to send (RTS-CTS) protection mode.
rate	
1	Sets the packet rate to 1 Mbps.
2	Sets the packet rate to 2 Mbps.

5.5	Sets the packet rate to 5.5 Mbps.
11	Sets the packet rate to 11 Mbps.

Default Values

By default, **protection-mode** is set to **auto**, **type** is set to **cts-only**, and the **rate** is set to **11**.

Command History

Release 15.1	Command was introduced

Functional Notes

Protection mode is used when 802.11b and 802.11g radios exist together on the same wireless local area network (WLAN) network. 802.11g devices are required to be backwards-compatible with legacy 802.11b devices. Both radios operate in the 2.4 GHz frequency range; however, each uses a different transmission type. 802.11b radios use direct sequence spread spectrum (DSSS) for transmitting data, and 802.11g radios use orthogonal frequency division multiplexing (OFDM) for transmitting data. Contention for media access on 802.11 networks is managed via carrier sense multiple access with collision avoidance (CSMA/CA), but the use of two different transmission types prevents 802.11b devices from hearing transmission attempts on the shared radio frequency (RF) medium. Protection mode addresses this problem and allows for coexistence of 802.11b and 802.11g devices on a network.

There are two protection mode types: CTS-only, also known as CTS-to-self, and RTS-CTS. Both types are used when an 802.11g AP associates with an 802.11b client. Compared to a network that contains solely 802.11g clients, use of a protection mode reduces throughput. Compared to each other, CTS-only mode requires slightly less protocol overhead than RTS-CTS mode. Protection frames must be transmitted at 802.11b rates (1 Mbps, 2 Mbps, 5.5 Mbps, or 11 Mbps) to ensure these frames are received and processed by all clients on the network.

During CTS-only mode, clients that have a frame for transmission on the RF medium will first transmit a CTS frame. The destination address specified in this CTS frame is the transmitting client's own medium access control (MAC) address. All clients connected to the RF medium are required to listen to CTS frames. A CTS frame is interpreted as a *do not send* command by all clients except by the one whose MAC address is specified in the destination field.

When RTS-CTS is employed, clients must request access to the RF medium by sending an RTS to the AP. The client refrains from accessing the medium and transmitting data until it receives a CTS from the AP. A CTS command is interpreted as a *do not send* command when it is received by a client that did not initiate the RTS. RTS-CTS requires more protocol overhead than CTS-only.

Usage Examples

The following example enables protection mode to automatically activate upon association of an 802.11b client with an 802.11g AP. RTS-CTS is specified, but the rate is not. This means that the default rate of 11 Mbps will be used.

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#protection-mode auto type rts-cts**

qos-mode wmm

Use the **qos-mode wmm** command to enable WiFi multimedia (WMM) quality of service (QoS) mode. Use the **no** form of this command to disable WMM mode. Variations of this command include the following:

qos-mode wmm
qos-mode wmm no-ack

Syntax Description

no-ack	Optional. Specifies the no acknowledgements be sent.

Default Values

By default, WMM QoS mode is disabled.

Command History

Release 15.1	Command was introduced.

Functional Notes

AOS supports WMM, which adds QoS functionality to the wireless network. QoS helps control the allocation of bandwidth on the wireless local area network (WLAN). The benefits of QoS may not be noticed if the traffic load on the wireless network is light. However, QoS benefits will become more apparent as the traffic load on the WLAN increases.

WMM in AOS is based on the enhanced distributed channel access (EDCA) method. This method ensures that higher priority traffic has a better chance of being transmitted on the WLAN than lower priority traffic. There are four priority classes defined in WMM to manage traffic from different applications: voice, video, best-effort, and background. According to algorithms defined in EDCA, a client with traffic in a higher priority class, such as voice, will typically back off of the radio frequency (RF) medium for a shorter period of time than a client with traffic in a lower priority class, such as email. In addition, each priority class is assigned a transmit opportunity (TXOP), which is a set amount of time during which a client can send as many frames as possible. Higher priority classes are given a longer TXOP interval than lower priority classes.

WMM must be enabled on both the access points (APs) and the clients running applications that require QoS. These applications must be able to support WMM for the QoS functionality to be used. In addition, the applications must be capable of assigning the appropriate priority class to their generated streams of traffic.

When acknowledgements are enabled, transmission is more reliable because an acknowledge frame is returned for every frame received. However, acknowledgement frames increase the amount of traffic on the WLAN, which results in decreased performance. Disabling acknowledgements means that transmission will not be as reliable, but performance will be better. For example, having no acknowledgements would be useful for voice traffic because the speed of transmission is most important and packet loss to a certain degree is tolerable.

Usage Examples

The following example enables WMM QoS mode without acknowledgements on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#qos-mode wmm no-ack**

radio-mode

Use the **radio-mode** command to set a specific radio type. Use the **no** form of this command to return to the default value. Variations of this command include the following:

radio-mode a
radio-mode b
radio-mode bg
radio-mode g

Syntax Description

a	Specifies radio type a.
b	Specifies radio type b.
bg	Specifies radio type g in backwards-compatible mode to radio type b.
g	Specifies radio type g.

Default Values

By default, the 802.11bg radio is set to **radio-mode bg** and the 802.11a radio is set to **radio-mode a**.

Command History

Release 15.1	Command was introduced.

Functional Notes

Adtran currently supports three of the IEEE 802.11 wireless local area network (WLAN) standards: 802.11a, 802.11b, and 802.11g. Each access point (AP) contains two integrated radios: one that supports 802.11a and one that supports 802.11b and/or 802.11g.

802.11b is a legacy protocol operating at 2.4 GHz with a maximum throughput of 11 Mbps. This throughput value is derived from the use of direct sequence spread spectrum (DSSS) technology for transmission. The North American channel set contains 11 channels, each 22 MHz wide. Out of these 11 channels, there are only three nonoverlapping or noninterfering channels. The use of three discreet access points (APs) in the same area, each set to one of the three nonoverlapping channels, will result in an aggregate bandwidth of 33 Mbps. The theoretical maximum distance for 802.11b is 100 meters. However, the actual distance is approximately 60 meters in a typical office environment.

802.11g operates at 2.4 GHz with a maximum throughput of 54 Mbps. The obvious benefit to using 802.11g over 802.11b is faster data transmission. The higher maximum throughput is achieved by using orthogonal frequency division multiplexing (OFDM) in addition to DSSS for transmission. 802.11g is backwards-compatible to 802.11b, helping to ease migration from an existing 802.11b network to an 802.11g network. However, the maximum throughput for an 802.11g network is reduced when operating in backwards-compatibility mode with 802.11b. The North American channel set for 802.11g contains 11 channels, each 22 MHz wide. Out of these 11 channels, there are only three nonoverlapping or noninterfering channels. The use of three discreet APs in the same area, each set to one of the three nonoverlapping channels, will result in an aggregate bandwidth of 162 Mbps. The theoretical maximum distance for 802.11g is 100 meters. However, the actual distance is approximately 75 meters in a typical office environment.

802.11a operates at 5.8 GHz with a maximum throughput of 54 Mbps. OFDM is used for transmission. The North American channel set for 802.11 is derived from the lower channels, UNII-1 and UNII-2, in the 5.8 GHz frequency range. There are eight nonoverlapping or noninterfering channels, each 33 MHz wide. The use of eight discreet APs in the same area, each set to one of the eight nonoverlapping channels, will result in an aggregate bandwidth of 432 Mbps. The theoretical maximum distance for 802.11a is 50 meters. However, the actual distance is approximately 25 meters in a typical office environment. 802.11a is not compatible with 802.11b or g.

The data rate associated with any of the radios will continue to drop as a user moves farther away from the AP. The highest data rates will be achieved in areas closest to the AP.

Usage Examples

The following example sets the radio mode to radio type **g** only on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#radio-mode g**

rtp quality-monitoring

Use the **rtp quality-monitoring** command to enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets on this interface. If the global command (**ip rtp quality-monitoring**) is disabled when this command is issued, the system will return the following warning: "Applied but not used, you must globally enable **ip rtp quality-monitoring** to use VQM." Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, VQM is enabled on all wide area network (WAN) and local area network (LAN) interfaces.

Command History

Release 17.1	Command was introduced.

Usage Examples

The following example enables RTP quality monitoring on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#rtp quality-monitoring**

rts threshold *<length>*

Use the **rts threshold** command to set the threshold for use of request to send (RTS) frames. RTS is used to gain access to the radio frequency (RF) medium when long frames need to be transmitted. The RTS threshold defines the minimum long frame length that will require RTS/clear to send (CTS) prior to transmission. Any frame that matches or is longer than the length specified in the **rts threshold** command must be preceded by a RTS/CTS on the RF medium. Use the **no** form of this command to return to the default value.

Syntax Description

<length>	Specifies the length of the RTS threshold in bytes. Range is **256** to **2346** bytes.

Default Values

By default, the RTS threshold is **2346** bytes.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Functional Notes

Generally, it is best to set the RTS threshold as high as possible. However, the threshold may need to be set lower if network throughput is sluggish or there are a high number of frame retransmissions.

Usage Examples

The following example sets the RTS threshold to **1024** bytes on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#rts threshold 1024**

short-slot-time

Use the **short-slot-time** command to enable short slot time (9 microseconds) for an 802.11bg radio. Use the **no** form of this command to return to the long slot time (20 microseconds).

This command is only available on the 802.11bg radio interface.

Syntax Description

No subcommands.

Default Values

By default, **short-slot-time** is enabled.

Short slot time is used only when the wireless network contains strictly 2.4 GHz, 802.11g devices and all of those devices support short slot time. If not all 802.11g devices support short slot time or the wireless network contains both 802.11b and g radios and/or clients, the radio automatically reverts to standard slot time.

Command History

Release 15.1	Command was introduced.

Functional Notes

Slot time is the amount of time a wireless device waits after a collision before retransmitting a packet. The standard slot time of 20 microseconds is used in 2.4 GHz, 802.11b and 802.11bg networks. If a wireless network is strictly 802.11g and all devices are capable of supporting the feature, short slot time (9 microseconds) can be enabled. Short slot time increases throughput by decreasing the backoff time calculated by the transmitting device when a collision occurs.

Usage Examples

The following example specifies use of long slot time for 802.11g exclusive networks on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#no short-slot-time**

speed

Use the **speed** command to set the active rate for the radio. Frames cannot be transmitted at a speed that is higher than the specified active rates. Use the **no** form of this command to return to the default value. Variations of this command include the following:

speed best
speed <*speed*>

Syntax Description

best	Sets the transmit speed of the radio to the best available.
<*speed*>	Sets the transmit speed of the radio. Available speeds vary based on the setting in the **radio-mode** command. For 802.11a radios, choose from 6, 9, 12, 18, 24, 36, 48, or 54 Mbps. For 802.11b radios, choose from 1, 2, 5.5, or 11 Mbps. For 802.11bg radios, choose 1, 2, 5.5, 6, 9, 11, 12, 18, 24, 36, 48, or 54 Mbps. For 802.11g radios, choose 6, 9, 12, 18, 24, 36, 48, or 54 Mbps.

*The **speed** setting **best** is recommended.*

Default Values

By default, the active rate is set to **best**.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Usage Examples

The following example sets the active rate to **best** on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#speed best**

speed default basic-set

Use the **speed default basic-set** command to configure the basic rate set for the radio. A client connecting to the radio must be able to support these rates. Use the **no** form of this command to return to the default basic rate set for the radio type. Variations of this command include the following:

speed default basic-set 802.11
speed default basic-set 802.11b
speed default basic-set 802.11g
speed default basic-set ofdm

Syntax Description

802.11	Speed for 802.11 (1, 2 Mbps).
802.11b	Speed for 802.11b (1, 2, 5.5, 11 Mbps).
802.11g	Speed for 802.11bg (protection mode) (1, 2, 5.5, 6, 11, 12, 24 Mbps).
ofdm	Speed for orthogonal frequency division multiplexing (OFDM) (6, 12, 24 Mbps).

The OFDM basic rate set on an 802.11bg radio should be specified for a network that only contains 802.11g access points (APs) and clients. This setting maximizes throughput for 802.11g networks, but will not allow 802.11b clients to associate with the access point (AP).

Default Values

By default, the 802.11bg radio is set to **802.11b** and the 802.11a radio is set to **ofdm**.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example sets the basic rate set for **802.11bg** (protection mode that supports 802.11b and g clients) on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#speed default basic-set 802.11g**

station-role access-point

Use the **station-role access-point** command to set the radio operation mode to access point (AP). Use the **no** form of this command to return to the default value.

Syntax Description

No subcommands.

Default Values

By default, the station role is set to **access-point**.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example sets the station role to **access-point** on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#station-role access-point**

vap-isolation

Use the **vap-isolation** command to enable virtual access point (VAP) isolation, which prevents clients from one VAP on a radio from directly accessing clients in another VAP on the same radio. Use the **no** form of this command to return to the default value.

Syntax Description

No subcommands.

Default Values

By default, VAP isolation is disabled.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example enables VAP isolation an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#vap-isolation**

world-mode dot11d

Use the **world-mode dot11d** command to enable 802.11d mode. This mode allows country codes to be transmitted in beacons sent from the access point (AP). Use the **no** form of this command to disable 802.11d mode.

Syntax Description

No subcommands.

Default Values

By default, **802.11d** mode is disabled.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Usage Examples

The following example enables 802.11d mode on an 802.11bg wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#world-mode dot11d**

NETVANTA 150 VAP INTERFACE COMMAND SET

The NetVanta 150 Virtual Access Point (VAP) Interface Configuration command set is used to configure service set identifiers (SSIDs) security and other parameters for each VAP.

A VAP is a logical entity that can exist within a physical wireless access point (AP). VAPs are virtual interfaces represented on wireless networks through the use of a wireless access controller (AC) running the Adtran Wireless Control Protocol (AWCP) and an AP. Each physical AP can support up to eight VAPs for each of the two radio bands for a total of 16 VAPs. VAPs are distinguished by an SSID and can be mapped to a virtual local area network (VLAN). VLAN information can be shared across switches with Ethernet trunks. A common configuration has two VAPs, one associated to a corporate VLAN, and one associated to a guest VLAN.

The associated AP and radio interfaces must be configured before attempting to configure the VAP. For more information on configuring the AP and radios, refer to *NetVanta 150 AP Interface Command Set on page 3494* and *NetVanta 150 Radio Interface Command Set on page 3510*. Each radio will have one default VAP configured. The VAP name is based on the interface to which the AP and radio are mapped using the following syntax, **interface dot11ap** *<ap/radio.vap>*.

To add a VAP or to enter its interface configuration mode, enter the **interface dot11ap** *<ap/radio.vap>* command identifying the appropriate AP and radio interface, followed by the VAP interface number. This command can be entered from the Global Configuration mode prompt or from any other interface configuration mode prompt. In the following example, VAP 1 is created for AP 1 with an 802.11b/g radio.

For example:

```
>enable
#configure terminal
(config)#interface dot11ap 1/1.1
(config-dot11ap 1/1.1-bg)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

accounting on page 3535
client-separation on page 3537
radius-server host on page 3538

accounting

Use the **accounting** command to enable remote authentication dial-in user service (RADIUS) accounting for associations with this virtual access point (VAP) and specify update intervals. Use the **no** form of this command to disable accounting for this VAP. Variations of this command include:

accounting enabled
accounting update
accounting update newinfo
accounting update periodic
accounting update periodic <*value*>

Syntax Description

enabled	Enables RADIUS accounting on this VAP.
update	Defines the RADIUS accounting update setting. Executing the **accounting update** command without specifying any further parameters will send updates when new information occurs. This is the same as executing the **accounting update newinfo** command.
newinfo	Specifies sending RADIUS accounting records as they occur.
periodic	Specifies collecting accounting records and sending them periodically. The default value is **5**.
<*value*>	Optional. Specifies the number of minutes between periodic accounting updates. Valid range is **1** to **99**.

Default Values

By default, RADIUS accounting is disabled.

Functional Notes

The RADIUS server host, access point (AP) IP address, and IP gateway must be configured on the access point for this feature to work. Refer to *radius-server host on page 3538*, *ip address <ipv4 address> <subnet mask> on page 3506*, and *ip default-gateway <ipv4 address> on page 3507* for more information on configuring these parameters.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Usage Examples

The following example enables RADIUS accounting for associations with this VAP:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#accounting enabled**

The following example enables sending RADIUS accounting updates as they occur for this VAP:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#accounting update newinfo**

client-separation

Use the **client-separation** command to prevent wireless clients within this virtual access point (VAP) from communicating directly with each other. Use the **no** form of this command to disable this feature, allowing clients to communicate with one another. It is recommended to enable this command.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Usage Examples

The following example prevents wireless clients on this VAP interface from communicating directly with each other:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#client-separation**

radius-server host

Use the **radius-server host** command to specify the parameters for a remote authentication dial-in user service (RADIUS) server to be used when sending RADIUS messages from the virtual access point (VAP). At a minimum, the Internet Protocol version 4 (IPv4) address of the server must be given. The other parameters are also allowed and (if not specified) will use default values or fall back on the global RADIUS server's default settings. Use the **no** form of this command to remove the RADIUS server properties. This prevents the VAP from using authentication, authorization, and accounting (AAA) methods. Variations of this command include:

radius-server host <*ipv4 address*> **acct-port** <*port*> **auth-port** <*port*> **key** <*key*>
radius-server host <*ipv4 address*> **acct-port** <*port*> **key** <*key*>
radius-server host <*ipv4 address*> **auth-port** <*port*> **acct-port** <*port*> **key** <*key*>
radius-server host <*ipv4 address*> **auth-port** <*port*> **key** <*key*>
radius-server host <*ipv4 address*> **key** <*key*>

Syntax Description

<*ipv4 address*>	Specifies a valid IPv4 address for the RADIUS server. IPv4 address should be expressed in dotted decimal notation (for example, **10.10.10.1**).
acct-port	Specifies the remote port to which to send accounting requests.
auth-port	Specifies a remote port to which to send authentication requests.
<*port*>	Specifies a User Datagram Protocol (UDP) port number to be used when sending authentication or accounting information to the RADIUS server. Valid range is **1** to **65535**.
key <*key*>	Defines the shared key used between the RADIUS server and the access point. The key must appear last on the input line since it reads the rest of the line beyond the **key** keyword. The maximum length is 64 bytes.

Default Values

By default, a RADIUS server is not defined. The default setting for **acct-port** is **1813** and for **auth-port** is **1812**. By default, no **key** is configured. The IPv4 address in this command refers to the default virtual routing and forwarding (VRF) instance only.

Command History

Release 15.1	Command was expanded to include the VAP interface.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Usage Examples

The following example defines the RADIUS server parameters with an IPv4 address of **10.10.10.1**, sets the accounting port to **1646**, and configures the shared key as **ABC123**:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#radius-server host 10.10.10.1 acct-port 1646 key ABC123**

security mode

Use the **security mode** command to configure the security mode settings for this virtual access point (VAP). Use the **no** form of this command to return to the default setting. Depending on the mode chosen between wired equivalency privacy (WEP) and wi-fi protected access (WPA), further command options are available. Variations of this command include:

security mode none
security mode wep open-key
security mode wep open-key eap
security mode wep open-key eap md5-static-key
security mode wep open-key eap md5-static-key-optional
security mode wep shared-key
security mode wpa aes-ccmp eap
security mode wpa aes-ccmp psk *<key>*
security mode wpa aes-ccmp tkip eap
security mode wpa aes-ccmp tkip psk *<key>*
security mode wpa tkip aes-ccmp eap
security mode wpa tkip aes-ccmp psk *<key>*
security mode wpa tkip eap
security mode wpa tkip psk *<key>*

Adtran does not recommend using the WEP security mode because it is not as secure as WPA.

In order to connect to the access point (AP), a client must support the same security mode as configured on this VAP.

Syntax Description

none	Specifies that no security be used on this VAP. There is no authentication required to connect to this VAP and no encryption is provided on the wireless connection.
wep	Configures the VAP for WEP security mode.
open-key	Specifies that the WEP security mode use open authentication with static WEP keys. The client and the VAP must be configured with the same static key. A static WEP key is configured on the VAP by using the command *security wep-key on page 3542*.
shared-key	Specifies that the WEP security mode use shared authentication with encrypted static keys. The client and the VAP must be configured with the same static key. A static WEP key is configured on the VAP by using the command *security wep-key on page 3542*.

eap	Specifies that the WPA security mode use the Extensible Authentication Protocol (EAP) as a universal authentication framework in the wireless network. A client must support WEP with 802.1x. Authentication is performed between the client and a remote authentication dial-in user service (RADIUS) server.
eap md5-static-key	Defines the WEP security mode for this VAP. A client must support WEP with 802.1x. Authentication is performed between the client and a RADIUS server. It indicates that all clients are using EAP-type message digest 5 (MD5). This EAP type does not perform key generation and requires appropriate static WEP keys be configured on this VAP (refer to *security wep-key on page 3542*). The user can specify security WEP keys 2 through 4, the first WEP key is obtained from the RADIUS server.
eap md5-static-key-optional	Defines the WEP security mode for this VAP. A client must support WEP with 802.1x. Authentication is performed between the client and a RADIUS server. It indicates that some clients are using EAP-type MD5 while other clients are using more advanced EAP types (transport layer security (TLS), Protected Extensible Authentication Protocol (PEAP), etc.). Unlike the advanced EAP types, EAP-type MD5 does not perform key generation and requires appropriate static WEP keys be configured on this VAP (refer to *security wep-key on page 3542*). The user can specify security WEP keys 2 through 4, the first WEP key is obtained from the RADIUS server.
wpa	Configures this VAP for WPA security mode.
aes-ccmp	Specifies using the WPA2 algorithms. This security setting can be used alone or in combination with Temporal Key Integrity Protocol (TKIP).
tkip	Specifies that the WPA security mode use TKIP as its keying structure. This protocol specifies the algorithms used for rotating keys. TKIP can be used alone or in combination with **aes-ccmp**.
psk	Specifies that the WPA security mode use preshared keys (PSKs) for key management. PSK may be used in combination with **tkip** and/or **aes-ccmp**. This method does not require a RADIUS authentication server. The PSK must be known on all VAP clients.
<key>	Defines the PSK for security. The key must consist of 8 to 63 ASCII or 16 to 126 hexadecimal characters. Clients supporting WPA PSK are allowed to connect to this VAP.

Default Values

By default, no security mode is defined.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Usage Examples

The following example shows a typical configuration of these parameters:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#security mode wpa tkip psk myPresharedKey**

security wep-key

Use the **security wep-key** command to define the wired equivalency privacy (WEP) keys for use in **wep shared-key** and **wep open-key** security modes (refer to the command *security mode on page 3539*). Up to four keys can be programmed. Set these keys before selecting the WEP security mode. Use the **no** form of this command to disable the specified key. Variations of this command include:

security wep-key *<index> <key>*
security wep-key *<index> <key>* **transmit-key**

*Specifying **security mode wep open-key eap** does not require any WEP keys to be defined on the virtual access point (VAP).*

Syntax Description

<index>	Indicates the WEP key index value. The value and order of WEP-static keys must match on the access point (AP) and all connecting clients. Valid entries are **1** to **4** for **wep shared-key** and **wep open-key**. For **eap md5-static-key** and **eap md5-static-key-optional** modes, the user can specify **security wep-key 2** through **security wep-key 4**, the first WEP key is obtained from the remote authentication dial-in user service (RADIUS) server.
<key>	Specifies the WEP key in hexadecimal characters. The key size is determined using the command *security mode on page 3539* for **wep shared-key** or **wep open-key** security. The key length must follow the setting of the *security wep-key-length on page 3545*.
transmit-key	Enables the specified key to encrypt all wireless traffic sent by this VAP. Only one WEP key index can be the current transmit key. The first index entered under a VAP becomes the transmit key by default. The most recent index specified with the **transmit-key** keyword becomes the current transmit key. The default is the first WEP key index entered for the VAP.

Default Values

By default, no keys are defined.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Functional Notes

The client and the AP must be configured with the same static key.

The corresponding number of hexadecimal or ASCII characters required is:

AP WEP Key Size	Hexadecimal Characters	ASCII Characters
40	10	5
104	26	13
128	32	16

The addition of 24-bit initialization vector (IV) makes the 40 bits become 64 bits, 104 bits become 128, and 128 bits become 152 on the client.

Usage Examples

The following example creates a static WEP key at index **2** with a hexadecimal value of **343f49546a**:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**# security wep-key 2 343f49546a**

security wep-key generate

Use the **security wep-key generate** command to generate wired equivalency privacy (WEP) keys for **shared-key** and **wep open-key** security modes (refer to the command *security mode on page 3539*). Up to four keys can be generated from the passphrase entered using the command *security wep-key seed <passphrase> on page 3546*.

Syntax Description

No subcommands.

Default Values

By default, no keys are defined or generated.

Command History

Release 17.2	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Functional Notes

The generation of WEP keys occurs through the use of a standard message digest 5 (MD5) key generator. The generator creates secure WEP keys by assigning random values for each element (letters or numbers) in the passphrase entered using the command *security wep-key seed <passphrase> on page 3546*.

Usage Examples

The following example enables WEP key generation on 802.11bg wireless radio virtual access point (VAP) 1 based on the passphrase **Adtran6808**:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#security wep-key seed Adtran6808**
(config-dot11ap 1/1.1-bg)**#security wep-key generate**

security wep-key-length

Use the **security wep-key-length** command to specify the length of the wired equivalency privacy (WEP) key to be programmed with the **security wep-key** command. Use the **no** form of this command to return to the default setting. Variations of this command include:

security wep-key-length 104
security wep-key-length 128
security wep-key-length 40

The addition of 24-bit initialization vector (IV) makes the 40 bits become 64 bits, 104 bits become 128, and 128 bits become 152 on the client.

Syntax Description

wep-key-length	Specifies the WEP key length. Valid entries are **40**, **104**, and **128**.

Default Values

By default, no keys are defined.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Functional Notes

There are four keys to program. At least one WEP key must be defined. The corresponding number of hexadecimal characters required is determined by:

key size on client, key size on AP = number of keys multiplied by the hexadecimal characters in the key

Examples:

64, 40 = 4 x 10
128, 104 = 4 x 26
152, 128 = 4 x 32

Usage Examples

The following example sets the WEP key length to **104**:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#security wep-key-length 104**

security wep-key seed *<passphrase>*

Use the **security wep-key seed** command to set a passphrase for the generation of wired equivalency privacy (WEP) keys for use in **wep shared-key** and **wep open-key** security modes (refer to the command *security mode on page 3539*). Use the **no** form of this command to clear the passphrase.

Syntax Description

<passphrase>	A phrase of **1** to **32** characters used as the basis for WEP key generation.

Default Values

By default, no passphrase is set.

Command History

Release 17.2	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Functional Notes

The generation of WEP keys occurs through the use of a standard message digest 5 (MD5) key generator. The generator creates secure WEP keys by assigning random values for each element (letters or numbers) in the passphrase. Refer to the command *security wep-key generate on page 3544* for more information.

Usage Examples

The following example creates a passphrase of **Adtran6808** to use in WEP key generation on 802.11bg wireless radio on virtual access point (VAP) 1:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#security wep-key seed Adtran6808**

security wpa group-key

Use the **security wpa group-key** command to enable group key (broadcast key) rotation for the specified virtual access point (VAP). Use the **no** form of this command to disable group key rotation. Variations of this command include:

security wpa group-key
security wpa group-key change <*minutes*>
security wpa group-key change <*minutes*> **membership-termination**

Syntax Description

change <*minutes*>	Enables a periodic change of the group key. Specify the number of minutes between group key changes. Valid range is **10** to **600** minutes, with the default being **30** minutes.
membership-termination	Optional. Specifies a change of the group key at the termination of any membership association.

Default Values

By default, group key rotation is disabled.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Usage Examples

The following example enables wired WPA group key rotation on the VAP:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#security wpa group-key**

The following example enables a **15**-minute change of the group key and also enables the group key to change any time a membership is terminated:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#security wpa group-key change 15 membership-termination**

ssid

Use the **ssid** command to assign the service set identifier (SSID) for this virtual access point (VAP) and indicate whether to broadcast the SSID over the network. The SSID is a unique identifier consisting of up to 32 characters (letters or numbers). Use the **no** form of this command to return to the default setting. Variations of this command include:

ssid broadcast-mode <*text*>
ssid non broadcast-mode <*text*>

Syntax Description

broadcast-mode	Enables broadcasting the SSID in beacons transmitted for this VAP.
non broadcast-mode	Blocks broadcasting the SSID for this VAP. This setting is used in closed wireless networks. Devices connecting to the access point (AP) in nonbroadcast mode require the wireless device to enter the SSID.
<*text*>	Specifies an SSID for the VAP. The SSID can consist of up to 32 characters using text or letters and can also include spaces.

Default Values

By default, the SSID is set as the concatenation of the string “Adtran”: the **radio-index.vap-index**.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Usage Examples

The following example configures the SSID of VAP interface **1** as **WLAN1** and blocks broadcasting this SSID:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#ssid non broadcast-mode WLAN1**

vlan-id *<vlan id>*

Use the **vlan-id** command to associate a virtual local area network (VLAN) with the virtual access point (VAP) interface. Encapsulation 802.1q must be enabled on the access point (AP) before wireless traffic is routed with the VLAN ID attached. To enable encapsulation, refer to the command *encapsulation 802.1q on page 3500*. Use the **no** form of this command to remove an entry.

Syntax Description

<vlan id>	Specifies a VLAN interface ID number. Range is **1** to **4095**.

Default Values

By default, the VLAN ID is the same number as the VAP interface number.

Functional Notes

Once encapsulation 802.1q is enabled on the AP, all wireless traffic received on the VAP's service set identifier (SSID) is mapped to the VLAN (specified by the VLAN ID) when sent out the AP's Ethernet interface. All wireless traffic received on this VLAN ID at the AP's Ethernet interface is mapped to this VAP's SSID for wireless transmission.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Usage Examples

The following example configures the **vlan-id** to **4** for VAP interface **1**:

```
(config)#interface dot11ap 1/1.1
(config-dot11ap 1/1.1-bg)#vlan-id 4
```

NETVANTA 160 SERIES AP INTERFACE COMMAND SET

The NetVanta 160 Series Access Point Interface Configuration command set is used to configure wireless access points (APs) connecting to an AOS platform running the Adtran Wireless Control Protocol (AWCP). The AP is either a physical standalone unit (such as the NetVanta 160 Series) or integrated within an AOS platform via a module, also known as an embedded access point module (EAPM).

Enter the **interface dot11ap** *<ap | ap/radio | ap/radio.vap>* **ap-type nv16x** command at the Global Configuration mode prompt to activate the NetVanta 160 Series AP Interface Configuration mode. For example:

```
>enable
#configure terminal
(config)#interface dot11ap 1 ap-type nv16x
(config-dot11ap 1)#
```

Additional steps must be performed before the NetVanta 160 Series AP is ready for connectivity. The radio-level settings are configured using the NetVanta 160 Series Radio Interface Command Set on page 3567. The virtual access point (VAP) settings are configured using the NetVanta 160 Series VAP Interface Command Set on page 3585.

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

access-point controller-standby

Use the **access-point controller-standby** command to release wireless access controller (AC) control of the NetVanta 160 Series wireless access point (AP). This command will cause the AC to stop responding to echo requests from the AP, releasing control of the AP. Use the **no** form of this command to disable this feature.

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command *dot11ap apply-changes on page 483*.

Syntax Description

No subcommands.

Default Values

By default, controller-standby mode is disabled.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Usage Examples

The following example enables controller-standby mode for this AP interface:

(config)**#interface dot11ap 1 ap-type nv16x**
(config-dot11ap 1)**#access-point controller-standby**

access-point mac-address *<mac address>*

Use the **access-point mac-address** command to specify the medium access control (MAC) address of the NetVanta 160 Series wireless access point (AP) physical Ethernet interface. Use the **no** form of this command to delete the MAC address of the AP.

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

<mac address>	Specifies a valid 48-bit MAC address. MAC addresses should be expressed in the following format xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).

Default Values

No default values are necessary for this command.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Functional Notes

This command binds the wireless access controller (AC) to the AP. Without specifying the MAC address, the AC cannot control the AP.

Usage Examples

The following example configures an AP MAC address of **00:0A:C8:5F:00:D2**:

(config)**#interface dot11ap 1 ap-type nv16x**
(config-dot11ap 1)**#access-point mac-address 00:0A:C8:5F:00:D2**

association access-list <*name*>

Use the **association access-list** command to specify a medium access control (MAC) address filter. This filter will only allow specific wireless clients access to the wireless network. A MAC access control list (ACL) must be created before it can be associated with this NetVanta 160 Series wireless access point (AP). Refer to *mac access-list standard <name> on page 1606* for more information. Use the **no** form of this command to remove an associated MAC ACL from this AP.

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command dot11ap apply-changes on page 483.

Syntax Description

<name>	Specifies the name of the previously created MAC ACL.

Default Values

By default, no MAC ACLs are associated with an AP.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Usage Examples

The following example configures the AP to use the MAC ACL named **ALLOWLIST** as a filter for allowing access:

(config)**#interface dot11ap 1 ap-type nv16x**
(config-dot11ap 1)**#association access-list ALLOWLIST**

country-region

Use the **country-region** command to specify the country region or domain where the NetVanta 160 Series wireless access point (AP) is being used so that the radio can modify its settings to conform to that country's regulations. Use the **no** form of this command to return to the default value. Variations of this command include:

country-region Australia
country-region Austria
country-region Belgium
country-region Bulgaria
country-region Canada
country-region Cyprus
country-region Czech_Republic
country-region Denmark
country-region Estonia
country-region Finland
country-region France
country-region Germany
country-region Greece
country-region Hungary
country-region Iceland
country-region Ireland
country-region Italy
country-region Latvia
country-region Lithuania
country-region Luxembourg
country-region Malta
country-region Mexico
country-region Netherlands
country-region Norway
country-region Poland
country-region Portugal
country-region Puerto_Rico
country-region Romania
country-region Singapore
country-region Slovak_Republic
country-region Slovenia
country-region Spain
country-region Sweden
country-region UK
country-region USA

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command *dot11ap apply-changes on page 483*.

Syntax Description

Australia	Specifies Australia configuration.
Austria	Specifies Austria configuration.
Belgium	Specifies Belgium configuration.
Bulgaria	Specifies Bulgaria configuration.
Canada	Specifies Canada configuration.
Cyprus	Specifies Cyprus configuration.
Czech_Republic	Specifies Czech Republic configuration.
Denmark	Specifies Denmark configuration.
Estonia	Specifies Estonia configuration.
Finland	Specifies Finland configuration.
France	Specifies France configuration.
Germany	Specifies Germany configuration.
Greece	Specifies Greece configuration.
Hungary	Specifies Hungary configuration.
Iceland	Specifies Iceland configuration.
Ireland	Specifies Ireland configuration.
Italy	Specifies Italy configuration.
Latvia	Specifies Latvia configuration.
Lithuania	Specifies Lithuania configuration.
Luxembourg	Specifies Luxembourg configuration.
Malta	Specifies Malta configuration.
Mexico	Specifies Mexico configuration.
Netherlands	Specifies Netherlands configuration.
Norway	Specifies Norway configuration.
Poland	Specifies Poland configuration.
Portugal	Specifies Portugal configuration.
Puerto_Rico	Specifies Puerto Rico configuration.
Romania	Specifies Romania configuration.
Singapore	Specifies Singapore configuration.
Slovak_Republic	Specifies Slovak Republic configuration.
Slovenia	Specifies Slovenia configuration.
Spain	Specifies Spain configuration.
Sweden	Specifies Sweden configuration.
UK	Specifies UK configuration.
USA	Specifies USA configuration.

Default Values

By default, the country-region is set to **USA**.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP and expanded to include additional country regions.
Release R11.6.0	Command was changed to remove the **uncertified** parameter from the Puerto Rico country region.

Usage Examples

The following example sets the country of operation to **Norway**:

(config)**#interface dot11ap 1 ap-type nv16x**
(config-dot11ap 1)**#country-region Norway**

encapsulation 802.1q

Use the **encapsulation 802.1q** command to set the NetVanta 160 Series wireless access point (AP) for virtual local area network (VLAN) encapsulation 802.1q mode. This will apply VLAN tags to the user traffic. Use the **no** form of this command to disable VLAN encapsulation. Variations of this command include:

encapsulation 802.1q
encapsulation 802.1q awcp-vlan <*vlan id*> **native**
encapsulation 802.1q awcp-vlan <*vlan id*> **native priority** <*level*>

> *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

awcp-vlan <*vlan id*>	Optional. Specifies an existing VLAN to be used for Adtran Wireless Control Protocol (AWCP) connection. Valid range is **1** to **4095**. For more information on creating a VLAN, refer to *VLAN Interface Command Set on page 3370*.
native	Enables native mode for the specified VLAN. Packets from this VLAN leaving the interface will not be tagged with the VLAN number. Any untagged packets received by the interface are considered a part of the native VLAN ID. Only one VLAN may be set to **native**. To change where the native VLAN resides, the current native must be disabled using the **no** form of this command before a new one is set.
priority <*level*>	Optional. Specifies the 802.1q priority level for AWCP packets generated by this AP when VLAN tags are applied. Valid range is **1** to **7**, with 1 being the highest priority.

Default Values

By default, **encapsulation 802.1q** is disabled on the AP.

Command History

Release 6.1	Command was introduced.
Release 15.1	Command was added to the NetVanta 150 AP.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Functional Notes

Settings (including encapsulation, VLAN, and native VLAN) for the AP's Ethernet interface must be coordinated with the physical interface to which the AP is connected.

Since all functions on an AP use the same Ethernet interface, there should be only one VLAN ID set to **native** on the entire AP. It is possible that a VLAN can be used on a virtual access point (VAP) and for the AWCP protocol on the AP's Ethernet, but this is not typical. Typically, the control protocol will use the native VLAN and the VAP's data will all be tagged on the Ethernet.

This means that one VLAN on one radio's VAP may be set to **native** or the control protocol (AWCP) VLAN may be set to **native**, but not both unless they both use the same VLAN ID. Typically, the control protocol will use the native VLAN.

If the control protocol and a VAP share the same VLAN ID, control protocol packets will be intercepted by the AP while noncontrol protocol packets will be forwarded to the VAP.

If the AP is to be in trunk mode and the AWCP VLAN is not the native VLAN for the trunk, care must be exercised in transitioning the AP and switchport from access port (nontrunk) mode. The AP should be configured first, then the switchport set to match. When transitioning the AP, set its AWCP VLAN first, then enable trunking mode (encapsulation 802.1q). If the AWCP VLAN is the native VLAN on the AP and switch, AWCP communication will not be lost no matter what combination of trunk mode settings is applied.

Usage Examples

The following example enables encapsulation 802.1q on this AP and makes VLAN 1 the native VLAN:

(config)**#interface dot11ap 1 ap-type nv16x**
(config-dot11ap 1)**#encapsulation 802.1q awcp-vlan 1 native**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address for the NetVanta 160 Series access point (AP) Ethernet interface. Use the **no** form of this command to remove a configured IPv4 address.

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command *dot11ap apply-changes on page 483*.

Syntax Description

<ipv4 address>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**).

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Functional Notes

The IPv4 address and subnet mask are only needed on the AP interface if the user wants to use remote authentication dial-in user service (RADIUS) authentication with the wireless clients. A default gateway may also need to be specified.

Usage Examples

The following example configures an IPv4 address of **192.22.72.101** and a subnet mask of **255.255.255.252**:

(config)**#interface dot11ap 1 ap-type nv16x**
(config-dot11ap 1)**#ip address 192.22.72.101 255.255.255.252**

ip default-gateway *<ipv4 address>*

Use the **ip default-gateway** command to assign a default gateway to the NetVanta 160 Series wireless access point (AP). This allows the AP to communicate with Internet Protocol version 4 (IPv4) devices on other IPv4 subnets. Use the **no** form of this command to remove the default gateway.

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

<ipv4 address>	Specifies the default gateway IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, there is no configured default gateway.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Usage Examples

The following example assigns the AP a default gateway for **10.10.10.1**:

(config)**#interface dot11ap 1 ap-type nv16x**
(config-dot11ap 1)**#ip default-gateway 10.10.10.1**

location *<name>*

Use the **location** command to specify the location of the NetVanta 160 Series wireless access point (AP). Use the **no** form of this command to remove the specified location.

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

<name>	Specifies the name of the location of the AP. The location name may be up to 32 characters.

Default Values

No default values are necessary for this command.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Usage Examples

The following example assigns the name **FLOOR5** as the location of AP 1:

(config)**#interface dot11ap 1 ap-type nv16x**
(config-dot11ap 1)**#location FLOOR5**

logging forwarding on

Use the **logging forwarding on** command to enable the event forwarding feature for the NetVanta 160 Series wireless access point (AP). Use the command *logging forwarding priority-level on page 3563* to specify the event matching the criteria used by AOS to determine whether a message should be forwarded to the remote receiver. Use the **no** form of this command to disable the event forwarding feature.

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command dot11ap apply-changes on page 483.

Syntax Description

No subcommands.

Default Values

By default, event notification is disabled on the AP.

Command History

Release R10.4.0	Command was introduced.

Usage Examples

The following example enables the AOS event forwarding feature for this AP:

(config)**#interface dot11ap 1 ap-type nv16x**
(config-dot11ap 1)**#logging forwarding on**

logging forwarding priority-level

Use the **logging forwarding priority-level** command to set the minimum priority threshold for NetVanta 160 Series wireless access point (AP) events sent to the configured remote receiver specified using the command *logging forwarding receiver-ip <ipv4 address> on page 3565*. All events with the specified priority or higher will be sent to all configured remote receivers. Use the **no** form of this command to return to the default priority. Variations of this command include:

logging forwarding priority-level alert
logging forwarding priority-level critical
logging forwarding priority-level debug
logging forwarding priority-level error
logging forwarding priority-level informational
logging forwarding priority-level notice
logging forwarding priority-level warning

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command dot11ap apply-changes on page 483.

Syntax Description

alert	Logs events with **alert** priority (severity level 1, most severe).
critical	Logs events with **critical** priority (severity level 2).
debug	Logs informational events (severity level 7, least severe).
error	Logs events with **error** priority (severity level 3).
informational	Logs **informational** events (severity level 6).
notice	Logs events with **notice** priority (severity level 5).
warning	Logs events with **warning** priority (severity level 4).

Default Values

By default, the **logging forwarding priority-level** is set to **warning**.

Command History

Release R10.4.0	Command was introduced.

Usage Examples

The following example sends all messages with **critical** level or greater to the remote receiver listed using the command *logging forwarding receiver-ip <ipv4 address> on page 3565*:

(config)**#interface dot11ap 1 ap-type nv16x**
(config-dot11ap 1)**#logging forwarding priority-level critical**

logging forwarding receiver-ip *<ipv4 address>*

Use the **logging forwarding receiver-ip** command to specify the Internet Protocol version 4 (IPv4) address of the remote receiver server to use when logging NetVanta 160 Series wireless access point (AP) events that match the criteria configured using the command *logging forwarding priority-level on page 3563* command. Use the **no** form of this command to remove a configured address.

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command dot11ap apply-changes on page 483.*

Syntax Description

<ipv4 address>	Specifies the IPv4 address of the remote receiver to use when logging messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, there are no configured syslog server addresses.

Command History

Release R10.4.0	Command was introduced.

Usage Examples

The following example specifies a remote receiver with address **172.5.67.99** to use when logging AP messages:

(config)**#interface dot11ap 1 ap-type nv16x**
(config-dot11ap 1)**#logging forwarding receiver-ip 172.5.67.99**

name <*name*>

Use the **name** command to specify a name for this NetVanta 160 Series wireless access point (AP). Use the **no** form of this command to remove the assigned name.

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

<name>	Specifies the name of the AP. The name may be up to 32 characters in length.

Default Values

By default, the name of the AP will be ADTN plus the last three bytes of the AP medium access control (MAC) address (all uppercase).

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series AP.

Usage Examples

The following example assigns the name **ACCOUNTING1** to AP 1:

(config)**#interface dot11ap 1 ap-type nv16x**
(config-dot11ap 1)**#name ACCOUNTING1**

NETVANTA 160 SERIES RADIO INTERFACE COMMAND SET

A radio interface is a virtual interface that can be programmed into an AOS platform running the Adtran Wireless Control Protocol (AWCP). This interface is used to configure radio-level commands for an 802.11 wireless access point (AP). The AP is either a physical standalone unit (such as the NetVanta 160 Series) or integrated within the AOS platform via a module, also known as an embedded access point module (EAPM).

The associated AP interface must be configured before access to the Radio Interface Configuration mode is possible. For more information on configuring the AP, refer to *NetVanta 150 AP Interface Command Set on page 3494*. Upon creation, each radio will have one default virtual access point (VAP) configured. More detailed information on configuring the VAP interface is provided in *NetVanta 150 VAP Interface Command Set on page 3533*.

There are only two radio types: 802.11a/n and 802.11b/g/n. Radio 802.11b/g/n defaults to **interface dot11ap** <*ap/***1**> and radio 802.11a/n defaults to **interface dot11ap** <*ap/***2**>. The only changes that can be made to the radio types is to specify the radio mode of the 802.11b/g/n radio as type b/g, b/g/n, or g/n, or the radio mode of the 802.11a/n radio as type a or a/n using the command *radio-mode on page 3579*.

The parent (AP) interface must be created before access to the NetVanta 160 Radio Interface Configuration mode is possible. Execute the command ***interface dot11ap*** *<ap>* ***ap-type nv16x*** *command to create an AP interface.*

To activate NetVanta 160 Radio Interface Configuration mode for an 802.11b/g, 802.11b/g/n, or 802.11g/n radio, enter the commands at the Global Configuration mode prompt as shown below:

```
>enable
#configure terminal
(config)#interface dot11ap 1/1
(config-dot11ap 1/1-bg)#
```

To activate Radio Interface Configuration mode for an 802.11a or 802.11a/n radio, enter the commands at the Global Configuration mode prompt as shown below:

```
>enable
#configure terminal
(config)#interface dot11ap 1/2
(config-dot11ap 1/2-a)#
```

By default, ***interface dot11ap*** *<ap/***1***> is radio type 802.11b/g/n and* ***interface dot11ap*** *<ap/***2***> is radio type 802.11a/n.*

*Not all radio interface commands apply to both radio types.Use the **?** command to display a list of valid commands.*

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

antenna on page 3569
beacon period <time> on page 3570
channel <number> on page 3571
channel-width-40MHz on page 3573
dtim-interval <number> on page 3574
fragment-threshold <length> on page 3575
inactivity-timeout max <value> on page 3576
packet-aggregation on page 3577
power local on page 3578
radio-mode on page 3579
rts threshold <length> on page 3580
secondary-channel <number> on page 3581
speed on page 3583
world-mode dot11d on page 3584

antenna

Use the **antenna** command to select the desired antenna mode. Use the **no** form of this command to return to the default value. Variations of this command include the following:

antenna mimo-1x1
antenna mimo-2x2

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command *dot11ap apply-changes on page 483*.

Syntax Description

mimo-1x1	Sets the antenna mode to transmit or receive on antenna 1.
mimo-2x2	Sets the antenna mode to transmit or receive on antenna 2.

Default Values

By default, the antenna is set to **mimo-2x2**.

Command History

Release R10.4.0	Command was introduced.

Usage Examples

The following example sets the antenna mode to transmit or receive on antenna 1 on an 802.11b/g/n wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#antenna mimo-1x1**

beacon period *<time>*

Use the **beacon period** command to set the time between beacons. Use the **no** form of this command to return to the default value.

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

<time>	Specifies the number of 802.11 time units (TUs) between beacons. One TU is 1024 microseconds. Range is **20** to **1000** TU.

Default Values

By default, the beacon period is **100** TU.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Functional Notes

A beacon is a type of management frame used in 802.11 wireless networks. Beacon frames carry important information, such as the basic service set, parameter sets, and capability. The beacon frame is sent to the broadcast medium access control (MAC) address, which means that all clients must be able to receive and process beacons.

Beacon frames are associated with some overhead, which decreases the throughput of the wireless network. The higher the beacon period, the fewer number of beacons sent, thus reducing overhead and increasing throughput on the network. However, fewer beacons can cause a delay in the association process because stations scanning for available access points (APs) may miss the beacons.

Usage Examples

The following example sets the beacon period to **500** TU on an 802.11b/g/n wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#beacon period 500**

channel *<number>*

Use the **channel** command to manually select a channel for the wireless radio. Use the **no** form of this command to return to the default value.

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point (AP), you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

<number>	Specifies the Institute of Electrical and Electronics Engineers, Inc. (IEEE) channel number. The range of channels is dependent on the radio type and country setting.

Default Values

By default, the channel number is automatically set to a channel corresponding to the AP number. The available channels depend on the radio type. For example, if there are three APs configured on a 2.4 Ghz radio, channels 1, 6, and 11 can be used. The first AP defaults to channel 1, the second AP defaults to channel 6, and the third AP defaults to channel 11. The available channels are different for a 5 Ghz radio.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.
Release R11.7.0	Command was altered to remove the **least-congested** parameter.

Functional Notes

The available channel range varies by the radio type and country setting specified on the NetVanta 160 Series AP. For more information about specific channels available to each radio type for a specific country, refer to the configuration guide *NetVanta 160 Series Wireless Configuration Guide*, available online at https://supportcommunity.adtran.com.

> NOTE *Type **channel ?** to display a list of valid channels from which to choose. The list of channels displayed is based on the selected radio type (refer to the command* *radio-mode on page 3579**) and country setting (refer to the command* *country-region on page 3498**).*

Usage Examples

The following example manually sets an 802.11b/g/n wireless radio to channel **6** in the United States:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#channel 6**

The following example manually sets an 802.11a/n wireless radio to channel **149** in the United States:

(config)**#interface dot11ap 1/2 radio-type 802.11a**
(config-dot11ap 1/1-a)**#channel 149**

channel-width-40MHz

Use the **channel-width-40MHz** command to enable the 40 MHz mode of the radio. Use the **no** form of this command to disable the radio's 40 MHz mode.

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

No subcommands.

Default Values

By default, the 40 MHz radio mode is disabled.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

This feature is only available on an 802.11n radio, such as the 802.11b/g/n, 802.11g/n, or 802.11a/n radios. Refer to the command *radio-mode on page 3579* for information about changing the AP's radio mode.

Usage Examples

The following example enables the 40 MHz channel width on the 802.11a/n radio:

(config)**#interface dot11ap 1/2 radio-type 802.11a**
(config-dot11ap 1/1-an)**#channel-width-40MHz**

dtim-interval <*number*>

Use the **dtim-interval** command to specify the delivery traffic indication message (DTIM) interval period on the radio. The DTIM interval period is a number of beacon intervals at which the radio sends buffered multicast and broadcast frames. This feature helps radios operating in power-saving mode. Use the **no** form of this command to return the DTIM interval to the default value.

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command *dot11ap apply-changes on page 483*.

Syntax Description

<*number*>	Specifies the number of DTIM beacon intervals. Valid range is **1** to **255**.

Default Values

By default, the DTIM interval is **1**.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

This feature is only available on an 802.11n radio, such as the 802.11b/g/n, 802.11g/n, or 802.11a/n radios. Refer to the command *radio-mode on page 3579* for information about changing the AP's radio mode.

Usage Example

The following example changes the DTIM interval to **10** on the 802.11 b/g/n wireless radio:

(config)**#interface dot11ap 1/1 radio-type bg**
(config-dot11ap 1/1-bg)**#dtim-interval 10**

fragment-threshold *<length>*

Use the **fragment-threshold** command to set the packet length threshold. Packets larger than the value set in this command will be fragmented when transmitted on the wireless link. Use the **no** form of this command to return to the default value.

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

<length>	Specifies the maximum packet length allowed before fragmentation will occur. Range is **256** to **2346** bytes.

Default Values

By default, the fragment threshold is set at **2346** bytes.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Functional Notes

The fragment threshold can be set to a lower number to prevent retransmission of large packets, but the overhead will increase. If the threshold is large, the overhead is relatively small but large packets will be retransmitted, lowering efficiency.

Usage Examples

The following example sets the fragment threshold at **572** bytes on an 802.11b/g/n wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#fragment-threshold 572**

inactivity-timeout max *<value>*

Use the **inactivity-timeout max** command to set the maximum length of inactivity allowed between an access point (AP) and its clients. If no response is seen from the client within the timeout period, the client will be disassociated. Use the **no** form of this command to return to the default value.

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

<value>	Specifies the maximum length of time a connection between an AP and a client is allowed to remain inactive. Range is **1** to **99** minutes.

Default Values

By default, the maximum inactivity timeout is **5** minutes.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Usage Examples

The following example sets the maximum inactivity timeout to **2** minutes on an 802.11b/g/n wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#inactivity-timeout max 2**

packet-aggregation

Use the **packet-aggregation** command to enable packet aggregation for 802.11n clients. Use the **no** form of this command to disable packet aggregation.

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

No subcommands.

Default Values

By default, packet aggregation is enabled.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

This feature is only available on an 802.11n radio, such as the 802.11b/g/n, 802.11g/n, or 802.11a/n radios. Refer to the command *radio-mode on page 3579* for information about changing the AP's radio mode.

Usage Examples

The following example disables packet-aggregation for the 802.11n clients on the 802.11b/g/n radio:

(config)**#interface dot11ap 1/1 radio-type bg**
(config-dot11ap 1/1-bg)**#no packet-aggregation**

power local

Use the **power local** command to select the radio's transmit power level. The range of the power level is relative to the country region currently specified for the radio. Use the **no** form of this command to return to the default value. Variations of this command include:

power local eighth
power local half
power local maximum
power local minimum
power local quarter

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command *dot11ap apply-changes on page 483*.

Syntax Description

eighth	Sets the power local level to one-eighth of the maximum output power setting.
half	Sets the power local level to one-half of the maximum output power setting.
maximum	Sets the power local level to the maximum output power setting.
minimum	Sets the power local level to the minimum output power setting.
quarter	Sets the power local level to one-fourth of the maximum output power setting.

Default Values

By default, the power local setting is **maximum**.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Functional Notes

Radio cell size and interference between cells can be reduced by lowering the radio's transmit power level.

Usage Examples

The following example sets the radio's transmit power to one-half maximum power on an 802.11b/g/n wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#power local half**

radio-mode

Use the **radio-mode** command to set the radio to use a specific 802.11 protocol. Use the **no** form of this command to return to the default value. Variations of this command include the following:

radio-mode a
radio-mode an
radio-mode bg
radio-mode bgn
radio-mode gn

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command *dot11ap apply-changes on page 483*.

Syntax Description

a	Specifies the radio operates using 802.11a.
an	Specifies the radio operates using 802.11a/n.
bg	Specifies the radio operates using 802.11b/g.
bgn	Specifies the radio operates using 802.11b/g/n.
gn	Specifies the radio operates using 802.11g/n.

Default Values

By default, the 802.11bg radio is set to **radio-mode bgn** and the 802.11a radio is set to **radio-mode an**.

Command History

Release R10.4.0	Command was introduced.

Functional Notes

Adtran currently supports these IEEE 802.11 wireless local area network (WLAN) standards: 802.11a, 802.11b, 802.11g, and 802.11n. Each access point (AP) contains two integrated radios: one that supports 802.11a and 802.11n, and one that supports 802.11b/g, and 802.11n.

Usage Examples

The following example sets the radio mode to radio type **gn** on an 802.11b/g/n wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#radio-mode gn**

rts threshold *<length>*

Use the **rts threshold** command to set the threshold for use of request to send (RTS) frames. RTS is used to gain access to the radio frequency (RF) medium when long frames need to be transmitted. The RTS threshold defines the minimum long frame length that will require RTS/clear to send (CTS) prior to transmission. Any frame that matches or is longer than the length specified in the **rts threshold** command must be preceded by a RTS/CTS on the RF medium. Use the **no** form of this command to return to the default value.

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command *dot11ap apply-changes on page 483*.

Syntax Description

<length>	Specifies the length of the RTS threshold in bytes. Range is **256** to **2346** bytes.

Default Values

By default, the RTS threshold is **2346** bytes.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Functional Notes

Generally, it is best to set the RTS threshold as high as possible. However, the threshold may need to be set lower if network throughput is sluggish or there are a high number of frame retransmissions.

Usage Examples

The following example sets the RTS threshold to **1024** bytes on an 802.11b/g/n wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#rts threshold 1024**

secondary-channel *<number>*

Use the **secondary-channel** command to set the 802.11n secondary operating channel when the radio is operating in the 40 MHz mode (refer to the command *channel-width-40MHz on page 3573*). Any valid channel, other than the primary channel set with the command *channel <number> on page 3571* can be used. Use the **no** form of this command to remove the secondary channel.

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point (AP), you must apply those changes for them to take effect using the command dot11ap apply-changes on page 483.*

Syntax Description

<number>	Specifies the secondary channel. Any valid channel, other than the primary channel, is accepted. Valid range is **1** to **13**, depending on the country setting of the radio.

Default Values

By default, the secondary 802.11n channel is set to **0**.

Command History

Release R10.4.0	Command was introduced.
Release R11.7.0	Command was altered to remove the **auto** parameter.

Functional Notes

The secondary channels available depend on the primary channel selected and the country. The secondary channels available are either four channels above, or four channels below the selected primary channel. The following table describes the available secondary channels based on the primary channel.

Primary Channel	Upper Secondary Channel	Lower Secondary Channel
1	5	N/A
2	6	N/A
3	7	N/A
4	8	N/A
5	9	1
6	10	2
7	11	3
8	12	4

Primary Channel	Upper Secondary Channel	Lower Secondary Channel
9	13	5
10	N/A	6
11	N/A	7
12	N/A	8
13	N/A	9

For more information about specific channels available to each radio type for a specific country, refer to the configuration guide *NetVanta 160 Series Wireless Configuration Guide*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the secondary 802.11n channel for the b/g/n radio is set to **1**:

(config)**#interface dot11ap 1/1 radio-type bg**
(config-dot11ap 1/1-bg)**#secondary-channel 1**

speed

Use the **speed** command to set the active rate for the radio. Frames cannot be transmitted at a speed that is higher than the specified active rates. Use the **no** form of this command to return to the default value. Variations of this command include the following:

speed best
speed <*speed*>

> *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

best	Sets the transmit speed of the radio to the best available.
<*speed*>	Sets the transmit speed of the radio. Available speeds vary based on the setting in the **radio-mode** command. Choose from 6, 9, 12, 18, 24, 36, 48, or 54 Mbps for a b/g/n radio, or 6, 9, 12, 18, 24, 36, 48, or 54 Mbps for an a/n radio.

> *The **speed** setting **best** is recommended.*

Default Values

By default, the active rate is set to **best**.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Usage Examples

The following example sets the active rate to **54** Mbps on an 802.11b/g/n wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#speed best**

world-mode dot11d

Use the **world-mode dot11d** command to enable 802.11d mode. This mode allows country codes to be transmitted in beacons sent from the access point (AP). Use the **no** form of this command to disable 802.11d mode.

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

No subcommands.

Default Values

By default, **802.11d** mode is enabled.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series radio interface.

Usage Examples

The following example enables 802.11d mode on an 802.11b/g/n wireless radio:

(config)**#interface dot11ap 1/1 radio-type 802.11bg**
(config-dot11ap 1/1-bg)**#world-mode dot11d**

NETVANTA 160 SERIES VAP INTERFACE COMMAND SET

The NetVanta 160 Virtual Access Point (VAP) Interface Configuration command set is used to configure service set identifiers (SSIDs) security and other parameters for each VAP.

A VAP is a logical entity that can exist within a physical wireless access point (AP). VAPs are virtual interfaces represented on wireless networks through the use of a wireless access controller (AC) running the Adtran Wireless Control Protocol (AWCP) and an AP. Each physical AP can support up to eight VAPs for each of the two radio bands for a total of 16 VAPs. VAPs are distinguished by an SSID and can be mapped to a virtual local area network (VLAN). VLAN information can be shared across switches with Ethernet trunks. A common configuration has two VAPs, one associated to a corporate VLAN, and one associated to a guest VLAN.

The associated AP and radio interfaces must be configured before attempting to configure the VAP. For more information on configuring the AP and radios, refer to *NetVanta 160 Series AP Interface Command Set on page 3550* and *NetVanta 160 Series Radio Interface Command Set on page 3567*. Each radio will have one default VAP already configured. The VAP name is based on the interface to which the AP and radio are mapped using the following syntax, **interface dot11ap** *<ap/radio.vap>*.

To add a VAP or to enter its interface configuration mode, enter the **interface dot11ap** *<ap/radio.vap>* command identifying the appropriate AP and radio interface, followed by the VAP interface number. This command can be entered from the Global Configuration mode prompt or from any other interface configuration mode prompt. In the following example, VAP 1 is created for AP 1 with an 802.11b/g/n radio. For example:

```
>enable
#configure terminal
(config)#interface dot11ap 1/1.1
(config-dot11ap 1/1.1-bg)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

accounting on page 3587
client-separation on page 3589
radius-server host on page 3590
security mode on page 3592

security wpa group-key on page 3594
ssid on page 3595
vlan-id <vlan id> on page 3596

accounting

Use the **accounting** command to enable remote authentication dial-in user service (RADIUS) accounting for associations with this virtual access point (VAP) and specify update intervals. Use the **no** form of this command to disable accounting for this VAP. Variations of this command include:

accounting enabled
accounting update
accounting update newinfo
accounting update periodic
accounting update periodic <*value*>

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command dot11ap apply-changes on page 483.*

Syntax Description

enabled	Enables RADIUS accounting on this VAP.
update	Defines the RADIUS accounting update setting. Executing the **accounting update** command without specifying any further parameters will send updates when new information occurs. This is the same as executing the **accounting update newinfo** command.
newinfo	Specifies sending RADIUS accounting records as they occur.
periodic	Specifies collecting accounting records and sending them periodically. The default value is **5**.
<*value*>	Optional. Specifies the number of minutes between periodic accounting updates. Valid range is **1** to **99**.

Default Values

By default, RADIUS accounting is disabled.

Functional Notes

The RADIUS server host, access point (AP) IP address, and IP gateway must be configured on the access point for this feature to function. Refer to *radius-server host on page 3590*, *ip address <ipv4 address> <subnet mask> on page 3559*, and *ip default-gateway <ipv4 address> on page 3560* for more information on configuring these parameters.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Usage Examples

The following example enables RADIUS accounting for associations with this VAP:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#accounting enabled**

The following example enables sending RADIUS accounting updates as they occur for this VAP:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#accounting update newinfo**

client-separation

Use the **client-separation** command to prevent wireless clients within this virtual access point (VAP) from communicating directly with each other. Use the **no** form of this command to disable this feature, allowing clients to communicate with one another. It is recommended to enable this command.

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command *dot11ap apply-changes on page 483*.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Usage Examples

The following example prevents wireless clients on this VAP interface from communicating directly with each other:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#client-separation**

radius-server host

Use the **radius-server host** command to specify the parameters for a remote authentication dial-in user service (RADIUS) server to be used when sending RADIUS messages from the virtual access point (VAP). At a minimum, the Internet Protocol version 4 (IPv4) address of the server must be given. The other parameters are also allowed and (if not specified) will use default values or fall back on the global RADIUS server's default settings. Use the **no** form of this command to remove the RADIUS server properties and prevent the VAP from using authentication, authorization, and accounting (AAA) methods. Variations of this command include:

radius-server host *<ipv4 address>* **acct-port** *<port>* **auth-port** *<port>* **key** *<key>*
radius-server host *<ipv4 address>* **acct-port** *<port>* **key** *<key>*
radius-server host *<ipv4 address>* **auth-port** *<port>* **acct-port** *<port>* **key** *<key>*
radius-server host *<ipv4 address>* **auth-port** *<port>* **key** *<key>*
radius-server host *<ipv4 address>* **key** *<key>*

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command *dot11ap apply-changes on page 483*.

Syntax Description

<ipv4 address>	Specifies a valid IPv4 address for the RADIUS server. IPv4 address should be expressed in dotted decimal notation (for example, **10.10.10.1**).
acct-port	Specifies the remote port to which to send accounting requests.
auth-port	Specifies a remote port to which to send authentication requests.
<port>	Specifies a User Datagram Protocol (UDP) port number to be used when sending authentication or accounting information to the RADIUS server. Valid range is **1** to **65535**.
key *<key>*	Defines the shared key used between the RADIUS server and the access point. The key must appear last on the input line since it reads the rest of the line beyond the **key** keyword. The maximum length is 64 bytes.

Default Values

By default, a RADIUS server is not defined. The default setting for **acct-port** is **1813** and for **auth-port** is **1812**. By default, no **key** is configured. The IPv4 address in this command refers to the default virtual routing and forwarding (VRF) instance only.

Command History

Release 15.1	Command was expanded to include the VAP interface.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Usage Examples

The following example defines the RADIUS server parameters with an IPv4 address of **10.10.10.1**, sets the accounting port to **1646**, and configures the shared key as **ABC123**:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#radius-server host 10.10.10.1 acct-port 1646 key ABC123**

security mode

Use the **security mode** command to configure the security mode settings for this virtual access point (VAP). Use the **no** form of this command to return to the default setting. Depending on the mode chosen none and wi-fi protected access (WPA), further command options are available. Variations of this command include:

security mode none
security mode wpa aes-ccmp eap
security mode wpa aes-ccmp psk <*key*>
security mode wpa aes-ccmp tkip eap
security mode wpa aes-ccmp tkip psk <*key*>
security mode wpa tkip aes-ccmp eap
security mode wpa tkip aes-ccmp psk <*key*>
security mode wpa tkip eap
security mode wpa tkip psk <*key*>

In order to connect to the access point (AP), a client must support the same security mode as configured on this VAP.

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command *dot11ap apply-changes on page 483*.

Syntax Description

none	Specifies that no security be used on this VAP. There is no authentication required to connect to this VAP and no encryption is provided on the wireless connection.
wpa	Configures this VAP for WPA security mode.
aes-ccmp	Specifies using the WPA2 algorithms. This security setting can be used alone or in combination with Temporal Key Integrity Protocol (TKIP).
eap	Specifies that the WPA security mode use the Extensible Authentication Protocol (EAP) as a universal authentication framework in the wireless network. Authentication is performed between the client and a remote authentication dial-in user service (RADIUS) server.
psk	Specifies that the WPA security mode use preshared keys (PSKs) for key management. PSK may be used in combination with **tkip** and/or **aes-ccmp**. This method does not require a RADIUS authentication server. The PSK must be known on all VAP clients.
<*key*>	Defines the PSK for security. The key must consist of 8 to 63 ASCII or 16 to 126 hexadecimal characters. Clients supporting WPA PSK are allowed to connect to this VAP.

tkip	Specifies that the WPA security mode use TKIP as its keying structure. This protocol specifies the algorithms used for rotating keys. TKIP can be used alone or in combination with **aes-ccmp**.

Default Values

By default, no security mode is defined.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.
Release R11.6.0	Command was changed to remove **wep open-key** and **wep shared-key** security modes.

Usage Examples

The following example shows a typical configuration of these parameters:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#security mode wpa tkip psk myPresharedKey**

security wpa group-key

Use the **security wpa group-key** command to enable group key (broadcast key) rotation for the specified virtual access point (VAP). Use the **no** form of this command to disable group key rotation. Variations of this command include:

security wpa group-key
security wpa group-key change <*minutes*>
security wpa group-key change <*minutes*> **membership-termination**

> NOTE *If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command* *dot11ap apply-changes on page 483*.

Syntax Description

change <*minutes*>	Enables a periodic change of the group key. Specify the number of minutes between group key changes. Valid range is **10** to **600** minutes, with the default being **30** minutes.
membership-termination	Optional. Specifies a change of the group key at the termination of any membership association.

Default Values

By default, group key rotation is disabled.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Usage Examples

The following example enables wired WPA group key rotation on the VAP:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#security wpa group-key**

The following example enables a **15**-minute change of the group key and also enables the group key to change any time a membership is terminated:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#security wpa group-key change 15 membership-termination**

ssid

Use the **ssid** command to assign the service set identifier (SSID) for this virtual access point (VAP) and indicate whether to broadcast the SSID over the network. The SSID is a unique identifier consisting of up to 32 characters (letters or numbers). Use the **no** form of this command to return to the default setting. Variations of this command include:

ssid broadcast-mode *<text>*
ssid nonbroadcast-mode *<text>*

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command *dot11ap apply-changes on page 483*.

Syntax Description

broadcast-mode	Enables broadcasting the SSID in beacons transmitted for this VAP.
nonbroadcast-mode	Blocks broadcasting the SSID for this VAP. This setting is used in closed wireless networks. Devices connecting to the access point (AP) in nonbroadcast mode require the wireless device to enter the SSID.
<text>	Specifies an SSID for the VAP. The SSID can consist of up to 32 characters using text or letters and can also include spaces.

Default Values

By default, the SSID is set as the concatenation of the string “Adtran”: the **radio-index.vap-index**.

Command History

Release 15.1	Command was introduced.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Usage Examples

The following example configures the SSID of VAP interface **1** as **WLAN1** and blocks broadcasting this SSID:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#ssid non broadcast-mode WLAN1**

vlan-id *<vlan id>*

Use the **vlan-id** command to associate a virtual local area network (VLAN) with the virtual access point (VAP) interface. Encapsulation 802.1q must be enabled on the access point (AP) before wireless traffic is routed with the VLAN ID attached. To enable encapsulation, refer to the command *encapsulation 802.1q on page 3557*. Use the **no** form of this command to remove an entry.

If you change any part of the configuration of the NetVanta 160 Series access point, you must apply those changes for them to take effect using the command *dot11ap apply-changes on page 483*.

Syntax Description

<vlan id>	Specifies a VLAN interface ID number. Range is **1** to **4094**.

Default Values

By default, the VLAN ID is the same number as the VAP interface number.

Functional Notes

Once encapsulation 802.1q is enabled on the AP, all wireless traffic received on the VAP's service set identifier (SSID) is mapped to the VLAN (specified by the VLAN ID) when sent out the AP's Ethernet interface. All wireless traffic received on this VLAN ID at the AP's Ethernet interface is mapped to this VAP's SSID for wireless transmission.

Command History

Release 15.1	Command was expanded to include the VAP interface.
Release R10.4.0	Command was added to the NetVanta 160 Series VAP interface.

Usage Examples

The following example configures the **vlan-id** to **4** for VAP interface **1**:

(config)**#interface dot11ap 1/1.1**
(config-dot11ap 1/1.1-bg)**#vlan-id 4**

CARRIER ETHERNET COMMAND SETS

The Carrier Ethernet command sets are divided into the following sections:

EFM NIM2 ETHERNET COMMAND SETS

This section includes the following command sets:

MEF EFM GROUP COMMAND SET

Metro Ethernet Forum (MEF) Ethernet in the first mile (EFM) groups are logical interfaces that represent an EFM bonding group. Interfaces are connected to the EFM group and provide physical links to carry bonded traffic. These groups are used with the EFM network interface modules (NIM2s).

EFM NIM2s are used by Adtran products to provide EFM capabilities across wide area network (WAN) interfaces. These NIM2 cards enable host devices to participate in existing Metro Ethernet networks (MENs) that are deployed with EFM technology. The EFM group operates as the MEN port for the AOS unit, allowing Ethernet virtual connections (EVCs) to be associated logically as a MEN port and to use the same interfaces for connection with the MEN.

EFM groups are created and configured using the **interface efm-group** <*slot/port*> command from the Global Configuration mode as follows:

```
>enable
#configure terminal
(config)#interface efm-group 1/1
(config-efm-group 1/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

connect on page 3600
loopback detection on page 3601
thresholds xcv on page 3602
xcv-link-removal on page 3603

connect

Use the **connect** command to specify a physical interface to connect to the Ethernet in the first mile (EFM) group. Use the **no** form of this command to remove the connected interface from the group. Variations of this command include:

connect e1 <*slot/port*>
connect shdsl <*slot/port*>
connect t1 <*slot/port*>

Syntax Description

e1 <*slot/port*>	Specifies that an E1 interface is connected to the group.
shdsl <*slot/port*>	Specifies that a single-pair high-speed digital subscriber line (SHDSL) interface is connected to the group.
t1 <*slot/port*>	Specifies that a T1 interface is connected to the group.

Default Values

By default, no interfaces are connected to the EFM group.

Command History

Release A3.01	Command was introduced.

Usage Examples

The following example connects the SHDSL interface **shdsl 1/1** to EFM group **1**:

(config)**#interface efm-group 1/1**
(config-efm-group 1/1)**#connect shdsl 1/1**

loopback detection

Use the **loopback detection** command to enable loopback detection on the Ethernet in the first mile (EFM) group. Use the **no** form of this command to disable loopback detection.

Syntax Description

No subcommands.

Default Values

By default, looback detection is enabled.

Command History

Release A5.02	Command was introduced.

Functional Notes

Loopback detection is a function of the EFM engine on the Quad single-pair high-speed digital subscriber line (SHDSL) and Quad T1/E1 EFM network interface modules (NIM2s). When loopback detection is enabled, the EFM engine attaches its media access control (MAC) address to EFM fragments when they leave the module. The EFM engine also inspects EFM framents to verify that the MAC address on the fragments does not match the EFM engine's own MAC address. If the EFM fragment does have the same MAC address as the EFM engine, a loopback detection condition is asserted, and the EFM engine automatically removes the offending link from the EFM group.

Usage Examples

The following example disables loopback detection

(config)**#interface efm-group 1/1**
(config-efm-group 1/1)**#no loopback detection.**

thresholds xcv

Use the **thresholds xcv** command to configure the excessive code violation threshold for the interface's link in the Ethernet in the first mile (EFM) group. When this threshold is crossed, the link is removed from the group. Use the **no** form of this command to return the threshold to the default value. Variations of this command include:

thresholds xcv 1e-5
thresholds xcv 1e-6
thresholds xcv 1e-7

Syntax Description

1e-5	Specifies that the threshold is set at a 1e-5 bit error rate.
1e-6	Specifies that the threshold is set at a 1e-6 bit error rate.
1e-7	Specifies that the threshold is set at a 1e-7 bit error rate.

Default Values

By default, thresholds are set to **1e-7**.

Command History

Release A3.01	Command was introduced.

Functional Notes

Once the threshold is set, the command *xcv-link-removal on page 3603* must be entered in the group's configuration so that the interface's link is removed when the threshold is crossed.

Usage Examples

The following example specifies that the excessive code violation threshold for interfaces connected to EFM group **1** is **1e-6**:

(config)**#interface efm-group 1/1**
(config-efm-group 1/1)**#thresholds xcv 1e-6**

xcv-link-removal

Use the **xcv-link-removal** command to remove an interface's link from the Ethernet in the first mile (EFM) group if the excessive code violation threshold is exceeded. This threshold is set using the command *thresholds xcv on page 3602*. Using the **no** form of this command disables the link removal.

Syntax Description

No subcommands.

Default Values

By default, link removal is enabled for the EFM group.

Command History

Release A3.01	Command was introduced.

Usage Examples

The following example specifies that an interface whose excessive code violations exceed the threshold is no longer linked to EFM group **1**:

(config)**#interface efm-group 1/1**
(config-efm-group 1/1)**#xcv-link-removal**

MEF ETHERNET INTERFACE

The Metropolitan Ethernet Forum (MEF) Ethernet interface is a virtual interface used by AOS products to interface with the Metro Ethernet network (MEN) and carrier Ethernet technologies. The MEF Ethernet interface functions as the user-network interface (UNI) in AOS products with the second-generation Ethernet in the First Mile (EFM) network interface modules (NIMs). The MEF Ethernet interface is used as the Layer 2 and 3 wide-area network (WAN) interface. For more information about configuring the MEF Ethernet interface as part of the EFM NIM2 configuration, refer to the configuration guide *Configuring EFM NIM2s and the MEF Ethernet Interface in AOS* available online at https://supportcommunity.adtran.com.

To activate the basic MEF Ethernet Interface Configuration mode, enter the **interface mef-ethernet** *<slot/port>* command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface mef-ethernet 0/1
(config-mef-ethernet 0/1)#
```

To activate the basic MEF Ethernet Subinterface Configuration mode, enter the **interface mef-ethernet** *<slot/port.subinterface>* command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#interface mef-ethernet 0/1.1
(config-mef-ethernet 0/1.1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

alias "<text>" on page 75
cross-connect on page 76
description <text> on page 80
do on page 81
end on page 82
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

arp arpa on page 3606
awcp on page 3607
bandwidth <value> on page 3608
crypto map <name> on page 3610
dynamic-dns on page 3612
encapsulation 802.1q on page 3614

arp arpa

Use the **arp arpa** command to set ARPA as the standard Address Resolution Protocol (ARP) on this interface. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

The default for this command is **arpa**.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Usage Examples

The following example enables standard ARP for the MEF Ethernet interface **0/1**:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#arp arpa**

awcp

Use the **awcp** command to enable Adtran Wireless Control Protocol (AWCP) on this interface. The AWCP is an Adtran proprietary protocol used by an access controller (AC) to communicate with an access point (AP). Use the **no** form of this command to disable AWCP for this interface.

Syntax Description

No subcommands.

Default Values

By default, AWCP is enabled on the interface.

Command History

Release 15.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

When the global-level command **dot11ap access-point-controller** (refer to *dot11ap access-point-control on page 1268* for more information) is enabled, the AWCP function can be disabled on a specific interface by using the **no** form of this command from the desired interface. When the global-level command **dot11ap access-point-controller** is disabled, it overrides the **awcp** command setting for the interface.

Usage Examples

The following example disables AWCP on the MEF Ethernet interface 0/1:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#no awcp**

bandwidth <*value*>

Use the **bandwidth** command to provide the bandwidth value of an interface to the higher level protocols. This value is used in cost calculations. Use the **no** form of this command to restore the default value.

Syntax Description

<*value*>	Specifies bandwidth in kbps. Range is **1** to **4294967295** kbps.

Default Values

To view default value, use the **show interfaces** command.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

The **bandwidth** command is an informational value that is communicated to the higher level protocols to be used in cost calculations. While this is a routing parameter that does not affect the physical interface, it does affect the amount of bandwidth available for use in Quality of Service (QoS) configurations.

It is important to note that there is an order of precedence in determining the interface bandwidth reported by the router for QoS. Under normal circumstances, the Layer 1 bandwidth is reported based on the interface type. For example, a T1 interface will report the available bandwidth as 1.536 Mbps. This can be misleading in QoS configurations if the **bandwidth** command has been applied to the IP interface for routing purposes because the command overrides the reported available bandwidth that can be utilized for QoS. Using the **bandwidth** command can severely disrupt the configuration of QoS on the interface, therefore, use the **max-reserved-bandwidth** command (*page 3660*) to adjust the bandwidth appropriately for QoS configurations.

When configuring QoS for an Ethernet or VLAN interface, the interface **traffic-shape rate** command can be used to configure traffic shaping without applying a QoS map. If traffic shaping is applied to the same interface that will also have a QoS map applied to it, the amount of bandwidth available for the QoS policy is reduced to the value set with the **traffic-shape rate** command (*page 3668*). This value should be set to match the upload speed of the circuit. For example, under normal circumstances, an Ethernet interface can negotiate to 100 Mbps. However, the throughput of the upstream equipment is usually significantly less than the negotiated rate. The **traffic-shape rate** command is used to define the limit of when QoS policies containing the commands *bandwidth on page 4466* or *priority on page 4481* should be enforced according to the upload speed of the circuit. If the **bandwidth** <*value*> command is also entered on the same IP interface as the **traffic-shape rate** command, it will overwrite the value of the **traffic-shape rate** command for QoS purposes. It is not recommended to use the **bandwidth** <*value*> command for QoS. Instead, use the **max-reserved-bandwidth** command (*page 3660*) to adjust the bandwidth appropriately because the **traffic-shape rate** command is required for QoS to function properly on VLAN and Ethernet WAN IP interfaces.

Usage Examples

The following example sets bandwidth of the MEF Ethernet 0/1 interface to 10 Mbps:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#bandwidth 10000**

crypto map *<name>*

Use the **crypto map** command to associate crypto maps with the interface. Use the **no** form of this command to remove a crypto map from an interface.

When you apply a map to an interface, you are applying all crypto maps with the given map name. This allows you to apply multiple crypto maps if you have created maps that share the same name, but have different map index numbers.

Syntax Description

<name>	Specifies the crypto map name that you wish to assign to the interface.

Default Values

By default, no crypto maps are assigned to an interface.

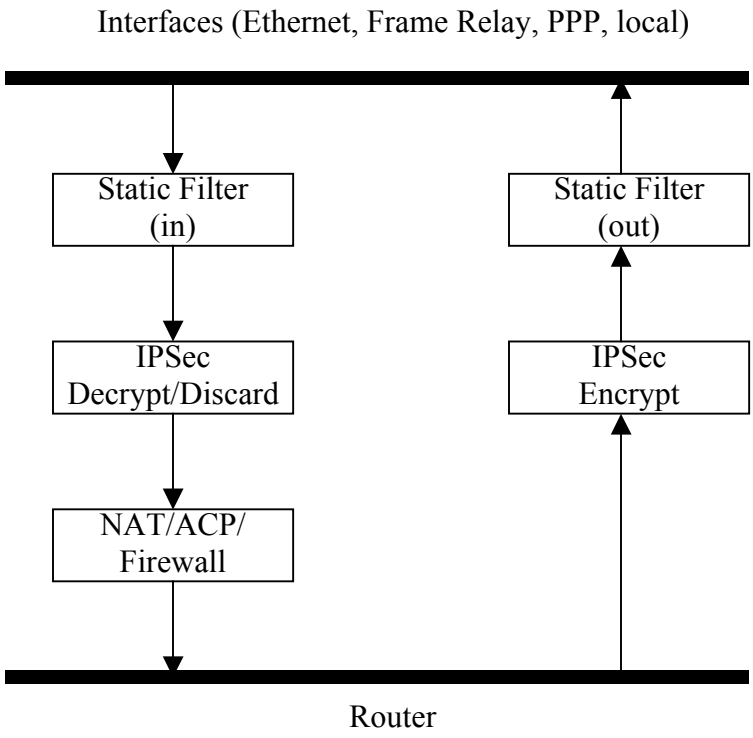
Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

When configuring a system to use both the stateful inspection firewall and Internet key exchange (IKE) negotiation for VPN, keep the following notes in mind.

When defining the policy class and associated access control lists (ACLs) that describe the behavior of the firewall, do not forget to include the traffic coming into the system over a VPN tunnel terminated by the system. The firewall should be set up with respect to the unencrypted traffic that is destined to be sent or received over the VPN tunnel. The following diagram represents typical AOS data-flow logic.



As shown in the diagram above, data coming into the product is first processed by the static filter associated with the interface on which the data is received. This access group is a true static filter and is available for use regardless of whether the firewall is enabled or disabled. Next (if the data is encrypted), it is sent to the IPSec engine for decryption. The decrypted data is then processed by the stateful inspection firewall. Therefore, given a terminating VPN tunnel, only unencrypted data is processed by the firewall.

The ACLs for a crypto map on an interface work in reverse logic to the ACLs for a policy class on an interface. When specifying the ACLs for a crypto map, the source information is the private local side, unencrypted source of the data. The destination information will be the far-end, unencrypted destination of the data. However, ACLs for a policy class work in reverse. The source information for the ACL in a policy class is the far end. The destination information is the local side.

Usage Examples

The following example applies all crypto maps with the name **MyMap** to the MEF Ethernet interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#crypto map MyMap**

dynamic-dns

Use the **dynamic-dns** command to configure Dynamic DNS service provided by Dynamic Network Services, Inc. (www.dyndns.org). Use the **no** form of this command to disable this feature. Variations of this command include:

dynamic-dns custom <*hostname*> <*minutes*>
dynamic-dns dyndns <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-custom <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-static <*hostname*> <*username*> <*password*>

Syntax Description

<*hostname*>	Specifies the host name for the server that updates the dynamic domain naming system (DNS).
<*minutes*>	Specifies the intervals in minutes to update the server with information (updates also occur when the interface's IP address changes regardless of the update intervals).
<*username*>	Specifies the user name.
<*password*>	Specifies the password.
	Refer to *Functional Notes* below for additional argument descriptions.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.
Release 12.1	Command was expanded.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

custom - Constanttime.com's Custom Dynamic DNS^{SM} service allows you complete access and management control over your domain name regardless of where you purchased/registered it. This allows you to manage IP address mappings (A records), domain aliases (CNAME records), and mail servers (mail exchange (MX) records).

dyndns - The Dynamic DNS^{SM} offered by Dynamic Network Services, Inc. (DynDNS.org) allows you to alias a dynamic IP address to a static host name in various domains. This allows your unit to be more easily accessed from various locations on the Internet. This service is provided for up to five host names.

dyndns-custom - DynDNS.org's Custom DNS^{SM} service provides a full DNS solution, giving you complete control over an entire domain name. A Web-based interface provides two levels of control over your domain, catering to average or advanced users. Five globally redundant DNS servers ensure that your domain will always resolve.

A choice of two interfaces is available. The basic interface is designed for most users. It comes preconfigured for most common configurations and allows for easy creation of most common record types. The advanced interface is designed for system administrators with a solid DNS background, and provides layout and functionality similar to a BIND zone file allowing for the creation of nearly any record type.

Custom DNS^{SM} can be used with both static and dynamic IPs, and has the same automatic update capability through Custom DNS-aware clients as Dynamic DNS.

dyndns-static - The Static DNS service is similar to DynDNS.org's Dynamic DNS^{SM} service in that it allows a host name, such as yourname.dyndns.org, to point to your IP address. Unlike a Dynamic DNS host, a Static DNS host does not expire after 35 days without updates, but updates take longer to propagate through the DNS system. This service is provided for up to five host names.

If your IP address does not change often or at all, but you still want an easy name to remember it by (without having to purchase your own domain name), Static DNS service is ideal for you.

If you would like to use your own domain name (such as yourname.com), you need Custom DNS service that also provides full dynamic and static IP address support.

Usage Examples

The following example sets the Dynamic DNS to **dyndns-custom** with host name **host**, user's name **user**, and password **pass**:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#dynamic-dns dyndns-custom host user pass**

encapsulation 802.1q

Use the **encapsulation 802.1q** command to put the interface into 802.1q virtual local area network (VLAN) mode.

If you are using 802.1q encapsulation with the MEF Ethernet interface, you must have a native VLAN MEF Ethernet subinterface configured for the EFM NIM2 to communicate with the AOS unit. Refer to the Functional Notes of this command for more information.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 6.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

To use 802.1q encapsulation with the MEF Ethernet interface, you must have a native VLAN MEF Ethernet subinterface configured using the command *vlan-id <vlan id> on page 3669*:

Usage Examples

The following example configures a MEF Ethernet subinterface for VLAN usage and puts the MEF Ethernet interface 0/1 in 802.1q mode:

(config)**#interface mef-ethernet 0/1.1**
(config-mef-ethernet 0/1.1)**#vlan-id 1 native**
(config-mef-ethernet 0/1.1)**#exit**

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#encapsulation 802.1q**

ethernet-cfm down

Use the **ethernet-cfm down** command to enable Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) on the Ethernet interface. Use the **no** form of this command to disable Ethernet OAM CFM on this interface.

Syntax Description

No subcommands.

Default Values

By default, Ethernet OAM CFM is disabled.

Command History

Release 17.4	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

For more information about Ethernet OAM CFM and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

For more information regarding specific Ethernet OAM CFM configuration commands on the Ethernet interface, refer to the *Ethernet OAM CFM Command Set on page 4405*.

Usage Examples

The following example enables Ethernet OAM CFM on the MEF Ethernet interface 0/1:

```
(config)#interface mef-ethernet 0/1
(config-mef-ethernet 0/1)#ethernet-cfm down
```

ethernet-cfm mep

Use the **ethernet-cfm mep** command to create an Ethernet operations, administration, and maintenance (OAM) connectivity fault management (CFM) maintenance endpoint (MEP) on the Ethernet interface. Use the **no** form of this command to remove the MEP from the interface. Variations of this command include:

ethernet-cfm mep *<name>* *<name>* *<mep id>* **down**
ethernet-cfm mep none *<name>* *<mep id>* **down**

Syntax Description

<name>	Specifies the MEP's maintenance domain.
<name>	Specifies the MEP's maintenance association.
<mep id>	Specifies the unique numerical ID for this MEP. Range is **1** to **8191**.
none	Optional. Specifies no domain name is used.
down	Specifies the direction of the MEP.

Default Values

By default, no MEPs exist on the interface.

Command History

Release 17.4	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

For more information about Ethernet OAM CFM and its operation on AOS products, refer to the *Ethernet OAM CFM in AOS* configuration guide available online at https://supportcommunity.adtran.com.

For more information about specific MEP configuration commands, refer to the *Ethernet OAM CFM Command Set on page 4405*.

Usage Examples

The following example creates an MEP, with the MEP ID **100**, on the MEF Ethernet interface **0/1**. The MEP is associated with maintenance domain **Domain1** and association **association1**:

```
(config)#interface mef-ethernet 0/1
(config-mef-ethernet 0/1)#ethernet-cfm mep Domain1 association1 100 down
(config-mef-ethernet 0/1-mep)
```

ip access-group *<ipv4 acl name>*

Use the **ip access-group** command to apply an Internet Protocol version 4 (IPv4) access control list (ACL) to be used for packets transmitted on or received from the specified interface. Use the **no** form of this command to disable this type of control. Variations of this command include:

ip access-group *<ipv4 acl name>* **in**
ip access-group *<ipv4 acl name>* **out**

Syntax Description

<ipv4 acl name>	Applies the named IPv4 ACL to the interface.
in	Enables access control on packets received on the specified interface.
out	Enables access control on packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

When this command is enabled, the IPv4 destination address of each packet must be validated before being passed through. If the packet is not acceptable per these settings, it is dropped.

Usage Examples

The following example configures the router to only allow Telnet traffic (as defined in the user-configured **TelnetOnly** ACL) into the MEF Ethernet interface:

(config)**#ip access-list extended TelnetOnly**
(config-ext-nacl)**#permit tcp any any eq telnet**
(config-ext-nacl)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip access-group TelnetOnly in**

ip address dhcp

Use the **ip address dhcp** command to use Dynamic Host Configuration Protocol (DHCP) to obtain an address on the interface. Use the **no** form of this command to remove a configured IP address (using DHCP) and disable DHCP operation on the interface. Variables that may be used with this command to further define the DHCP configuration include:

ip address dhcp class-id [ascii *<string>* **| hex** *<value>***] [client-id [***<interface>* **|** *<identifier>***]] [hostname** *<"string">***] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp client-id [*<interface>* **|** *<identifier>***] [hostname** *<"string">***] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp hostname *"<string>"* **[no-default-route | no-domain-name | no-nameservers] [track** *<name>***] [***<administrative distance>***]**
ip address dhcp [no-default-route | no-domain-name | no-nameservers] [track *<name>***] [***<administrative distance>***]**
ip address dhcp track *<name>* **[***<administrative distance>***]**

Syntax Description

<administrative distance>	Optional. Specifies the administrative distance to use when adding the DHCP gateway into the route table. It is used to determine the best route when multiple routes to the same destination exist. The lower the administrative distance, the more reliable the route. Range is **1** to **255**.
class-id	Optional. Specifies the vendor class identifier for the interface.
ascii *<string>*	Specifies the vendor class identifier in an ASCII string of up to **255** bytes.
hex *<value>*	Specfies the vendor class identifier in hexadecimal format. Valid range is up to **510** hexadecimal numbers. An even number of digits is required.
client-id	Optional. Specifies the client identifier used when obtaining an IP address from a DHCP server.
<interface>	Specifies an interface, thus defining the client identifier as the hexadecimal medium access control (MAC) address of the specified interface (including a hexadecimal number added to the front of the MAC address to identify the media type). For example, specifying the **client-id ethernet 0/1** (where the Ethernet interface has a MAC address of d217.0491.1150) defines the client identifier as **01:d2:17:04:91:11:50** (where 01 defines the media type as Ethernet). Refer to *hardware-address on page 4344* for a detailed listing of media types.
<identifier>	Specifies a custom client-identifier using a text string (that is converted to a hexadecimal equivalent) or 7 to 28 hexadecimal numbers (with colon delimiters). For example, a custom client identifier of **0f:ff:ff:ff:ff:51:04:99:a1** may be entered using the *<identifier>* option.
hostname *<"string">*	Optional. Specifies a text string (to override the global router name) to use as the name in the DHCP option 12 field. The string is enclosed in quotation marks and can consist of up to 35 characters.

no-default-route Optional. Specifies that no default route is obtained via DHCP.

no-domain-name Optional. Specifies that no domain name is obtained via DHCP.

no-nameservers Optional. Specifies that no domain naming system (DNS) servers are obtained via DHCP.

track *<name>* Optional. Attaches a network monitoring track to the DHCP client. The DHCP gateway route for this client will only reside in the route table while the track is in the pass state. For more information on configuring track objects, refer to *track <name> on page 1886*.

Default Values

<administrative distance> By default, the administrative distance value is 1.

class-id Optional. By default, no vendor class identifier is configured.

client-id Optional. By default, the client identifier is populated using the following formula:

TYPE: INTERFACE SPECIFIC INFO : MAC ADDRESS

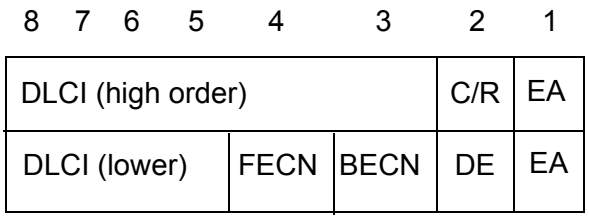
Where TYPE specifies the media type in the form of one hexadecimal byte (refer to *hardware-address on page 4344* for a detailed listing of media types), and the MAC ADDRESS is the medium access control (MAC) address assigned to the first Ethernet interface in the unit in the form of six hexadecimal bytes. (For units with a single Ethernet interface, the MAC ADDRESS assigned to Ethernet 0/1 is used in this field.)

INTERFACE SPECIFIC INFO is only used for Frame Relay interfaces and can be determined using the following:

FR_PORT#: Q.922 ADDRESS

Where the FR_PORT# specifies the label assigned to the virtual Frame Relay interface using four hexadecimal bytes. For example, a virtual Frame Relay interface labeled 1 would have a FR_PORT# of 00:00:00:01.

The Q.922 ADDRESS field is populated using the following:



Where the FECN, BECN, C/R, DE, and high order extended address (EA) bits are assumed to be 0 and the lower order EA bit is set to 1.

The following list provides a few example DLCIs and associated Q.922 address:

DLCI (decimal) / Q.922 address (hex)

16 / 0x0401
50 / 0x0C21
60 / 0x0CC1
70 / 0x1061
80 / 0x1401

hostname *"<string>"* — By default, the host name is the name configured using the Global Configuration **hostname** command.

Command History

Release 2.1	Command was introduced.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 13.1	Command was expanded to include the track and administrative distance.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.10.0	Command was expanded to include the **class-id** parameter in support of DHCP Option 60.

Functional Notes

DHCP allows interfaces to acquire a dynamically assigned IP address from a configured DHCP server on the network. Many service providers require the use of DHCP when connecting to their services. Using DHCP reduces the number of dedicated IP addresses the ISP must obtain. Consult your ISP to determine the proper values for the **client-id** and **hostname** fields.

The vendor class identifier is sent to the DHCP server in DHCP discover and request messages via DHCP Option 60. This option gives the DHCP server details regarding DHCP client configuration and also allows the server to send any vendor-specific information to the client in DHCP offer messages via Option 43.

Usage Examples

The following example enables DHCP operation on the interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip address dhcp**

The following example enables DHCP operation on the interface utilizing host name **adtran** and does not allow obtaining a default route, domain name, or name servers. It also sets the administrative distance as **5**:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip address dhcp hostname "adtran" no-default-route no-domain-name no-nameservers 5**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the specified interface (only one primary address is allowed). Use the optional **secondary** keyword to define a secondary IP address. Use the **no** form of this command to remove a configured IP address. Variations of this command include:

ip address <*ipv4 address*> <*subnet mask*>
ip address <*ipv4 address*> <*subnet mask*> **secondary**

Syntax Description

<*ipv4 address*>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*subnet mask*>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the specified interface.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a secondary IPv4 address of **192.22.72.101 /30**:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip address 192.22.72.101 /30 secondary**

ip address range *<start ip address> <end ip address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the specified interface. Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip dhcp

Use the **ip dhcp** command to release or renew the Dynamic Host Configuration Protocol (DHCP) Internet Protocol version 4 (IPv4) address. This command is only applicable when using DHCP for IP address assignment. Variations of this command include:

ip dhcp release
ip dhcp renew

Syntax Description

release	Releases the DHCP IPv4 address.
renew	Renews the DHCP IPv4 address.

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.
Release 8.1	Command was added to the asynchronous transfer mode (ATM) subinterface.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release R10.1.0	Command was added to the bridged virtual interface (BVI).

Usage Examples

The following example releases the IPv4 address assigned (by DHCP) on the MEF Ethernet interface 0/1:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip dhcp release**

ip directed-broadcast

Use the **ip directed-broadcast** command to allow reception/forwarding of directed broadcasts. Use the **no** form of this command to disable this feature. Variations of this command include:

ip directed-broadcast
ip directed-broadcast <*name*>

Syntax Description

<*name*>	Optional. Specifies IP access control list (ACL) name to filter traffic.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

A directed broadcast is a packet intended for all nodes on a nonlocal network. For example, the broadcast address 255.255.255.255 reaches all nodes on a network; the directed broadcast address 128.1.255.255 is intended for all nodes whose network address is 128.1.0.0. A router not directly attached to 128.1.0.0 simply forwards the directed broadcast packet to the next hop. A router on network 128.1.0.0 that has **ip directed-broadcast** enabled, accepts and forwards the packet to all nodes whose network address is 128.1.0.0. Routers connecting subnets of 128.1.0.0 also accept and forward the packet to the nodes on their respective subnets. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is distributed as a broadcast on the destination subnet. The packet is then sent as a link-layer broadcast.

The **ip directed-broadcast** command controls the distribution of directed broadcasts when they reach their target subnets. Only the final transmission of the directed broadcast on its ultimate destination subnet is affected. It does not affect the transit unicast routing of IP directed broadcasts.

If **ip directed-broadcast** is enabled for this interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which this interface is attached will be forwarded as broadcasts on that subnet. Forwarding of the packets can be limited by specifying an ACL with this command. In this case, only directed broadcasts that are permitted by the specified ACL will be forwarded, and all other directed broadcasts directed to this interface subnet will be dropped.

Disabling the **ip directed-broadcast** command will cause directed broadcasts destined for the subnet to which this interface is attached to be dropped.

This option is a requirement for routers as described in RFC 1812, section 4.2.2.11. Furthermore, it is disabled by default (RFC 2644), with the intended goal of reducing the efficacy of certain types of denial of service (DoS) attacks.

Usage Examples

The following example enables forwarding of directed broadcasts on the interface **mef-ethernet 0/1**:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip directed-broadcast**

ip ffe

Use the **ip ffe** command to enable the RapidRoute Engine on this interface with the default number of entries. Use the **no** form of this command to disable this feature. Variations of this command include:

ip ffe
ip ffe max-entries <*value*>

Issuing this command will cause all RapidRoute entries on this interface to be cleared.

Syntax Description

max-entries <*value*>	Optional. Specifies the maximum number of entries stored in the flow table. Valid range is from **1** to **8192**.

Default Values

By default, the RapidRoute Engine is disabled. The default number of **max-entries** is **4096**.

Command History

Release 13.1	Command was introduced.
Release 17.6	Command was expanded to include the high level data link control (HDLC) and tunnel interfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

RapidRoute can be used to help reduce routing overhead, and thus reduce overall routing times. Routing times are reduced by the creation of a flow table on the ingress interface. The maximum number of entries that can be stored in the flow table at any one time may be specified by using the **max-entries** parameters.

Usage Examples

The following example enables RapidRoute and sets the maximum number of entries in the flow table to **50**:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip ffe max-entries 50**

Technology Review

The RapidRoute system goal is to increase IP packet throughput by moving as much of the packet processing into the engine as possible. Packets are classified into flows based upon the IP protocol (Transmission Control Protocol (TCP), User Datagram Protocol (UDP), Internet Control Message Protocol (ICMP), etc.), the source and destination IP addresses, IP type of service (ToS), and the protocol-specific information, such as the source and destination port numbers. Flows are defined as the unidirectional representation of a conversation between two IP hosts. Each ingress interface keeps its own flow table, a collection of flow entries.

The first packet in a flow that is forwarded through the unit will build a flow entry. When a flow entry is looked up but no entry is found, a RapidRouteBuilder object is allocated and attached to the packet. As the packet passes through the various processing layers, each subsystem will add processing to the RapidRouteBuilder. When packet is about to be forwarded out of the egress interface, the RapidRouteBuilder will be finalized. That is, the flow entry being built will be checked for completeness and committed to the flow table on the ingress interface. Subsequent flow matches can then bypass the normal processing layers.

ip flow

Use the **ip flow** command to enable integrated traffic monitoring (ITM) for all traffic received or forwarded on an interface. Use the **no** form of this command to disable traffic monitoring. Variations of this command include:

ip flow egress
ip flow egress <*name*>
ip flow ingress
ip flow ingress <*name*>

Syntax Description

egress	Specifies that all outgoing traffic be monitored.
ingress	Specifies that all incoming traffic be monitored.
<*name*>	Optional. Specifies the name of an access control list (ACL) to use for filtering traffic.

Default Values

By default, no traffic monitoring is enabled.

Command History

Release 16.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Usage Examples

The following example enables traffic monitoring on a MEF Ethernet interface to monitor **incoming** traffic through an ACL called **myacl**:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip flow ingress myacl**

ip helper-address *<ip address>*

Use the **ip helper-address** command to configure AOS to forward User Datagram Protocol (UDP) broadcast packets received on the interface. Use the **no** form of this command to disable forwarding packets.

*The **ip helper-address** command must be used in conjunction with the **ip forward-protocol** command to configure AOS to forward UDP broadcast packets.*

Syntax Description

<ip address>	Specifies the destination IP address for the forwarded UDP packets. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, broadcast UDP packets are not forwarded.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

When used in conjunction with the **ip forward-protocol** command, the **ip helper-address** feature allows you to customize which broadcast packets are forwarded.

To implement the helper address feature, assign helper address(es) (specifying the device that needs to receive the broadcast traffic) to the interface closest to the host that transmits the broadcast packets. When broadcast packets (of the specified type forwarded using the **ip forward-protocol** command) are received on the interface, they will be forwarded to the device that needs the information.

Only packets meeting the following criteria are considered eligible by the **ip helper-address** feature:

1. The packet IP protocol is UDP.
2. Any UDP port specified using the **ip forward-protocol** command.
3. The medium access control (MAC) address of the frame is an all-ones broadcast address (ffff.ffff.ffff).
4. The destination IP address is broadcast defined by all ones (**255.255.255.255**) or a subnet broadcast (for example, **192.33.4.251** for the **192.33.4.248 /30** subnet).

Usage Examples

The following example forwards all domain naming system (DNS) broadcast traffic to the DNS server with IP address **192.33.5.99**:

(config)**#ip forward-protocol udp domain**
(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip helper-address 192.33.5.99**

ip igmp

Use the **ip igmp** command to configure multicasting related functions for the interface. Variations of this command include:

ip igmp immediate-leave
ip igmp last-member-query-interval <*milliseconds*>
ip igmp querier-timeout <*seconds*>
ip igmp query-interval <*seconds*>
ip igmp query-max-response-time <*seconds*>
ip igmp static-group <*address*>
ip igmp version [1 | 2]

Syntax Description

immediate-leave	Specifies that if only one host (or Internet Group Management Protocol (IGMP) snooping switch) is connected to the interface, when a leave is received, multicast of that group is immediately terminated as opposed to sending a group query and timing out the group if no device responds. Works in conjunction with **ip igmp last-member-query-interval**. Applies to all groups when configured. Use the **no** form of this command to disable the **immediate-leave** feature.
last-member-query-interval <*milliseconds*>	Controls the timeout (in milliseconds) used to detect whether any group receivers remain on an interface after a receiver leaves a group. If a receiver sends a leave-group message (IGMP Version 2), the router sends a group-specific query on that interface. After twice the time specified by this command plus as much as one second longer, if no receiver responds, the router removes that interface from the group and stops sending that group's multicast packets to the interface. Range is **100** to **65535** ms. Use the **no** form of this command to return to the default setting.
querier-timeout <*seconds*>	Specifies the interval (in seconds) that the router waits after the current querier's last query before it takes over as querier (IGMP V2). Range is **60** to **300** seconds. Use the **no** form of this command to return to the default setting.
query-interval <*seconds*>	Specifies the interval (in seconds) at which IGMP queries are sent on an interface. Host query messages are addressed to the all-hosts multicast group with an IP time to live (TTL) of 1. The router uses queries to detect whether multicast group members are on the interface and to select an IGMP designated router (DR) for the attached segment (if more than one multicast router exists). Only the DR for the segment sends queries. For IGMP V2, the DR is the router with the lowest IP address on the segment. Range is **0** to **65535** seconds. Use the **no** form of this command to return to the default setting.
query-max-response-time <*seconds*>	Specifies the maximum response time (in seconds) advertised by this interface in queries when using IGMP V2. Hosts are allowed a random time within this period to respond, reducing response bursts. Use the **no** form of this command to return to the default setting.

Syntax Description

static-group <*address*>	Configures the router's interface to be a statically connected member of the specified group. Packets received on the correct reverse path forwarding (RPF) interface are forwarded to this interface regardless of whether any receivers have joined the specified group using IGMP. Use the **no** form of this command to remove a configured static group.
version [1 | 2]	Sets the interface's IGMP version. Use the **no** form of this command to return to the default setting.

Default Values

The defaults for this command are:

last-member-query-interval	**1000** milliseconds
querier-timeout	2x the **query-interval** value
query-interval	**60** seconds
query-max-response-time	**10** seconds
version	Version **1**

There are no default values for **immediate-leave** and **static-group**.

Command History

Release 7.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Usage Examples

The following example sets the query message interval on the MEF Ethernet interface to **200** milliseconds:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip igmp last-member-query-interval 200**

ip mcast-stub downstream

Use the **ip mcast-stub downstream** command to enable multicast forwarding and Internet Group Management Protocol (IGMP) (router mode) on an interface, and to place it in multicast stub downstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub upstream** commands. Downstream interfaces connect to segments with multicast hosts. Multiple interfaces may be configured in downstream mode; however, interfaces connecting to the multicast network (upstream) should not be configured in downstream mode. Interfaces configured as downstream should have the lowest IP address of all IGMP-capable routers on the connected segment in order to be selected as the designated router (DR) and ensure proper forwarding. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub upstream on page 3636* for more information.

Usage Examples

The following example enables multicast forwarding and IGMP on the MEF Ethernet interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip mcast-stub downstream**

ip mcast-stub fixed

Use the **ip mcast-stub fixed** command to allow forwarding of multicast traffic on a selected interface after enabling multicast routing. Use the **no** form of this command to disable this mode.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 12.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

Multicast routing must be enabled prior to setting **ip mcast-stub fixed** on the selected interface. Also, use the **ip igmp static-group** <*ip address*> command to receive multicast traffic without host-initiated Internet Group Management Protocol (IGMP) activity on the selected interface. Otherwise, all host-initiated IGMP transactions will enter multicast routes on the router's interface involved with IGMP activities.

Usage Examples

The following example enables multicast traffic forwarding and IGMP on the MEF Ethernet interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip mcast-stub fixed**

ip mcast-stub helper-enable

Use the **ip mcast-stub helper-enable** command to assign the **ip mcast-stub helper-address** as the Internet Group Management Protocol (IGMP) proxy. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 8.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address**, **ip mcast-stub upstream**, and **ip mcast-stub downstream** commands. When enabled, the interface becomes a helper forwarding interface. The IGMP host function is dynamically enabled and the interface becomes the active upstream interface, enabling the unit to perform as an IGMP proxy. Refer to *ip mcast-stub helper-address <ip address> on page 1418*, *ip mcast-stub downstream on page 3633*, and *ip mcast-stub upstream on page 3636* for more information.

Usage Examples

The following example sets the helper address as the IGMP proxy:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip mcast-stub helper-enable**

ip mcast-stub upstream

Use the **ip mcast-stub upstream** command to enable multicast forwarding on an interface and place it in multicast stub upstream mode. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 7.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

This command is used in IP multicast stub applications in conjunction with the **ip mcast-stub helper-address** and **ip mcast-stub downstream** commands. When enabled, the interface becomes a candidate to be a helper forwarding interface. If chosen as the best path toward the helper address by the router's unicast route table, the Internet Group Management Protocol (IGMP) host function is dynamically enabled and the interface becomes the active upstream interface, enabling the router to perform as an IGMP proxy. Though multiple interfaces may be candidates, no more than one interface will actively serve as the helper forwarding interface. Refer to *ip mcast-stub helper-address <ip address> on page 1418* and *ip mcast-stub downstream on page 3633* for more information.

Usage Examples

The following example enables multicast forwarding on the MEF Ethernet interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip mcast-stub upstream**

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the active interface. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces	(all types)1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.

Functional Notes

Open shortest path first (OSPF) will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the MEF Ethernet interface 0/1:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip mtu 1200**

ip ospf

Use the **ip ospf** command to customize open shortest path first (OSPF) settings (if needed). Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf authentication-key <*password*>
ip ospf cost <*value*>
ip ospf dead-interval <*seconds*>
ip ospf hello-interval <*seconds*>
ip ospf message-digest-key [1 | 2] md5 <*key*>
ip ospf priority <*value*>
ip ospf retransmit-interval <*seconds*>
ip ospf transmit-delay <*seconds*>

Syntax Description

authentication-key <*password*>	Assigns a simple-text authentication password to be used by other routers using the OSPF simple password authentication.
cost <*value*>	Specifies the OSPF cost of sending a packet on the interface. This value overrides any computed cost value. Range is **1** to **65535**.
dead-interval <*seconds*>	Sets the maximum interval (in seconds) allowed between hello packets. If the maximum is exceeded, neighboring devices will determine that the device is down. Range is **0** to **32767** seconds.
hello-interval <*seconds*>	Specifies the interval (in seconds) between hello packets sent on the interface. Range is **0** to **32767** seconds.
message-digest-key [1 | 2] md5 <*key*>	Configures OSPF message digest 5 (MD5) authentication (16 byte maximum) keys.
priority <*value*>	Sets the OSPF priority. The value set in this field helps determine the designated router (DR) for this network. Range is **0** to **255**.
retransmit-interval <*seconds*>	Specifies the interval (in seconds) between link state advertisements (LSAs). Range is **0** to **32767** seconds.
transmit-delay <*seconds*>	Sets the estimated time (in seconds) required to send a link state advertisement (LSA) on the interface. Range is **0** to **32767** seconds.

Default Values

The defaults for this command are:

dead-interval <*seconds*>	40 seconds
hello-interval <*seconds*>	10 seconds: Ethernet, Frame Relay, and Point-to-Point Protocol (PPP)
priority <*value*>	1
retransmit-interval <*seconds*>	5 seconds
transmit-delay <*seconds*>	1 second

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Usage Examples

The following example specifies an OSPF priority of **120** on the MEF Ethernet interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip ospf priority 120**

ip ospf authentication

Use the **ip ospf authentication** command to authenticate an interface that is performing open shortest path first (OSPF) authentication. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf authentication
ip ospf authentication message-digest
ip ospf authentication null

Syntax Description

message-digest	Optional. Selects message-digest authentication type.
null	Optional. Specifies that no authentication is used.

Default Values

By default, this is set to **null** (meaning no authentication is used).

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Usage Examples

The following example specifies that no authentication will be used on the MEF Ethernet interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip ospf authentication null**

ip ospf network

Use the **ip ospf network** command to specify the type of network on this interface. Use the **no** form of this command to return to the default setting. Variations of this command include:

ip ospf network broadcast
ip ospf network point-to-point

Syntax Description

broadcast	Sets the network type for broadcast.
point-to-point	Sets the network type for point-to-point.

Default Values

By default, Ethernet defaults to **broadcast**. Point-to-Point Protocol (PPP) and Frame Relay default to point-to-point.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

A point-to-point network will not elect designated routers.

Usage Examples

The following example designates a broadcast network type:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip ospf network broadcast**

ip pim sparse-mode

Use the **ip pim sparse-mode** command to enable protocol-independent multicast (PIM) sparse mode for this interface. Use the **no** form of this command to disable PIM sparse mode.

Syntax Description

No subcommands.

Default Values

By default, PIM sparse mode for this interface is disabled.

Command History

Release 11.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

PIM sparse mode is a multicast routing protocol that makes use of the unicast forwarding table. It builds unidirectional shared trees rooted at a rendezvous point (RP) for a multicast group or a shortest path tree rooted at a specific source for a multicast group.

Usage Examples

The following example enables PIM sparse mode on the MEF Ethernet interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip pim sparse-mode**

ip pim-sparse dr-priority <*value*>

Use the **ip pim-sparse dr-priority** command to specify the priority for the designated router (DR). This command modifies the router's priority in the DR election process. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the priority of this interface (to be used when determining the DR). Valid range is **1** to **4294967295**.

Default Values

By default, the priority of all protocol-independent multicast (PIM) interfaces is **1**.

Command History

Release 11.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

Interfaces advertise their configured priority values in the hello messages transmitted on the interface. Routers use the priority values to determine the appropriate DR. The router on the network segment with the highest priority is selected as the DR. If a hello message is received on the interface from a router on the network segment and it does not contain a priority, the entire network segment defaults to DR selection based on IP addresses instead of priority. In this instance, the DR is selected as the router on the network segment that has the highest IP address. AOS will always include a priority in all transmitted hello messages. If no priority is specifically designated by the user, the priority is set as the default of 1.

Usage Examples

The following example specifies a priority of **100** on the MEF Ethernet 0/1 interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip pim-sparse dr-priority 100**

ip pim-sparse hello-timer <*value*>

Use the **ip pim-sparse hello-timer** command to specify protocol-independent multicast (PIM) sparse hello timer period. This is the time interval at which periodic hellos are sent out on all interfaces of a PIM-capable router. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the interval (in seconds) at which periodic hellos are sent out of the interface. Valid range is **10** to **3600** seconds.

Default Values

By default, the hellos are transmitted on PIM interfaces every **60** seconds.

Command History

Release 11.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

Hello messages are used to inform neighbors of a router's presence. Hello messages normally generate a small amount of traffic on an interface. Setting the **hello-timer** to a small interval increases the number of hellos sent (thus increasing the amount of traffic). Set the **hello-timer** to a reasonable value, taking into consideration the bandwidth available on the interface.

Usage Examples

The following example specifies hellos be sent on the MEF Ethernet 0/1 interface every **3600** seconds:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip pim-sparse hello-timer 3600**

ip pim-sparse nbr-timeout <*value*>

Use the **ip pim-sparse nbr-timeout** command to specify protocol-independent multicast (PIM) sparse neighbor timeout. This is the time interval after which a PIM-capable router will consider a neighbor not present. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the time interval in seconds after which a neighbor is considered not present. Valid range is **30** to **10800** seconds.

Default Values

By default, the nbr-timeout is set to **105** seconds.

Command History

Release 11.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Usage Examples

The following example sets the neighbor timeout to **300** seconds:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip pim-sparse nbr-timeout 300**

ip pim-sparse override-interval <*value*>

Use the **ip pim-sparse override-interval** command to specify the protocol-independent multicast (PIM) sparse join/prune override interval. This delay interval is the period after a join/prune that another router on the local area network (LAN) may override a join/prune. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the delay time in milliseconds. Valid range is **0** to **65535** milliseconds.

Default Values

By default, the override interval is set to **2500** milliseconds.

Command History

Release 11.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Usage Examples

The following example sets the override interval to **3000** milliseconds:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip pim-sparse override-interval 3000**

ip pim-sparse propagation-delay *<value>*

Use the **ip pim-sparse propagation-delay** command to specify the expected propagation delay for join/prune messages. Set the propagation delay (in milliseconds) to estimate the amount of delay found in the local link. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the expected propagation delay in the local link in milliseconds. Valid range is **0** to **32767** milliseconds.

Default Values

By default, the propagation delay is set to **500** milliseconds.

Command History

Release 11.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Usage Examples

The following example sets the propagation delay to **300** milliseconds:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip pim-sparse propagation-delay 300**

ip policy route-map *<name>*

Use the **ip policy route-map** command to assign a policy route map to this interface. Use the **no** form of this command to remove the route-map policy.

Syntax Description

<name>	Specifies the name of the policy route map to assign to this interface.

Default Values

By default, no policy route map is assigned to this interface.

Command History

Release 11.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Usage Examples

The following example assigns the policy route map **policy1** to the MEF Ethernet interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip policy route-map policy1**

ip proxy-arp

Use the **ip proxy-arp** command to enable proxy Address Resolution Protocol (ARP) on the interface. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, proxy ARP is enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

In general, the principle of proxy ARP allows a router to insert its IP address in the source IP address field of a packet (if the packet is from a host on one of its subnetworks). This allows hosts to reach devices on other subnetworks without implementing routing or specifying a default gateway.

If proxy ARP is enabled, AOS will respond to all ARP requests with its specified medium access control (MAC) address and forward packets accordingly.

Enabling proxy ARP on an interface may introduce unnecessary ARP traffic on the network.

Usage Examples

The following example enables proxy ARP on the MEF Ethernet interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip proxy-arp**

ip rip receive version

Use the **ip rip receive version** command to configure the Routing Information Protocol (RIP) version the unit accepts in all RIP packets received on the interface. Variations of this command include:

ip rip receive version 1
ip rip receive version 2

Syntax Description

1	Accepts only RIP version 1 packets received on the interface.
2	Accepts only RIP version 2 packets received on the interface.

Default Values

By default, all interfaces implement RIP version **1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

Use the **ip rip receive version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only accepts one version (either **1** or **2**) on a given interface.

Usage Examples

The following example configures the MEF Ethernet interface to accept only RIP version **2** packets:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip rip receive version 2**

ip rip send version

Use the **ip rip send version** command to configure the Routing Information Protocol (RIP) version the unit sends in all RIP packets transmitted on the interface. Variations of this command include:

ip rip send version 1
ip rip send version 2

Syntax Description

1	Transmits only RIP version 1 packets on the interface.
2	Transmits only RIP version 2 packets on the interface.

Default Values

By default, all interfaces transmit RIP version **1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

Use the **ip rip send version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only transmits one version (either **1** or **2**) on a given interface.

Usage Examples

The following example configures the MEF Ethernet interface to transmit only RIP version **2** packets:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip rip send version 2**

ip rip summary-address *<ip address> <subnet mask>*

Use the **ip rip summary-address** command to manually summarize the routes Routing Information Protocol (RIP) will advertise and send out a specified interface. Use the **no** form of this command to disable this mode.

Syntax Description

<ip address>	Specifies the summarized network IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.0**).
<subnet mask>	Specifies the subnet mask that corresponds to the range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no manual summarization is applied by RIP.

Command History

Release 12.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

Unlike the automatic summarization on classful network boundaries, only specific network advertisements are made by RIP using the **ip rip summary-address** command. This command is only effective if RIP version 2 is configured.

Usage Examples

The following example enables manual summarization on the specified IP address:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip rip summary-address 10.10.123.0 255.255.255.0**

ip route-cache

Use the **ip route-cache** command to enable fast-cache switching on the interface. Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

*Using network address translation (NAT) or the AOS firewall capabilities on an interface requires process switching mode (using the **no ip route-cache** command).*

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

Fast switching allows an IP interface to provide optimum performance when processing IP traffic.

Usage Examples

The following example enables fast switching on the MEF Ethernet interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip route-cache**

ip urlfilter *<name>*

Use the **ip urlfilter** command to apply a universal resource locator (URL) filter to the interface for all inbound or outbound traffic. Use the **no** form of this command to remove the URL filter from an interface. Variations of this command include:

ip urlfilter *<name>* **in**
ip urlfilter *<name>* **out**

Syntax Description

<name>	Specifies the URL filter name to use on the interface.
in	Applies the filter to the inbound traffic.
out	Applies the filter to the outbound traffic.

Default Values

By default, there are no URL filters applied to any interfaces.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be created by using the **ip urlfilter** *<filtername>* **http** command before applying it to the interface. Refer to *ip urlfilter allowmode on page 1493* for more information on using this command.

Usage Examples

The following example performs URL filtering on all traffic entering through the MEF Ethernet interface and matches the URL filter named **MyFilter**:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#ip urlfilter MyFilter in**

lldp receive

Use the **lldp receive** command to allow Link Layer Discovery Protocol (LLDP) packets to be received on this interface. Use the **no** form of this command to prevent LLDP packets from being received on the interface.

Syntax Description

No subcommands.

Default Values

By default, all interfaces are configured to send and receive LLDP packets.

Command History

Release 8.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Usage Examples

The following example configures the MEF Ethernet interface 0/1 to receive LLDP packets:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#lldp receive**

lldp send

Use the **lldp send** command to configure this interface to transmit Link Layer Discovery Protocol (LLDP) packets or to control the types of information contained in the LLDP packets transmitted by this interface. Use the **no** form of this command to prevent certain information from being transmitted by the interface. Variations of this command include:

lldp send 802.3-info mac-phy-config
lldp send management-address
lldp send med-info network-policy
lldp send port-description
lldp send system-capabilities
lldp send system-description
lldp send system-name
lldp send-and-receive

Syntax Description

802.3-info mac-phy-config	Enables transmission of the capability and settings of the duplex and speed on this interface.
management-address	Enables transmission of management address information on this interface.
med-info network-policy	Enables transmission of LLDP-Media Endpoint Discovery (LLDP-MED) network policy information on the interface.
port-description	Enables transmission of port description information on this interface.
system-capabilities	Enables transmission of this device's system capabilities on this interface.
system-description	Enables transmission of this device's system description on this interface.
system-name	Enables transmission of this device's system name on this interface.
and-receive	Configures this interface to both transmit and receive LLDP packets. This is the default setting.

Default Values

By default, all interfaces that support LLDP except routed Ethernet are configured to transmit and receive LLDP packets. LLDP is disabled by default on routed Ethernet interfaces.

The 802.3 MAC/PHY status configuration and LLDP-MED network policy time length values (TLVs) are only supported on switchport interfaces and NetVanta 1524ST Gigabit Ethernet interfaces.

Command History

Release 8.1	Command was introduced.
Release 17.2	Command was expanded to include the 802.3 and LLDP-MED information.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

Individual LLDP information can be enabled or disabled using the various forms of the **lldp send** command. For example, use the **lldp send-and-receive** command to enable transmit and receive of all LLDP information. Then use the **no lldp send port-description** command to prevent LLDP from transmitting port description information.

Usage Examples

The following example configures the MEF Ethernet interface 0/1 to transmit LLDP packets containing all enabled information types:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#lldp send**

The following example configures the MEF Ethernet interface 0/1 to transmit and receive LLDP packets containing all enabled information types:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#lldp send-and-receive**

mac-address *<mac address>*

Use the **mac-address** command to specify the medium access control (MAC) address of the unit. Only the last three values of the MAC address can be modified. The first three values contain the Adtran reserved number (00:0A:C8) by default. Use the **no** form of this command to return to the default MAC address programmed by Adtran.

Syntax Description

<mac address>	Specifies a valid 48-bit MAC address. MAC addresses should be expressed in the following format xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).

Default Values

A unique default MAC address is programmed in each unit shipped by Adtran.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Gigabit Ethernet interfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Usage Examples

The following example configures a MAC address of **00:0A:C8:5F:00:D2**:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#mac-address 00:0A:C8:5F:00:D2**

max-reserved-bandwidth *<value>*

Use the **max-reserved-bandwidth** command to specify the percentage of interface bandwidth reserved for use in user-defined (priority or class-based) queues. The remainder of the interface bandwidth is reserved for system-critical traffic and is not available to user-defined queues. Use the **no** form of this command to restore the default value.

Reserving a portion of the interface bandwidth for system-critical traffic is necessary for proper operation. Specifying the entire interface bandwidth for use in user-defined queues can cause undesirable operation.

Syntax Description

<value>	Specifies the maximum percentage of bandwidth to reserve for quality of service (QoS). This setting is configured as a percentage of the total interface speed. Range is **1** to **100** percent.

Default Values

By default, **max-reserved-bandwidth** is set to **75** percent, which reserves 25 percent of the interface bandwidth for system-critical traffic.

Command History

Release 11.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet subinterface.

Usage Examples

The following example specifies **85** percent of the bandwidth on the MEF Ethernet subinterface 0/1.1 be available for use in user-defined queues:

(config)**#interface mef-ethernet 0/1.1**
(config-mef-ethernet 0/1.1)**#max-reserved-bandwidth 85**

media-gateway ip

Use the **media-gateway ip** command to associate an Internet Protocol version 4 (IPv4) address source to use for Realtime Transport Protocol (RTP) traffic. When configuring Voice over Internet Protocol (VoIP), RTP traffic must have an IPv4 address associated with it. However, some interfaces allow dynamic configuration of IPv4 addresses, causing this value to change periodically. Use the **no** form of this command to disable this function. Variations of this command include:

media-gateway ip loopback <*interface id*>
media-gateway ip primary
media-gateway ip secondary <*ipv4 address*>

Syntax Description

loopback <*interface id*>	Specifies an IPv4 address statically defined to a loopback interface for RTP traffic. This is helpful when using a single IPv4 address across multiple wide area network (WAN) interfaces for RTP traffic. The valid range for loopback interface identifiers is **1** to **1024**. The interface ID is used to uniquely identify a loopback interface. The entered value cannot be in use by another loopback interface.
primary	Specifies using this interface's configured primary IPv4 address for RTP traffic. Applies to static, Dynamic Host Configuration Protocol (DHCP), or negotiated addresses.
secondary <*ipv4 address*>	Specifies using this interface's statically defined secondary IPv4 address for RTP traffic. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, **media-gateway ip** is disabled.

Command History

Release 10.1	Command was introduced.
Release 17.3	Command was updated with the loopback interface identification option.
Release A3.01	Command was expanded to include the Metro Ethernet forum (MEF) Ethernet interface.

Usage Examples

The following example configures the unit to use the primary IPv4 address for RTP traffic:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#media-gateway ip primary**

qos-policy

Use the **qos-policy** command to apply a previously configured quality of service (QoS) map to incoming or outgoing packets on an interface. Use the **no** form of this command to remove the map from the interface. Variations of this command include:

qos-policy in *<name>*
qos-policy out *<name>*

Syntax Description

<name>	Specifies the name of a previously created QoS map (refer to *qos map <name> <number> on page 1673* for more information).
in	Assigns a QoS map to this interface's input.
out	Assigns a QoS map to this interface's output.

Default Values

No default values are necessary for this command.

Command History

Release 9.1	Command was introduced.
Release 15.1	Command was expanded to include the **in** parameter.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

When a QoS policy is applied to an interface, it may be disabled if the interface bandwidth is not adequate to support the requested bandwidth on the map set. Once the bandwidth problem is resolved, the map will work again. The bandwidth will be rechecked on any of the following changes:

1. A priority or class-based entry is added to, deleted from, or changed in a QoS map set.
2. The interface bandwidth is changed by the **bandwidth** command on the interface.
3. A QoS policy is applied to an interface.
4. A cross connect is created that includes an interface with a QoS policy.
5. The interface queuing method is changed to fair queue to use weighted fair queuing (WFQ).
6. The interface operational status changes.
7. The interface bandwidth changes for other reasons (e.g., when asymmetric digital subscriber line (ADSL) finishes training).

In order to prevent the map from being disabled in cases of temporary inadequate bandwidth (e.g., a single link goes down in a dual T1 multilink configuration where the map requests more than one T1's worth of bandwidth), the QoS map uses the maximum theoretical bandwidth on an interface, not the actual bandwidth at that time. This actually helps QoS keep higher priority class-based traffic working better than best-effort traffic when the bandwidth drops.

Usage Examples

The following example applies the QoS map **VOICEMAP** to the MEF Ethernet interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#qos-policy out VOICEMAP**

rtp quality-monitoring

Use the **rtp quality-monitoring** command to enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets on this interface. If the global command (**ip rtp quality-monitoring**) is disabled when this command is issued, the system will return the following warning: "Applied but not used, you must globally enable **ip rtp quality-monitoring** to use VQM." Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, VQM is enabled on all wide area network (WAN) and local area network (LAN) interfaces.

Command History

Release 17.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Usage Examples

The following example enables RTP quality monitoring on the MEF Ethernet 0/2 interface:

(config)**#interface mef-ethernet 0/2**
(config-mef-ethernet 0/2)**#rtp quality-monitoring**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Usage Examples

The following example enables SNMP capability on the MEF Ethernet interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the MEF Ethernet interface:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#no snmp trap link-status**

subtended-host mode

Use the **subtended-host mode** command to enable or disable subtended host listening on the interface. This command allows the interface to receive pre-provisioning information from another AOS unit. Variations of this command include:

subtended-host mode disabled
subtended-host mode listener

Syntax Description

disabled	Disables the interface from receiving any pre-provisioning information from another unit.
listener	Enables the interface to receive pre-provisioning information from another unit.

Default Values

By default, the first configured MEF Ethernet interface has pre-provisioning listening enabled. In addition, the Gigabit Ethernet interface **0/1** and EFM group **1/1** interfaces have pre-provisioning listening enabled by default. Any additional interfaces have pre-provisioning listening disabled.

Command History

Release A4.05	Command was introduced.
Release R11.1.0	Command was expanded to include the Gigabit Ethernet and EFM group interfaces.

Functional Notes

Only one interface at a time can have the subtended-host mode set to **listener**. If all interfaces have a subtended-host mode of **disabled**, then all pre-provisioning information is discarded.

Usage Examples

The following example enables the MEF Ethernet interface 0/1 to receive subtended-host provisioning:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)#subtended-host mode listener

traffic-shape rate <*value*>

Use the **traffic-shape rate** command to specify and enforce an output bandwidth for Ethernet and virtual local area network (VLAN) interfaces. Variations of this command include:

traffic-shape rate <*value*>
traffic-shape rate <*value*> **count-eth-overhead**
traffic-shape rate <*value*> <*burst*>
traffic-shape rate <*value*> <*burst*> **count-eth-overhead**

Syntax Description

<*value*>	Specifies the rate (in bits per second) at which the interface should be shaped.
<*burst*>	Optional. Specifies the allowed burst in bytes. By default, the burst is specified as the rate divided by 5 and represents the number of bytes that would flow within 200 ms.
count-eth-overhead	Optional. Indicates to include the Ethernet header overhead bytes when determining packet size.

Default Values

By default, traffic-shaping rate is disabled.

Command History

Release 10.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release R11.1.0	Command was expanded to include the **count-eth-overhead** parameter, system management Ethernet virtual connection (EVC) and the system control EVC.

Functional Notes

Traffic shaping can be used to limit an Ethernet segment to a particular rate or to specify use of quality of service (QoS) on Ethernet or VLAN interfaces.

Usage Examples

The following example sets the outbound rate of the MEF Ethernet interface 0/1 to 128 kbps and applies a QoS policy that gives all Realtime Transport Protocol (RTP) traffic priority over all other traffic:

(config)**#qos map voip 1**
(config-qos-map)**#match ip rtp 10000 10500 all**
(config-qos-map)**#priority unlimited**
(config-qos-map)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#traffic-shape rate 128000**
(config-mef-ethernet 0/1)**#qos-policy out voip**

vlan-id <*vlan id*>

Use the **vlan-id** command to set a virtual local area network (VLAN) ID for the MEF Ethernet subinterface. Use the **no** form of this command to remove an entry. Variations of this command include:

vlan-id <*vlan id*>
vlan-id <*vlan id*> **native**

Syntax Description

<*vlan id*>	Specifies a valid VLAN interface ID number. Range is **1** to **4095**.
native	Optional. Specifies that data for that VLAN ID goes out untagged. If **native** is not specified, data for that VLAN ID goes out tagged.

Default Values

By default, no VLAN ID is set.

Command History

Release 6.1	Command was introduced.
Release A4.05	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet subinterface.

Usage Examples

The following example configures a native VLAN of 5 for the MEF Ethernet subinterface 0/1.1:

(config)**#interface mef-ethernet 0/1.1**
(config-mef-ethernet 0/1.1)**#vlan-id 5 native**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an interface to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the interface from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an interface's VRF association will clear all IP-related settings on that interface.

Syntax Description

<*name*>	Specifies the name of the VRF to which to assign the interface.

Default Values

By default, interfaces are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release 17.8	Command syntax was changed to remove the **ip** keyword for Adtran internetworking products.
Release R10.1.0	Command syntax was changed to remove the **ip** keyword for Adtran voice products.

Functional Notes

VRF instances must be created first before an interface can be assigned. An interface can only be assigned to one VRF, but multiple interfaces can be assigned to the same VRF.

An interface will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the MEF Ethernet interface 0/1 to the VRF instance named **RED**:

(config)**#interface mef-ethernet 0/1**
(config-mef-ethernet 0/1)**#vrf forwarding RED**

vrrp <*number*>

Use the **vrrp** command to configure Virtual Router Redundancy Protocol (VRRP) routers within a router group. Use the **no** form of this command to remove the VRRP router's configurations. Variations of this command include:

vrrp <*number*> **description** <*text*>
vrrp <*number*> **ip** <*address*>
vrrp <*number*> **ip** <*address*> **secondary**
vrrp <*number*> **preempt**
vrrp <*number*> **preempt delay minimum** <*time*>
vrrp <*number*> **priority** <*level*>
vrrp <*number*> **shutdown**
vrrp <*number*> **startup-delay** <*delay*>
vrrp <*number*> **timers advertise** <*interval*>
vrrp <*number*> **timers learn**
vrrp <*number*> **track** <*name*>
vrrp <*number*> **track** <*name*> **decrement** <*value*>

Syntax Description

<*number*>	Specifies the VRRP router group's virtual router ID (VRID) number. Range is **1** to **255**.
description <*text*>	Specifies the textual description of the VRRP router within the group.
ip <*address*>	Specifies the IP address to be used by the VRRP router. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
secondary	Optional. Specifies the entry of an additional VRRP router supported IP address.
preempt	Allows a VRRP router to preempt the current master router if its priority level is higher than the current master's.
delay minimum <*time*>	Optional. Specifies a delay (in seconds) before the specified router will attempt to preempt the current master router. Range is **0** to **255** seconds.
priority <*level*>	Specifies the configured priority level of the VRRP router. Level range is **1** to **254**.
shutdown	Disables the VRRP router.
startup-delay <*delay*>	Specifies a time delay (in seconds) before a VRRP router becomes active. Range is **0** to **255** seconds.
timers	Specifies the configuration of the VRRP timers.
advertise <*interval*>	Specifies the time (in seconds) between advertisements sent by the master router. Range is **1** to **255** seconds.
learn	Specifies that the backup VRRP router learns the advertisement interval of the master router.
track <*name*>	Specifies a change in priority level of the VRRP router based upon the specified track.

decrement <*value*>	Optional. Specifies the numerical amount to decrement the VRRP's priority level if the track transitions to a FAIL state. Decrement value range is **1** to **254**.

Default Values

By default, VRRP is enabled.

By default, a VRRP router will preempt with no additional delay.

The default configured priority for a VRRP router that is either a backup router or not the IP address owner is **100**. The default actual priority of a VRRP router that is the IP address owner is **255**.

By default, startup-delay is enabled with a default value of **35** seconds.

By default, the advertisement interval is **1** second.

By default, the default decrement value is **10**.

Command History

Release 16.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet subinterface.

Functional Notes

A VRRP router may be part of more than one virtual router group. Although VRRP group VRIDs can be numbered between 1 and 255, only two VRRP routers per interface are supported.

It is recommended that the **timers advertise** setting is kept at the default value. If it is necessary to change this setting, ensure that all VRRP routers are configured with the new value, as all VRRP routers in the virtual group must have the same advertisement interval value. It is also recommended that if the **timers learn** function is enabled on one router in a virtual router group, then the **timers learn** function should be enabled on all routers in the group.

When the virtual router's specified IP address is independent of the IP addresses assigned to real interfaces on the VRRP routers, there is no IP address owner. This addressing method is preferred if object tracking will be used to monitor the network connection. The IP address used for the virtual router must be on the same subnet as either the primary or secondary IP addresses assigned to the VRRP router's real interface.

A track must be created before the **vrrp track** command can be issued. Refer to the *Network Monitor Track Command Set on page 4098* for more information on creating tracks. If a VRRP router owns the virtual router IP address, then the VRRP router's priority level cannot be decremented as a result of the track command. If object tracking will be used, it is important that no VRRP router own the virtual router IP address.

Usage Examples

The following example describes a VRRP router within virtual router group **1** as the **Default Master Router**:

(config)**#interface mef-ethernet 0/1.1**
(config-mef-ethernet 0/1.1)**#vrrp 1 description Default Master Router**
The following example specifies an IP address of **10.0.0.1** for a VRRP router within virtual router group **1**:

(config)**#interface mef-ethernet 0/1.1**
(config-mef-ethernet 0/1.1)**#vrrp 1 ip 10.0.0.1**

The following example specifies that the VRRP router within virtual router group **1** preempts the current master router after a **30** second delay:

(config)**#interface mef-ethernet 0/1.1**
(config-mef-ethernet 0/1.1)**#vrrp 1 preempt delay minimum 30**

The following example specifies the configured priority for the VRRP router within virtual router group **1** is **254**:

(config)**#interface mef-ethernet 0/1.1**
(config-mef-ethernet 0/1.1)**#vrrp 1 priority 254**

The following example disables the VRRP router within virtual router group **1**:

(config)**#interface mef-ethernet 0/1.1**
(config-mef-ethernet 0/1.1)**#vrrp 1 shutdown**

The following example configures a VRRP router on group **1** to delay **45** seconds before becoming active:

(config)**#interface mef-ethernet 0/1.1**
(config-mef-ethernet 0/1.1)**#vrrp 1 startup-delay 45**

MEF EVC COMMAND SET

A Metro Ethernet Forum (MEF) Ethernet virtual connection (EVC) connects two endpoints (for example, the Ethernet in the first mile (EFM) group and the MEF Ethernet interface) and passes Ethernet service frames through these endpoints. The EVCs prevent data transfer between subscriber sites that are not part of the same EVC, thus providing data privacy and security similar to a Frame Relay or an asynchronous transfer mode (ATM) permanent virtual circuit (PVC). EVCs are configured to be part of a bonding group (EFM group).

Each EVC has an associated subscriber tag (s-tag). This tag is the service provider VLAN ID and the outer tag in Q-in-Q VLAN tagging, whose VLAN ID is unique among other EVCs in the Metro Ethernet network (MEN). This unique s-tag allows the EVC to be identified and separated from other EVCs within the MEN. The s-tag exists only within the MEN and is not transmitted from or received at the customer edge of the network. In addition, the customer-side VLAN ID can be preserved on EVC traffic across the MEN if necessary. The customer equipment (CE) VLAN ID is the VLAN ID of the MEF Ethernet subinterface on the AOS unit. This inner tag in Q-in-Q VLAN tagging can be preserved or stripped by the EFM module on both inbound and outbound frames.

The configurable attributes of the EVC include the EVC name, the MEN port to which the EVC is connected, whether the CE VLAN ID is preserved in the EVC traffic, and whether the EVC is enabled. Once these parameters are configured for the EVC, the EVC must be associated with a MEN port for traffic to flow.

For more information about EVCs and their function in MENs, refer to the configuration guide *Configuring EFM NIM2s and the MEF Ethernet Interface in AOS*, available online at https://supportcommunity.adtran.com.

EVCs are created and configured using the **mef evc** <*name*> command from the Global Configuration mode as follows:

```
>enable
#configure terminal
(config)#mef evc DATA
(config-evc-DATA)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

connect men-port efm-group <group id> on page 3675
preserve-ce-vlan on page 3676
s-tag <vlan id> on page 3677

connect men-port efm-group *<group id>*

Use the **connect men-port efm-group** command to associate the Ethernet virtual connection (EVC) with a specific Metro Ethernet network (MEN) port (Ethernet in the first mile (EFM) group) so that traffic can flow to the MEN. Use the **no** form of this command to remove the association between this EVC and the specified EFM group.

Syntax Description

<group id>	Specifies the EFM group to associate with the EVC. Valid range is **1** to **1024**.

Default Values

By default, no interfaces are connected to the EVC.

Command History

Release A3.01	Command was introduced.

Functional Notes

Multiple EVCs can be associated with a single EFM group. The EFM group must be created before associating the EVC and the group. For more information about configuring EFM groups, refer to *MEF EFM Group Command Set on page 3599*.

Usage Examples

The following example associates EVC **DATA** with EFM group **1**:

(config)**#mef evc DATA**
(config-evc-DATA)**#connect men-port efm-group 1**

preserve-ce-vlan

Use the **preserve-ce-vlan** command to specify whether the customer equipment (CE) virtual local area network (VLAN) ID is preserved in traffic outbound on the Ethernet virtual connection (EVC). Use the **no** form of this command to disable CE VLAN ID preservation.

Syntax Description

No subcommands.

Default Values

By default, the CE VLAN ID is preserved.

Command History

Release A3.01	Command was introduced.

Functional Notes

The CE VLAN ID is the ID of the VLAN on the Metro Ethernet Forum (MEF) Ethernet subinterface. A VLAN on the MEF Ethernet subinterface must be configured to preserve the CE VLAN ID. The preserved CE VLAN ID can be used for matching traffic in EVC maps, although for most applications you will not need to preserve the CE VLAN ID.

Usage Examples

The following example disables CE VLAN ID preservation for outbound traffic on EVC **DATA**:

(config)**#mef evc DATA**
(config-evc-DATA)**#preserve-ce-vlan**

s-tag *<vlan id>*

Use the **s-tag** command to specify the virtual local area network (VLAN) ID used by the service provider for the Ethernet virtual connection (EVC). This VLAN ID, the s-tag, is used by the carrier to mark outbound traffic from this EVC in the Metro Ethernet network (MEN). Use the **no** form of this command to return the s-tag value to the default.

Syntax Description

<vlan id>	Specifies ID of the service provider VLAN. Valid range is **1** to **4094**.

Default Values

By default, the s-tag is **0**, which indicates the traffic on the EVC is untagged.

Command History

Release A3.01	Command was introduced.

Usage Examples

The following example specifies the s-tag for traffic outbound on EVC **DATA** is **20**:

(config)**#mef evc DATA**
(config-evc-DATA)**#s-tag 20**

MEF EVC MAP COMMAND SET

The Metro Ethernet Forum (MEF) Ethernet virtual connection (EVC) map is a traffic filter that matches traffic based on specific criteria and associates the traffic with a specific EVC. Each map is associated with a single EVC and user network interface (UNI), and it includes the customer virtual local area network (VLAN) ID and class of service (CoS) behavior of the traffic. Maps are used to classify traffic for a specific EVC for forwarding to a UNI, and for use by the MEF Policer Policy for rate limiting. For more information about EVCs, refer to the *MEF EVC Command Set on page 3674*. For more information about MEF Policer Policies, refer to the *MEF Policer Policy Command Set on page 3684*.

The configurable attributes of the EVC map include the map name, the UNI associated with the map, the EVC associated with the map, the matching criteria used to match traffic (includes the customer VLAN ID, customer priority bit, differentiated services code point (DSCP) bits, or untagged traffic), and the priority bits and egress queues the EVC uses for matched traffic. When determining traffic match criteria, keep in mind you can specify multiple criteria for a single map. Multiple match statements function as a logical AND.

Once these parameters are configured for the EVC map, the map must be associated with both an EVC and a UNI. The UNI in this case is the MEF Ethernet interface to which you want to map the traffic. Even if you are using 802.1q encapsulation, the main interface will be used as the UNI. EVC maps will always have two connection statements: one to an EVC and one to a UNI, unless the traffic matching the EVC map is to be discarded.

After configuring the EVC map and associating it with an EVC, you can also optionally specify 802.1p values for the s-tag of the traffic and the queue used when the traffic is sent to the Metro Ethernet network (MEN).

EVC maps are created and configured using the **mef evc-map** <*name*> command from the Global Configuration mode as follows:

```
>enable
#configure terminal
(config)#mef evc-map Map1
(config-evc-map-Map1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

connect on page 3679
connect discard on page 3680
match on page 3681
men-pri on page 3682
men-queue on page 3683

connect

Use the **connect** command to associate the Ethernet virtual connection (EVC) map with an EVC component. EVC maps must be associated with both an EVC and a user network interface (UNI) for the map to function properly. Use the **no** form of this command to remove the association between the EVC map and the EVC or the UNI. Variations of this command include:

connect evc <*name*>
connect uni mef-ethernet <*slot/port*>

Syntax Description

evc <*name*>	Specifies the EVC to which the matching traffic is mapped.
uni efm-group <*name*>	Specifies the Ethernet in the First Mile (EFM) group as the UNI from which traffic is evaluated.
uni gigabit-ethernet <*slot/port*>	Specifies the Gigabit Ethernet interface as the UNI from which traffic is evaluated.
uni mef-ethernet <*slot/port*>	Specifies the Metro Ethernet Forum (MEF) Ethernet interface as the UNI from which the traffic is evaluated.

Default Values

By default, no EVC components are connected to the EVC map.

Command History

Release A3.01	Command was introduced.

Functional Notes

EVC maps are associated with both an EVC and a UNI (MEF Ethernet interface) to specify where the traffic comes from as it is evaluated (UNI) and where it is mapped to if it matches the criteria outlined in the map (EVC). Both variations of this command must be entered as separate commands for the EVC map to function properly.

Usage Examples

The following example specifies that EVC map **Map1** is associated with MEF Ethernet interface **1/1** and with the EVC **DATA**:

(config)**#mef evc-map Map1**
(config-evc-map-Map1)**#connect uni mef-ethernet 1/1**
(config-evc-map-Map1)**#connect evc DATA**

connect discard

Use the **connect discard** command to specify that traffic matching the Ethernet virtual connection (EVC) map criteria is discarded. Using the **no** form of this command disables traffic discard.

Syntax Description

No subcommands.

Default Values

By default, no traffic is discarded.

Command History

Release A3.01	Command was introduced.

Usage Examples

The following example specifies that traffic matching the criteria outlined in EVC map **Map1** is discarded:

```
(config)#mef evc-map Map1
(config-evc-map-Map1)#connect discard
```

match

Use the **match** command to specify the traffic matching criteria used by the Ethernet virtual connection (EVC) map to identify which traffic to send to the associated EVC. Use the **no** form of this command to remove the matching criteria from the EVC map. Variations of this command include:

match ce-vlan-id <*vlan id*>
match ce-vlan-pri <*value*>
match dscp <*value*>
match untagged

Syntax Description

ce-vlan-id <*vlan id*>	Specifies that traffic with a customer equipment (CE) virtual local area network (VLAN) ID that matches the specified ID is mapped to the associated EVC. Valid range is **1** to **4095**.
ce-vlan-pri <*value*>	Specifies that traffic with a CE VLAN priority value that matches the specified value is mapped to the associated EVC. The priority value is also the CE VLAN 802.1p value. Valid range is **0** to **7**.
dscp <*value*>	Specifies that traffic matching the specified differentiated services code point (DSCP) value is mapped to the associated EVC. Valid range is **0** to **63**.
untagged	Specifies that untagged traffic is mapped to the associated EVC.

Default Values

By default, no matching criteria is specified.

Command History

Release A3.01	Command was introduced.

Functional Notes

Traffic is compared to the first criteria entered in the map's configuration. Subsequent criteria are then compared to the traffic in the order the criteria are entered. Multiple matches form a logical AND, meaning that if multiple criteria are entered in the map, the traffic must match all criteria to be matched to the EVC.

Usage Examples

The following example configures EVC map **Map1** to send all traffic with a CE VLAN ID of **5** and a DSCP value of **10** to the EVC associated with the map:

(config)**#mef evc-map Map1**
(config-evc-map-Map1)**#match ce-vlan-id 5**
(config-evc-map-Map1)**#match dscp 10**

men-pri

Use the **men-pri** command to specify the Metro Ethernet network (MEN) priority that the Ethernet virtual connection (EVC) will use for traffic matching the EVC map. Use the **no** form of this command to return to the default setting. Variations of this command include:

men-pri inherit
men-pri <*value*>

Syntax Description

inherit	Specifies that the MEN priority value for the matched traffic is inherited from the 802.1p value of the customer equipment (CE) virtual local area network (VLAN).
<*value*>	Specifies a specific priority value is given to the matched traffic in the EVC. Valid range is **0** to **7**.

Default Values

By default, matched traffic has an inherited priority.

Command History

Release A3.01	Command was introduced.

Usage Examples

The following example specifies that traffic matching EVC map **Map1** is given a priority of **5** in the associated EVC:

(config)**#mef evc-map Map1**
(config-evc-map-Map1)**#men-pri 5**

men-queue

Use the **men-queue** command to specify the output queue used by the Ethernet virtual connection (EVC) for traffic that matches the EVC map. Use the **no** form of this command to return to the default setting. Variations of this command include:

men-queue inherit
men-queue <*value*>

Syntax Description

inherit	Specifies that the queue used by the EVC for matched traffic is based on the Metro Ethernet network (MEN) priority setting (specified using the command *men-pri on page 3682*).
<*value*>	Specifies the queue to which the matched traffic is mapped by the EVC. Valid range is **1** to **8**.

Default Values

By default, matched traffic inherits the queue information.

Command History

Release A3.01	Command was introduced.

Usage Examples

The following example specifies that traffic matching EVC map **Map1** is queued in output queue **4**:

(config)**#mef evc-map Map1**
(config-evc-map-Map1)**#men-queue 4**

MEF POLICER POLICY COMMAND SET

The Metro Ethernet Forum (MEF) policer policy is a bandwidth-limiting profile that limits the amount of outbound traffic from the AOS unit to the Metro Ethernet network (MEN). The amount of traffic can be limited on Ethernet virtual connections (EVCs), user network interfaces (UNIs), or EVC maps based on traffic committed burst size (CBS), committed information rate (CIR), excess burst size (EBS), and excess information rate (EIR). The CBS and CIR thresholds specify the committed burst sizes and transmission rates of traffic. When these thresholds are exceeded, traffic may be dropped. The EBS and EIR thresholds specify the excess burst sizes or transmission rates (over and above the committed sizes or rates), specifying the maximum burst size or rate allowable before the traffic is dropped. In this way, the MEF policer policy functions similarly to Frame Relay policing. Properly configuring the MEF policer policy relies on specifying the name and the thresholds for the policy, and applying the policy to an EVC component (UNI, EVC, or EVC map).

MEF policer policies are created and configured using the **mef policer** <*name*> command from the Global Configuration mode as follows:

```
>enable
#configure terminal
(config)#mef policer Policy1
(config-policer-Policy1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

cbs <number> on page 3685
cir <number> on page 3686
ebs <number> on page 3687
eir <number> on page 3688
per on page 3689

cbs *<number>*

Use the **cbs** command to configure the committed burst size (CBS) for the Metro Ethernet Forum (MEF) policer policy. The CBS threshold specifies the maximum allowable number of bytes transmitted as a burst before the policer policy can drop the traffic. Use the **no** form of this command to return to the default setting.

Syntax Description

<number>	Specifies the CBS threshold in bytes. Valid range is **0** to **2147483647**.

Default Values

By default, the CBS is **0** bytes.

Command History

Release A3.01	Command was introduced.

Usage Examples

The following example specifies that MEF policer **Policy1** uses a CBS threshold of **6500000**:

(config)**#mef policer Policy1**
(config-policer-Policy1)**#cbs 6500000**

cir *<number>*

Use the **cir** command to configure the committed information rate (CIR) for the Metro Ethernet Forum (MEF) policer policy. The CIR threshold specifies the average maximum data transmission rate of traffic in kilobits per second (kbps) allowed before the traffic can be dropped. Use the **no** form of this command to return to the default setting.

Syntax Description

<number>	Specifies the CIR threshold in kbps. Valid range is **250** to **600000**.

Default Values

By default, the CIR is **600000** kbps.

Command History

Release A3.01	Command was introduced.

Usage Examples

The following example specifies that MEF policer **Policy1** uses a CIR threshold of **10000**:

(config)**#mef policer Policy1**
(config-policer-Policy1)**#cir 10000**

ebs *<number>*

Use the **ebs** command to configure the excess burst size (EBS) for the Metro Ethernet Forum (MEF) policer policy. The EBS threshold specifies the maximum number of bytes transmitted as a burst of data in excess of the committed burst size (CBS) threshold before the policer policy drops traffic. Set the CBS threshold using the command *cbs <number> on page 3685*. Use the **no** form of this command to return to the default setting.

Syntax Description

<number>	Specifies the EBS threshold in bytes. Valid range is **0** to **2147483647**.

Default Values

By default, the EBS is **0** bytes.

Command History

Release A3.01	Command was introduced.

Usage Examples

The following example specifies that MEF policer **Policy1** uses an EBS threshold of **60000**:

(config)**#mef policer Policy1**
(config-policer-Policy1)**#ebs 60000**

eir <*number*>

Use the **eir** command to configure the excess information rate (EIR) for the Metro Ethernet Forum (MEF) policer policy. The EIR threshold specifies the maximum rate in kilobits per second (kbps), over and above the committed information rate (CIR) threshold, before the policer policy drops traffic. The EIR value must be greater than or equal to the CIR value. Use the **no** form of this command to return to the default setting.

Syntax Description

<*number*>	Specifies the EIR threshold in kbps. Valid range is **250** to **600000**.

Default Values

By default, the EIR is **600000** kbps.

Command History

Release A3.01	Command was introduced.

Usage Examples

The following example specifies that MEF policer **Policy1** uses an EIR threshold of **1000**:

(config)**#mef policer Policy1**
(config-policer-Policy1)**#eir 1000**

per

Use the **per** command to apply the Metro Ethernet Forum (MEF) policer policy to an Ethernet virtual connection (EVC) component. Use the **no** form of this command to remove the policer policy from the EVC component. Variations of this command include:

per custom add-map <*name*>
per custom remove-map <*name*>
per evc <*name*>
per uni mef-ethernet <*slot/port*>

Syntax Description

custom add-map <*name*>	Adds the MEF policer policy to the named EVC map.
custom remove-map <*map*>	Removes the MEF policer policy from the named EVC map.
evc <*name*>	Applies the MEF policer policy to the named EVC.
uni mef-ethernet <*slot/port*>	Applies the MEF policer policy to the specified MEF Ethernet interface (the user network interface (UNI)).

Default Values

By default, no policer policies are applied to any EVC components.

Command History

Release A3.01	Command was introduced.

Functional Notes

When MEF policer policies are applied to an EVC, they are applied on egress traffic. When MEF policer policies are applied to a MEF Ethernet interface, they are applied on ingress traffic.

Usage Examples

The following example applies MEF policer **Policy1** to EVC map **Map1**:

(config)**#mef policer Policy1**
(config-policer-Policy1)**#per custom add-map Map1**

CARRIER ETHERNET SERVICES COMMAND SETS

This section includes the following command sets:

CARRIER ETHERNET EFM GROUP COMMAND SET

Ethernet in the first mile (EFM) groups are logical interfaces that represent an EFM bonding group. Interfaces are connected to the EFM group and provide physical links to carry bonded traffic. These groups are used in Layer 2/Layer 3 carrier Ethernet connections to the Metro Ethernet network (MEN). The EFM group operates as the MEN port for the AOS unit, allowing Ethernet virtual connections (EVCs) to be associated logically as a MEN port and to use the same interfaces for connection with the MEN.

EFM groups are created and configured using the **interface efm-group** <*slot/group*> or **interface efm-group** <*slot/group.subinterface id*> commands from the Global Configuration mode as follows:

```
>enable
#configure terminal
(config)#interface efm-group 1/1
(config-efm-group 1/1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

bonding on page 3692
connect on page 3693
link <slot/port> on page 3694
snmp trap on page 3695
snmp trap link-status on page 3696
subtended-host mode on page 3697
thresholds xcv on page 3698
xcv-link-removal on page 3699

bonding

Use the **bonding** command to specify the bonding type to use with the specified Ethernet in the first mile (EFM) group. Use the **no** form of this command to return to the default setting.

Syntax Description

auto-detect	Specifies automatic detection of bonded or non-bonded links. The bonded mode is automatically set based upon the advertised mode received from the DSLAM during the initial handshake.
forced-on	Specifies using bonded service only.

Default Values

By default, bonding is set to **forced-on**.

Command History

Release R11.4.0	Command was introduced.

Functional Notes

The first link within the EFM group to train sets the service type to bonded or non-bonded. If non-bonding service is detected, only the first link in the candidate list to train is used for service, ignoring the rest.

Usage Examples

The following example sets the EFM-bonding for EFM group **1/1** to **auto-detect**:

(config)**#interface efm-group 1/1**
(config-efm-group 1/1)**#bonding auto-detect**

connect

Use the **connect** command to specify a physical interface to connect to the Ethernet in the first mile (EFM) group. Use the **no** form of this command to remove the connected interface from the group. Variations of this command include:

connect e1 <*slot/port*>
connect shdsl <*slot/port*>
connect t1 <*slot/port*>

Syntax Description

e1 <*slot/port*>	Specifies that an E1 interface is connected to the group.
shdsl <*slot/port*>	Specifies that a single-pair high-speed digital subscriber line (SHDSL) interface is connected to the group.
t1 <*slot/port*>	Specifies that a T1 interface is connected to the group.

Default Values

By default, no interfaces are connected to the EFM group.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the Layer 2/Layer 3 EFM group.

Usage Examples

The following example connects the SHDSL interface **e1 1/1** to EFM group **1/1**:

(config)**#interface efm-group 1/1**
(config-efm-group 1/1)**#connect e1 1/1**

link <*slot/port*>

Use the **link** command to establish a link or range of links to an Ethernet in the first mile (EFM) group. Use the **no** form of this command to remove the link. Variations of this command include:

link <*slot/port*>
link <*slot/port-to-port*>

Syntax Description

<*slot/port*>	Specifies the slot and port to link to the EFM group.
<*slot/port-to-port*>	Specifies a range of ports to link to the EFM group.

Default Values

By default, no links are configured for EFM groups.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example links the EFM group to slot and port **1/1**:

(config)**#interface efm-group 1/1**
(config-efm-group 1/1)**#link 1/1**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Us the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the single-pair high-speed digital subscriber line (SHDSL) interface, Ethernet in the first mile (EFM) group, system management Ethernet virtual connection (EVC) and the system control EVC.

Usage Examples

The following example enables SNMP capability on the EFM group 1/1:

(config)**#interface efm-group 1/1**
(config-efm-group 1/1)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the single-pair high-speed digital subscriber line (SHDSL) interface, Ethernet in the first mile (EFM) group, system management Ethernet virtual connection (EVC) and the system control EVC.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the EFM group 1/1:

(config)**#interface efm-group 1/1**
(config-efm-group 1/1)**#no snmp trap link-status**

subtended-host mode

Use the **subtended-host mode** command to enable or disable subtended host listening on the interface. This command allows the interface to receive pre-provisioning information from another AOS unit. Variations of this command include:

subtended-host mode listener
subtended-host mode disabled

Syntax Description

listener	Enables the interface to receive pre-provisioning information from another unit.
disabled	Disables the interface from receiving any pre-provisioning information from another unit.

Default Values

By default, the first configured MEF Ethernet interface has pre-provisioning listening enabled. In addition, the Gigabit Ethernet interface **0/1** and EFM group **1/1** interfaces have pre-provisioning listening enabled by default. Any additional interfaces have pre-provisioning listening disabled.

Command History

Release A4.05	Command was introduced.
Release R11.1.0	Command was expanded to include the Gigabit Ethernet and EFM group interfaces.

Functional Notes

Only one interface at a time can have the subtended-host mode set to **listener**. If all interfaces have a subtended-host mode of **disabled**, then all pre-provisioning information is discarded.

Usage Examples

The following example enables the MEF Ethernet interface 0/1 to receive subtended-host provisioning:

(config)**#interface efm-group 1/1**
(config-efm-group 1/1)**#subtended-host mode listener**

thresholds xcv

Use the **thresholds xcv** command to configure the excessive code violation threshold for the interface's link in the Ethernet in the first mile (EFM) group. When this threshold is crossed, the link is removed from the group. Use the **no** form of this command to return the threshold to the default value. Variations of this command include:

thresholds xcv 1e-5
thresholds xcv 1e-6
thresholds xcv 1e-7

Syntax Description

1e-5	Specifies that the threshold is set at a 1e-5 bit error rate.
1e-6	Specifies that the threshold is set at a 1e-6 bit error rate.
1e-7	Specifies that the threshold is set at a 1e-7 bit error rate.

Default Values

By default, thresholds are set to **1e-7**.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the Layer 2/Layer 3 EFM group.

Functional Notes

Once the threshold is set, the command *xcv-link-removal on page 3699* must be entered in the group's configuration so that the interface's link is removed when the threshold is crossed.

Usage Examples

The following example specifies that the excessive code violation threshold for interfaces connected to EFM group **1/1** is **1e-6**:

(config)**#interface efm-group 1/1**
(config-efm-group 1/1)**#thresholds xcv 1e-6**

xcv-link-removal

Use the **xcv-link-removal** command to remove an interface's link from the Ethernet in the first mile (EFM) group if the excessive code violation threshold is exceeded. This threshold is set using the command *thresholds xcv on page 3698*. Using the **no** form of this command disables the link removal.

Syntax Description

No subcommands.

Default Values

By default, link removal is enabled for the EFM group.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the Layer 2/Layer 3 EFM group.

Usage Examples

The following example specifies that an interface whose excessive code violations exceed the threshold is no longer linked to EFM group **1/1**:

(config)**#interface efm-group 1/1**
(config-efm-group 1/1)**#xcv-link-removal**

CARRIER ETHERNET EVC COMMAND SET

A carrier Ethernet Ethernet virtual connection (EVC) connects two endpoints (for example, the Metro Ethernet network (MEN) port and the User Network Interface (UNI)) and passes both Layer 2 and Layer 3 Ethernet service frames through these endpoints for carrier Ethernet services. The EVCs prevent data transfer between subscriber sites that are not part of the same EVC, thus providing data privacy and security similar to a Frame Relay or an asynchronous transfer mode (ATM) permanent virtual circuit (PVC).

Each EVC has an associated subscriber tag (s-tag). This tag is the service provider VLAN ID and the outer tag in Q-in-Q VLAN tagging, whose VLAN ID is unique among other EVCs in the Metro Ethernet network (MEN). This unique s-tag allows the EVC to be identified and separated from other EVCs within the MEN. The s-tag exists only within the MEN and is not transmitted from or received at the customer edge of the network. In addition, the customer-side VLAN ID can be preserved on EVC traffic across the MEN if necessary. The customer equipment (CE) VLAN ID is the VLAN ID of the MEF Ethernet subinterface on the AOS unit. This inner tag in Q-in-Q VLAN tagging can either be preserved or stripped by the EFM module on both inbound and outbound frames.

The configurable attributes of the EVC include the EVC name, the MEN port to which the EVC is connected, whether the CE VLAN ID is preserved in the EVC traffic, and whether the EVC is enabled. Once these parameters are configured for the EVC, the EVC must be associated with a MEN port for traffic to flow.

EVCs are created and configured using the **evc** <*name*> command from the Global Configuration mode as follows:

```
>enable
#configure terminal
(config)#evc DATA
(config-evc DATA)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

do on page 81
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

connect men-port on page 3701
performance-statistics on page 3702
preserve-ce-vlan on page 3703
s-tag <vlan id> on page 3704

connect men-port

Use the **connect men-port** command to associate the Layer 2/Layer 3 Ethernet virtual connection (EVC) with a specific Metro Ethernet network (MEN) port so that traffic can flow to the MEN. Use the **no** form of this command to remove the association between this EVC and the port. Variations of this command include:

connect men-port efm-group <*slot/group*>
connect men-port gigabit-ethernet <*slot/port*>

Syntax Description

efm-group <*slot/group*>	Specifies the Ethernet in the first mile (EFM) group to associate with the EVC using the group's slot number and group ID.
gigabit-ethernet <*slot/port*>	Specifies a Gigabit Ethernet interface to associate with the EVC.

Default Values

By default, no interfaces are connected to the EVC.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the Layer 2/Layer 3 EVC and the EFM group and Gigabit Ethernet interfaces.

Functional Notes

Multiple EVCs can be associated with a single EFM group. The EFM group must be created before associating the EVC and the group. For more information about configuring EFM groups, refer to *Carrier Ethernet EFM Group Command Set on page 3691*.

Usage Examples

The following example associates EVC **DATA** with EFM group **1/1**:

(config)**#evc DATA**
(config-evc DATA)**#connect men-port efm-group 1/1**

performance-statistics

Use the **performance-statistics** command to enable gathering performance monitoring statistics on the EVC. Use the **no** form of this command to disable the performance monitoring feature.

Syntax Description

No subcommands.

Default Values

By default, performance monitoring is enabled.

Command History

Release R10.10.0	Command was introduced.
Release R11.5.0	Command expanded to include the Carrier Ethernet EVC.

Usage Examples

The following example enables performance monitoring on the EVC **DATA**:

(config)**#interface evc DATA**
(config-evc DATA)**#performance-statistics**

preserve-ce-vlan

Use the **preserve-ce-vlan** command to specify whether the customer equipment (CE) virtual local area network (VLAN) ID is preserved in traffic outbound on the Ethernet virtual connection (EVC). Use the **no** form of this command to disable CE VLAN ID preservation.

Syntax Description

No subcommands.

Default Values

By default, the CE VLAN ID is preserved.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the Layer 2/Layer 3 EVC.

Usage Examples

The following example disables CE VLAN ID preservation for outbound traffic on EVC **DATA**:

(config)**#evc DATA**
(config-evc DATA)**#no preserve-ce-vlan**

s-tag *<vlan id>*

Use the **s-tag** command to specify the virtual local area network (VLAN) ID used by the service provider for the Layer 2/Layer 3 Ethernet virtual connection (EVC). This VLAN ID, the s-tag, is used by the carrier to mark outbound traffic from this EVC in the Metro Ethernet network (MEN). Use the **no** form of this command to return the s-tag value to the default.

Syntax Description

<vlan id>	Specifies ID of the service provider VLAN. Valid range is **2** to **4094**.

Default Values

By default, the s-tag is not specified, which prevents the EVC from becoming active.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the Layer 2/Layer 3 EVC.

Usage Examples

The following example specifies the s-tag for traffic outbound on EVC **DATA** is **20**:

(config)**#evc DATA**
(config-evc DATA)**#s-tag 20**

CARRIER ETHERNET EVC MAP COMMAND SET

The carrier Ethernet Ethernet virtual connection (EVC) map is a traffic filter that matches Layer 2 traffic based on specific criteria and associates the traffic with a specific EVC for Layer 2 carrier Ethernet services. Each map is associated with a single EVC and user network interface (UNI), and it includes the customer virtual local area network (VLAN) ID and class of service (CoS) behavior of the traffic. Maps are used to classify traffic for a specific EVC for forwarding to a UNI, and for use by the EVC Policer Policy for rate limiting. For more information about EVCs, refer to the *Carrier Ethernet EVC Command Set on page 3700*. For more information about EVC Policer Policies, refer to the *Carrier Ethernet Policer Command Set on page 3719*.

The configurable attributes of the EVC map include the map name, the UNI associated with the map, the EVC associated with the map, the matching criteria used to match traffic (includes the customer VLAN ID, customer priority bit, differentiated services code point (DSCP) bits, or untagged traffic), and the priority bits and egress queues the EVC uses for matched traffic. Multiple traffic match criteria can be specified for a single map. Multiple match statements function as a logical AND.

Once these parameters are configured for the EVC map, the map must be associated with both an EVC and a UNI. The UNI in this case is the Ethernet in the first mile (EFM) group or Gigabit Ethernet interface to which you want to map the traffic. Even if you are using 802.1q encapsulation, the main interface will be used as the UNI. EVC maps will always have two connection statements: one to an EVC and one to a UNI, unless the traffic matching the EVC map is to be discarded.

After configuring the EVC map and associating it with an EVC, you can also optionally specify 802.1p values for the s-tag of the traffic and the queue used when the traffic is sent to the Metro Ethernet network (MEN).

EVC maps are created and configured using the **evc-map** <*name*> command from the Global Configuration mode as follows:

```
>enable
#configure terminal
(config)#evc-map Map1
(config-evc-map Map1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

do on page 81
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

block uni ingress-only on page 3707
ce-vlan-tpid on page 3708
connect on page 3709
connect discard on page 3710

block uni ingress-only

Use the **block uni ingress-only** command to enable ETREE traffic separation on the Ethernet virtual connection (EVC) map. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release R11.5.0	Command was introduced.

Usage Examples

The following example enables ETREE traffic separation on the EVC map:

```
(config)# evc-map Map1
(config-evc-map Map1)#block uni ingress-only
```

ce-vlan-tpid

Use the **ce-vlan-tpid** command to specify that an Ethernet virtual connection (EVC) map uses the globally set customer-edge (CE) virtual local area network (VLAN) tag protocol identifier (TPID) value. Use the **no** form of this command to use the default value of 0x8100 instead of the global setting.

Syntax Description

No subcommands.

Default Values

By default, an EVC map uses the global setting.

Command History

Release R11.6.0	Command was introduced.

Functional Note

All EVC maps default to the globally-specified EtherType for CE VLAN ID matching. In addition, all EVC maps default to using the specified EtherType for adding CE VLAN IDs to traffic flowing in the Metro Ethernet Network (MEN) to UNI direction when the CE VLAN ID is not preserved as well as using the specified EtherType for adding c-tags to traffic flowing in the UNI to MEN direction. For more information, refer to the *Carrier Ethernet Services in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the EVC map uses the default setting instead of the global setting:

```
(config)# evc-map Map1
(config-evc-map Map1)#no ce-vlan-tpid
```

connect

Use the **connect** command to associate the Ethernet virtual connection (EVC) map with an EVC component. EVC maps must be associated with both an EVC and a user network interface (UNI) for the map to function properly. Use the **no** form of this command to remove the association between the EVC map and the EVC or the UNI. Variations of this command include:

connect evc <*name*>
connect uni efm-group <*slot/group*>
connect uni gigabit-ethernet <*slot/port*>

Syntax Description

evc <*name*>	Specifies the EVC to which the matching traffic is mapped.
uni efm-group <*slot/group*>	Specifies the Ethernet in the First Mile (EFM) group as the UNI from which traffic is evaluated.
uni gigabit-ethernet <*slot/port*>	Specifies the Gigabit Ethernet interface as the UNI from which traffic is evaluated.

Default Values

By default, no EVC components are connected to the EVC map.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the carrier Ethernet EVC Map and the **uni efm-group** and **uni gigabit-ethernet** parameters.

Functional Notes

EVC maps are associated with both an EVC and a UNI (Gigabit Ethernet interface) to specify where the traffic comes from as it is evaluated (UNI) and where it is mapped to if it matches the criteria outlined in the map (EVC). Both variations of this command must be entered as separate commands for the EVC map to function properly.

Usage Examples

The following example specifies that EVC map **Map1** is associated with Gigabit Ethernet interface **1/1** and with the EVC **DATA**:

(config)**# evc-map Map1**
(config-evc-map Map1)**#connect uni gigabit-ethernet 1/1**
(config-evc-map Map1)**#connect evc DATA**

connect discard

Use the **connect discard** command to specify that traffic matching the Ethernet virtual connection (EVC) map criteria is discarded. Using the **no** form of this command disables traffic discard.

Syntax Description

No subcommands.

Default Values

By default, no traffic is discarded.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the carrier Ethernet EVC map.

Usage Examples

The following example specifies that traffic matching the criteria outlined in EVC map **Map1** is discarded:

(config)**#mef evc-map Map1**
(config-evc-map Map1)**#connect discard**

match

Use the **match** command to specify the traffic matching criteria used by the Ethernet virtual connection (EVC) map to identify which traffic to send to the associated EVC. Use the **no** form of this command to remove the matching criteria from the EVC map. Variations of this command include:

match broadcast
match ce-vlan-id <*vlan id*>
match ce-vlan-pri <*value*>
match dscp <*value*>
match l2cp
match multicast
match unicast
match untagged

Syntax Description

broadcast	Specifies that broadcast traffic is mapped to the associated EVC.
ce-vlan-id <*vlan id*>	Specifies that traffic with a customer equipment (CE) virtual local area network (VLAN) ID that matches the specified ID is mapped to the associated EVC. VLAN IDs can be a single ID, multiple IDs, or a range of IDs. Multiple VLAN IDs should be separated with a comma (**600,200,800**). A range can be specified with a hyphen (**400-500**).Valid range is **1** to **4094**.
ce-vlan-pri <*value*>	Specifies that traffic with a CE VLAN priority value that matches the specified value is mapped to the associated EVC. The priority value is also the CE VLAN 802.1p value. Valid range is **0** to **7**.
dscp <*value*>	Specifies that IPv4 and IPv6 traffic matching the specified differentiated services code point (DSCP) value is mapped to the associated EVC. Valid range is **0** to **63**.
l2cp	Specifies that L2CP traffic is mapped to the associated EVC.
multicast	Specifies that multicast traffic is mapped to the associated EVC.
unicast	Specifies that unicast traffic is mapped to the associated EVC.
untagged	Specifies that untagged traffic is mapped to the associated EVC.

Default Values

By default, all traffic on the connected user network interface (UNI) port is matched.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the EVC map and the **broadcast**, **12cp**, **multicast**, and **unicast** parameters.
Release R11.6.0	Command was expanded to include support for matching on multiple CE VLAN IDs.

Functional Notes

Traffic is compared to the first criteria entered in the map's configuration. Subsequent criteria are then compared to the traffic in the order the criteria are entered. Multiple matches form a logical AND, meaning that if multiple criteria are entered in the map, the traffic must match all criteria to be matched to the EVC.

In AOS firmware release R11.6.0, support for matching multiple VLANs to a single EVC map was added. This feature is available on Gigabit Ethernet ports configured as UNIs on Carrier Ethernet products. Identical VLAN bundles (a set of multiple VLAN IDs) can exist on two or more different EVC maps, provided there is at least one additional match criteria that allows the EVC maps to become active. Different VLAN bundles that overlap on two EVC maps on the same UNI are not allowed and will prevent both EVC maps from becoming active. For example, one EVC map with VLAN IDs 201-400 conflicts with another EVC map with VLAN IDs 301-500 if they are on the same UNI since VLAN IDs 301-400 are overlapping in both VLAN bundles.

Usage Examples

The following example configures EVC map **Map1** to send all traffic with a CE VLAN ID of **5** and a DSCP value of **10** to the EVC associated with the map:

(config)**#evc-map Map1**
(config-evc-map Map1)**#match ce-vlan-id 5**
(config-evc-map Map1)**#match dscp 10**

match destination mac address <*mac address*>

Use the **match destination mac address** command to specify a media access control (MAC) address to use as matching criteria in the Ethernet virtual connection (EVC) map. Use the **no** form of this command to remove this criteria from the map.

Syntax Description

<*mac address*>	Specifies the MAC address to use for matching. MAC addresses are specified in the format **HH:HH:HH:HH:HH:HH**.

Default Values

By default, no MAC addresses are associated with the EVC map.

Command History

Release R11.5.0	Command was introduced.

Usage Examples

The following example specifies the EVC map matches destination MAC address **00:A0:C8:00:00:01**:

(config)**# evc-map Map1**
(config-evc-map Map1)**#match destination mac address 00:A0:C8:00:00:01**

match ethertype *<value>*

Use the **match ethertype** command to specify an EtherType filter to use as matching criteria on the Ethernet virtual connection (EVC) map. EtherType filters allow you to specify a certain EtherType (such as Address Resolution Protocol (ARP) or Internet Protocol version 6 (IPv6)) as EVC map matching criteria for allowed traffic into the UNI interface. This feature can also be configured to drop certain EtherTypes by associating an EVC map with a discard type, rather than a valid EVC. Use the **no** form of this command to remove the matching criteria from the EVC map.

Syntax Description

<value>	Specifies an EtherType, in hexadecimal format, to use as matching criteria in the EVC map.

Default Values

By default, no EtherType matching is configured.

Command History

Release R11.5.0	Command was introduced.

Usage Examples

The following example specifies that ARP is used as a matching criteria in the EVC map:

(config)**# evc-map Map1**
(config-evc-map Map1)**#match ethertype 0x0806**

men-c-tag <*value*>

Use the **men-c-tag** command to specify that the C-tag is inserted on the matching packets as they leave the Metro Ethernet network (MEN) and is used to further identify traffic on the Ethernet virtual connection (EVC). Use the **no** form of this command to remove the C-tag value.

Syntax Description

<*value*>	Specifies the value for the C-tag. Valid range is **2** to **4094**.

Default Values

By default, the C-tag is not specified.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies a C-tag value of **100** for the traffic associated with the EVC map **Map1**:

(config)**#evc-map Map1**
(config-evc-map Map1)**#men-c-tag 100**

men-c-tag-pri

Use the **men-c-tag-pri** command to specify the 802.1p value of the C-tag. The C-tag is used to identify traffic within an Ethernet virtual connection (EVC). Use the **no** form of this command to return to the default value. Variations of this command include:

men-c-tag-pri inherit
men-c-tag-pri <*value*>

Syntax Description

inherit	Specifies that the C-tag 802.1p value for the matched traffic is inherited from the 802.1p value of the customer edge (CE) virtual local area network (VLAN).
<*value*>	Specifies the C-tag priority. Valid range is **0** to **7**.

Default Values

By default, the C-tag priority is set to **inherit**.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies the C-tag priority as **6** on EVC map **Map1**:

(config)**#evc-map Map1**
(config-evc-map Map1)**#men-c-tag-pri 6**

men-pri

Use the **men-pri** command to specify the 802.1p value to the service virtual local area network (VLAN) tag (S-tag) that the Ethernet virtual connection (EVC) will use for traffic matching the EVC map. Use the **no** form of this command to return to the default setting. Variations of this command include:

men-pri inherit
men-pri <*value*>

Syntax Description

inherit	Specifies that the S-tag priority value for the matched traffic is inherited from the 802.1p value of the customer edge (CE) VLAN.
<*value*>	Specifies a specific priority value is given to the matched traffic in the EVC. Valid range is **0** to **7**.

Default Values

By default, matched traffic has an inherited priority.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the carrier Ethernet EVC map.

Usage Examples

The following example specifies that traffic matching EVC map **Map1** is given a priority of **5** in the associated EVC:

(config)**#evc-map Map1**
(config-evc-map Map1)**#men-pri 5**

men-queue

Use the **men-queue** command to specify the output queue used by the Ethernet virtual connection (EVC) for traffic that matches the EVC map. Use the **no** form of this command to return to the default setting. Variations of this command include:

men-queue inherit
men-queue <*value*>

Syntax Description

inherit	Specifies that the queue used by the EVC for matched traffic is based on the Metro Ethernet network (MEN) priority-to-queue mapping.
<*value*>	Specifies the queue to which the matched traffic is mapped by the EVC. Valid range is **0** to **7**.

Default Values

By default, matched traffic inherits the queue information.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the carrier Ethernet EVC map.

Usage Examples

The following example specifies that traffic matching EVC map **Map1** is queued in output queue **4**:

(config)**#evc-map Map1**
(config-evc-map Map1)**#men-queue 4**

CARRIER ETHERNET POLICER COMMAND SET

The policer is a bandwidth limiting profile that limits the amount of outbound traffic from the AOS unit to the Metro Ethernet network (MEN). The amount of traffic can be limited on Ethernet virtual connections (EVCs), user network interfaces (UNIs), or EVC maps based on traffic committed burst size (CBS), committed information rate (CIR), excess burst size (EBS), and excess information rate (EIR). The CBS and CIR thresholds specify the committed burst sizes and transmission rates of traffic. When these thresholds are exceeded, traffic can be dropped. The EBS and EIR thresholds specify the excess burst sizes or transmission rates (over and above the committed sizes or rates), specifying the maximum burst size or rate allowable before the traffic is dropped. In this way, the EVC policer functions similarly to Frame Relay policing. Traffic can also go through a second tier of policing in order to limit the overall rate or burst size in addition to the first tier policing of individual services. Properly configuring the policer relies on specifying the name and the thresholds for the policy, and applying the policy to a component (UNI, EVC, or EVC map) or a first tier policer.

Policers are created and configured using the **policer** <*name*> **[**<*slot*>**]** command from the Global Configuration mode as follows:

```
>enable
#configure terminal
(config)#policer Policer1
(config-policer Policer1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

do on page 81
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

cbs <number> on page 3720
cir <number> on page 3721
color-aware on page 3722
coupling on page 3723
ebs <number> on page 3724
eir <number> on page 3725
per on page 3726

cbs *<number>*

Use the **cbs** command to configure the committed burst size (CBS) for the policer. The CBS threshold specifies the maximum allowable number of bytes transmitted as a burst before the policer drops the traffic. Use the **no** form of this command to return to the default setting.

Syntax Description

<number>	Specifies the CBS threshold in bytes. Valid range is **0** to **999999**.

Default Values

By default, the CBS is **3125** bytes.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the carrier Ethernet policer.

Usage Examples

The following example specifies that EVC policer **Policer1** uses a CBS threshold of **6500**:

(config)**#policer Policer1**
(config-policer Policer1)**#cbs 6500**

cir *<number>*

Use the **cir** command to configure the committed information rate (CIR) for the policer. The CIR threshold specifies the average maximum data transmission rate of traffic in kilobits per second (kbps) allowed before the traffic is dropped. Use the **no** form of this command to return to the default setting.

Syntax Description

<number>	Specifies the CIR threshold in kbps. Valid range is **250** to **100000**.

Default Values

By default, the CIR is **0** kbps.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the carrier Ethernet policer.

Usage Examples

The following example specifies that policer **Policer1** uses a CIR threshold of **10000**:

```
(config)#policer Policer1
(config-policer Policer1)#cir 10000
```

color-aware

Use the **color-aware** command to enable the policer to consider color marking when examining incoming packets. When enabled, the policer takes the color marking of a packet into consideration when determining the new color marking. Incoming green packets can be declared green, yellow, or red (dropped) by a color-aware policer. Incoming yellow packets can only be declared yellow or red. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, the policer pays no attention to color marking.

Command History

Release R11.5.0	Command was introduced.

Usage Examples

The following example specifies that policer **Policer1** examines color markings:

(config)**#policer Policer1**
(config-policer Policer1)**#color-aware**

coupling

Use the **coupling** command to couple internal operation for token refills from the committed information rate (CIR) to excess information rate (EIR) buckets for the policer. Tokens that cannot fill the green bucket when it is full (i.e., when no green traffic is currently running) will overflow into the yellow bucket so that yellow traffic is processed at a rate of CIR + EIR. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, coupling is disabled.

Command History

Release R11.5.0	Command was introduced.

Functional Notes

Coupling should be used with a policer that is color aware. Coupling will have little effect on a policer that has **color-aware** disabled.

Usage Examples

The following example enables coupling for the policer **Policer1**:

```
(config)#policer Policer1
(config-policer Policer1)#coupling
```

ebs *<number>*

Use the **ebs** command to configure the excess burst size (EBS) for the policer. The EBS threshold specifies the maximum number of bytes transmitted as a burst of data in excess of the committed burst size (CBS) threshold before the policer policy drops traffic. Set the CBS threshold using the command *cbs <number> on page 3720*. Use the **no** form of this command to return to the default setting.

Syntax Description

<number>	Specifies the EBS threshold in bytes. Valid range is **0** to **999999**.

Default Values

By default, the EBS is **12500** bytes.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the carrier Ethernet policer.

Usage Examples

The following example specifies that policer **Policer1** uses an EBS threshold of **60000**:

(config)**#policer Policer1**
(config-policer Policer1)**#ebs 60000**

eir *<number>*

Use the **eir** command to configure the excess information rate (EIR) for the policer. The EIR threshold specifies the maximum rate in kilobits per second (kbps), over and above the committed information rate (CIR) threshold, before the policer policy drops traffic. The EIR value must be greater than or equal to the CIR value. Use the **no** form of this command to return to the default setting.

Syntax Description

<number>	Specifies the EIR threshold in kbps. Valid range is **250** to **600000**.

Default Values

By default, the EIR is **100000** kbps.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the carrier Ethernet policer.

Usage Examples

The following example specifies that policer **Policer1** uses an EIR threshold of **10000**:

(config)**#policer Policer1**
(config-policer Policer1)**#eir 1000**

per

Use the **per** command to apply the policer to an EVC component. Use the **no** form of this command to remove the policer from the component. Variations of this command include:

per custom evc-map <*name*>
per custom interface efm-group <*slot/group.subinterface*>
per custom interface gigabit-ethernet <*slot/port.subinterface*>
per custom evc <*name*>
per policer <*name*>
per uni efm-group <*slot/group*>
per uni gigabit-ethernet <*slot/port*>

Syntax Description

custom	
evc-map <*name*>	Adds the policer to the named EVC map.
interface efm-group <*slot/group.subinterface*>	Applies the policer to all ingress traffic on the Ethernet in the first mile (EFM) group subinterface.
interface gigabit-ethernet <*slot/port.subinterface*>	Applies the policer to all ingress traffic on the Gigabit Ethernet subinterface.
evc <*name*>	Applies the policer to all EVC maps associated with the named EVC.
policer <*name*>	Specifies the policer is in **per policer** mode. The **per policer** mode identifies this policer as the second tier policer and specifies the name of the first tier policer with the parameter <*name*>. If the policer named in <*name*> doesn't exist when the command is issued, it will be created.
uni efm-group <*slot/group*>	Applies the policer to all EVC maps associated with the specified EFM group (the user network interface (UNI)).
uni gigabit-ethernet <*slot/port*>	Applies the policer to all EVC maps associated with the specified Gigabit Ethernet interface.

Default Values

By default, no policer are applied to any EVC components.

Command History

Release R10.10.0	Command was introduced.
Release R11.5.0	Command was expanded to include **per policer** <*name*> parameter.

Functional Notes

A policer can be configured to police multiple first tier policers by specifying multiple **per policer** <*name*> commands. Each new command will be added to any existing **per policer** commands in the configuration. If the policer is already configured for a different policer mode (**per uni**, **per evc**, or **per custom**), the policer mode will be changed to **per policer** and any existing **per uni**, **per evc**, or **per custom** configuration will be automatically removed.

Usage Examples

The following example applies policer **Policer1** to EVC map **Map1**:

(config)**#policer Policer1**
(config-policer Policer1)**#per custom evc-map Map1**

CARRIER ETHERNET QUEUE COMMAND SET

The carrier Ethernet Ethernet virtual connection (EVC) queue provices eight hardware queues per Metro Ethernet network (MEN) port, whether an Ethernet in the first mile (EFM) group or Gigabit Ethernet interface, allowing for traffic management and congestion avoidance. These queues absorb packets when the ingress rate of traffic exceeds the egress rate, allowing bursts of packets to be transmitted through the system without incurring loss.

Carrier ethernet EVC queues must be managed to prevent packet loss and delay along the network. From the EVC Queue Configuration mode you can specify the algorithms, class of service (CoS) settings, drop probabilities, queue depth, thresholds, and weights of traffic traversing the MEN port interface.

The EVC Queue Configuration mode is accessed using the **queue interface** command from the Global Configuration mode as follows:

```
(config)#queue interface efm-group 1/1 3
(config-queue 3)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

do on page 81
exit on page 83

All other commands for this command set are described in this section in alphabetical order.

algorithm wred on page 3729
cos group lower-adjacent on page 3730
cos <value> on page 3731
drop-probability on page 3732
max-depth <number> on page 3733
thresholds wred on page 3734
weight on page 3735

algorithm wred

Use the **algorithm wred** command to enable weighted random early detection (WRED) in the Ethernet virtual connection (EVC) queue. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, WRED is disabled.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

WRED is an active queue congestion management discipline that adds packet color to the thresholds of the drop probability slopes for queued traffic. Different slopes can be configured to treat conforming (green colored) and nonconforming (yellow colored) packets differently. As the average queue depth increases, the AOS unit begins to randomly discard yellow packets before randomly discarding green packets. Once the maximum threshold of the average queue depth is reached, all packets are discarded. Packet color and average queue depth are used to determine drop probability.

When using WRED, make sure to configure the yellow maximum threshold to be less than or equal to the green minimum threshold (using the command *thresholds wred on page 3734*) to avoid dropping green packets before all yellow packets are dropped.

Usage Examples

The following example enables WRED in the EVC queue:

(config)**#queue interface efm-group 1/1 3**
(config-queue 3)**#algorithm wred**

cos group lower-adjacent

Use the **cos group lower-adjacent** command to lower the adjacency of the Ethernet virtual connection (EVC) queue class of service (CoS). Use the **no** form of this command to disable queue CoS adjacency.

Syntax Description

No subcommands.

Default Values

CoS adjacency is disabled by default.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example lowers the adjacency of the EVC queue CoS:

(config)**#queue interface efm-group 1/1 3**
(config-queue 3)**#cos group lower-adjacent**

cos *<value>*

Use the **cos** command to set the class of service (CoS) value for a particular Ethernet virtual connection (EVC) queue. Queues with the same CoS value enable the scheduling of packets between the same CoS queues using the deficit weighted round robin (DWRR) algorithm. Use the **no** form of this command to disable CoS for the queue.

Syntax Description

<value>	Specifies the CoS value for the queue. Valid range is **0** to **7**.

Default Values

By default, queues do not have a CoS value.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies a CoS value of **2** for the EVC queue:

(config)**#queue interface efm-group 1/1 3**
(config-queue 3)**#cos 2**

drop-probability

Use the **drop-probability** command to set the drop probability of traffic entering the Ethernet virtual connection (EVC) queue. Use the **no** form of this command to return to the default value. Variations of this command include:

drop-probability green <*value*>
drop-probability yellow <*value*>

Syntax Description

green <*value*>	Specifies the weighted random early detection (WRED) drop probability for green-colored traffic. Valid range is **0** to **100**.
yellow <*value*>	Specifies the WRED drop probability for yellow-colored traffic. Valid range is **0** to **100**.

Default Values

By default, the drop probability is set to **0**.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

When using WRED, make sure to configure the yellow maximum threshold to be less than or equal to the green minimum threshold (using the command *thresholds wred on page 3734*) to avoid dropping green packets before all yellow packets are dropped.

Usage Examples

The following example specifies the EVC queue has a drop probability of **3** for green traffic:

(config)**#queue interface efm-group 1/1 3**
(config-queue 3)**#drop-probability green 3**

max-depth *<number>*

Use the **max-depth** command to specify the maximum number of packets that can be held by the Ethernet virtual connection (EVC) queue. Use the **no** form of this command to return to the default value.

Syntax Description

<number>	Specifies the maximum number of packets that can be held by the queue. Valid range is **1** to **16383**.

Default Values

By default, the queue holds **255** packets.

Command History

Release R10.10.0	Command was introduced.
Release R11.10.2	Maximum queue depth was increased to **16383** packets.

Usage Examples

The following example specifies the EVC queue can hold a maximum of **100** packets:

(config)**#queue interface efm-group 1/1 3**
(config-queue 3)**#max-depth 100**

thresholds wred

Use the **thresholds wred** command to specify the congestion management thresholds for dropping weighted random early detection (WRED) traffic from the Ethernet virtual connection (EVC) queue. Use the **no** form of this command to return to the default setting. Variations of this command include:

thresholds wred green maximum <*value*>
thresholds wred green minimum <*value*>
thresholds wred yellow maximum <*value*>
thresholds wred yellow minimum <*value*>

Syntax Description

green	Configures the threshold for WRED conforming (green) traffic.
yellow	Configures the threshold for WRED nonconforming (yellow) traffic.
maximum <*value*>	Specifies the maximum threshold for dropping traffic. Valid range is **1** to **255**.
minimum <*value*>	Specifies the minimum threshold for dropping traffic. Valid range is **1** to **255**.

Default Values

By default, the threshold is set to **1**.

Command History

Release R10.10.0	Command was introduced.

Functional Notes

When using WRED, make sure to configure the yellow maximum threshold to be less than or equal to the green minimum threshold to avoid dropping green packets before all yellow packets are dropped.

Usage Examples

The following example sets the maximum threshold for green traffic to **255**:

(config)**#queue interface efm-group 1/1 3**
(config-queue 3)**#thresholds wred green maximum 255**

weight

Use the **weight** command to specify the weight given to traffic for a specific Ethernet virtual connection (EVC) queue when using weighted fair queueing (WFQ). Use the **no** form of this command to return to the default setting. Variations of this command include:

weight dynamic
weight <*number*>

Syntax Description

dynamic	Specifies that traffic is weighted dynamically.
<*number*>	Assigns a percentage weight to the traffic. Valid range is **1** to **100** percent.

Default Values

By default, traffic is weighted dynamically.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies that traffic for the EVC queue is weighed by **25** percent:

(config)**#queue interface efm-group 1/1 3**
(config-queue 3)**#weight 25**

CARRIER ETHERNET SHAPER COMMAND SET

The carrier Ethernet Ethernet virtual connection (EVC) traffic shaper is used to smooth bursts of traffic traveling between the AOS unit and the Metro Ethernet network (MEN). When a packet arrives at the shaper, if there are sufficient tokens available, the packet is transmitted without delay. If there are insufficient tokens, the packet is delayed until there are enough tokens to allow transmission. Shapers do not drop frames with a small burst of traffic, but they can add latency.

The EVC Shaper Configuration mode is accessed using the **shaper** <*name*> **[**<*slot*>**]** command from the Global Configuration mode as follows:

```
(config)#shaper SHAPER1 0
(config-shaper shaper1 0)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

do on page 81
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

per interface on page 3737
rate <value> on page 3738

per interface

Use the **per interface** command to specify the interface or queue to which the Ethernet virtual connection (EVC) shaper is applied. Use the **no** form of this command to remove the shaper from the interface or queue. Variations of this command include:

per interface efm-group <*slot/group*>
per interface efm-group <*slot/group*> <*queue*>
per interface gigabit-ethernet <*slot/port*>
per interface gigabit-ethernet <*slot/port*> <*queue*>

Syntax Description

efm-group <*slot/group*>	Specifies that the shaper is applied to the Ethernet in the first mile (EFM) group.
gigabit-ethernet <*slot/port*>	Specifies that the shaper is applied to a Gigabit Ethernet interface.
<*queue*>	Optional. Specifies that the shaper is applied to an interface queue. Valid range is **0** to **7**. Separate queues in a list using commas (for example, **1,3**) or use a hyphen to define a range (for example, **1-3**).

Default Values

By default, no EVC shapers are configured.

Command History

Release R10.10.0	Command was introduced.
Release R11.1.0	Command was expanded to include the <*queue*> option.

Functional Notes

You can apply a shaper to an interface or apply a shaper to an interface queue, but you cannot do both with a single shaper. These actions are mutually exclusive.

An interface can have up to seven unique per-queue shapers and one per-interface shaper applied to it. If more than seven unique per-queue shapers are applied to an interface, they are displayed as **disabled** in the output of the **show shaper** command.

Usage Examples

The following example specifies that the EVC shaper **SHAPER1** is applied to the EFM group **1/1**:

(config)**#shaper SHAPER1 0**
(config-shaper shaper1 0)**#per interface efm-group 1/1**

The following example specifies that the EVC shaper **SHAPER1** is applied to queues **1**, **3**, **4**, and **5** on the Gigabit Ethernet interface **0/1**:

(config)**#shaper SHAPER1 0**
(config-shaper shaper1 0)**#per interface gigabit-ethernet 0/1 1, 3-5**

rate <*value*>

Use the **rate** command to configure the Ethernet virtual connection (EVC) shaper egress traffic rate. Use the **no** form of this command to return to the default shaper rate value.

Syntax Description

<*value*>	Specifies the EVC shaper rate in kilobits per second (kbps). Valid range is **0** to **1000000**.

Default Values

By default, the EVC shaper (when configured) uses a rate of **1000000** kbps.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies that EVC shaper **SHAPER1** uses an egress traffic rate of **3500** kbps:

(config)**#shaper SHAPER1 0**
(config-shaper shaper1 0)**#rate 3500**

CARRIER ETHERNET TERMINAL LOOPBACK COMMAND SET

In a Carrier Ethernet terminal loopback test, traffic is sent up-stream to a remote AOS device and then looped back just prior to egressing the remote AOS unit. A flow approaching the remote device's user network interface (UNI) port interface is turned back toward the switch fabric as close as possible to the UNI interface and returns traffic to the originating AOS device that is subject the same conditioning associated with the remote device's configured egress queue management and classification rules for down-stream traffic (such as Quality of Service (QoS) policers, shapers, matching criteria, and queues). Terminal loopbacks are commonly used to validate how a remote devices perform QoS on down-stream traffic by providing insight into rate limiting functionality on configured policers, traffic prioritization in egress queues, and traffic shaping as it is looped back towards the originating device.

Because Ethernet address rules do not allow frames containing the same source MAC address to arrive from different ports on a device, the AOS unit must swap the destination and source MAC address of packets that are returned (looped back) during a terminal loopback test. The source MAC address and destination MAC addresses in the frame are swapped when the data is looped back so that the incoming source and destination addresses become the outgoing destination and source addresses, respectively.

The Carrier Ethernet Terminal Loopback command set is used to configure the parameters of a terminal loopback object.

To create a terminal loopback object and/or activate the Carrier Ethernet Terminal Loopback Configuration mode, enter the **ethernet loopback terminal** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ethernet loopback terminal TERMINAL 0
Facility loopback "TERMINAL" created
(config-eth-lbk-term TERMINAL 0)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

match on page 3740
set interface on page 3741

match

Use the **match** command to specify the traffic matching criteria used by the terminal loopback object to identify which traffic should be looped back. Packets about to egress the User Network Interface (UNI) port interface specified in the terminal loopback object will be looped back if the packet matches the criteria specified by the command. Use the **no** form of this command to remove the match criteria. Variations of this command include:

match destination mac address <*mac address*>
match destination mac address system
match single-tag s-tag <*vlan id*>

Syntax Description

destination mac address	Specifies that traffic will be looped back based on the destination MAC address. Packets just about to egress the interface specified in the terminal loopback object will be looped back if the packet's destination MAC address matches the specified MAC address.
<*mac address*>	Specifies a valid 48-bit MAC address as the destination MAC address for filtering traffic before egressing the interface. MAC addresses should be expressed in the following format: xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).
system	Specifies the system loopback MAC address as the destination MAC address for matching looped back traffic just prior to egressing the interface. This keyword can only be used if a system loopback MAC address has been specified. For more information on configuring the system loopback MAC address, refer to *ethernet loopback system mac address on page 1281*.
single-tag s-tag <*vlan id*>	Specifies that traffic will be looped back based on the service provider's virtual local area network (VLAN) ID. Valid <*vlan id*> range is **2** to **4094**.

Default Values

By default, all traffic on the connected UNI port interface is matched.

Command History

Release R13.7.0	Command was introduced.

Usage Examples

The following example specifies that traffic about to egress the UNI port interface should be filtered based on the destination MAC address **00:AO:C8:00:00:02**:

(config)**#ethernet loopback facility TERMINAL 0**
Facility loopback "TERMINAL" created
(config-eth-lbk-term TERMINAL 0)**#match destination mac address 00:A0:C8:00:00:02**

set interface

Use the **set interface** command to specify the User Network Interface (NNI) port interface that will loop back matching traffic. Traffic about to egress this interface will be looped back if it matches the match criteria specified in the termanl loopback object. If no match criteria is specified, all traffic egressing the interface will be looped back. Use the **no** form of this command to remove the specified association. Variations of this command include:

set interface efm-group <*slot/group*>
set interface gigabit-ethernet <*slot/port*>

Syntax Description

efm-group <*slot/group*>	Specifies an Ethernet in the first mile (EFM) group as the UNI port interface that will loop back matching traffic.
gigabit-ethernet <*slot/port*>	Specifies a Gigabit Ethernet interface as the UNI port interface that will loop back matching traffic.

Default Values

No default values are necessary for this command.

Command History

Release R13.7.0	Command was introduced.

Usage Examples

The following example specifies Gigabit Ethernet **0/1** interface as the UNI port interface that will loop back traffic:

(config)**#ethernet loopback facility TERMINAL 0**
Facility loopback “TERMINAL” created
(config-eth-lbk-term TERMINAL 0)**#set interface gigabit-ethernet 0/1**

FACILITY MAC SWAP LOOPBACK COMMAND SET

In a facility media access control (MAC) swap loopback test, traffic is looped back upon ingressing the AOS unit. A flow ingressing the Metro Ethernet network (MEN) port interface is turned back toward that interface immediately upon entering the switch fabric. This loopback incorporates only the conditioning associated with the device's MEN port (shaping). Facility loopbacks are commonly used to validate round-trip data flow between a test head and a remote device's interface to the Ethernet backhaul.

Because Ethernet address rules do not allow frames containing the same source MAC address to arrive from different ports on a device, the AOS unit must swap the destination and source MAC address of packets that are returned (looped back) during a facility MAC swap loopback test. The source MAC address and destination MAC addresses in the frame are swapped when the data is looped back so that the incoming source and destination addresses become the outgoing destination and source addresses, respectively.

The Facility MAC Swap Loopback command set is used to configure the parameters of a facility loopback object.

To create a facility loopback object and/or activate the Facility MAC Swap Loopback Configuration mode, enter the **ethernet loopback facility** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ethernet loopback facility FACILITY 0
Facility loopback "FACILITY" created
(config-eth-lbk-fac FACILITY 0)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

match on page 3743
set interface on page 3744

match

Use the **match** command to specify the traffic matching criteria used by the facility loopback object to identify which traffic should be looped back. Packets ingressing the Metro Ethernet network (MEN) port interface specified in the facility loopback object will be looped back if the packet matches the criteria specified by the command. Use the **no** form of this command to remove the match criteria. Variations of this command include:

match destination mac address <*mac address*>
match destination mac address system

Syntax Description

destination mac address	Specifies that traffic will be looped back based on the destination MAC address. Packets ingressing the interface specified in the facility loopback object will be looped back if the packet's destination MAC address matches the specified MAC address.
<*mac address*>	Specifies a valid 48-bit MAC address as the destination MAC address for filtering traffic ingressing the interface. MAC addresses should be expressed in the following format: xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).
system	Specifies the system loopback MAC address as the destination MAC address for matching looped back traffic ingressing the interface. This keyword can only be used if a system loopback MAC address has been specified. For more information on configuring the system loopback MAC address, refer to *ethernet loopback system mac address on page 1281*.

Default Values

By default, all traffic on the connected MEN port interface is matched.

Command History

Release R11.1.0	Command was introduced.

Usage Examples

The following example specifies that traffic ingressing the MEN port interface should be filtered based on the destination MAC address **00:AO:C8:00:00:02**:

(config)**#ethernet loopback facility FACILITY 0**
Facility loopback "FACILITY" created
(config-eth-lbk-fac FACILITY 0)**#match destination mac address 00:A0:C8:00:00:02**

set interface

Use the **set interface** command to specify the Metro Ethernet network (MEN) port interface that will loop back matching traffic. Traffic ingressing this interface will be looped back if it matches the match criteria specified in the facility loopback object. If no match criteria is specified, all traffic ingressing the interface will be looped back. Use the **no** form of this command to remove the specified association. Variations of this command include:

set interface efm-group <*slot/group*>
set interface gigabit-ethernet <*slot/port*>

Syntax Description

efm-group <*slot/group*>	Specifies an Ethernet in the first mile (EFM) group as the MEN port interface that will loop back matching traffic.
gigabit-ethernet <*slot/port*>	Specifies a Gigabit Ethernet interface as the MEN port interface that will loop back matching traffic.

Default Values

No default values are necessary for this command.

Command History

Release R11.1.0	Command was introduced.

Usage Examples

The following example specifies Gigabit Ethernet **0/1** interface as the MEN port interface that will loop back traffic:

(config)**#ethernet loopback facility FACILITY 0**
Facility loopback “FACILITY” created
(config-eth-lbk-fac FACILITY 0)**#set interface gigabit-ethernet 0/1**

SYSTEM CONTROL EVC COMMAND SET

The system control Ethernet virtual connection (EVC) command set is used to configure the system control EVC. The EVC is used to separate the session control Point-to-Point Protocol over Ethernet (PPPoE) from regular customer services on the AOS device and to provide dynamic provisioning. The EVC is linked logically to the system control virtual routing and forwarding (VRF) instance and is always present in the AOS configuration.

To enter the System Control EVC Configuration Mode, enter the **system-control-evc** from the Global Configuration mode prompt as follows:

```
(config)#system-control-evc
(config-sys-ctrl-evc)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

acfc accept-compressed on page 3747
connect men-port on page 3748
connect uni gigabit-ethernet <slot/port> on page 3749
dynamic-dns on page 3750
encap on page 3752
ip commands begin on page 3753
ipv6 commands begin on page 3782
keepalive <value> on page 3818
max-reserved-bandwidth <value> on page 3819
men-pri on page 3820
peer default ip address <ipv4 address> on page 3821
peer default ipv6 interface-id <interface id> on page 3822
ppp commands begin on page 3823
pppoe ac-name <name> on page 3833
pppoe service-name <name> on page 3834
qos-policy on page 3835
rtp quality-monitoring on page 3837
snmp trap on page 3838
snmp trap link-status on page 3839

s-tag on page 3840
traffic-shape rate <value> on page 3841
vrf forwarding <name> on page 3842

acfc accept-compressed

Use the **acfc accept-compressed** command to enable accepting header compressed frames even if compression is not negotiated. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release 14.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control Ethernet virtual connection (EVC).

Usage Examples

The following example enables accepting compressed frames:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#acfc accept-compressed**

connect men-port

Use the **connect men-port** command to associate the Ethernet virtual connection (EVC) with a specific Metro Ethernet network (MEN) port so that traffic can flow to the MEN. Use the **no** form of this command to remove the association between this EVC and the specified EFM group. Variations of this command include:

connect men-port efm-group <*slot/group*>
connect men-port gigabit-ethernet <*slot/port*>

Syntax Description

efm-group <*slot/group*>	Specifies the Ethernet in the first mile (EFM) group to associate with the EVC. Valid group range is **1** to **1024**.
gigabit-ethernet <*slot/port*>	Specifies the Gigabit Ethernet subinterface to associate with the EVC.

Default Values

By default, no interfaces are connected to the EVC.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example associates the system control EVC with EFM group **1**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#connect men-port efm-group 1/1**

connect uni gigabit-ethernet <*slot/port*>

Use the **connect uni** command to associate the system control Ethernet virtual connection (EVC) with a user network interface (UNI). Use the **no** form of this command to remove the association between the EVC and the UNI.

Syntax Description

gigabit-ethernet <*slot/port*>	Specifies the Gigabit Ethernet subinterface to associate with the system control EVC.

Default Values

By default, the system control EVC is not associated with an interface.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example associates the system control EVC with the Gigabit Ethernet subinterface 1/1:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#connect uni gigabit-ethernet 1/1**

dynamic-dns

Use the **dynamic-dns** command to configure Dynamic DNS service provided by Dynamic Network Services, Inc. (www.dyndns.org). Use the **no** form of this command to disable this feature. Variations of this command include:

dynamic-dns custom <*hostname*> <*minutes*>
dynamic-dns dyndns <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-custom <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-static <*hostname*> <*username*> <*password*>

Syntax Description

<*hostname*>	Specifies the host name for the server that updates the dynamic domain naming system (DNS).
<*minutes*>	Specifies the intervals in minutes to update the server with information (updates also occur when the interface's IP address changes regardless of the update intervals).
<*username*>	Specifies a user name using an alphanumerical string up to 30 characters in length (the user name is case sensitive).
<*password*>	Specifies a password using an alphanumerical string up to 30 characters in length (the password is case sensitive). Refer to *Functional Notes* below for additional argument descriptions.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.
Release 12.1	Command was expanded.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release R10.10.0	Command was expanded to include the system control Ethernet virtual connection (EVC).

Functional Notes

custom - Constanttime.com's Custom Dynamic DNS^{SM} service allows you complete access and management control over your domain name regardless of where you purchased/registered it. This allows you to manage IP address mappings (A records), domain aliases (CNAME records), and mail servers (mail exchange (MX) records).

dyndns - The Dynamic DNS^{SM} offered by Dynamic Network Services, Inc. (DynDNS.org) allows you to alias a dynamic IP address to a static host name in various domains. This allows your unit to be more easily accessed from various locations on the Internet. This service is provided for up to five host names.

dyndns-custom - DynDNS.org's Custom DNS^{SM} service provides a full DNS solution, giving you complete control over an entire domain name. A Web-based interface provides two levels of control over your domain, catering to average or advanced users. Five globally redundant DNS servers ensure that your domain will always resolve.

A choice of two interfaces is available. The basic interface is designed for most users. It comes preconfigured for most common configurations and allows for easy creation of most common record types. The advanced interface is designed for system administrators with a solid DNS background, and provides layout and functionality similar to a BIND zone file allowing for the creation of nearly any record type.

Custom DNS^{SM} can be used with both static and dynamic IPs, and has the same automatic update capability through Custom DNS-aware clients as Dynamic DNS.

dyndns-static - The Static DNS service is similar to DynDNS.org's Dynamic DNS^{SM} service in that it allows a host name, such as yourname.dyndns.org, to point to your IP address. Unlike a Dynamic DNS host, a Static DNS host does not expire after 35 days without updates, but updates take longer to propagate through the DNS system. This service is provided for up to five host names.

If your IP address does not change often or at all, but you still want an easy name to remember it by (without having to purchase your own domain name), Static DNS service is ideal for you.

If you would like to use your own domain name (such as yourname.com), you need Custom DNS service that also provides full dynamic and static IP address support.

Usage Examples

The following example sets the Dynamic DNS to **dyndns-custom** with host name **host**, user name **user**, and password **pass**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#dynamic-dns dyndns-custom host user pass**

encap

Use the **encap** command to enable encapsulation mode in the system control Ethernet virtual connection (EVC). Use the **no** form of this command to disable encapsulation. Variations of this command include:

encap ethernet
encap pppoe

Syntax Description

ethernet	Specifies that the encapsulation mode of the EVC is Ethernet.
pppoe	Specifies that the encapsulation mode of the EVC is Point-to-Point Protocol over Ethernet (PPPoE).

Default Values

By default, the system control EVC encapsulation mode is set to **pppoe**.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example sets the system control EVC encapsulation mode to **ethernet**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#encap ethernet**

ip access-group *<ipv4 acl name>*

Use the **ip access-group** command to apply an Internet Protocol version 4 (IPv4) access control list (ACL) to be used for IPv4 packets transmitted on or received from the system control Ethernet virtual connection (EVC). Use the **no** form of this command to disable this type of control. Variations of this command include:

ip access-group <*ipv4 acl name*> **in**
ip access-group <*ipv4 acl name*> **out**

Syntax Description

<ipv4 acl name>	Applies the named IPv4 ACL to the EVC.
in	Enables access control on IPv4 packets received on the specified interface.
out	Enables access control on IPv4 packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

When this command is enabled, the IPv4 destination address of each packet must be validated before being passed through. If the packet is not acceptable per these settings, it is dropped.

Usage Examples

The following example configures the router to only allow IPv4 Telnet traffic (as defined in the user-configured **TelnetOnly** ACL) into the system control EVC:

(config)**#ip access-list extended TelnetOnly**
(config-ext-nacl)**#permit tcp any any eq telnet**
(config-ext-nacl)**#system-control-evc**
(config-sys-ctrl-evc)**#ip access-group TelnetOnly in**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to the system control Ethernet virtual connection (EVC). IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

> NOTE *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an EVC.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the system control EVC:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the system control EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip access-policy PRIVATE**

ip address dhcp

Use the **ip address dhcp** command to use Dynamic Host Configuration Protocol (DHCP) to obtain an address on the interface. Use the **no** form of this command to remove a configured IP address (using DHCP) and disable DHCP operation on the interface. Variables that may be used with this command to further define the DHCP configuration include:

ip address dhcp class-id [ascii <*string*> **| hex** <*value*>**] [client-id [**<*interface*> **|** <*identifier*>**]] [hostname** <*"string"*>**] [track** <*name*>**] [**<*administrative distance*>**]**
ip address dhcp client-id [<*interface*> **|** <*identifier*>**] [hostname** <*"string"*>**] [track** <*name*>**] [**<*administrative distance*>**]**
ip address dhcp hostname *"*<*string*>*"* **[no-default-route | no-domain-name | no-nameservers] [track** <*name*>**] [**<*administrative distance*>**]**
ip address dhcp [no-default-route | no-domain-name | no-nameservers] [track <*name*>**] [**<*administrative distance*>**]**
ip address dhcp track <*name*> **[**<*administrative distance*>**]**

Syntax Description

<*administrative distance*>	Optional. Specifies the administrative distance to use when adding the DHCP gateway into the route table. It is used to determine the best route when multiple routes to the same destination exist. The lower the administrative distance, the more reliable the route. Range is **1** to **255**.
class-id	Optional. Specifies the vendor class identifier for the interface.
ascii <*string*>	Specifies the vendor class identifier in an ASCII string of up to **255** bytes.
hex <*value*>	Specfies the vendor class identifier in hexadecimal format. Valid range is up to **510** hexadecimal numbers. An even number of digits is required.
client-id	Optional. Specifies the client identifier used when obtaining an IP address from a DHCP server.
<*interface*>	Specifies an interface, thus defining the client identifier as the hexadecimal medium access control (MAC) address of the specified interface (including a hexadecimal number added to the front of the MAC address to identify the media type). For example, specifying the **client-id ethernet 0/1** (where the Ethernet interface has a MAC address of d217.0491.1150) defines the client identifier as **01:d2:17:04:91:11:50** (where 01 defines the media type as Ethernet). Refer to *hardware-address on page 4344* for a detailed listing of media types.
<*identifier*>	Specifies a custom client-identifier using a text string (that is converted to a hexadecimal equivalent) or 7 to 28 hexadecimal numbers (with colon delimiters). For example, a custom client identifier of **0f:ff:ff:ff:ff:51:04:99:a1** may be entered using the <*identifier*> option.
hostname <*"string"*>	Optional. Specifies a text string (to override the global router name) to use as the name in the DHCP option 12 field. The string is enclosed in quotation marks and can consist of up to 35 characters.

no-default-route Optional. Specifies that no default route is obtained via DHCP.

no-domain-name Optional. Specifies that no domain name is obtained via DHCP.

no-nameservers Optional. Specifies that no domain naming system (DNS) servers are obtained via DHCP.

track *<name>* Optional. Attaches a network monitoring track to the DHCP client. The DHCP gateway route for this client will only reside in the route table while the track is in the pass state. For more information on configuring track objects, refer to *track <name> on page 1886*.

Default Values

<administrative distance> By default, the administrative distance value is 1.

class-id Optional. By default, no vendor class identifier is configured.

client-id Optional. By default, the client identifier is populated using the following formula:

TYPE: INTERFACE SPECIFIC INFO : MAC ADDRESS

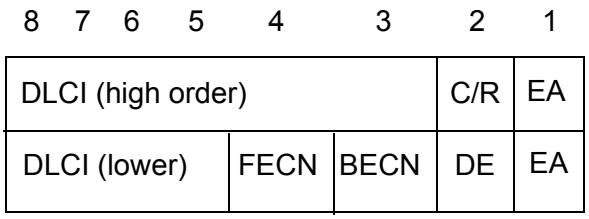
Where TYPE specifies the media type in the form of one hexadecimal byte (refer to *hardware-address on page 4344* for a detailed listing of media types), and the MAC ADDRESS is the medium access control (MAC) address assigned to the first Ethernet interface in the unit in the form of six hexadecimal bytes. (For units with a single Ethernet interface, the MAC ADDRESS assigned to Ethernet 0/1 is used in this field.)

INTERFACE SPECIFIC INFO is only used for Frame Relay interfaces and can be determined using the following:

FR_PORT#: Q.922 ADDRESS

Where the FR_PORT# specifies the label assigned to the virtual Frame Relay interface using four hexadecimal bytes. For example, a virtual Frame Relay interface labeled 1 would have a FR_PORT# of 00:00:00:01.

The Q.922 ADDRESS field is populated using the following:



Where the FECN, BECN, C/R, DE, and high order extended address (EA) bits are assumed to be 0 and the lower order EA bit is set to 1.

The following list provides a few example DLCIs and associated Q.922 address:

DLCI (decimal) / Q.922 address (hex)

16 / 0x0401
50 / 0x0C21
60 / 0x0CC1
70 / 0x1061
80 / 0x1401

hostname *“<string>”* By default, the host name is the name configured using the Global Configuration **hostname** command.

Command History

Release 2.1	Command was introduced.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 13.1	Command was expanded to include the track and administrative distance.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.10.0	Command was expanded to include the **class-id** parameter in support of DHCP Option 60.

Functional Notes

DHCP allows interfaces to acquire a dynamically assigned IP address from a configured DHCP server on the network. Many service providers require the use of DHCP when connecting to their services. Using DHCP reduces the number of dedicated IP addresses the ISP must obtain. Consult your ISP to determine the proper values for the **client-id** and **hostname** fields.

The vendor class identifier is sent to the DHCP server in DHCP discover and request messages via DHCP Option 60. This option gives the DHCP server details regarding DHCP client configuration and also allows the server to send any vendor-specific information to the client in DHCP offer messages via Option 43.

Usage Examples

The following example enables DHCP operation on the interface:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip address dhcp**

The following example enables DHCP operation on the interface utilizing host name **adtran** and does not allow obtaining a default route, domain name, or name servers. It also sets the administrative distance as **5**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip address dhcp hostname “adtran” no-default-route no-domain-name no-nameservers 5**

ip address negotiated

Use the **ip address negotiated** command to allow the system control Ethernet virtual connection (EVC) to negotiate (i.e., be assigned) an Internet Protocol version 4 (IPv4) address from the far-end Point-to-Point Protocol (PPP) connection. Use the **no** form of this command to disable the negotiation for an IP address. Variations of this command include:

ip address negotiated
ip address negotiated <*ipv4 address*>
ip address negotiated <*ipv4 address*> **no-default**

Syntax Description

<*ipv4 address*>	Optional. Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
no-default	Optional. Prevents the insertion of a default route. Some systems already have a default route configured and need a static route to the PPP interface to function correctly.

Default Values

By default, the EVC is not assigned an address.

Command History

Release 5.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Usage Examples

The following example enables the system control EVC to negotiate an IPv4 address from the far-end connection:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip address negotiated**

The following example enables the system control EVC to negotiate an IPv4 address from the far-end connection without inserting a default route:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip address negotiated no-default**

ip address range *<start ipv4 address> <end ipv4 address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the system control Ethernet virtual connection (EVC). Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single EVC (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the system control Ethernet virtual connection (EVC) (only one primary address is allowed). Use the optional **secondary** keyword to define a secondary IPv4 address. Use the **no** form of this command to remove a configured IPv4 address. Variations of this command include:

ip address <*ipv4 address*> <*subnet mask*>
ip address <*ipv4 address*> <*subnet mask*> **secondary**

Syntax Description

<*ipv4 address*>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*subnet mask*>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the EVC.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IP addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a secondary IPv4 address of **192.22.72.101 /30**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip address 192.22.72.101 /30 secondary**

ip crypto map *<name>*

Use the **ip crypto map** command to associate Internet Protocol version 4 (IPv4) crypto maps with the system control Ethernet virtual connection (EVC). Use the **no** form of this command to remove a crypto map from an interface.

> NOTE *When you apply a map to an EVC, you are applying all crypto maps with the given map name. This allows you to apply multiple crypto maps if you have created maps that share the same name, but have different map index numbers.*

Syntax Description

<name>	Specifies the IPv4 crypto map name that you wish to assign to the EVC.

Default Values

By default, no crypto maps are assigned to an EVC.

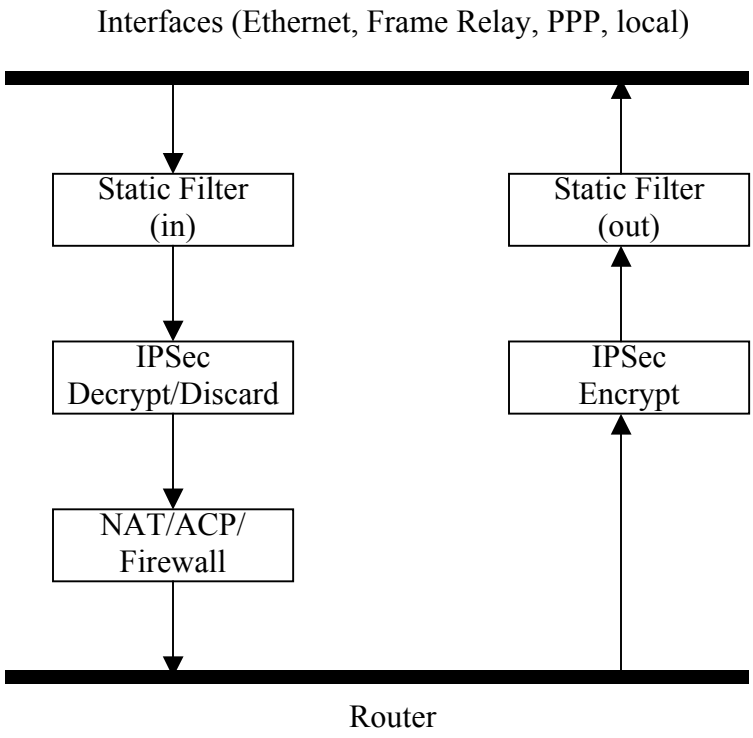
Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 9.1	Command was expanded to include the High-Level Data Link Control (HDLC) interface.
Release 11.1	Command was expanded to include the demand interface.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.7.0	Command syntax was changed to require the **ip** keyword.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

When configuring a system to use both the stateful inspection firewall and Internet key exchange (IKE) negotiation for VPN, keep the following notes in mind.

When defining the IPv4 policy class and associated access control lists (ACLs) that describe the behavior of the IPv4 firewall, do not forget to include the traffic coming into the system over a VPN tunnel terminated by the system. The firewall should be set up with respect to the unencrypted traffic that is destined to be sent or received over the VPN tunnel. The following diagram represents typical AOS data-flow logic.



As shown in the diagram above, data coming into the product is first processed by the static filter associated with the EVC on which the data is received. This access group is a true static filter and is available for use regardless of whether the IPv4 firewall is enabled or disabled. Next (if the data is encrypted), it is sent to the IPSec engine for decryption. The decrypted data is then processed by the stateful inspection firewall. Therefore, given a terminating VPN tunnel, only unencrypted data is processed by the firewall.

The IPv4 ACLs for a crypto map on an interface work in reverse logic to the ACLs for a policy class on an EVC. When specifying the ACLs for a crypto map, the source information is the private local side, unencrypted source of the data. The destination information will be the far-end, unencrypted destination of the data. However, ACLs for a policy class work in reverse. The source information for the ACL in a policy class is the far end. The destination information is the local side.

Usage Examples

The following example applies all IPv4 crypto maps with the name **MyMap** to the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip crypto map MyMap**

ip dhcp relay destination *<ipv4 address>*

Use the **ip dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 4 (IPv4) and to specify the IPv4 address for the DHCPv4 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv4 relay functionality is disabled on the interface.

Syntax Description

<ipv4 address>	Specifies the IPv4 address for the DHCPv4 messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**)..

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.10.0	Command was expanded to include the system control Ethernet virtual connection (EVC).

Usage Examples

The following example enables DHCPv4 relay agent functionality and specifies the destination address as **192.33.4.251**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip dhcp relay destination 192.33.4.251**

ip dhcp

Use the **ip dhcp** command to release or renew the Dynamic Host Configuration Protocol (DHCP) Internet Protocol version 4 (IPv4) address. This command is only applicable when using DHCP for IP address assignment. Variations of this command include:

ip dhcp release
ip dhcp renew

Syntax Description

release	Releases the DHCP IPv4 address.
renew	Renews the DHCP IPv4 address.

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.
Release 8.1	Command was added to the asynchronous transfer mode (ATM) subinterface.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release R10.1.0	Command was added to the bridged virtual interface (BVI).
Release R10.10.0	Command was expanded to include the system control Ethernet virtual connection (EVC).

Usage Examples

The following example releases the IPv4 address assigned (by DHCP) on the system control EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip dhcp release**

ip directed-broadcast

Use the **ip directed-broadcast** command to allow reception/forwarding of directed broadcasts. Use the **no** form of this command to disable this feature. Variations of this command include:

ip directed-broadcast
ip directed-broadcast <*name*>

Syntax Description

<*name*>	Specifies IP access control list (ACL) name.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control Ethernet virtual connection (EVC).

Functional Notes

A directed broadcast is a packet intended for all nodes on a nonlocal network. For example, the broadcast address 255.255.255.255 reaches all nodes on a network; the directed broadcast address 128.1.255.255 is intended for all nodes whose network address is 128.1.0.0. A router not directly attached to 128.1.0.0 simply forwards the directed broadcast packet to the next hop. A router on network 128.1.0.0 that has **ip directed-broadcast** enabled, accepts and forwards the packet to all nodes whose network address is 128.1.0.0. Routers connecting subnets of 128.1.0.0 also accept and forward the packet to the nodes on their respective subnets. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is distributed as a broadcast on the destination subnet. The packet is then sent as a link-layer broadcast.

The **ip directed-broadcast** command controls the distribution of directed broadcasts when they reach their target subnets. Only the final transmission of the directed broadcast on its ultimate destination subnet is affected. It does not affect the transit unicast routing of IP directed broadcasts.

If **ip directed-broadcast** is enabled for this interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which this EVC is attached will be forwarded as broadcasts on that subnet. Forwarding of the packets can be limited by specifying an ACL with this command. In this case, only directed broadcasts that are permitted by the specified ACL will be forwarded, and all other directed broadcasts directed to this EVC subnet will be dropped.

Disabling the **ip directed-broadcast** command will cause directed broadcasts destined for the subnet to which this EVC is attached to be dropped.

This option is a requirement for routers as described in RFC 1812, section 4.2.2.11. Furthermore, it is disabled by default (RFC 2644), with the intended goal of reducing the efficacy of certain types of denial of service (DoS) attacks.

Usage Examples

The following example enables forwarding of directed broadcasts on the system control EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip directed-broadcast**

ip flow

Use the **ip flow** command to enable integrated traffic monitoring (ITM) for all traffic received or forwarded on the system control Ethernet virtual connection (EVC). Use the **no** form of this command to disable traffic monitoring. Variations of this command include:

ip flow egress
ip flow egress <*name*>
ip flow ingress
ip flow ingress <*name*>

Syntax Description

egress	Specifies that all outgoing traffic be monitored.
ingress	Specifies that all incoming traffic be monitored.
<*name*>	Optional. Specifies the name of an access control list (ACL) to use for filtering traffic.

Default Values

By default, no traffic monitoring is enabled.

Command History

Release 16.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Usage Examples

The following example enables traffic monitoring on the system control EVC to monitor **incoming** traffic through an ACL called **MYACL**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip flow ingress MYACL**

ip helper-address *<ipv4 address>*

Use the **ip helper-address** command to configure AOS to forward User Datagram Protocol (UDP) broadcast packets received on the system control Ethernet virtual connection (EVC). Use the **no** form of this command to disable forwarding packets.

> NOTE *The **ip helper** command must be used in conjunction with the **ip forward-protocol** command to configure AOS to forward UDP broadcast packets. Refer to ip forward-protocol udp <value> on page 1398 for more information.*

Syntax Description

<ipv4 address>	Specifies the destination IP address for the forwarded UDP packets. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, broadcast UDP packets are not forwarded.

Command History

Release 1.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

When used in conjunction with the **ip forward-protocol** command, the **ip helper-address** feature allows you to customize which broadcast packets are forwarded.

To implement the helper address feature, assign a helper address(es) (specifying the device that needs to receive the broadcast traffic) to the interface closest to the host that transmits the broadcast packets. When broadcast packets (of the specified type forwarded using the **ip forward-protocol** command) are received on the interface, they will be forwarded to the device that needs the information.

Only packets meeting the following criteria are considered eligible by the **ip helper-address** feature:

1. The packet IP protocol is UDP.
2. Any UDP port specified using the **ip forward-protocol** command.
3. The medium access control (MAC) address of the frame is an all-ones broadcast address (ffff.ffff.ffff).
4. The destination IPv4 address is broadcast defined by all ones (255.255.255.255) or a subnet broadcast (for example, 192.33.4.251 for the 192.33.4.248 /30 subnet).

Usage Examples

The following example forwards all domain naming system (DNS) broadcast traffic to the DNS server with IPv4 address **192.33.5.99**:

(config)**#ip forward-protocol udp domain**
(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip helper-address 192.33.5.99**

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the system control Ethernet virtual connection (EVC). Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces (all types)	1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

OSPFv2 will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip mtu 1200**

ip policy route-map *<name>*

Use the **ip policy route-map** command to assign a policy route-map to the system control Ethernet virtual connection (EVC). Use the **no** form of this command to remove the route-map policy.

Syntax Description

<name>	Specifies the name of the policy route map to assign to this EVC.

Default Values

By default, no policy route map is assigned to this EVC.

Command History

Release 11.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Usage Examples

The following example assigns the policy route map **policy1** to the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip policy route-map policy1**

ip proxy-arp

Use the **ip proxy-arp** command to enable proxy Address Resolution Protocol (ARP) on the system control Ethernet virtual connection (EVC). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, proxy ARP is enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

In general, the principle of proxy ARP allows a router to insert its IP address in the source IP address field of a packet (if the packet is from a host on one of its subnetworks). This allows hosts to reach devices on other subnetworks without implementing routing or specifying a default gateway.

If proxy ARP is enabled, AOS will respond to all ARP requests with its specified medium access control (MAC) address and forward packets accordingly.

Enabling proxy ARP on an EVC may introduce unnecessary ARP traffic on the network.

Usage Examples

The following example enables proxy ARP on the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip proxy-arp**

ip rip authentication

Use the **ip rip authentication** command to enable specify the Internet Protocol version 4 (IPv4) Routing Information Protocol (RIP) authentication method on the Ethernet virtual connection (EVC). Use the **no** form of this command to disable RIP authentication. Variations of this command include:

ip rip authentication key-chain <*name*>
ip rip authentication mode md5
ip rip authentication mode text

Syntax Description

key-chain <*name*>	Specifies that RIP authentication is completed using an authentication key, and specifies the key name.
mode md5	Specifies that RIP authentication is completed using message digest authentication.
mode text	Specifies that RIP authentication is completed using clear text authentication.

Default Values

By default, RIP authentication is disabled.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example enables RIP authentication on the EVC and specifies authentication is completed using clear text:

(config)**#system-control-evc**
(config-sys-ctrl-evc)#

ip rip receive version

Use the **ip rip receive version** command to configure the Routing Information Protocol (RIP) version the unit accepts in all RIP packets received on the system control Ethernet virtual connection (EVC). Variations of this command include:

ip rip receive version 1
ip rip receive version 2

Syntax Description

1	Accepts only RIP version 1 packets received on the EVC.
2	Accepts only RIP version 2 packets received on the EVC.

Default Values

By default, the EVC implements RIP version **1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

Use the **ip rip receive version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only accepts one version (either **1** or **2**) on an EVC.

Usage Examples

The following example configures the EVC to accept only RIP version **2** packets:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip rip receive version 2**

ip rip send version

Use the **ip rip send version** command to configure the Routing Information Protocol (RIP) version the unit sends in all RIP packets transmitted on the system control Ethernet virtual connection (EVC). Variations of this command include:

ip rip send version 1
ip rip send version 2

Syntax Description

1	Transmits only RIP version 1 packets on the EVC.
2	Transmits only RIP version 2 packets on the EVC.

Default Values

By default, the EVC transmit RIP version **1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

Use the **ip rip send version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only transmits one version (either **1** or **2**) on an EVC.

Usage Examples

The following example configures the EVC to transmit only RIP version **2** packets:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip rip send version 2**

ip rip summary-address *<ipv4 address> <subnet mask>*

Use the **ip rip summary-address** command to manually summarize the routes Routing Information Protocol (RIP) will advertise and send out the system control Ethernet virtual connection (EVC). Use the **no** form of this command to disable this mode.

Syntax Description

<ipv4 address>	Specifies the summarized network IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.0**).
<subnet mask>	Specifies the subnet mask that corresponds to the range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no manual summarization is applied by RIP.

Command History

Release 12.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

Unlike the automatic summarization on classful network boundaries, only specific network advertisements are made by RIP using the **ip rip summary-address** command. This command is only effective if RIP version 2 is configured.

Usage Examples

The following example enables manual summarization on the specified IPv4 address:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip rip summary-address 10.10.123.0 255.255.255.0**

ip route-cache

Use the **ip route-cache** command to enable Internet Protocol version 4 (IPv4) fast-cache switching on the system control Ethernet virtual connection (EVC). Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

*Using network address translation (NAT) or the AOS firewall capabilities on an EVC requires process switching mode (using the **no ip route-cache** command).*

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on the EVC.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

Fast switching allows an EVC to provide optimum performance when processing IPv4 traffic.

Usage Examples

The following example enables IPv4 fast switching on the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip route-cache**

ip split-horizon

Use the **ip split-horizon** command to enable Internet Protocol version 4 (IPv4) Routing Information Protocol (RIP) split horizon on the Ethernet virtual connection (EVC). Use the **no** form of this command to disable the feature.

Syntax Description

No subcommands.

Default Values

By default, RIP split horizon is disabled.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example enables RIP split horizon on the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip split-horizon**

ip urlfilter *<name>*

Use the **ip urlfilter** command to apply a universal resource locator (URL) filter to the system control Ethernet virtual connection (EVC) for all inbound or outbound traffic. Use the **no** form of this command to remove the URL filter from the EVC. Variations of this command include:

ip urlfilter <*name*> **in**
ip urlfilter <*name*> **out**

Syntax Description

<name>	Specifies the URL filter name to use on the EVC.
in	Applies the filter to the inbound traffic.
out	Applies the filter to the outbound traffic.

Default Values

By default, there are no URL filters applied to any EVCs.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be created by using the **ip urlfilter** *<filter name>* **http** command before applying it to the EVC. Refer to *ip urlfilter <name> http on page 1495* for more information on using this command.

Usage Examples

The following example performs URL filtering on all traffic entering through the EVC and matches the URL filter named **MyFilter**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ip urlfilter MyFilter in**

ipv6

Use the **ipv6** command to enable Internet Protocol version 6 (IPv6) processing and create a link-local address on the system control Ethernet virtual connection (EVC). Use the **no** form of this command to disable IPv6 processing and remove all IPv6 configuration on the EVC.

Syntax Description

No subcommands.

Default Values

By default, IPv6 is not enabled on the EVC.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

Because AOS uses the dual-stack for IPv6 implementation, IPv6 features must be enabled for the supported IPv6 features to be used. Enabling IPv6 in AOS is completed by using an IPv6 address or using the **ipv6** keyword with specific commands. For example, to enable IPv6 on an interface and cause the EVC to join the link scoped all-nodes and all-routers multicast group, enter an IPv6 address on the EVC.

Use the **ipv6** command to enable IPv6 processing and create a link-local address on an EVC when other unicast IPv6 addresses are not needed on the EVC. This command is not necessary nor effectual when any other form of an IPv6 address command is also present on the EVC.

Usage Examples

The following example enables IPv6 and creates a link-local IPv6 address on the EVC:

```
(config)#system-control-evc
(config-sys-ctrl-evc)#ipv6
```

ipv6 access-group *<ipv6 acl name>*

Use the **ipv6 access-group** command to apply an Internet Protocol version 6 (IPv6) access control list (ACL) to be used for IPv6 packets transmitted on or received from the system control Ethernet virtual connection (EVC). Use the **no** form of this command to disable this type of control. Variations of this command include:

ipv6 access-group *<ipv6 acl name>* **in**
ipv6 access-group *<ipv6 acl name>* **out**

Syntax Description

<ipv6 acl name>	Applies the named IPv6 ACL to the EVC.
in	Enables access control on IPv6 packets received on the EVC.
out	Enables access control on IPv6 packets transmitted on the EVC.

Default Values

By default, these commands are disabled.

Command History

Release 18.1	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

Only one IPv6 ACL can be applied in each traffic direction.

Unlike in IPv4, IPv6 traffic filters include an implicit **permit** for neighbor solicitation and advertisement packets in an ACL before the traditional implicit **deny** at the end of the ACL. This prevents blocking of address resolution and unreachability detection, although this can be overridden by entering explicit **deny** commands in the IPv6 ACL.

Usage Examples

The following example applies the IPv6 ACL **Privatev6** to incoming IPv6 traffic on the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 access-group Privatev6 in**

ipv6 access-policy *<ipv6 acp>*

Use the **ipv6 access-policy** command to assign a specified Internet Protocol version 6 (IPv6) access control policy (ACP) to the system control Ethernet virtual connection (EVC). IPv6 ACPs are applied to IPv6 traffic entering the EVC. Use the **no** form of this command to remove an ACP association.

Syntax Description

<ipv6 acp>	Identifies the configured IPv6 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv6 ACPs associated with the EVC.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Usage Examples

The following example applies the IPv6 ACP **PRIVATEv6** to the EVC:

Enable the AOS security features:
(config)**#ipv6 firewall**

Associate the ACP with the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 access-policy PRIVATEv6**

ipv6 address *<ipv6 address/prefix-length>*

Use the **ipv6 address** command to assign a unicast Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the system control Ethernet virtual connection (EVC). Use the **no** form of this command to remove the IPv6 address from the EVC.

Syntax Description

<ipv6 address/prefix-length>	Specifies the IPv6 unicast address to add to the interface. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

Default Values

By default, no IPv6 address is configured on the EVC and IPv6 processing is not enabled.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the EVC using the command *ipv6 address <ipv6 link-local address> link-local on page 3787*.

The address created by this command is a manually configured IPv6 address, which must have all parts (prefix and host bits) specified.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the EVC. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the EVC.

Usage Examples

The following example adds a unicast IPv6 address to the EVC and enables IPv6 processing on the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 address 2001:DB8::/32**

ipv6 address *<ipv6 prefix/prefix-length>* eui-64

Use the **ipv6 address eui-64** command to assign a unicast Internet Protocol version 6 (IPv6) address and enable IPv6 processing on the system control Ethernet virtual connection (EVC). Use the **no** form of this command to remove the IPv6 address from the EVC.

Syntax Description

<ipv6 prefix/prefix-length>	Specifies the IPv6 prefix. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
eui-64	Specifies that the IPv6 address is constructed using the specified prefix in the high-order bits and followed by the EUI-64 Interface ID in the lower 64 bits.

Default Values

By default, no IPv6 address is configured on the EVC and IPv6 processing is not enabled.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the EVC using the command *ipv6 address <ipv6 link-local address> link-local on page 3787*.

The address created by this command is an EUI-64 unicast address. For this type of address, the EUI-64 interface ID is automatically placed in the IPv6 address. Any manually configured bits beyond the address's prefix length are set to **0**; however, any manually configured bits within the prefix length that extend into the lower 64 bits take precedence over the Interface ID bits.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the EVC. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the EVC.

Usage Examples

The following example adds a unicast IPv6 address with an EUI-64 Interface ID to the EVC and enables IPv6 processing on the EVC:

(config)#**system-control-evc**
(config-sys-ctrl-evc)#**ipv6 address 2001:DB8:3F::/48 eui-64**

ipv6 address <*ipv6 link-local address*> link-local

Use the **ipv6 address link-local** command to manually assign a link-local Internet Protocol version 6 (IPv6) address to the system control Ethernet virtual connection (EVC) and enable IPv6 processing on the EVC. Use the **no** form of this command to remove the IPv6 address from the EVC.

Syntax Description

<*ipv6 link-local address*>	Specifies the link-local IPv6 address. Link-local addresses are specified in colon hexadecimal notation, and begin with **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since link-local addresses have no prefix, the bits entered form the entire IPv6 address.
link-local	Specifies this is a manually configured link-local address. Manually configured link-local addresses replace automatically configured link-local addresses on the EVC.

Default Values

By default, no IPv6 address is configured for the EVC and IPv6 processing is not enabled.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

A single link-local address can be manually configured on an EVC. The lower 64 bits of the specified address become the Interface ID for the EVC, overriding the default interface ID. Any other address that uses the EUI-64 parameter to automatically place the interface ID in the lower 64 bits of the IPv6 address use the new value for the interface ID.

The <*ipv6 address*> for a link-local IPv6 address is specified in the format **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since this form of address has no prefix, the bits entered form the entire IPv6 address. These bits also become the new interface ID for the EVC and can be derived from the EVC's medium access control (MAC) address.

The **link-local** parameter specifies this is a manually configured link-local address. Any manually configured link-local address will replace an automatically configured link-local address for the EVC.

Using the **no** form of this command with a specified IPv6 address removes that IPv6 address from the EVC. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the EVC.

Usage Examples

The following example manually creates a link-local IPv6 address on the EVC and enables IPv6 processing:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 address FE80::220:8FF:FE54:F9D8 link-local**

ipv6 address autoconfig

Use the **ipv6 address autoconfig** command to enable Internet Protocol version 6 (IPv6) processing on the system control Ethernet virtual connection (EVC), create a local-link IPv6 address for the EVC, and allow the EVC to automatically configure itself based on advertisements from other routers on the link. Use the **no** form of this command to remove all autoconfigured addresses, prefixes, and any resulting routes from the EVC and also causes the EVC to cease processing received router advertisements (RAs).Variations of this command include:

ipv6 address autoconfig
ipv6 address autoconfig default
ipv6 address autoconfig default metric <*value*>

Syntax Description

default	Optional. Specifies that the EVC maintain a list of advertising routers that are willing to be IPv6 default routers.
metric <*value*>	Optional. Specifies the administrative distance for a default router maintained in the default router list. Range is **1** to **255**. Routes with lower administrative distance are favored.

Default Values

By default, no IPv6 addresses are configured for the EVC and IPv6 processing is not enabled. When an IPv6 address is configured automatically, the administrative distance for default routers is **2** by default.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

When autoconfiguration is enabled, the EVC listens for RA messages that tell the EVC how it should be configured. The EVC then creates addresses for advertised 64-bit prefixes with the A flag in the IPv6 address set using stateless address autoconfiguration (SLAAC). The addresses use the EUI-64 interface ID in the lower 64 bits of the address. A route type of *Connected* is added to the route table if the L flag on the prefix advertisement (on-link flag) is also set.

Usage Examples

The following example enables IPv6 processing on the EVC, creates a link-local IPv6 address for the EVC, and allows the EVC to automatically configure itself for IPv6:

(config)#**system-control-evc**
(config-sys-ctrl-evc)#**ipv6 address autoconfig**

ipv6 address dhcp

Use the **ipv6 address dhcp** command to enable Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) on the interface, place the interface in DHCPv6 client mode, and configure the address parameters of the DHCPv6 client. Use the **no** form of this command to disable the DHCPv6 client on the interface. Variations of this command include:

ipv6 address dhcp
ipv6 address dhcp hostname <*partial fqdn*>
ipv6 address dhcp hostname fqdn <*fqdn*>
ipv6 address dhcp no-domain-name
ipv6 address dhcp no-nameservers
ipv6 address dhcp no-ntp
ipv6 address dhcp no-sntp-server
ipv6 address dhcp rapid-commit

Syntax Description

hostname <*partial fqdn*>	Optional. Specifies the name to be sent to the DHCPv6 server as the host portion of its fully qualified domain name (FQDN). FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
fqdn <*fqdn*>	Optional. Specifies a name to be sent to the DHCPv6 server as the system's FQDN. FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
no-domain-name	Optional. Specifies that no domain names are obtained using this DHCPv6 client.
no-nameservers	Optional. Specifies that no domain naming server (DNS) addresses are obtained through DHCPv6.
no-ntp	Optional. Specifies that no Network Time Protocol (NTP) server values are obtained through this DHCPv6 client.
no-sntp-server	Optional. Specifies that no Simple Network Time Protocol (SNTP) server values are obtained through this DHCPv6 client.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Functional Notes

To enable an interface as a DHCPv6 client, you must first enable IPv6 on the interface using the command *ipv6 on page 3782*.

Enabling the interface as a DHCPv6 client using the **ipv6 address dhcp** command places the interface into DHCPv6 client mode. DHCPv6 modes (**client**, **server**, **relay**) are mutually exclusive at the interface. Any existing mode must be removed before a different mode can be applied. For example, if the interface is configured as a DHCPv6 relay agent, you must first disable the **relay** mode before you can specify the interface is in **client** mode.

Usage Examples

The following example enables the interface as a DHCPv6 client and specifies the client's host name:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 address 2001:DB8:1::1/64**
(config-sys-ctrl-evc)**#ipv6 address dhcp fqdn client@company.com**

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*

Use the **ipv6 address named-prefix** command to create an Internet Protocol version 6 (IPv6) address for the Ethernet virtual connection (EVC) using the values in a named prefix. Use the **no** form of this command to remove the address from the EVC. Variations of this command include:

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*
ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>* **eui-64**

Syntax Description

<prefix name>	Specifies the named prefix to use to create the address.
<ipv6 address/prefix-length>	Specifies the address portion appended to the named prefix to create a 128-bit host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
eui-64	Optional. Indicates that the interface ID is to be placed in the lower 64 bits of the address.

Default Values

By default, no IPv6 addresses are specified on the EVC.

Command History

Release R10.9.0	Command was introduced.
Release R10.10.0	Command was expanded to include the system control and system managment EVCs.

Usage Examples

The following example creates an IPv6 address on the EVC using the named prefix **PREFIX1**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 address named-prefix PREFIX1 2001:1:0:/48**

ipv6 crypto map *<name>*

Use the **ipv6 crypto map** command to associate Internet Protocol version 6 (IPv6) crypto maps with the system control Ethernet virtual connection (EVC). Use the **no** form of this command to remove a crypto map from the EVC.

Syntax Description

<name>	Specifies the IPv6 crypto map name that you wish to assign to the EVC.

Default Values

By default, no crypto maps are assigned to an EVC.

Command History

Release R10.7.0	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

Only one IPv6 crypto map can be specified per EVC, and the crypto map is applied within the virtual routing and forwarding (VRF) instance to which the EVC belongs. To apply the IPv6 crypto map, the EVC must have IPv6 enabled. In addition, the EVC must have an IPv6 address of appropriate scope to allow connectivity to peer's addresses as specified in the crypto map's entries.

Usage Examples

The following example applies all IPv6 crypto maps with the name **MyMap** to the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6**
(config-sys-ctrl-evc)**#ipv6 crypto map MyMap**

ipv6 dhcp client information refresh minimum <*seconds*>

Use the **ipv6 dhcp client information refresh minimum** command to specify the minimum value the Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) client on the system control Ethernet virtual connection (EVC) accepts as its information refresh timer. Use the **no** version of this command to return to the default setting.

Syntax Description

<*seconds*>	Specifies the refresh timer in seconds. Valid range is **600** to **3600** seconds.

Default Values

By default, the DHCPv6 client refresh timer is set to **600** seconds.

Command History

Release R10.9.0	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Usage Examples

The following example specifies the DHCPv6 client refresh timer for the EVC is **800** seconds:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 dhcp client information refresh minimum 600**

ipv6 dhcp client pd <*prefix name*>

Use the **ipv6 dhcp client pd** command to enable the Dynamic Control Host Protocol for Internet Protocol version 6 (DHCPv6) client on the interface and specify that the interface acquires an IPv6 prefix for the DHCPv6 client. Use the **no** form of this command to disable this feature. Variations of this command include:

ipv6 dhcp client pd <*prefix name*>
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*>
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*> **tag** <*value*>
ipv6 dhcp client pd <*prefix name*> **no-aggregate-route**
ipv6 dhcp client pd <*prefix name*> **rapid-commit**

Syntax Description

<*prefix name*>	Specifies the variable of the prefix stored on the AOS system. Variables are expressed in ASCII text of up to **80** characters.
distance <*distance*>	Optional. Specifies the administrative distance to assign to the injected route. Valid range is **1** to **255** with a default distance of **1**.
no-aggregate-route	Optional. Specifies that a route to the null 0 interface is not injected into the route table for the prefixes assigned.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.
tag <*value*>	Optional. Specifies a number to use as a tag for labeling and filtering routers. Valid range is **1** to **65535**.

Default Values

By default, the DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Usage Examples

The following example enables the DHCPv6 client on the interface and assigns the prefix **PREFIX1**:

(config)**#system-control-evc**
(config-syst-ctrl-evc)**#ipv6 dhcp client pd PREFIX1**

ipv6 dhcp relay destination *<ipv6 address>*

Use the **ipv6 dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 6 (IPv6) and to specify the IPv6 address for the DHCPv6 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv6 relay functionality is disabled on the system control Ethernet virtual connection (EVC). Variations of this command include:

ipv6 dhcp relay destination *<ipv6 address>*
ipv6 dhcp relay destination *<ipv6 address>* *<interface>*
ipv6 dhcp relay destination *<ipv6 address>* **system-control-evc**
ipv6 dhcp relay destination *<ipv6 address>* **system-management-evc**

Syntax Description

<ipv6 address>	Specifies the IPv6 address for the DHCPv6 messages. IPv6 addresses should be specified in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<interface>	Optional. Specifies an output interface to use when sending messages to the DHCPv6 server. If no interface is specified, the interface is selected by the routing table. This parameter is only required when the IPv6 address is a link-scoped address. Interfaces are specified in the *<interface type> <slot/port | interface id>* format. For example, for an Ethernet interface, use **eth 0/1**. Type **ipv6 dhcp relay destination** *<ipv6 address>* **?** to display a list of valid interfaces.
system-control-evc	Optional. Specifies the output interface for sending messages to the DHCPv6 server is the system control EVC.
system-management-evc	Optional. Specifies the output interface for sending messages to the DHCPv6 server is the system management EVC.

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.
Release R10.5.0	Command was expanded to include the loopback interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

To configure an EVC to function as a DHCPv6 relay agent, you must first enable IPv6 on the EVC using the command *ipv6 on page 3782*.

Usage Examples

The following example enables DHCPv6 relay agent functionality and specifies the destination address as **2001:DB8:2::1**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6**
(config-sys-ctrl-evc)**#ipv6 dhcp relay destination 2001:DB8:2::1**

Technology Review

DHCPv6, like DHCP in IPv4, is used in IP networks to supply hosts with IP addresses and other networking information. DHCPv6, however, functions slightly differently than DHCPv4 by providing relay agents with the ability to send relay-forward and relay-reply messages. In addition, in DHCPv4, when DHCP messages are sent to a DHCP server whose address is not known, the IPv4 client uses the broadcast address. In DHCPv6, the IPv6 client sends messages using the link-scoped mulitcast address. This address is the All DHCP Relay Agents and Servers link, designated as **FF02::1:2**.

In AOS, DHCPv6 relay agents are used when the DHCP server is not on the same link as the DHCP client. The relay is typically a router on the same link as the client, which acts as an intermediary to help the client's DHCP messages reach the DHCP server. DHCPv6 relay agents operate transparently to the DHCP client, and can be configured in chains, meaning that information about each agent encountered is encapsulated into the relay message. Relay agents add fields to the DHCP message as they send these messages to the server, thus providing a method to properly manage the DHCP client.

For more information about DHCPv6 functionality in AOS, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

ipv6 dhcp server

Use the **ipv6 dhcp server** command to enable Internet Protocol version 6 (IPv6) Dynamic Host Control Protocol (DHCP) on the system control Ethernet virtual connection (EVC) and specify that the EVC is functioning as a DHCPv6 server. This command not only enables the DHCPv6 server on the EVC, it also configures specific parameters of the DHCPv6 server. Hence, the parameters of this command can be entered multiple times and in any order. Use the **no** form of this command to disable DHCPv6 on the EVC. Variations of this command include:

ipv6 dhcp server automatic
ipv6 dhcp server automatic allow-hint
ipv6 dhcp server automatic preference <*number*>
ipv6 dhcp server automatic rapid-commit
ipv6 dhcp server <*pool name*>
ipv6 dhcp server <*pool name*> **allow-hint**
ipv6 dhcp server <*pool name*> **preference** <*number*>
ipv6 dhcp server <*pool name*> **rapid-commit**

Syntax Description

automatic	Enables automatic selection of the DHCPv6 server pool based on information extracted from the DHCPv6 client's request. You must specify the pool selection method before configuring other options for this command.
<*pool name*>	Specifies the DHCPv6 server pool that services this EVC. All DHCPV^ requests received on this EVC are serviced from this pool. If a pool name is not specified, the server pool is selected automatically. You must specify the pool selection method before configuring the other options for this command.
allow-hint	Optional. Specifies that the DHCPv6 server attempts to honor the DHCPv6 client's request for specific values as hinted in the client's request (if they are valid and not already assigned). If this option is not specified, any hints from the DHCPv6 client are ignored.
preference <*number*>	Optional. Specifies the preference value advertised by the server. This option is sent by the server to a DHCPv6 client to influence the selection of a server when there are multiple servers from which to choose. Valid range is **0** to **255**, with a default value of **0**. When the preference value is set to a non-zero value, the server includes a preference option containing the value. If the preference value is not set, or is set to 0, the option is omitted and the client assumes the value is 0.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 server mode is not enabled on the EVC.

Command History

Release R10.1.0	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

Enabling the EVC as a DHCPv6 server using this command places the EVC into DHCPv6 server mode. DHCPv6 modes (server, client, or relay) are mutually exclusive at the EVC. Any existing mode will be removed if a different mode is specified, and a message will be shown indicating the change in DHCPv6 mode.

Usage Examples

The following example enables the EVC as a DHCPv6 server, and specifies that the DHCPv6 server pool **POOL1** is associated with the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 address 2001:DB8:1::1/64**
(config-sys-ctrl-evc)**#ipv6 dhcp server POOL1**

ipv6 mode host unicast

Use the **ipv6 mode host unicast** command to place the system control Ethernet virtual connection (EVC) in host mode using an Internet Protocol version 6 (IPv6) unicast address. Use the **no** form of this command to disable host mode on the EVC.

Syntax Description

No subcommands.

Default Values

By default, host mode is disabled.

Command History

Release R10.9.0	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Command History

When this command is configured on an interface, the MTU value is learned from received router advertisements. Link MTU value is learned in host mode from the following locations (in decreasing order of priority): the provisioned MTU value in the interface configuration, the router advertisements received on the interface, and the default MTU value (1500).

Usage Examples

The following example places the EVC in host mode:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 mode host unicast**

ipv6 mtu *<size>*

Use the **ipv6 mtu** command to specify the maximum transmission unit (MTU) for Internet Protocol version 6 (IPv6) packets on the system control Ethernet virtual connection (EVC). Use the **no** form of this command to return to the default value.

Syntax Description

<size>	Specifies the MTU value. Valid range is **1280** to **1500** bytes.

Default Values

By default, the MTU of the EVC is set to **1280** bytes.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

In IPv6, the minimum MTU is 1280 octets. Any link that has an MTU less than 1280 octets must use link fragmentation and reassembly that is transparent to IPv6 (for example, the Fragmentation Header). Sources in the IPv6 network are expected to perform path maximum transmission unit (PMTU) discovery to send packets larger than 1280 octets. PMTU works in the following manner: First, the sending node assumes the link MTU of the interface from which the traffic is being forwarded and then sends the IPv6 packet at the link MTU size. If a router on the path is unable to forward the packet, it sends an ICMP *Packet Too Big* message back to the sending node containing the link MTU of the link on which the packet forwarding failed. The sending node then rests the PMTU to the value of the MTU field in the Internet Control Message Protocol version 6 (ICMPv6) *Packet Too Big* message, and the packet is resent.

The MTU for IPv6 packets can be set on a per-EVC basis. There are two methods for setting MTUs for EVCs if required: one for Layer 3 EVCs, and one for the underlying Layer 1 and Layer 2 EVCs. For all EVC types, use the **ipv6 mtu** *<size>* command to specify the IPv6 MTU in bytes from the EVC's configuration mode. The minimum MTU setting for IPv6 is **1280** bytes, and the maximum is **1500** bytes. The IPv6 MTU value is independent of the IPv4 MTU setting (set with the command *ip mtu <size> on page 3771*).

When the EVC is forwarding the IPv6 packet as a router, if the packet size exceeds the IPv6 MTU of the egress EVC, the packet is dropped and ICMPv6 *Packet Too Big* message is sent to the source. When originating an IPv6 packet from the local IPv6 stack, and the packet is larger than the IPv6 MTU of the egress EVC, the packet is fragmented and sent.

Usage Examples

The following example specifies the IPv6 MTU value for the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 mtu 1350**

ipv6 nd advertisement-interval

Use the **ipv6 nd advertisement-interval** command to specify that the Advertisement Interval Option is sent in Internet Protocol version 6 (IPv6) router advertisement (RA) messages from the router. This command is effectual only when the system control Ethernet virtual connection (EVC) is in router mode. Use the **no** form of this command to return to the default interval.

Syntax Description

No subcommands.

Default Values

By default, Advertisement Interval Options are not sent in RA messages.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

Sending the Advertisement Interval Option should be enabled when the router is functioning in a mobile IP environment to aid movement detection by mobile nodes. This option contains the current value of the maximum router advertisement interval configured using the command *ipv6 nd ra interval on page 3812*.

Usage Examples

The following example specifies that the EVC include Advertisement Interval Options in RA messages sent from the router:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd advertisement-interval**

ipv6 nd cache max-incomplete <*number*>

Use the **ipv6 nd cache max-incomplete** command to specify the maximum number of incomplete entries the Neighbor Discovery (ND) cache retains. Use the **no** form of this command to return to the default value.

Syntax Description

<*number*>	Specifies the number of incomplete ND entries to retain in the cache. Valid range is **1** to **321**.

Default Values

By default, the incomplete ND entries can take at maximum one-third of the possible ND cache entries (varies by product).

Command History

Release R11.10.0	Command was introduced.

Usage Examples

The following example specifies that the interface stores **150** incomplete entries in the ND cache:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd cache max-incomplete 150**

ipv6 nd dad attempts *<number>*

Use the **ipv6 nd dad attempts** command to specify the number of neighbor solicitation (NS) messages sent by the system control Ethernet virtual connection (EVC) when performing Internet Protocol version 6 (IPv6) duplicate address detection (DAD). This command is effectual when the EVC is in either host or router mode. Use the **no** form of this command to return to the default value.

Syntax Description

<number>	Specifies the number of NS messages that will be sent. Range is **0** to **10** messages. A value of **0** disables DAD on the interface.

Default Values

By default, the EVC sends **1** NS message.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

DAD is used by devices to determine if IPv6 addresses are unique before they are applied to EVCs. DAD is used in NS messages to detect duplicate unicast addresses. The Target Address fields in the NS messages are set to the IPv6 address for which duplication is being detected. Destination IPv6 addresses for DAD in NS messages are the solicited-node multicast version of the address being tested. Source IPv6 addresses for DAD are set to the IPv6 unspecified address (::). Once the IPv6 address is determined by DAD to be unique, it can be applied to the EVC on the node.

DAD in AOS is performed when an EVC transitions state from DOWN to UP or when manually configuring an address. When performing DAD because of an interface transition, DAD will happen immediately after the EVC transition and again 40 seconds later to cooperate with the port being connected to an Ethernet switch.

Usage Examples

The following example specifies that **3** NS messages are sent by the EVC when performing DAD:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd dad attempts 3**

ipv6 nd generate-packet

Use the **ipv6 nd generate-packet** command to generate and send test packets from the Ethernet virtual connection (EVC) for Internet Protocol version 6 (IPv6) Neighbor Discovery (ND) messages. Use the **no** form of this command to disable packet generation. Variations of this command include:

ipv6 nd generate-packet neighbor-advertisement <*source ipv6 address*> <*destination ipv6 address*> <*Layer 2 address*>
ipv6 nd generate-packet neighbor-solicitation <*source ipv6 address*> <*destination ipv6 address*> <*target ipv6 address*>
ipv6 nd generate-packet router-advertisement

Syntax Description

neighbor-advertisement	Specifies that test packets are generated for neighbor advertisement (NA) messages.
neighbor-solicitation	Specifies that test packets are generated for neighbor solicitation (NS) messages.
router-advertisement	Specifies that test packets are generated for router advertisement (RA) messages.
<*source ipv6 address*>	Specifies the source address of the test packet. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<*destination ipv6 address*>	Specifies the destination address of the test packet. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<*Layer 2 address*>	Specifies the Layer 2 destination address for the test packet using a medium access control (MAC) address. MAC addresses should be expressed in the following format xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**) or 0xABCDEF format (for example, **1x234567**).
<*target ipv6 address*>	Specifies the IPv6 address of the target neighbor for NS test packets. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.

Default Values

By default, test packets are not generated for ND messages.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example generates test packets for RA messages on the EVC:

(config)**#system-control-evc**
(config-system-cntrl-evc)**#ipv6 nd generate-packet router-advertisement**

ipv6 nd managed-config-flag

Use the **ipv6 nd managed-config-flag** command to specify the M flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. The M flag instructs hosts receiving the RA that they can use stateful Dynamic Host Configuration Protocol version 6 (DHCPv6) to configure addresses and nonaddress information. Use the **no** form of this command to disable the setting of the M flag.

Syntax Description

No subcommands.

Default Values

By default, the M flag is not set in RAs.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control Ethernet virtual connection (EVC).

Functional Notes

If you specify that the M flag is set in RA messages, you do not need to set the 0 flag (it becomes redundant).

Usage Examples

The following example sets the M flag for RA messages sent by the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd managed-config-flag**

ipv6 nd ns-interval *<value>*

Use the **ipv6 nd ns-interval** command to specify the interval between transmission of certain Internet Protocol version 6 (IPv6) Neighbor Discovery (ND) messages and to control what ND value is advertised in router advertisement (RA) messages. This command is effectual whether the system control Ethernet virtual connection (EVC) is in host or router mode. Use the **no** form of this command to return the interval to the default value.

Syntax Description

<value>	Specifies the time (in milliseconds) between neighbor message transmissions. Valid range is **1000** to **3600000** ms.

Default Values

By default, the interval is set to **1000** ms for internal use by the router and **0** (unspecified) is sent in RA messages.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

This command controls the spacing of neighbor solicitation (NS) messages for functions such as address resolution, reachability detection, and duplicate address detection (DAD). For DAD it also serves as the amount of time after the last transmission before the detection phase of autoconfiguration terminates. In addition, the command controls the interval between unsolicited neighbor advertisement (NA) messages.

Usage Examples

The following example changes the interval between RA messages sent from the EVC to **2000** ms:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd ns-interval 2000**

ipv6 nd other-config-flag

Use the **ipv6 nd other-config-flag** command to specify the O flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the system control Ethernet virtual connection (EVC) is in router mode. When the O flag is set, hosts receiving the RA messages are instructed that they may use stateless Dynamic Host Configuration Protocol version 6 (DHCPv6) to receive information that is not IPv6 addressing information, and to use some other method (whether through manual configuration, stateless address autoconfiguration (SLAAC), etc.) for addressing information. Use the **no** form of this command to disable the O flag setting.

Syntax Description

No subcommands.

Default Values

By default, the O flag is not set in RA messages.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

If the M flag is set for RA messages, you do not need to set the O flag.

Usage Examples

The following example sets the O flag in RA messages from the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd other-config-flag**

ipv6 nd prefix

Use the **ipv6 nd prefix** command to specify the Internet Protocol version 6 (IPv6) address prefixes used in router advertisement (RA) messages sent from the system control Ethernet virtual connection (EVC). Use the **no** form of this command to remove the specified prefix configuration from the EVC. Variations of this command include:

ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise] [**<*valid lifetime*> | **infinite]** <*preferred lifetime* | **infinite**>
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite] [no-advertise] [no-autoconfig] [no-rtr-address] [no-onlink] [off-link]**

Syntax Description

named-prefix <*prefix name*>	Optional. Specifies that a named prefix is used in RA messages. When a named prefix is used, the default prefix cannot be used.
<*ipv6 prefix/prefix-length*>	Specifies the IPv6 prefix and length to be advertised. Pv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
default	Specifies the default values for the IPv6 prefix parameters. Refer to the *Functional Notes* below for more information.
<*valid lifetime*>	Optional. Specifies the valid lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
<*preferred lifetime*>	Optional. Specifies the preferred lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
infinite	Optional. Specifies that the the valid and preferred lifetimes of the prefix do not expire.
no-advertise	Optional. Specifies that the prefix is excluded from the RA message.
no-autoconfig	Optional. Sets the A flag in the RA message to **0**, indicating that hosts may not create an address for this prefix using stateless address autoconfiguration (SLAAC). This parameter only affects hosts receiving the RA message, it does not affect the operation of the local router.
no-rtr-address	Optional. Sets the R flag in the RA message to **0** and specifies the full router IPv6 address is not included in the RA message.
no-onlink	Optional. Specifies that the IPv6 prefix in the RA message is not to be used for on-link determination.
off-link	Optional. Sets the L flag value to **0** in RA messages, which indicates the RA makes no statement about the on-link or off-link properties of the IPv6 prefix.

Default Values

By default, all prefixes derived from the EVC's configured IPv6 addresses are advertised using the system default values.

By default, the valid lifetime advertised for a prefix is **2592000** seconds and the preferred lifetime advertised is **604800** seconds.

By default, the L flag is set to **1**, the R flag is set to **1**, and the A flag is set to **1**.

Command History

Release 18.1	Command was introduced.
Release R10.9.0	Command was expanded to include the **named-prefix** and *<prefix name>* options.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

This command works for both routers and hosts, but in host implementations it is used to manually add on-link prefixes that do not have an IPv6 address or to make off-link a prefix generated by an IPv6 address command. Hosts do not send RA messages, so the command only adds prefixes to RA messages when the EVC is in router mode. This command can also be used to change the defaults used on configured prefixes when all options are not specified.

Changing the prefix defaults will affect prefixes derived from configured IPv6 addresses, as well as prefixes configured using the ***ipv6 nd prefix*** *command.*

Prefixes advertised can be a subset or a superset of the prefixes derived from the IPv6 addresses configured on the EVC. Prefixes for IPv6 addresses configured on a router EVC are automatically eligible to be advertised on that interface using system or configured default values without having to enter a prefix command. To impose additional controls on those prefixes, an entry must be made using this command with the desired settings.

The **default** parameter is used to change the default settings for the IPv6 prefix parameters. Changing these settings can be useful when multiple prefixes are implemented that will use the same set of parameters. When configuring IPv6 prefixes, the prefix default values are only used if no other parameters are specified after specifying the IPv6 prefix and length (for example, **ipv6 nd prefix 2001:DB8::/64**). If additional parameters are specified, any unspecified parameters use the system default values rather than the configured default values. When the default values are changed, any prefix that uses them will also change. Using this command to change prefix default values also affects prefixes derived from configured IPv6 addresses on the EVC.

The optional *<valid lifetime>* parameter specifies the valid lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep this prefix until the valid lifetime expires.

The optional <*preferred lifetime*> parameter specifies the preferred lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep the prefix in the preferred state during this time period. After the preferred time period expires, the prefix transitions to the deprecated state where it remains until the valid lifetime expires and the route is removed. The <*preferred lifetime*> value must be set to be shorter than the <*valid lifetime*> value.

The optional **off-link** parameter sets the L flag (on-link flag) value to **0** in RA messages. When the L flag is set to 0, the advertisement makes no statement about on-link or off-link properties of the prefix. When the L flag is set, the prefix is considered on-link and locally reachable by hosts on the link (meaning a router is not needed). Hosts attached to the link will add on-link prefixes to their prefix list or route table. When off-link is not specified, a connected route is added to the route table of this router for this prefix. When off-link is specified, no route is added to the route table. By default, prefixes are advertised as on-link with the L flag set to 1.

The optional **no-rtr-address** parameter sets the R flag (router flag) of the RA to **0** and does not include the full router address in the advertisement. The router address is typically included in the RA to assist in Mobile IP environments. By default, the R flag is set to 1 and the router address is sent in RA messages.

The optional **no-autoconfig** parameter sets the A flag of the RA to **0**, indicating that hosts may not create an address for this prefix using SLAAC. If the A flag is set to **1** (the default setting), hosts perform SLAAC to generate an address based on the prefix. This parameter only affects hosts receiving the RA, it does not effect the operation of the local router.

The optional **no-advertise** parameter specifies that the prefix is excluded from RA messages. By default, the prefix is included in RA messages. The **no-onlink** parameter informs the router that the prefix is not to be used for on-link determination.

By default, all prefixes derived from the EVC's configured IPv6 addresses are advertised using the system default values.

Usage Examples

The following example specifies that the IPv6 prefix **2001:DB8:3F::/48** has an infinite valid and preferred lifetime advertised in RA messages sent from the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd prefix 2001:DB8:3F::/48 infinite infinite**

The following example changes the default values and behaviors of prefixes included in RA messages to infinite valid and preferred lifetimes, and specifies that the on- or off-link state of the prefix is not included in the RA and that hosts receiving the RA may not use the prefix for creating an IPv6 address:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd prefix default infinite infinite off-link no-autoconfig**

ipv6 nd purge-timer <*value*>

Use the **ipv6 nd purge-timer** command to specify the maximum amount of time an unused Internet Protocol version 6 (IPv6) neighbor entry remains in the neighbor cache. This command is effectual for the system control Ethernet virtual connection (EVC) in either host or router mode. Use the **no** form of this command to return the purging interval to the default value.

Syntax Description

<*value*>	Specifies the neighbor cache entry storage time in minutes. Valid range is **10** to **1440** minutes.

Default Values

By default, idle (STALE) neighbor cache entries are cleared after **1440** minutes (24 hours).

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

This command applies to EVCs in either router or host mode. A neighbor entry is typically purged when neighbor unreachability detection (NUD) is invoked and the neighbor is determined to no longer be reachable. However, NUD is not performed on idle (STALE) neighbor entries, so this command provides a method for purging unused entries after a specified amount of time.

Usage Examples

The following example specifies that idle neighbor entries in the neighbor cache are removed after **800** minutes:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd purge-timer 800**

ipv6 nd ra interval

Use the **ipv6 nd ra interval** command to specify the interval between transmission of Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the system control Ethernet virtual connection (EVC) is in router mode. Use the **no** form of this command to return to the default value. Variations of this command include:

ipv6 nd ra interval *<max time>*
ipv6 nd ra interval *<max time> <min time>*
ipv6 nd ra interval msec *<max time>*
ipv6 nd ra interval msec *<max time> <min time>*

Syntax Description

<max time>	Specifies the maximum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **4** to **1800** seconds and **70** to **1800000** ms.
<min time>	Optional. Specifies the minimum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **3** seconds to 75 percent of the configured maximum time value in seconds, or **30** ms to 75 percent of the configured maximum time value in ms.
msec	Optional. Specifies that the time values are in milliseconds.

Default Values

By default, the interval is set in seconds and has a maximum interval time of **200** seconds and a minimum interval time of 75 percent of the maximum seconds value, but not less than **3** seconds.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

If this router is used as a default router, the interval between RA messages should not be set to a larger value than the RA lifetime set by the command *ipv6 nd ra lifetime <value> on page 3813*, which has a default value of **1800** seconds.

Usage Examples

The following example specifies that the maximum interval in seconds between RA message transmissions is **300**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd ra interval 300**

ipv6 nd ra lifetime <*value*>

Use the **ipv6 nd ra lifetime** command to specify the router lifetime advertised in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the system control Ethernet virtual connection (EVC) is in router mode. Use the **no** form of this command to return to the default setting. Variations of this command include:

ipv6 nd ra lifetime <*value*>
ipv6 nd ra lifetime default-route

Syntax Description

<*value*>	Specifies the router lifetime in seconds. Range is **0** to **9000** seconds. A value of **0** indicates this is not a default router. A value other than 0 indicates to other nodes that this router can be used as a default router.
default-route	Specifies the RA lifetime is **0** if no default route exists on any IPv6 interface.

Default Values

By default, the router lifetime is set to **1800** seconds.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.
Release R11.5.0	Command was expanded to include the **default-route** parameter.

Functional Notes

A value other than **0** for a router lifetime should be larger than the router advertisement interval specified in the command *ipv6 nd ra interval on page 3812*.

Usage Examples

In the following example, the router lifetime advertised in RA messages is **3000** seconds:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd ra lifetime 3000**

ipv6 nd ra reachable-time *<value>*

Use the **ipv6 nd ra reachable-time** command to specify the value advertised for reachable time in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command also specifies the internal base reachable time used by the router. This command is effectual for the system control Ethernet virtual connection (EVC) in either host or router mode. Use the **no** form of this command to return the reachability value to the default setting.

Syntax Description

<value>	Specifies the reachability time in milliseconds. Range is **0** to **3600000** ms. A value of **0** indicates the reachable time is unspecified.

Default Values

By default, the router advertises a reachability time of **0** ms and uses an internal value of **30000** ms.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

This command is effectual for EVCs in either router or host mode. For hosts, this value sets the internal reachable time used by the host if no RAs are received specifying a different value. For routers, the value indicates the amount of time a device is considered reachable after having received a reachability confirmation in neighbor unreachabililty detection (NUD).

Usage Examples

The following example specifies that a reachability time of **50000** ms is advertised in RA messages:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd ra reachable-time 50000**

ipv6 nd ra suppress

Use the **ipv6 nd ra suppress** command to specify whether Internet Protocol version 6 (IPv6) router advertisement (RA) messages will be suppressed. This command is only effectual when the system control Ethernet virtual connection (EVC) is in router mode. Use the **no** form of this command to begin sending RA messages.

Syntax Description

No subcommands.

Default Values

By default, RA messages are not suppressed. When IPv6 routing is not enabled on the router, or when implemented in a host-only mode, the default setting is to suppress advertisements on all EVC types.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Usage Examples

The following example suppresses RA messages on the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd ra suppress**

ipv6 nd router-preference

Use the **ipv6 nd router-preference** command to specify the default router preference value set in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. Setting this preference helps the receivers of RA messages to determine the preference of one router over another as a default router in environments with multiple routers. Use the **no** form of this command to return the preference to the default setting. Variations of this command include:

ipv6 nd router-preference high
ipv6 nd router-preference low
ipv6 nd router-preference medium

Syntax Description

high	Specifies the preference value is high.
low	Specifies the preference value is low.
medium	Specifies the preference value is medium.

Default Values

By default, the router preference is set to medium.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control Ethernet virtual connection (EVC).

Usage Examples

The following example specifies that the advertised default router preference is high:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 nd router-preference high**

ipv6 route-cache

Use the **ipv6 route-cache** command to enable Internet Protocol version 6 (IPv6) fast-cache switching on the system control Ethernet virtual connection (EVC). Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 18.2	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

Fast switching allows an EVC to provide optimum performance when processing IPv6 traffic.

Usage Examples

The following example enables IPv6 fast switching on the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ipv6 route-cache**

keepalive *<value>*

Use the **keepalive** command to enable the transmission of keepalive packets on the system control Ethernet virtual connection (EVC) and specify the time interval in seconds between transmitted packets. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Defines the time interval (in seconds) between transmitted keepalive packets. Valid range is **0** to **32767** seconds.

Default Values

By default, the time interval between transmitted keepalive packets is **10** seconds.

Command History

Release 1.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

If three keepalive packets are sent to an EVC with no response, the EVC is considered down. To detect EVC failures quickly, specify a smaller keepalive time.

Usage Examples

The following example specifies a keepalive time of **5** seconds on the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#keepalive 5**

max-reserved-bandwidth <*value*>

Use the **max-reserved-bandwidth** command to specify the percentage of interface bandwidth reserved for use in user-defined (priority or class-based) queues. The remainder of the interface bandwidth is reserved for system-critical traffic and is not available to user-defined queues. Use the **no** form of this command to restore the default value.

Reserving a portion of the interface bandwidth for system-critical traffic is necessary for proper operation. Specifying the entire interface bandwidth for use in user-defined queues can cause undesirable operation.

Syntax Description

<*value*>	Specifies the maximum percentage of bandwidth to reserve for quality of service (QoS). This setting is configured as a percentage of the total interface speed. Range is **1** to **100** percent.

Default Values

By default, **max-reserved-bandwidth** is set to **75** percent, which reserves 25 percent of the interface bandwidth for system-critical traffic.

Command History

Release 11.1	Command was introduced.
elease 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet subinterface.
Release R11.1.0	Command was expanded to include the system control Ethernet virtual connection (EVC) and system management EVC.

Usage Examples

The following example specifies **85** percent of the bandwidth on the system control EVC be available for use in user-defined queues:

(config)**#system-control-evc**
(config-sys-cntrl-evc)**#max-reserved-bandwidth 85**

men-pri

Use the **men-pri** command to specify the default value of the S-tag used in the system control Ethernet virtual connection (EVC) communication. Use the **no** form of this command to return to the default setting. Variations of this command include:

men-pri inherit
men-pri <*value*>

Syntax Description

inherit	Specifies that the S-tag priority value is inherited from the customer equipment (CE) virtual local area network (VLAN).
<*value*>	Specifies a priority value for the S-tag. Valid range is **0** to **7**.

Default Values

By default, the S-tag is set to **inherit**.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies that the S-tag has a priority of **5** on the EVC:

(config)#**system-control-evc**
(config-sys-ctrl-evc)#**men-pri 5**

peer default ip address *<ipv4 address>*

Use the **peer default ip address** command to specify the default peer Internet Protocol version 4 (IPv4) address of the remote end of the system control Ethernet virtual connection (EVC). Use the **no** form of this command to remove an assigned IPv4 address.

Syntax Description

<ipv4 address>	Specifies the default peer IPv4 address for the remote end. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, there is no assigned default peer IPv4 address.

Command History

Release 3.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

This command is useful if the peer does not send the IPv4 address option during Point-to-Point Protocol (PPP) negotiations.

Usage Examples

The following example sets the default peer IPv4 address to **192.22.71.50**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#peer default ip address 192.22.71.50**

peer default ipv6 interface-id *<interface id>*

Use the **peer default ipv6 interface-id** command to specify the default peer Internet Protocol version 6 (IPv6) interface ID of the remote end of the system control Ethernet virtual connection (EVC). Use the **no** form of this command to remove an assigned IPv6 interface ID.

Syntax Description

<interface id>	Specifies the default peer IPv6 interface ID for the remote end. IPv6 interface IDs should be expressed in colon hexadecimal notation (**X:X:X:X**). For example, **2AA:FF:FE3F:2A1C**.

Default Values

By default, there is no assigned default peer IPv6 interface ID.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Usage Examples

The following example sets the default peer IPv6 interface ID to **2AA:FF:FE3F:2A1C**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#peer default ipv6 interface-id 2AA:FF:FE3F:2A1C**

ppp authentication

Use the **ppp authentication** command to specify the authentication protocol on the system control Ethernet virtual connection (EVC) that the peer should use to authenticate itself. Use the **no** form of this command to disable this feature. Variations of this command include:

ppp authentication chap
ppp authentication pap

Syntax Description

chap	Configures Challenge-Handshake Authentication Protocol (CHAP) on the interface.
pap	Configures Password Authentication Protocol (PAP) on the interface.

Default Values

By default, PPP endpoints have no authentication configured.

Command History

Release 1.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Technology Review

CHAP and PAP are two authentication methods that enjoy widespread support. Both methods are included in AOS and are easily configured.

The authentication method set up on the local router can be different from that on the peer. Also, just because one router requires authentication from its peer does not mean it also has to authenticate itself to the peer.

Defining PAP

PAP is used to verify that the PPP peer is a permitted device by checking a user name and password configured on the peer. The user name and password are both sent unencrypted across the connecting private circuit.

PAP requires two-way message passing. First, the router that is required to be authenticated (for example, the peer) sends an authentication request with its user name and password to the router requiring authentication (for example, the local router). The local router then looks up the user name and password in the user name database within the system control EVC, and if they match sends an authentication acknowledge back to the peer.

The PPP user name and password database is separate and distinct from the global user name password database. For PAP and CHAP, use the database under the EVC configuration.

Several example scenarios are given below for clarity.

Configuring PAP Example 1: Only the local router requires the peer to authenticate itself.

On the local router (host name **Local**):

Local(config-sys-ctrl-evc)**#ppp authentication pap**
Local(config-sys-ctrl-evc)**#username farend password far**

On the peer (host name **Peer**):

Peer(config-sys-ctrl-evc)**#ppp pap sent-username farend password far**

The first line of the configuration sets the authentication mode as PAP. This means the peer is required to authenticate itself to the local router via PAP. The second line is the user name and password expected to be sent from the peer. On the peer, the **ppp pap sent-username** command is used to specify the appropriate matching user name and password.

Configuring PAP Example 2: Both routers require the peer to authenticate itself.

On the local router (host name **Local**):

Local(config-sys-ctrl-evc)**#ppp authentication pap**
Local(config-sys-ctrl-evc)**#username farend password far**
Local(config-sys-ctrl-evc)**#ppp pap sent-username nearend password near**

On the peer (host name **Peer**):

Peer(config-sys-ctrl-evc)**#ppp authentication pap**
Peer(config-sys-ctrl-evc)**#username nearend password near**
Peer(config-sys-ctrl-evc)**#ppp pap sent-username farend password far**

Now both routers send the authentication request, verify that the user name and password sent match what is expected in the database, and send an authentication acknowledge.

Defining CHAP

CHAP is a three-way authentication protocol composed of a challenge response and success or failure. The message digest 5 (MD5) protocol is used to protect user names and passwords in the response.

First, the local router (requiring its peer to be authenticated) sends a challenge containing the unencrypted user name of the peer and a random number. The user name of the peer is found in the user name database within the system control EVC of the local router. The peer then looks up the user name in the user name database within the EVC, and if found takes the corresponding password and its own host name and sends a response back to the local router. This data is encrypted. The local router verifies that the user name and password are in its own user name database within the EVC, and if so sends a success back to the peer.

The PPP user name and password database is separate and distinct from the global user name password database. For PAP and CHAP, use the database under the EVC configuration.

Several example scenarios are given below for clarity.

Configuring CHAP Example 1: Only the local router requires the peer to authenticate itself.

On the local router (host name **Local**):

Local(config-sys-ctrl-evc)**#ppp authentication chap**
Local(config-sys-ctrl-evc)**#username Peer password same**

On the peer (host name **Peer**):

Peer(config-sys-ctrl-evc)**#ppp chap password same**

The first line of this configuration sets the authentication mode to CHAP. This means the peer is required to authenticate itself to the local router via CHAP. The second line is the user name and password expected to be sent from the peer. The peer uses its **hostname** and **ppp chap password** commands to send the proper authentication information.

Both ends must have identical passwords.

Configuring CHAP Example 2: Using the ppp chap hostname command as an alternate solution.

On the local router (host name **Local**):

Local(config-sys-ctrl-evc)**#ppp authentication chap**
Local(config-sys-ctrl-evc)**#username farend password same**

On the peer (host name **Peer**):

Peer(config-sys-ctrl-evc)**#ppp chap hostname farend**
Peer(config-sys-ctrl-evc)**#ppp chap password same**

Notice the local router is expecting user name **farend** even though the peer router's host name is **Peer**. Therefore, the peer router can use the **ppp chap hostname** command to send the correct name in the challenge.

Both ends must have identical passwords.

Configuring CHAP Example 3: Both routers require each other to authenticate themselves using the same shared password.

On the local router (host name **Local**):

Local(config-sys-ctrl-evc)**#ppp authentication chap**
Local(config-sys-ctrl-evc)**#username Peer password same**

On the peer (host name **Peer**):

Peer(config-sys-ctrl-evc)**#ppp authentication chap**
Peer(config-sys-ctrl-evc)**#username Local password same**

This is basically identical to Example 1 except that both routers will now challenge each other and respond.

Both ends must have identical passwords.

Configuring CHAP Example 4: Both routers require each other to authenticate themselves using two separate shared passwords.

On the local router (host name **Local**):

Local(config-sys-ctrl-evc)**#ppp authentication chap**
Local(config-sys-ctrl-evc)**#username Peer password far**
Local(config-sys-ctrl-evc)**#ppp chap password near**

On the peer (host name **Peer**):

Peer(config-sys-ctrl-evc)**#ppp authentication chap**
Peer(config-sys-ctrl-evc)**#username Local password near**
Peer(config-sys-ctrl-evc)**#ppp chap password far**

This is basically identical to Example 3, except that there are two separate shared passwords.

Notice this example has both ends using different sets of passwords.

ppp bcp tagged-frame

Use the **ppp bcp tagged-frame** command to allow negotiation of IEEE 802.1Q-tagged packets over Bridging Control Protocol (BCP). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release 14.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control Ethernet virtual connection (EVC).

Usage Examples

The following example configures the EVC to negotiate tagged frames over BCP:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ppp bcp tagged-frame**

ppp chap hostname *<name>*

Use the **ppp chap hostname** command to configure an alternate host name for Challenge-Handshake Authentication Protocol (CHAP) Point-to-Point Protocol (PPP) authentication. Use the **no** form of this command to remove a configured host name. For more information on Password Authentication Protocol (PAP) and CHAP functionality, refer to the *Technology Review* section for the command *ppp authentication on page 3823*.

Syntax Description

<name>	Specifies a host name using an alphanumeric string up to 80 characters in length.

Default Values

By default, there are no configured PPP CHAP host names.

Command History

Release 1.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control Ethernet virtual connection (EVC).

Usage Examples

The following example specifies a PPP CHAP host name of **my_host**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ppp chap hostname my_host**

ppp chap password *<password>*

Use the **ppp chap password** command to configure an alternate password when the peer requires Challenge-Handshake Authentication Protocol (CHAP) Point-to-Point Protocol (PPP) authentication. Use the **no** form of this command to remove a configured password. For more information on Password Authentication Protocol (PAP) and CHAP functionality, refer to the *Technology Review* section for the command *ppp authentication on page 3823*.

Syntax Description

<password>	Specifies a password using an alphanumeric string up to 80 characters in length.

Default Values

By default, there is no defined PPP CHAP password.

Command History

Release 1.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control Ethernet virtual connection (EVC).

Usage Examples

The following example specifies a PPP CHAP password of **my_password**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ppp chap password my_password**

ppp mtu *<size>*

Use the **ppp mtu** command to configure the Point-to-Point Protocol (PPP) maximum transmission unit (MTU) size for the system control Ethernet virtual connection (EVC). Use the **no** form of this command to return to the default value.

Syntax Description

<size>	Configures the window size for transmitted packets. The valid range is **64** to **2100** bytes.

Default Values

By default, the PPP MTU on an EVC is set to **1500** bytes.

Command History

Release 17.9	Command was introduced.
Release R10.10.0	Command was expanded to include the system control EVC.

Usage Examples

The following example specifies a PPP MTU of **1200** on the EVC:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ppp mtu 1200**

ppp multilink

Use the **ppp multilink** command to enable Multilink Point-to-Point Protocol (MLPPP) operation on the system control Ethernet virtual connection (EVC). Use the **no** form of this command to disable this feature. Variations of this command include:

ppp multilink fragmentation
ppp multilink interleave
ppp multilink maximum <*number*>

Syntax Description

fragmentation	Enables multilink fragmentation operation.
interleave	Enables multilink interleave operation.
maximum <*number*>	Specifies the maximum number of links allowed in a PPP multilink bundle.

Default Values

By default, MLPPP is disabled.

Command History

Release 7.1	Command was introduced.
Release 7.2	Fragmentation and interleave operation were added.
Release 11.1	Command was expanded to include the demand interface.
Release R10.10.0	Command was expanded to include the system control EVC.

Functional Notes

When enabled, the EVC is capable of the following:

- Combining multiple physical links into one logical link.
- Receiving upper layer protocol data units (PDUs), fragmenting and transmitting over the physical links.
- Receiving fragments over the physical links and reassembling them into PDUs.

The fragmentation and interleave options can be used to enhance the multilink operation. Fragmentation is used to reduce serialization delays of large packets. The fragmentation process evenly divides the data among all links in the bundle with a minimum packet size of 96 bytes. The interleave operation is used with streaming protocols to reduce delay by giving priority to packets identified as high priority. In order delivery is guaranteed with multilink fragmentation, but is not guaranteed with multilink interleave operation.

The multilink bundle will remain active with a minimum of one physical link. Physical links may be dynamically added or removed from the multilink bundle with minor interruption to traffic flow.

Usage Examples

The following example enables MLPPP:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#ppp multilink**

ppp pap sent-username <*username*> password <*password*>

Use the **ppp pap sent-username password** command to configure a user name and password when the peer requires Password Authentication Protocol (PAP) Point-to-Point Protocol (PPP) authentication. Use the **no** form of this command to remove a configured password. For more information on PAP and Challenge-Handshake Authentication Protocol (CHAP) functionality, refer to the *Technology Review* section for the command *ppp authentication on page 3823*.

Syntax Description

<username>	Specifies a user name by alphanumeric string up to 80 characters in length (the user name is case sensitive).
<password>	Specifies a password by alphanumeric string up to 80 characters in length (the password is case sensitive).

Default Values

By default, there is no defined **ppp pap sent-username** and **password**.

Command History

Release 1.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control Ethernet virtual connection (EVC).

Usage Examples

The following example specifies a PPP PAP sent user name of **local** and a password of **my_password**:

```
(config)#system-control-evc
(config-sys-ctrl-evc)#ppp pap sent-username local password my_password
```

pppoe ac-name *<name>*

Use the **pppoe ac-name** command to identify the access controller (AC) with which AOS expects to establish a Point-to-Point Protocol over Ethernet (PPPoE) session. Use the **no** form of this command to return to the default setting.

Syntax Description

<name>	Specifies an AC by text string (up to 255 characters) corresponding to the AC-Name Tag under RFC 2516. If this field is not specified, any AC is acceptable. The AC value may be a combination of trademark, model, and serial ID information (or simply the medium access control (MAC) address of the unit).

Default Values

By default, no AC is specified.

Command History

Release 5.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control Ethernet virtual connection (EVC).

Usage Examples

The following example identifies the AC with which AOS expects to establish a PPPoE session:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#pppoe ac-name Access_Controller_Name**

pppoe service-name <*name*>

Use the **pppoe service-name** command to use this tag value to filter Point-to-Point Protocol over Ethernet (PPPoE) session offers from PPPoE servers. Use the **no** form of this command to return to the default setting.

Syntax Description

<*name*>	Specifies a service name by text string (up to 255 characters) corresponding to the Service-Name Tags under RFC 2516. This string indicates an Internet service provider (ISP) name (or a class of service (CoS) or quality of service (QoS)). If this field is not specified, any service is acceptable.

Default Values

By default, no names are specified.

Command History

Release 5.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system control Ethernet virtual connection (EVC).

Usage Examples

The following example defines a service type that is not to be accepted by AOS:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#pppoe service-name Service_Name**

qos-policy

Use the **qos-policy** command to apply a previously configured quality of service (QoS) map to incoming or outgoing packets on an interface. Use the **no** form of this command to remove the map from the interface. Variations of this command include:

qos-policy in <*name*>
qos-policy out <*name*>

Syntax Description

<*name*>	Specifies the name of a previously created QoS map (refer to *qos map <name> <number> on page 1673* for more information).
in	Assigns a QoS map to this interface's input.
out	Assigns a QoS map to this interface's output.

Default Values

No default values are necessary for this command.

Command History

Release 9.1	Command was introduced.
Release 15.1	Command was expanded to include the **in** parameter.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the system control Ethernet virtual connection (EVC) and system management EVC.

Functional Notes

When a QoS policy is applied to an interface, it may be disabled if the interface bandwidth is not adequate to support the requested bandwidth on the map set. Once the bandwidth problem is resolved, the map will work again. The bandwidth will be rechecked on any of the following changes:

1. A priority or class-based entry is added to, deleted from, or changed in a QoS map set.
2. The interface bandwidth is changed by the **bandwidth** command on the interface.
3. A QoS policy is applied to an interface.
4. A cross connect is created that includes an interface with a QoS policy.
5. The interface queuing method is changed to fair queue to use weighted fair queuing.
6. The interface operational status changes.
7. The interface bandwidth changes for other reasons (e.g., when asymmetric digital subscriber line (ADSL) finishes training).

In order to prevent the map from being disabled in cases of temporary inadequate bandwidth (e.g., a single link goes down in a dual T1 multilink configuration where the map requests more than one T1's worth of bandwidth), the QoS map uses the maximum theoretical bandwidth on an interface, not the actual bandwidth at that time. This actually helps QoS keep higher priority class-based traffic working better than best-effort traffic when the bandwidth drops.

Usage Examples

The following example applies the QoS map **VOICEMAP** to the system control EVC:

(config)#**system-control-evc**
(config-sys-cntrl-evc)#**qos-policy out VOICEMAP**

rtp quality-monitoring

Use the **rtp quality-monitoring** command to enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets on this interface. If the global command (**ip rtp quality-monitoring**) is disabled when this command is issued, the system will return the following warning: "Applied but not used, you must globally enable **ip rtp quality-monitoring** to use VQM." Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, VQM is enabled on all wide area network (WAN) and local area network (LAN) interfaces.

Command History

Release 17.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release R11.2.0	Command was expanded to include the system control Ethernet virtual connection (EVC) and system management EVC.

Usage Examples

The following example enables RTP quality monitoring on the system control EVC:

(config)**#system-control-evc**
(config-sys-cntrl-evc)**#rtp quality-monitoring**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Us the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the single-pair high-speed digital subscriber line (SHDSL) interface, Ethernet in the first mile (EFM) group, system management Ethernet virtual connection (EVC) and the system control EVC.

Usage Examples

The following example enables SNMP capability on the system control EVC:

(config)**#system-control-evc**
(config-sys-cntrl-evc)**#snmp trap**

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the single-pair high-speed digital subscriber line (SHDSL) interface, Ethernet in the first mile (EFM) group, system management Ethernet virtual connection (EVC) and the system control EVC.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the system control EVC:

(config)**#system-control-evc**
(config-sys-cntrl-evc)**#no snmp trap link-status**

s-tag

Use the **s-tag** command to specify the virtual local area network (VLAN) ID used by the service provider in the system control Ethernet virtual connection (EVC) to identify traffic in the control LAN. This VLAN ID, the s-tag, is used by the carrier to mark outbound traffic from this EVC in the Metro Ethernet network (MEN). Use the **no** form of this command to return the s-tag value to the default. Variations of this command include:

s-tag *<vlan id>*
s-tag none

Syntax Description

<vlan id>	Specifies ID of the service provider VLAN. Valid range is **1** to **4094**.
none	Specifies no S-tag is used.

Default Values

By default, the s-tag is **0**, which indicates the traffic on the EVC is untagged.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the **none** parameter and the system control EVC.

Usage Examples

The following example specifies the s-tag for traffic outbound on the EVC is **20**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#s-tag 20**

traffic-shape rate <*value*>

Use the **traffic-shape rate** command to specify and enforce an output bandwidth for the system control Ethernet virtual connection (EVC). Variations of this command include:

traffic-shape rate <*value*>
traffic-shape rate <*value*> **count-eth-overhead**
traffic-shape rate <*value*> <*burst*>
traffic-shape rate <*value*> <*burst*> **count-eth-overhead**

Syntax Description

<*value*>	Specifies the rate (in bits per second) at which the interface should be shaped.
<*burst*>	Optional. Specifies the allowed burst in bytes. By default, the burst is specified as the rate divided by 5 and represents the number of bytes that would flow within 200 ms.
count-eth-overhead	Optional. Indicates to include the Ethernet header overhead bytes when determining packet size.

Default Values

By default, traffic-shaping rate is disabled.

Command History

Release 10.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the **count-eth-overhead** parameter, system management Ethernet virtual connection (EVC) and the system control EVC.

Functional Notes

Traffic shaping can be used to limit an Ethernet segment to a particular rate or to specify use of quality of service (QoS) on Ethernet or VLAN interfaces.

Usage Examples

The following example sets the outbound rate of traffic on the system control EVC to 128 kbps:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#traffic-shape rate 128000**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an Ethernet virtual connection (EVC) to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the EVC from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an EVC's VRF association will clear all IP-related settings on that EVC.

Syntax Description

<*name*>	Specifies the name of the VRF to which to assign the EVC.

Default Values

By default, EVCs are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release 17.8	The keyword **ip** was removed from this command.
Release R10.10.0	Command was expanded to include the system control and system management EVCs.

Functional Notes

VRF instances must be created first before an EVC can be assigned. An EVC can only be assigned to one VRF, but multiple EVCs can be assigned to the same VRF.

An EVC will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the system control EVC to the VRF instance named **RED**:

(config)**#system-control-evc**
(config-sys-ctrl-evc)**#vrf forwarding RED**

SYSTEM MANAGEMENT EVC COMMAND SET

The system management Ethernet virtual connection (EVC) command set is used to provide an inband IP network interface for system management and control. It allows local IP address information to be provisioned and configures the underlying hardware to forward packets to the CPU for local IP stack processing. The EVC is linked logically to the system control virtual routing and forwarding (VRF) instance and is always present in the AOS configuration.

To enter the System Management EVC Configuration Mode, enter the **system-management-evc** command from the Global Configuration mode prompt as follows:

```
(config)#system-management-evc
(config-sys-mgmt-evc)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

connect men-port

Use the **connect men-port** command to associate the Ethernet virtual connection (EVC) with a specific Metro Ethernet network (MEN) port so that traffic can flow to the MEN. Use the **no** form of this command to remove the association between this EVC and the specified EFM group. Variations of this command include:

connect men-port efm-group <*slot/group*>
connect men-port gigabit-ethernet <*slot/port*>

Syntax Description

efm-group <*slot/group*>	Specifies the Ethernet in the first mile (EFM) group to associate with the EVC. Valid group range is **1** to **1024**.
gigabit-ethernet <*slot/port*>	Specifies the Gigabit Ethernet subinterface to associate with the EVC.

Default Values

By default, no interfaces are connected to the EVC.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example associates the system management EVC with EFM group **1**:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#connect men-port efm-group 1/1**

connect uni gigabit-ethernet <*slot/port*>

Use the **connect uni** command to associate the system management Ethernet virtual connection (EVC) with a user network interface (UNI). Use the **no** form of this command to remove the association between the EVC and the UNI.

Syntax Description

gigabit-ethernet <*slot/port*>	Specifies the Gigabit Ethernet subinterface to associate with the system control EVC.

Default Values

By default, the system control EVC is not associated with an interface.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example associates the system management EVC with the Gigabit Ethernet subinterface 1/1:

```
(config)#system-management-evc
(config-sys-mgmt-evc)#connect uni gigabit-ethernet 1/1
```

dynamic-dns

Use the **dynamic-dns** command to configure Dynamic DNS service provided by Dynamic Network Services, Inc. (www.dyndns.org). Use the **no** form of this command to disable this feature. Variations of this command include:

dynamic-dns custom <*hostname*> <*minutes*>
dynamic-dns dyndns <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-custom <*hostname*> <*username*> <*password*>
dynamic-dns dyndns-static <*hostname*> <*username*> <*password*>

Syntax Description

<*hostname*>	Specifies the host name for the server that updates the dynamic domain naming system (DNS).
<*minutes*>	Specifies the intervals in minutes to update the server with information (updates also occur when the interface's IP address changes regardless of the update intervals).
<*username*>	Specifies a user name using an alphanumerical string up to 30 characters in length (the user name is case sensitive).
<*password*>	Specifies a password using an alphanumerical string up to 30 characters in length (the password is case sensitive). Refer to *Functional Notes* below for additional argument descriptions.

Default Values

No default values are necessary for this command.

Command History

Release 8.1	Command was introduced.
Release 12.1	Command was expanded.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release R10.10.0	Command was expanded to include the system management Ethernet virtual connection (EVC).

Functional Notes

custom - Constanttime.com's Custom Dynamic DNS^{SM} service allows you complete access and management control over your domain name regardless of where you purchased/registered it. This allows you to manage IP address mappings (A records), domain aliases (CNAME records), and mail servers (mail exchange (MX) records).

dyndns - The Dynamic DNS^{SM} offered by Dynamic Network Services, Inc. (DynDNS.org) allows you to alias a dynamic IP address to a static host name in various domains. This allows your unit to be more easily accessed from various locations on the Internet. This service is provided for up to five host names.

dyndns-custom - DynDNS.org's Custom DNS^{SM} service provides a full DNS solution, giving you complete control over an entire domain name. A Web-based interface provides two levels of control over your domain, catering to average or advanced users. Five globally redundant DNS servers ensure that your domain will always resolve.

A choice of two interfaces is available. The basic interface is designed for most users. It comes preconfigured for most common configurations and allows for easy creation of most common record types. The advanced interface is designed for system administrators with a solid DNS background, and provides layout and functionality similar to a BIND zone file allowing for the creation of nearly any record type.

Custom DNS^{SM} can be used with both static and dynamic IPs, and has the same automatic update capability through Custom DNS-aware clients as Dynamic DNS.

dyndns-static - The Static DNS service is similar to DynDNS.org's Dynamic DNS^{SM} service in that it allows a host name, such as yourname.dyndns.org, to point to your IP address. Unlike a Dynamic DNS host, a Static DNS host does not expire after 35 days without updates, but updates take longer to propagate through the DNS system. This service is provided for up to five host names.

If your IP address does not change often or at all, but you still want an easy name to remember it by (without having to purchase your own domain name), Static DNS service is ideal for you.

If you would like to use your own domain name (such as yourname.com), you need Custom DNS service that also provides full dynamic and static IP address support.

Usage Examples

The following example sets the Dynamic DNS to **dyndns-custom** with host name **host**, user name **user**, and password **pass**:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#dynamic-dns dyndns-custom host user pass**

ip access-group *<ipv4 acl name>*

Use the **ip access-group** command to apply an Internet Protocol version 4 (IPv4) access control list (ACL) to be used for IPv4 packets transmitted on or received from the system management Ethernet virtual connection (EVC). Use the **no** form of this command to disable this type of control. Variations of this command include:

ip access-group <*ipv4 acl name*> **in**
ip access-group <*ipv4 acl name*> **out**

Syntax Description

<ipv4 acl name>	Applies the named IPv4 ACL to the EVC.
in	Enables access control on IPv4 packets received on the specified interface.
out	Enables access control on IPv4 packets transmitted on the specified interface.

Default Values

By default, these commands are disabled.

Command History

Release 3.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

When this command is enabled, the IPv4 destination address of each packet must be validated before being passed through. If the packet is not acceptable per these settings, it is dropped.

Usage Examples

The following example configures the router to only allow IPv4 Telnet traffic (as defined in the user-configured **TelnetOnly** ACL) into the system management EVC:

(config)**#ip access-list extended TelnetOnly**
(config-ext-nacl)**#permit tcp any any eq telnet**
(config-ext-nacl)**#system-management-evc**
(config-sys-mgmt-evc)**#ip access-group TelnetOnly in**

ip access-policy *<ipv4 acp name>*

Use the **ip access-policy** command to assign a specified Internet Protocol version 4 (IPv4) access control policy (ACP) to the system management Ethernet virtual connection (EVC). IPv4 ACPs are applied to IPv4 traffic entering an interface. Use the **no** form of this command to remove an ACP association. For more information on using IPv4 ACPs, refer to *ip policy-class <ipv4 acp name> on page 1434*.

> NOTE *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv4 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

Syntax Description

<ipv4 acp name>	Identifies the configured IPv4 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv4 ACPs associated with an EVC.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 6.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*.

Usage Examples

The following example associates the IPv4 ACP **PRIVATE** (to allow inbound IPv4 traffic to the Web server) to the system management EVC:

Enable the AOS security features:
(config)**#ip firewall**

Associate the ACP with the system management EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip access-policy PRIVATE**

ip address dhcp

Use the **ip address dhcp** command to use Dynamic Host Configuration Protocol (DHCP) to obtain an address on the interface. Use the **no** form of this command to remove a configured IP address (using DHCP) and disable DHCP operation on the interface. Variables that may be used with this command to further define the DHCP configuration include:

ip address dhcp class-id [ascii <*string*> **| hex** <*value*>**] [client-id [**<*interface*> **|** <*identifier*>**]] [hostname** <*"string"*>**] [track** <*name*>**] [**<*administrative distance*>**]**
ip address dhcp client-id [<*interface*> **|** <*identifier*>**] [hostname** <*"string"*>**] [track** <*name*>**] [**<*administrative distance*>**]**
ip address dhcp hostname *"*<*string*>*"* **[no-default-route | no-domain-name | no-nameservers] [track** <*name*>**] [**<*administrative distance*>**]**
ip address dhcp [no-default-route | no-domain-name | no-nameservers] [track <*name*>**] [**<*administrative distance*>**]**
ip address dhcp track <*name*> **[**<*administrative distance*>**]**

Syntax Description

<*administrative distance*>	Optional. Specifies the administrative distance to use when adding the DHCP gateway into the route table. It is used to determine the best route when multiple routes to the same destination exist. The lower the administrative distance, the more reliable the route. Range is **1** to **255**.
class-id	Optional. Specifies the vendor class identifier for the interface.
ascii <*string*>	Specifies the vendor class identifier in an ASCII string of up to **255** bytes.
hex <*value*>	Specfies the vendor class identifier in hexadecimal format. Valid range is up to **510** hexadecimal numbers. An even number of digits is required.
client-id	Optional. Specifies the client identifier used when obtaining an IP address from a DHCP server.
<*interface*>	Specifies an interface, thus defining the client identifier as the hexadecimal medium access control (MAC) address of the specified interface (including a hexadecimal number added to the front of the MAC address to identify the media type). For example, specifying the **client-id ethernet 0/1** (where the Ethernet interface has a MAC address of d217.0491.1150) defines the client identifier as **01:d2:17:04:91:11:50** (where 01 defines the media type as Ethernet). Refer to *hardware-address on page 4344* for a detailed listing of media types.
<*identifier*>	Specifies a custom client-identifier using a text string (that is converted to a hexadecimal equivalent) or 7 to 28 hexadecimal numbers (with colon delimiters). For example, a custom client identifier of **0f:ff:ff:ff:ff:51:04:99:a1** may be entered using the <*identifier*> option.
hostname <*"string"*>	Optional. Specifies a text string (to override the global router name) to use as the name in the DHCP option 12 field. The string is enclosed in quotation marks and can consist of up to 35 characters.

no-default-route Optional. Specifies that no default route is obtained via DHCP.

no-domain-name Optional. Specifies that no domain name is obtained via DHCP.

no-nameservers Optional. Specifies that no domain naming system (DNS) servers are obtained via DHCP.

track *<name>* Optional. Attaches a network monitoring track to the DHCP client. The DHCP gateway route for this client will only reside in the route table while the track is in the pass state. For more information on configuring track objects, refer to *track <name> on page 1886*.

Default Values

<administrative distance> By default, the administrative distance value is 1.

class-id Optional. By default, no vendor class identifier is configured.

client-id Optional. By default, the client identifier is populated using the following formula:

TYPE: INTERFACE SPECIFIC INFO : MAC ADDRESS

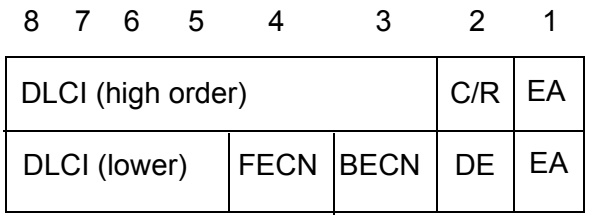
Where TYPE specifies the media type in the form of one hexadecimal byte (refer to *hardware-address on page 4344* for a detailed listing of media types), and the MAC ADDRESS is the medium access control (MAC) address assigned to the first Ethernet interface in the unit in the form of six hexadecimal bytes. (For units with a single Ethernet interface, the MAC ADDRESS assigned to Ethernet 0/1 is used in this field.)

INTERFACE SPECIFIC INFO is only used for Frame Relay interfaces and can be determined using the following:

FR_PORT#: Q.922 ADDRESS

Where the FR_PORT# specifies the label assigned to the virtual Frame Relay interface using four hexadecimal bytes. For example, a virtual Frame Relay interface labeled 1 would have a FR_PORT# of 00:00:00:01.

The Q.922 ADDRESS field is populated using the following:



Where the FECN, BECN, C/R, DE, and high order extended address (EA) bits are assumed to be 0 and the lower order EA bit is set to 1.

The following list provides a few example DLCIs and associated Q.922 address:

DLCI (decimal) / Q.922 address (hex)

16 / 0x0401
50 / 0x0C21
60 / 0x0CC1
70 / 0x1061
80 / 0x1401

hostname *“<string>”* By default, the host name is the name configured using the Global Configuration **hostname** command.

Command History

Release 2.1	Command was introduced.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 13.1	Command was expanded to include the track and administrative distance.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.
Release R10.10.0	Command was expanded to include the **class-id** parameter in support of DHCP Option 60.

Functional Notes

DHCP allows interfaces to acquire a dynamically assigned IP address from a configured DHCP server on the network. Many service providers require the use of DHCP when connecting to their services. Using DHCP reduces the number of dedicated IP addresses the ISP must obtain. Consult your ISP to determine the proper values for the **client-id** and **hostname** fields.

The vendor class identifier is sent to the DHCP server in DHCP discover and request messages via DHCP Option 60. This option gives the DHCP server details regarding DHCP client configuration and also allows the server to send any vendor-specific information to the client in DHCP offer messages via Option 43.

Usage Examples

The following example enables DHCP operation on the interface:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip address dhcp**

The following example enables DHCP operation on the interface utilizing host name **adtran** and does not allow obtaining a default route, domain name, or name servers. It also sets the administrative distance as **5**:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip address dhcp hostname “adtran” no-default-route no-domain-name no-nameservers 5**

ip address *<ipv4 address> <subnet mask>*

Use the **ip address** command to define an Internet Protocol version 4 (IPv4) address on the system management Ethernet virtual connection (EVC) (only one primary address is allowed). Use the optional **secondary** keyword to define a secondary IPv4 address. Use the **no** form of this command to remove a configured IPv4 address. Variations of this command include:

ip address <*ipv4 address*> <*subnet mask*>
ip address <*ipv4 address*> <*subnet mask*> **secondary**

Syntax Description

<*ipv4 address*>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*subnet mask*>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
secondary	Optional. Configures a secondary IPv4 address for the EVC.

Default Values

By default, there are no assigned IPv4 addresses.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single interface (when you need more IP addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a secondary IPv4 address of **192.22.72.101 /30**:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip address 192.22.72.101 /30 secondary**

ip address range *<start ipv4 address> <end ipv4 address> <subnet mask>* secondary

Use the **ip address range secondary** command to specify a range of secondary Internet Protocol version 4 (IPv4) addresses on the system management Ethernet virtual connection (EVC). Use the **no** form of this command to remove the range of configured IPv4 addresses.

Syntax Description

<start ipv4 address>	Specifies the first IPv4 address in the range.
<end ipv4 address>	Specifies the last IPv4 address in the range. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no IPv4 address range is defined.

Command History

Release 17.4	Command was introduced.
Release R10.1.0	Command was added to the facility data link (FDL) interface.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

Use secondary IPv4 addresses to allow dual subnets on a single EVC (when you need more IPv4 addresses than the primary subnet can provide). When using secondary IPv4 addresses, avoid routing loops by verifying that all devices on the network segment are configured with secondary IPv4 addresses on the secondary subnet.

Usage Examples

The following example configures a range of secondary IPv4 addresses from **192.22.72.1** to **192.22.72.10** on subnet **255.255.255.252**:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip address range 192.22.72.1 192.22.72.10 255.255.255.252 secondary**

ip crypto map *<name>*

Use the **ip crypto map** command to associate Internet Protocol version 4 (IPv4) crypto maps with the system management Ethernet virtual connection (EVC). Use the **no** form of this command to remove a crypto map from an interface.

> NOTE *When you apply a map to an EVC, you are applying all crypto maps with the given map name. This allows you to apply multiple crypto maps if you have created maps that share the same name, but have different map index numbers.*

Syntax Description

<name>	Specifies the IPv4 crypto map name that you wish to assign to the EVC.

Default Values

By default, no crypto maps are assigned to an EVC.

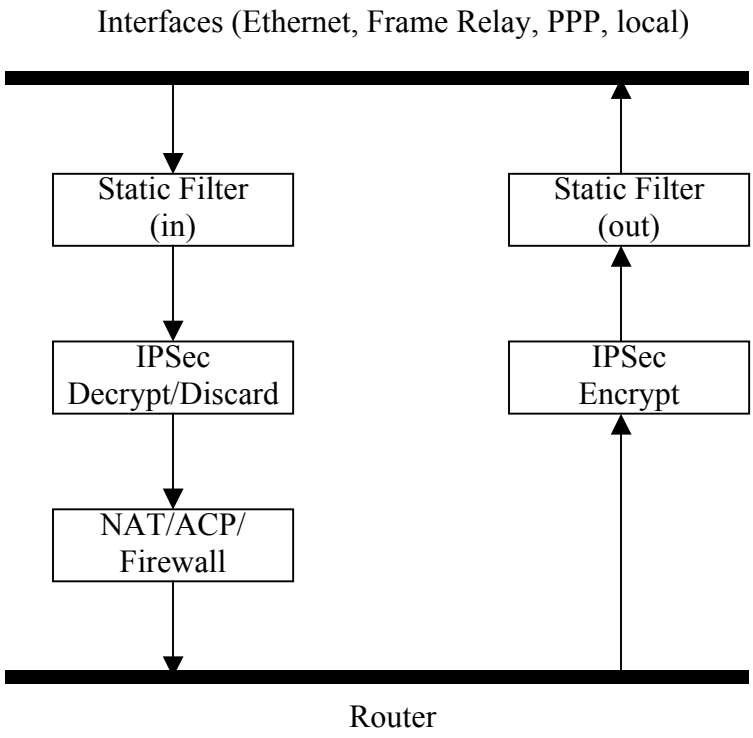
Command History

Release 4.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release 8.1	Command was expanded to include the asynchronous transfer mode (ATM) subinterface.
Release 9.1	Command was expanded to include the High-Level Data Link Control (HDLC) interface.
Release 11.1	Command was expanded to include the demand interface.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.7.0	Command syntax was changed to require the **ip** keyword.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

When configuring a system to use both the stateful inspection firewall and Internet key exchange (IKE) negotiation for VPN, keep the following notes in mind.

When defining the IPv4 policy class and associated access control lists (ACLs) that describe the behavior of the IPv4 firewall, do not forget to include the traffic coming into the system over a VPN tunnel terminated by the system. The firewall should be set up with respect to the unencrypted traffic that is destined to be sent or received over the VPN tunnel. The following diagram represents typical AOS data-flow logic.



As shown in the diagram above, data coming into the product is first processed by the static filter associated with the EVC on which the data is received. This access group is a true static filter and is available for use regardless of whether the IPv4 firewall is enabled or disabled. Next (if the data is encrypted), it is sent to the IPSec engine for decryption. The decrypted data is then processed by the stateful inspection firewall. Therefore, given a terminating VPN tunnel, only unencrypted data is processed by the firewall.

The IPv4 ACLs for a crypto map on an interface work in reverse logic to the ACLs for a policy class on an EVC. When specifying the ACLs for a crypto map, the source information is the private local side, unencrypted source of the data. The destination information will be the far-end, unencrypted destination of the data. However, ACLs for a policy class work in reverse. The source information for the ACL in a policy class is the far end. The destination information is the local side.

Usage Examples

The following example applies all IPv4 crypto maps with the name **MyMap** to the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip crypto map MyMap**

ip dhcp

Use the **ip dhcp** command to release or renew the Dynamic Host Configuration Protocol (DHCP) Internet Protocol version 4 (IPv4) address. This command is only applicable when using DHCP for IP address assignment. Variations of this command include:

ip dhcp release
ip dhcp renew

Syntax Description

release	Releases the DHCP IPv4 address.
renew	Renews the DHCP IPv4 address.

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.
Release 8.1	Command was added to the asynchronous transfer mode (ATM) subinterface.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release R10.1.0	Command was added to the bridged virtual interface (BVI).
Release R10.10.0	Command was expanded to include the system management Ethernet virtual connection (EVC).

Usage Examples

The following example releases the IPv4 address assigned (by DHCP) on the system management EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip dhcp release**

ip dhcp relay destination *<ipv4 address>*

Use the **ip dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 4 (IPv4) and to specify the IPv4 address for the DHCPv4 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv4 relay functionality is disabled on the interface.

Syntax Description

<ipv4 address>	Specifies the IPv4 address for the DHCPv4 messages. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**)..

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.10.0	Command was expanded to include the system management Ethernet virtual connection (EVC).

Usage Examples

The following example enables DHCPv4 relay agent functionality and specifies the destination address as **192.33.4.251**:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip dhcp relay destination 192.33.4.251**

ip directed-broadcast

Use the **ip directed-broadcast** command to allow reception/forwarding of directed broadcasts. Use the **no** form of this command to disable this feature. Variations of this command include:

ip directed-broadcast
ip directed-broadcast <*name*>

Syntax Description

<*name*>	Specifies IP access control list (ACL) name.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management Ethernet virtual connection (EVC).

Functional Notes

A directed broadcast is a packet intended for all nodes on a nonlocal network. For example, the broadcast address 255.255.255.255 reaches all nodes on a network; the directed broadcast address 128.1.255.255 is intended for all nodes whose network address is 128.1.0.0. A router not directly attached to 128.1.0.0 simply forwards the directed broadcast packet to the next hop. A router on network 128.1.0.0 that has **ip directed-broadcast** enabled, accepts and forwards the packet to all nodes whose network address is 128.1.0.0. Routers connecting subnets of 128.1.0.0 also accept and forward the packet to the nodes on their respective subnets. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is distributed as a broadcast on the destination subnet. The packet is then sent as a link-layer broadcast.

The **ip directed-broadcast** command controls the distribution of directed broadcasts when they reach their target subnets. Only the final transmission of the directed broadcast on its ultimate destination subnet is affected. It does not affect the transit unicast routing of IP directed broadcasts.

If **ip directed-broadcast** is enabled for this interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which this EVC is attached will be forwarded as broadcasts on that subnet. Forwarding of the packets can be limited by specifying an ACL with this command. In this case, only directed broadcasts that are permitted by the specified ACL will be forwarded, and all other directed broadcasts directed to this EVC subnet will be dropped.

Disabling the **ip directed-broadcast** command will cause directed broadcasts destined for the subnet to which this EVC is attached to be dropped.

This option is a requirement for routers as described in RFC 1812, section 4.2.2.11. Furthermore, it is disabled by default (RFC 2644), with the intended goal of reducing the efficacy of certain types of denial of service (DoS) attacks.

Usage Examples

The following example enables forwarding of directed broadcasts on the system management EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip directed-broadcast**

ip flow

Use the **ip flow** command to enable integrated traffic monitoring (ITM) for all traffic received or forwarded on the system management Ethernet virtual connection (EVC). Use the **no** form of this command to disable traffic monitoring. Variations of this command include:

ip flow egress
ip flow egress <*name*>
ip flow ingress
ip flow ingress <*name*>

Syntax Description

egress	Specifies that all outgoing traffic be monitored.
ingress	Specifies that all incoming traffic be monitored.
<*name*>	Optional. Specifies the name of an access control list (ACL) to use for filtering traffic.

Default Values

By default, no traffic monitoring is enabled.

Command History

Release 16.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Usage Examples

The following example enables traffic monitoring on the system management EVC to monitor **incoming** traffic through an ACL called **MYACL**:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip flow ingress MYACL**

ip helper-address *<ipv4 address>*

Use the **ip helper-address** command to configure AOS to forward User Datagram Protocol (UDP) broadcast packets received on the system management Ethernet virtual connection (EVC). Use the **no** form of this command to disable forwarding packets.

> NOTE *The **ip helper** command must be used in conjunction with the **ip forward-protocol** command to configure AOS to forward UDP broadcast packets. Refer to ip forward-protocol udp <value> on page 1398 for more information.*

Syntax Description

<ipv4 address>	Specifies the destination IP address for the forwarded UDP packets. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, broadcast UDP packets are not forwarded.

Command History

Release 1.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

When used in conjunction with the **ip forward-protocol** command, the **ip helper-address** feature allows you to customize which broadcast packets are forwarded.

To implement the helper address feature, assign a helper address(es) (specifying the device that needs to receive the broadcast traffic) to the interface closest to the host that transmits the broadcast packets. When broadcast packets (of the specified type forwarded using the **ip forward-protocol** command) are received on the interface, they will be forwarded to the device that needs the information.

Only packets meeting the following criteria are considered eligible by the **ip helper-address** feature:

1. The packet IP protocol is UDP.
2. Any UDP port specified using the **ip forward-protocol** command.
3. The medium access control (MAC) address of the frame is an all-ones broadcast address (ffff.ffff.ffff).
4. The destination IPv4 address is broadcast defined by all ones (255.255.255.255) or a subnet broadcast (for example, 192.33.4.251 for the 192.33.4.248 /30 subnet).

Usage Examples

The following example forwards all domain naming system (DNS) broadcast traffic to the DNS server with IPv4 address **192.33.5.99**:

(config)**#ip forward-protocol udp domain**
(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip helper-address 192.33.5.99**

ip mtu <*size*>

Use the **ip mtu** command to configure the Internet Protocol version 4 (IPv4) maximum transmission unit (MTU) size for the system management Ethernet virtual connection (EVC). Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Configures the window size for transmitted IPv4 packets. The valid ranges for the various interfaces are listed below:	
	ATM subinterfaces	64 to 1520
	BVIs	64 to 2100
	Demand interfaces	64 to 1520
	Ethernet interfaces (all types)	64 to 1500
	FDL interfaces	64 to 256
	Frame Relay subinterfaces	64 to 1520
	HDLC interfaces (NetVanta 5305)	64 to 4600
	HDLC interfaces (all other NetVanta products)	64 to 2100
	Loopback interfaces	64 to 1500
	PPP interfaces (NetVanta 5305)	64 to 4600
	PPP interfaces (all other NetVanta products)	64 to 2100
	Tunnel interfaces	64 to 18190

Default Values

<*size*>	The default values for the various interfaces are listed below:	
	ATM subinterfaces	1500
	BVIs	1500
	Demand interfaces	1500
	Ethernet interfaces (all types)	1500
	FDL interfaces	256
	Frame Relay subinterfaces	1500
	HDLC interfaces	1500
	Loopback interfaces	1500
	PPP interfaces	1500
	Tunnel interfaces	1476

Command History

Release 1.1	Command was introduced.
Release 11.1	Command was expanded to include the demand interface.
Release 17.9	Command was changed to require the **ip** keyword for Adtran internetworking products only.
Release R10.1.0	Command was changed to require the **ip** keyword for Adtran voice products.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

OSPFv2 will not become adjacent on links where the MTU sizes do not match. If router A and router B are exchanging hello packets but their MTU sizes do not match, they will never reach adjacency. This is by design and required by the RFC.

Usage Examples

The following example specifies an IPv4 MTU of 1200 on the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip mtu 1200**

ip policy route-map *<name>*

Use the **ip policy route-map** command to assign a policy route-map to the system management Ethernet virtual connection (EVC). Use the **no** form of this command to remove the route-map policy.

Syntax Description

<name>	Specifies the name of the policy route map to assign to this EVC.

Default Values

By default, no policy route map is assigned to this EVC.

Command History

Release 11.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system management EVC.

Usage Examples

The following example assigns the policy route map **policy1** to the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip policy route-map policy1**

ip proxy-arp

Use the **ip proxy-arp** command to enable proxy Address Resolution Protocol (ARP) on the system management Ethernet virtual connection (EVC). Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, proxy ARP is enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

In general, the principle of proxy ARP allows a router to insert its IP address in the source IP address field of a packet (if the packet is from a host on one of its subnetworks). This allows hosts to reach devices on other subnetworks without implementing routing or specifying a default gateway.

If proxy ARP is enabled, AOS will respond to all ARP requests with its specified medium access control (MAC) address and forward packets accordingly.

Enabling proxy ARP on an EVC may introduce unnecessary ARP traffic on the network.

Usage Examples

The following example enables proxy ARP on the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip proxy-arp**

ip rip authentication

Use the **ip rip authentication** command to enable specify the Internet Protocol version 4 (IPv4) Routing Information Protocol (RIP) authentication method on the Ethernet virtual connection (EVC). Use the **no** form of this command to disable RIP authentication. Variations of this command include:

ip rip authentication key-chain <*name*>
ip rip authentication mode md5
ip rip authentication mode text

Syntax Description

key-chain <*name*>	Specifies that RIP authentication is completed using an authentication key, and specifies the key name.
mode md5	Specifies that RIP authentication is completed using message digest authentication.
mode text	Specifies that RIP authentication is completed using clear text authentication.

Default Values

By default, RIP authentication is disabled.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example enables RIP authentication on the EVC and specifies authentication is completed using clear text:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#**

ip rip receive version

Use the **ip rip receive version** command to configure the Routing Information Protocol (RIP) version the unit accepts in all RIP packets received on the system management Ethernet virtual connection (EVC). Variations of this command include:

ip rip receive version 1
ip rip receive version 2

Syntax Description

1	Accepts only RIP version 1 packets received on the EVC.
2	Accepts only RIP version 2 packets received on the EVC.

Default Values

By default, the EVC implements RIP version **1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

Use the **ip rip receive version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only accepts one version (either **1** or **2**) on an EVC.

Usage Examples

The following example configures the EVC to accept only RIP version **2** packets:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip rip receive version 2**

ip rip send version

Use the **ip rip send version** command to configure the Routing Information Protocol (RIP) version the unit sends in all RIP packets transmitted on the system management Ethernet virtual connection (EVC). Variations of this command include:

ip rip send version 1
ip rip send version 2

Syntax Description

1	Transmits only RIP version 1 packets on the EVC.
2	Transmits only RIP version 2 packets on the EVC.

Default Values

By default, the EVC transmit RIP version **1** (the default value for the **version** command).

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

Use the **ip rip send version** command to specify a RIP version that overrides the **version** (in the Router RIP) configuration. Refer to *version on page 4220* for more information.

AOS only transmits one version (either **1** or **2**) on an EVC.

Usage Examples

The following example configures the EVC to transmit only RIP version **2** packets:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip rip send version 2**

ip rip summary-address *<ipv4 address> <subnet mask>*

Use the **ip rip summary-address** command to manually summarize the routes Routing Information Protocol (RIP) will advertise and send out the system management Ethernet virtual connection (EVC). Use the **no** form of this command to disable this mode.

Syntax Description

<ipv4 address>	Specifies the summarized network IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.0**).
<subnet mask>	Specifies the subnet mask that corresponds to the range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, no manual summarization is applied by RIP.

Command History

Release 12.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

Unlike the automatic summarization on classful network boundaries, only specific network advertisements are made by RIP using the **ip rip summary-address** command. This command is only effective if RIP version 2 is configured.

Usage Examples

The following example enables manual summarization on the specified IPv4 address:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip rip summary-address 10.10.123.0 255.255.255.0**

ip route-cache

Use the **ip route-cache** command to enable Internet Protocol version 4 (IPv4) fast-cache switching on the system management Ethernet virtual connection (EVC). Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

*Using network address translation (NAT) or the AOS firewall capabilities on an EVC requires process switching mode (using the **no ip route-cache** command).*

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on the EVC.

Command History

Release 2.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

Fast switching allows an EVC to provide optimum performance when processing IPv4 traffic.

Usage Examples

The following example enables IPv4 fast switching on the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip route-cache**

ip split-horizon

Use the **ip split-horizon** command to enable Internet Protocol version 4 (IPv4) Routing Information Protocol (RIP) split horizon on the Ethernet virtual connection (EVC). Use the **no** form of this command to disable the feature.

Syntax Description

No subcommands.

Default Values

By default, RIP split horizon is disabled.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example enables RIP split horizon on the EVC:

```
(config)#system-management-evc
(config-sys-mgmt-evc)#ip split-horizon
```

ip urlfilter *<name>*

Use the **ip urlfilter** command to apply a universal resource locator (URL) filter to the system management Ethernet virtual connection (EVC) for all inbound or outbound traffic. Use the **no** form of this command to remove the URL filter from the EVC. Variations of this command include:

ip urlfilter <*name*> **in**
ip urlfilter <*name*> **out**

Syntax Description

<name>	Specifies the URL filter name to use on the EVC.
in	Applies the filter to the inbound traffic.
out	Applies the filter to the outbound traffic.

Default Values

By default, there are no URL filters applied to any EVCs.

Command History

Release 12.1	Command was introduced.
Release 14.1	Command was expanded to include the virtual local area network (VLAN) interfaces.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

The firewall must be enabled using the **ip firewall** command in order to use URL filters. The URL filter must be created by using the **ip urlfilter** *<filter name>* **http** command before applying it to the EVC. Refer to *ip urlfilter <name> http on page 1495* for more information on using this command.

Usage Examples

The following example performs URL filtering on all traffic entering through the EVC and matches the URL filter named **MyFilter**:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ip urlfilter MyFilter in**

ipv6

Use the **ipv6** command to enable Internet Protocol version 6 (IPv6) processing and create a link-local address on the system management Ethernet virtual connection (EVC). Use the **no** form of this command to disable IPv6 processing and remove all IPv6 configuration on the EVC.

Syntax Description

No subcommands.

Default Values

By default, IPv6 is not enabled on the EVC.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

Because AOS uses the dual-stack for IPv6 implementation, IPv6 features must be enabled for the supported IPv6 features to be used. Enabling IPv6 in AOS is completed by using an IPv6 address or using the **ipv6** keyword with specific commands. For example, to enable IPv6 on an interface and cause the EVC to join the link scoped all-nodes and all-routers multicast group, enter an IPv6 address on the EVC.

Use the **ipv6** command to enable IPv6 processing and create a link-local address on an EVC when other unicast IPv6 addresses are not needed on the EVC. This command is not necessary nor effectual when any other form of an IPv6 address command is also present on the EVC.

Usage Examples

The following example enables IPv6 and creates a link-local IPv6 address on the EVC:

```
(config)#system-management-evc
(config-sys-mgmt-evc)#ipv6
```

ipv6 access-group *<ipv6 acl name>*

Use the **ipv6 access-group** command to apply an Internet Protocol version 6 (IPv6) access control list (ACL) to be used for IPv6 packets transmitted on or received from the system management Ethernet virtual connection (EVC). Use the **no** form of this command to disable this type of control. Variations of this command include:

ipv6 access-group *<ipv6 acl name>* **in**
ipv6 access-group *<ipv6 acl name>* **out**

Syntax Description

<ipv6 acl name>	Applies the named IPv6 ACL to the EVC.
in	Enables access control on IPv6 packets received on the EVC.
out	Enables access control on IPv6 packets transmitted on the EVC.

Default Values

By default, these commands are disabled.

Command History

Release 18.1	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

Only one IPv6 ACL can be applied in each traffic direction.

Unlike in IPv4, IPv6 traffic filters include an implicit **permit** for neighbor solicitation and advertisement packets in an ACL before the traditional implicit **deny** at the end of the ACL. This prevents blocking of address resolution and unreachability detection, although this can be overridden by entering explicit **deny** commands in the IPv6 ACL.

Usage Examples

The following example applies the IPv6 ACL **Privatev6** to incoming IPv6 traffic on the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 access-group Privatev6 in**

ipv6 access-policy *<ipv6 acp>*

Use the **ipv6 access-policy** command to assign a specified Internet Protocol version 6 (IPv6) access control policy (ACP) to the system management Ethernet virtual connection (EVC). IPv6 ACPs are applied to IPv6 traffic entering the EVC. Use the **no** form of this command to remove an ACP association.

Syntax Description

<ipv6 acp>	Identifies the configured IPv6 ACP by alphanumeric descriptor (all ACP descriptors are case sensitive).

Default Values

By default, there are no configured IPv6 ACPs associated with the EVC.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Usage Examples

The following example applies the IPv6 ACP **PRIVATEv6** to the EVC:

Enable the AOS security features:
(config)**#ipv6 firewall**

Associate the ACP with the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 access-policy PRIVATEv6**

ipv6 address autoconfig

Use the **ipv6 address autoconfig** command to enable Internet Protocol version 6 (IPv6) processing on the system management Ethernet virtual connection (EVC), create a local-link IPv6 address for the EVC, and allow the EVC to automatically configure itself based on advertisements from other routers on the link. Use the **no** form of this command to remove all autoconfigured addresses, prefixes, and any resulting routes from the EVC and also causes the EVC to cease processing received router advertisements (RAs).Variations of this command include:

ipv6 address autoconfig
ipv6 address autoconfig default
ipv6 address autoconfig default metric <*value*>

Syntax Description

default	Optional. Specifies that the EVC maintain a list of advertising routers that are willing to be IPv6 default routers.
metric <*value*>	Optional. Specifies the administrative distance for a default router maintained in the default router list. Range is **1** to **255**. Routes with lower administrative distance are favored.

Default Values

By default, no IPv6 addresses are configured for the EVC and IPv6 processing is not enabled. When an IPv6 address is configured automatically, the administrative distance for default routers is **2** by default.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

When autoconfiguration is enabled, the EVC listens for RA messages that tell the EVC how it should be configured. The EVC then creates addresses for advertised 64-bit prefixes with the A flag in the IPv6 address set using stateless address autoconfiguration (SLAAC). The addresses use the EUI-64 interface ID in the lower 64 bits of the address. A route type of *Connected* is added to the route table if the L flag on the prefix advertisement (on-link flag) is also set.

Usage Examples

The following example enables IPv6 processing on the EVC, creates a link-local IPv6 address for the EVC, and allows the EVC to automatically configure itself for IPv6:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 address autoconfig**

ipv6 address *<ipv6 address/prefix-length>*

Use the **ipv6 address** command to assign a unicast Internet Protocol version 6 (IPv6) address to the interface and enable IPv6 processing on the system management Ethernet virtual connection (EVC). Use the **no** form of this command to remove the IPv6 address from the EVC.

Syntax Description

<ipv6 address/prefix-length>	Specifies the IPv6 unicast address to add to the interface. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

Default Values

By default, no IPv6 address is configured on the EVC and IPv6 processing is not enabled.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the EVC using the command *ipv6 address <ipv6 link-local address> link-local on page 3882*.

The address created by this command is a manually configured IPv6 address, which must have all parts (prefix and host bits) specified.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the EVC. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the EVC.

Usage Examples

The following example adds a unicast IPv6 address to the EVC and enables IPv6 processing on the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 address 2001:DB8::/32**

ipv6 address *<ipv6 prefix/prefix-length>* eui-64

Use the **ipv6 address eui-64** command to assign a unicast Internet Protocol version 6 (IPv6) address and enable IPv6 processing on the system management Ethernet virtual connection (EVC). Use the **no** form of this command to remove the IPv6 address from the EVC.

Syntax Description

<ipv6 prefix/prefix-length>	Specifies the IPv6 prefix. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
eui-64	Specifies that the IPv6 address is constructed using the specified prefix in the high-order bits and followed by the EUI-64 Interface ID in the lower 64 bits.

Default Values

By default, no IPv6 address is configured on the EVC and IPv6 processing is not enabled.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

The IPv6 unicast address can be a global unicast address or a unique local address, but it cannot be a link-local IPv6 address (**FE80::**). Link-local addresses are created on the EVC using the command *ipv6 address <ipv6 link-local address> link-local on page 3882*.

The address created by this command is an EUI-64 unicast address. For this type of address, the EUI-64 interface ID is automatically placed in the IPv6 address. Any manually configured bits beyond the address's prefix length are set to **0**; however, any manually configured bits within the prefix length that extend into the lower 64 bits take precedence over the Interface ID bits.

Using the **no** form of this command with a specified IPv6 address removes only that IPv6 address from the EVC. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the EVC.

Usage Examples

The following example adds a unicast IPv6 address with an EUI-64 Interface ID to the EVC and enables IPv6 processing on the EVC:

(config)#**system-management-evc**
(config-sys-mgmt-evc)#**ipv6 address 2001:DB8:3F::/48 eui-64**

ipv6 address <*ipv6 link-local address*> link-local

Use the **ipv6 address link-local** command to manually assign a link-local Internet Protocol version 6 (IPv6) address to the system management Ethernet virtual connection (EVC) and enable IPv6 processing on the EVC. Use the **no** form of this command to remove the IPv6 address from the EVC.

Syntax Description

<*ipv6 link-local address*>	Specifies the link-local IPv6 address. Link-local addresses are specified in colon hexadecimal notation, and begin with **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since link-local addresses have no prefix, the bits entered form the entire IPv6 address.
link-local	Specifies this is a manually configured link-local address. Manually configured link-local addresses replace automatically configured link-local addresses on the EVC.

Default Values

By default, no IPv6 address is configured for the EVC and IPv6 processing is not enabled.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

A single link-local address can be manually configured on an EVC. The lower 64 bits of the specified address become the Interface ID for the EVC, overriding the default interface ID. Any other address that uses the EUI-64 parameter to automatically place the interface ID in the lower 64 bits of the IPv6 address use the new value for the interface ID.

The <*ipv6 address*> for a link-local IPv6 address is specified in the format **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since this form of address has no prefix, the bits entered form the entire IPv6 address. These bits also become the new interface ID for the EVC and can be derived from the EVC's medium access control (MAC) address.

The **link-local** parameter specifies this is a manually configured link-local address. Any manually configured link-local address will replace an automatically configured link-local address for the EVC.

Using the **no** form of this command with a specified IPv6 address removes that IPv6 address from the EVC. Using the **no** form of this command without a specified IPv6 address removes all manually configured IPv6 addresses from the EVC.

Usage Examples

The following example manually creates a link-local IPv6 address on the EVC and enables IPv6 processing:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 address FE80::220:8FF:FE54:F9D8 link-local**

ipv6 address dhcp

Use the **ipv6 address dhcp** command to enable Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) on the interface, place the interface in DHCPv6 client mode, and configure the address parameters of the DHCPv6 client. Use the **no** form of this command to disable the DHCPv6 client on the interface. Variations of this command include:

ipv6 address dhcp
ipv6 address dhcp hostname <*partial fqdn*>
ipv6 address dhcp hostname fqdn <*fqdn*>
ipv6 address dhcp no-domain-name
ipv6 address dhcp no-nameservers
ipv6 address dhcp no-ntp
ipv6 address dhcp no-sntp-server
ipv6 address dhcp rapid-commit

Syntax Description

hostname <*partial fqdn*>	Optional. Specifies the name to be sent to the DHCPv6 server as the host portion of its fully qualified domain name (FQDN). FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
fqdn <*fqdn*>	Optional. Specifies a name to be sent to the DHCPv6 server as the system's FQDN. FQDNs are expressed in ASCII text of up to **254** characters. The string can be enclosed in quotation marks.
no-domain-name	Optional. Specifies that no domain names are obtained using this DHCPv6 client.
no-nameservers	Optional. Specifies that no domain naming server (DNS) addresses are obtained through DHCPv6.
no-ntp	Optional. Specifies that no Network Time Protocol (NTP) server values are obtained through this DHCPv6 client.
no-sntp-server	Optional. Specifies that no Simple Network Time Protocol (SNTP) server values are obtained through this DHCPv6 client.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Functional Notes

To enable an interface as a DHCPv6 client, you must first enable IPv6 on the interface using the command *ipv6 on page 3876*.

Enabling the interface as a DHCPv6 client using the **ipv6 address dhcp** command places the interface into DHCPv6 client mode. DHCPv6 modes (**client**, **server**, **relay**) are mutually exclusive at the interface. Any existing mode must be removed before a different mode can be applied. For example, if the interface is configured as a DHCPv6 relay agent, you must first disable the **relay** mode before you can specify the interface is in **client** mode.

Usage Examples

The following example enables the interface as a DHCPv6 client and specifies the client's host name:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 address 2001:DB8:1::1/64**
(config-sys-mgmt-evc)**#ipv6 address dhcp fqdn client@company.com**

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*

Use the **ipv6 address named-prefix** command to create an Internet Protocol version 6 (IPv6) address for the Ethernet virtual connection (EVC) using the values in a named prefix. Use the **no** form of this command to remove the address from the EVC. Variations of this command include:

ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>*
ipv6 address named-prefix *<prefix name> <ipv6 address/prefix-length>* **eui-64**

Syntax Description

<prefix name>	Specifies the named prefix to use to create the address.
<ipv6 address/prefix-length>	Specifies the address portion appended to the named prefix to create a 128-bit host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
eui-64	Optional. Indicates that the interface ID is to be placed in the lower 64 bits of the address.

Default Values

By default, no IPv6 addresses are specified on the EVC.

Command History

Release R10.9.0	Command was introduced.
Release R10.10.0	Command was expanded to include the system control and system management EVCs.

Usage Examples

The following example creates an IPv6 address on the EVC using the named prefix **PREFIX1**:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 address named-prefix PREFIX1 2001:1:0:/48**

ipv6 crypto map *<name>*

Use the **ipv6 crypto map** command to associate Internet Protocol version 6 (IPv6) crypto maps with the system management Ethernet virtual connection (EVC). Use the **no** form of this command to remove a crypto map from the EVC.

Syntax Description

<name>	Specifies the IPv6 crypto map name that you wish to assign to the EVC.

Default Values

By default, no crypto maps are assigned to an EVC.

Command History

Release R10.7.0	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

Only one IPv6 crypto map can be specified per EVC, and the crypto map is applied within the virtual routing and forwarding (VRF) instance to which the EVC belongs. To apply the IPv6 crypto map, the EVC must have IPv6 enabled. In addition, the EVC must have an IPv6 address of appropriate scope to allow connectivity to peer's addresses as specified in the crypto map's entries.

Usage Examples

The following example applies all IPv6 crypto maps with the name **MyMap** to the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6**
(config-sys-mgmt-evc)**#ipv6 crypto map MyMap**

ipv6 dhcp client information refresh minimum <*seconds*>

Use the **ipv6 dhcp client information refresh minimum** command to specify the minimum value the Dynamic Host Control Protocol for Internet Protocol version 6 (DHCPv6) client on the system management Ethernet virtual connection (EVC) accepts as its information refresh timer. Use the **no** version of this command to return to the default setting.

Syntax Description

<*seconds*>	Specifies the refresh timer in seconds. Valid range is **600** to **3600** seconds.

Default Values

By default, the DHCPv6 client refresh timer is set to **600** seconds.

Command History

Release R10.9.0	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Usage Examples

The following example specifies the DHCPv6 client refresh timer for the EVC is **800** seconds:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 dhcp client information refresh minimum 600**

ipv6 dhcp client pd <*prefix name*>

Use the **ipv6 dhcp client pd** command to enable the Dynamic Control Host Protocol for Internet Protocol version 6 (DHCPv6) client on the interface and specify that the interface acquires an IPv6 prefix for the DHCPv6 client. Use the **no** form of this command to disable this feature. Variations of this command include:

ipv6 dhcp client pd <*prefix name*>
ipv6 dhcp client pd <*prefix name*> **no-aggregate-route**
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*>
ipv6 dhcp client pd <*prefix name*> **distance** <*distance*> **tag** <*value*>
ipv6 dhcp client pd <*prefix name*> **rapid-commit**

Syntax Description

<*prefix name*>	Specifies the variable of the prefix stored on the AOS system. Variables are expressed in ASCII text of up to **80** characters.
no-aggregate-route	Optional. Specifies that a route to the null 0 interface is not injected into the route table for the prefixes assigned.
distance <*distance*>	Optional. Specifies the administrative distance to assign to the injected route. Valid range is **1** to **255** with a default distance of **1**.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.
tag <*value*>	Optional. Specifies a number to use as a tag for labeling and filtering routers. Valid range is **1** to **65535**.

Default Values

By default, the DHCPv6 client mode is not enabled on the interface.

Command History

Release R10.9.0	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.
Release R11.1.0	Command was expanded to include the **rapid-commit** parameter.

Usage Examples

The following example enables the DHCPv6 client on the interface and assigns the prefix **PREFIX1**:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 dhcp client pd PREFIX1**

ipv6 dhcp relay destination *<ipv6 address>*

Use the **ipv6 dhcp relay destination** command to enable Dynamic Host Control Protocol (DHCP) for Internet Protocol version 6 (IPv6) and to specify the IPv6 address for the DHCPv6 messages. Using the **no** form of this command disables the relay functionality for the specified destination. When all destinations are removed, DHCPv6 relay functionality is disabled on the system management Ethernet virtual connection (EVC). Variations of this command include:

ipv6 dhcp relay destination *<ipv6 address>*
ipv6 dhcp relay destination *<ipv6 address>* *<interface>*
ipv6 dhcp relay destination *<ipv6 address>* **system-control-evc**
ipv6 dhcp relay destination *<ipv6 address>* **system-management-evc**

Syntax Description

<ipv6 address>	Specifies the IPv6 address for the DHCPv6 messages. IPv6 addresses should be specified in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<interface>	Optional. Specifies an output interface to use when sending messages to the DHCPv6 server. If no interface is specified, the interface is selected by the routing table. This parameter is only required when the IPv6 address is a link-scoped address. Interfaces are specified in the *<interface type> <slot/port | interface id>* format. For example, for an Ethernet interface, use **eth 0/1**. Type **ipv6 dhcp relay destination** *<ipv6 address>* **?** to display a list of valid interfaces.
system-control-evc	Optional. Specifies the output interface for sending messages to the DHCPv6 server is the system control EVC.
system-management-evc	Optional. Specifies the output interface for sending messages to the DHCPv6 server is the system management EVC.

Default Values

By default, no DHCP relay agent destinations are configured and the relay agent mode is disabled.

Command History

Release 18.2	Command was introduced.
Release R10.1.0	Command was expanded to include the tunnel interface.
Release R10.5.0	Command was expanded to include the loopback interface.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

To configure an EVC to function as a DHCPv6 relay agent, you must first enable IPv6 on the EVC using the command *ipv6 on page 3876*.

Usage Examples

The following example enables DHCPv6 relay agent functionality and specifies the destination address as **2001:DB8:2::1**:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6**
(config-sys-mgmt-evc)**#ipv6 dhcp relay destination 2001:DB8:2::1**

Technology Review

DHCPv6, like DHCP in IPv4, is used in IP networks to supply hosts with IP addresses and other networking information. DHCPv6, however, functions slightly differently than DHCPv4 by providing relay agents with the ability to send relay-forward and relay-reply messages. In addition, in DHCPv4, when DHCP messages are sent to a DHCP server whose address is not known, the IPv4 client uses the broadcast address. In DHCPv6, the IPv6 client sends messages using the link-scoped mulitcast address. This address is the All DHCP Relay Agents and Servers link, designated as **FF02::1:2**.

In AOS, DHCPv6 relay agents are used when the DHCP server is not on the same link as the DHCP client. The relay is typically a router on the same link as the client, which acts as an intermediary to help the client's DHCP messages reach the DHCP server. DHCPv6 relay agents operate transparently to the DHCP client, and can be configured in chains, meaning that information about each agent encountered is encapsulated into the relay message. Relay agents add fields to the DHCP message as they send these messages to the server, thus providing a method to properly manage the DHCP client.

For more information about DHCPv6 functionality in AOS, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

ipv6 dhcp server

Use the **ipv6 dhcp server** command to enable Internet Protocol version 6 (IPv6) Dynamic Host Control Protocol (DHCP) on the system management Ethernet virtual connection (EVC) and specify that the EVC is functioning as a DHCPv6 server. This command not only enables the DHCPv6 server on the EVC, it also configures specific parameters of the DHCPv6 server. Hence, the parameters of this command can be entered multiple times and in any order. Use the **no** form of this command to disable DHCPv6 on the EVC. Variations of this command include:

ipv6 dhcp server automatic
ipv6 dhcp server automatic allow-hint
ipv6 dhcp server automatic preference <*number*>
ipv6 dhcp server automatic rapid-commit
ipv6 dhcp server <*pool name*>
ipv6 dhcp server <*pool name*> **allow-hint**
ipv6 dhcp server <*pool name*> **preference** <*number*>
ipv6 dhcp server <*pool name*> **rapid-commit**

Syntax Description

automatic	Enables automatic selection of the DHCPv6 server pool based on information extracted from the DHCPv6 client's request. You must specify the pool selection method before configuring other options for this command.
<*pool name*>	Specifies the DHCPv6 server pool that services this EVC. All DHCPV^ requests received on this EVC are serviced from this pool. If a pool name is not specified, the server pool is selected automatically. You must specify the pool selection method before configuring the other options for this command.
allow-hint	Optional. Specifies that the DHCPv6 server attempts to honor the DHCPv6 client's request for specific values as hinted in the client's request (if they are valid and not already assigned). If this option is not specified, any hints from the DHCPv6 client are ignored.
preference <*number*>	Optional. Specifies the preference value advertised by the server. This option is sent by the server to a DHCPv6 client to influence the selection of a server when there are multiple servers from which to choose. Valid range is **0** to **255**, with a default value of **0**. When the preference value is set to a non-zero value, the server includes a preference option containing the value. If the preference value is not set, or is set to 0, the option is omitted and the client assumes the value is 0.
rapid-commit	Optional. Allows the client to request the use of a two message DHCPv6 address exchange instead of the normal four message exchange. This option should not be used if more than one DHCPv6 server is available to clients on the network being served.

Default Values

By default, DHCPv6 server mode is not enabled on the EVC.

Command History

Release R10.1.0	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

Enabling the EVC as a DHCPv6 server using this command places the EVC into DHCPv6 server mode. DHCPv6 modes (server, client, or relay) are mutually exclusive at the EVC. Any existing mode will be removed if a different mode is specified, and a message will be shown indicating the change in DHCPv6 mode.

Usage Examples

The following example enables the EVC as a DHCPv6 server, and specifies that the DHCPv6 server pool **POOL1** is associated with the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 address 2001:DB8:1::1/64**
(config-sys-mgmt-evc)**#ipv6 dhcp server POOL1**

ipv6 mode host unicast

Use the **ipv6 mode host unicast** command to place the system management Ethernet virtual connection (EVC) in host mode using an Internet Protocol version 6 (IPv6) unicast address. Use the **no** form of this command to disable host mode on the EVC.

Syntax Description

No subcommands.

Default Values

By default, host mode is disabled.

Command History

Release R10.9.0	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Command History

When this command is configured on an interface, the MTU value is learned from received router advertisements. Link MTU value is learned in host mode from the following locations (in decreasing order of priority): the provisioned MTU value in the interface configuration, the router advertisements received on the interface, and the default MTU value (1500).

Usage Examples

The following example places the EVC in host mode:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 mode host unicast**

ipv6 mtu *<size>*

Use the **ipv6 mtu** command to specify the maximum transmission unit (MTU) for Internet Protocol version 6 (IPv6) packets on the system management Ethernet virtual connection (EVC). Use the **no** form of this command to return to the default value.

Syntax Description

<size>	Specifies the MTU value. Valid range is **1280** to **1500** bytes.

Default Values

By default, the MTU of the EVC is set to **1280** bytes.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

In IPv6, the minimum MTU is 1280 octets. Any link that has an MTU less than 1280 octets must use link fragmentation and reassembly that is transparent to IPv6 (for example, the Fragmentation Header). Sources in the IPv6 network are expected to perform path maximum transmission unit (PMTU) discovery to send packets larger than 1280 octets. PMTU works in the following manner: First, the sending node assumes the link MTU of the interface from which the traffic is being forwarded and then sends the IPv6 packet at the link MTU size. If a router on the path is unable to forward the packet, it sends an ICMP *Packet Too Big* message back to the sending node containing the link MTU of the link on which the packet forwarding failed. The sending node then rests the PMTU to the value of the MTU field in the Internet Control Message Protocol version 6 (ICMPv6) *Packet Too Big* message, and the packet is resent.

The MTU for IPv6 packets can be set on a per-EVC basis. There are two methods for setting MTUs for EVCs if required: one for Layer 3 EVCs, and one for the underlying Layer 1 and Layer 2 EVCs. For all EVC types, use the **ipv6 mtu** *<size>* command to specify the IPv6 MTU in bytes from the EVC's configuration mode. The minimum MTU setting for IPv6 is **1280** bytes, and the maximum is **1500** bytes. The IPv6 MTU value is independent of the IPv4 MTU setting (set with the command *ip mtu <size> on page 3865*).

When the EVC is forwarding the IPv6 packet as a router, if the packet size exceeds the IPv6 MTU of the egress EVC, the packet is dropped and ICMPv6 *Packet Too Big* message is sent to the source. When originating an IPv6 packet from the local IPv6 stack, and the packet is larger than the IPv6 MTU of the egress EVC, the packet is fragmented and sent.

Usage Examples

The following example specifies the IPv6 MTU value for the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 mtu 1350**

ipv6 nd advertisement-interval

Use the **ipv6 nd advertisement-interval** command to specify that the Advertisement Interval Option is sent in Internet Protocol version 6 (IPv6) router advertisement (RA) messages from the router. This command is effectual only when the system management Ethernet virtual connection (EVC) is in router mode. Use the **no** form of this command to return to the default interval.

Syntax Description

No subcommands.

Default Values

By default, Advertisement Interval Options are not sent in RA messages.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

Sending the Advertisement Interval Option should be enabled when the router is functioning in a mobile IP environment to aid movement detection by mobile nodes. This option contains the current value of the maximum router advertisement interval configured using the command *ipv6 nd ra interval on page 3906*.

Usage Examples

The following example specifies that the EVC include Advertisement Interval Options in RA messages sent from the router:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 nd advertisement-interval**

ipv6 nd cache max-incomplete <*number*>

Use the **ipv6 nd cache max-incomplete** command to specify the maximum number of incomplete entries the Neighbor Discovery (ND) cache retains. Use the **no** form of this command to return to the default value.

Syntax Description

<*number*>	Specifies the number of incomplete ND entries to retain in the cache. Valid range is **1** to **321**.

Default Values

By default, the incomplete ND entries can take at maximum one-third of the possible ND cache entries (varies by product).

Command History

Release R11.10.0	Command was introduced.

Usage Examples

The following example specifies that the interface stores **150** incomplete entries in the ND cache:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 nd cache max-incomplete 150**

ipv6 nd dad attempts *<number>*

Use the **ipv6 nd dad attempts** command to specify the number of neighbor solicitation (NS) messages sent by the system management Ethernet virtual connection (EVC) when performing Internet Protocol version 6 (IPv6) duplicate address detection (DAD). This command is effectual when the EVC is in either host or router mode. Use the **no** form of this command to return to the default value.

Syntax Description

<number>	Specifies the number of NS messages that will be sent. Range is **0** to **10** messages. A value of **0** disables DAD on the interface.

Default Values

By default, the EVC sends **1** NS message.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

DAD is used by devices to determine if IPv6 addresses are unique before they are applied to EVCs. DAD is used in NS messages to detect duplicate unicast addresses. The Target Address fields in the NS messages are set to the IPv6 address for which duplication is being detected. Destination IPv6 addresses for DAD in NS messages are the solicited-node multicast version of the address being tested. Source IPv6 addresses for DAD are set to the IPv6 unspecified address (::). Once the IPv6 address is determined by DAD to be unique, it can be applied to the EVC on the node.

DAD in AOS is performed when an EVC transitions state from DOWN to UP or when manually configuring an address. When performing DAD because of an interface transition, DAD will happen immediately after the EVC transition and again 40 seconds later to cooperate with the port being connected to an Ethernet switch.

Usage Examples

The following example specifies that **3** NS messages are sent by the EVC when performing DAD:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 nd dad attempts 3**

ipv6 nd generate-packet

Use the **ipv6 nd generate-packet** command to generate and send test packets from the Ethernet virtual connection (EVC) for Internet Protocol version 6 (IPv6) Neighbor Discovery (ND) messages. Use the **no** form of this command to disable packet generation. Variations of this command include:

ipv6 nd generate-packet neighbor-advertisement <*source ipv6 address*> <*destination ipv6 address*> <*Layer 2 address*>
ipv6 nd generate-packet neighbor-solicitation <*source ipv6 address*> <*destination ipv6 address*> <*target ipv6 address*>
ipv6 nd generate-packet router-advertisement

Syntax Description

neighbor-advertisement	Specifies that test packets are generated for neighbor advertisement (NA) messages.
neighbor-solicitation	Specifies that test packets are generated for neighbor solicitation (NS) messages.
router-advertisement	Specifies that test packets are generated for router advertisement (RA) messages.
<*source ipv6 address*>	Specifies the source address of the test packet. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<*destination ipv6 address*>	Specifies the destination address of the test packet. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.
<*Layer 2 address*>	Specifies the Layer 2 destination address for the test packet using a medium access control (MAC) address. MAC addresses should be expressed in the following format xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**) or 0xABCDEF format (for example, **1x234567**).
<*target ipv6 address*>	Specifies the IPv6 address of the target neighbor for NS test packets. Specify an IPv6 address in colon hexadecimal format (**X:X:X:X::X**), for example, **2001:DB8:1::1**.

Default Values

By default, test packets are not generated for ND messages.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example generates test packets for RA messages on the EVC:

(config)**#system-management-evc**
(config-system-mgmt-evc)**#ipv6 nd generate-packet router-advertisement**

ipv6 nd managed-config-flag

Use the **ipv6 nd managed-config-flag** command to specify the M flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. The M flag instructs hosts receiving the RA that they can use stateful Dynamic Host Configuration Protocol version 6 (DHCPv6) to configure addresses and nonaddress information. Use the **no** form of this command to disable the setting of the M flag.

Syntax Description

No subcommands.

Default Values

By default, the M flag is not set in RAs.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management Ethernet virtual connection (EVC).

Functional Notes

If you specify that the M flag is set in RA messages, you do not need to set the 0 flag (it becomes redundant).

Usage Examples

The following example sets the M flag for RA messages sent by the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 nd managed-config-flag**

ipv6 nd ns-interval *<value>*

Use the **ipv6 nd ns-interval** command to specify the interval between transmission of certain Internet Protocol version 6 (IPv6) Neighbor Discovery (ND) messages and to control what ND value is advertised in router advertisement (RA) messages. This command is effectual whether the system management Ethernet virtual connection (EVC) is in host or router mode. Use the **no** form of this command to return the interval to the default value.

Syntax Description

<value>	Specifies the time (in milliseconds) between neighbor message transmissions. Valid range is **1000** to **3600000** ms.

Default Values

By default, the interval is set to **1000** ms for internal use by the router and **0** (unspecified) is sent in RA messages.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

This command controls the spacing of neighbor solicitation (NS) messages for functions such as address resolution, reachability detection, and duplicate address detection (DAD). For DAD it also serves as the amount of time after the last transmission before the detection phase of autoconfiguration terminates. In addition, the command controls the interval between unsolicited neighbor advertisement (NA) messages.

Usage Examples

The following example changes the interval between RA messages sent from the EVC to **2000** ms:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 nd ns-interval 2000**

ipv6 nd other-config-flag

Use the **ipv6 nd other-config-flag** command to specify the O flag in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the system management Ethernet virtual connection (EVC) is in router mode. When the O flag is set, hosts receiving the RA messages are instructed that they may use stateless Dynamic Host Configuration Protocol version 6 (DHCPv6) to receive information that is not IPv6 addressing information, and to use some other method (whether through manual configuration, stateless address autoconfiguration (SLAAC), etc.) for addressing information. Use the **no** form of this command to disable the O flag setting.

Syntax Description

No subcommands.

Default Values

By default, the O flag is not set in RA messages.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

If the M flag is set for RA messages, you do not need to set the O flag.

Usage Examples

The following example sets the O flag in RA messages from the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 nd other-config-flag**

ipv6 nd prefix

Use the **ipv6 nd prefix** command to specify the Internet Protocol version 6 (IPv6) address prefixes used in router advertisement (RA) messages sent from the system management Ethernet virtual connection (EVC). Use the **no** form of this command to remove the specified prefix configuration from the EVC. Variations of this command include:

ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite]**
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [no-advertise] [**<*valid lifetime*> | **infinite]** <*preferred lifetime* | **infinite**>
ipv6 nd prefix [named-prefix <*prefix name*>**] [**<*ipv6 prefix/prefix-length*> | **default] [**<*valid lifetime*> | **infinite] [**<*preferred lifetime*> | **infinite] [no-advertise] [no-autoconfig] [no-rtr-address] [no-onlink] [off-link]**

Syntax Description

named-prefix <*prefix name*>	Optional. Specifies that a named prefix is used in RA messages. When a named prefix is used, the default prefix cannot be used.
<*ipv6 prefix/prefix-length*>	Specifies the IPv6 prefix and length to be advertised. Pv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
default	Specifies the default values for the IPv6 prefix parameters. Refer to the *Functional Notes* below for more information.
<*valid lifetime*>	Optional. Specifies the valid lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
<*preferred lifetime*>	Optional. Specifies the preferred lifetime to advertise for this route in each RA message. Range is **0** to **4294967295** seconds.
infinite	Optional. Specifies that the the valid and preferred lifetimes of the prefix do not expire.
no-advertise	Optional. Specifies that the prefix is excluded from the RA message.
no-autoconfig	Optional. Sets the A flag in the RA message to **0**, indicating that hosts may not create an address for this prefix using stateless address autoconfiguration (SLAAC). This parameter only affects hosts receiving the RA message, it does not affect the operation of the local router.
no-rtr-address	Optional. Sets the R flag in the RA message to **0** and specifies the full router IPv6 address is not included in the RA message.
no-onlink	Optional. Specifies that the IPv6 prefix in the RA message is not to be used for on-link determination.
off-link	Optional. Sets the L flag value to **0** in RA messages, which indicates the RA makes no statement about the on-link or off-link properties of the IPv6 prefix.

Default Values

By default, all prefixes derived from the EVC's configured IPv6 addresses are advertised using the system default values.

By default, the valid lifetime advertised for a prefix is **2592000** seconds and the preferred lifetime advertised is **604800** seconds.

By default, the L flag is set to **1**, the R flag is set to **1**, and the A flag is set to **1**.

Command History

Release 18.1	Command was introduced.
Release R10.9.0	Command was expanded to include the **named-prefix** and *<prefix name>* options.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

This command works for both routers and hosts, but in host implementations it is used to manually add on-link prefixes that do not have an IPv6 address or to make off-link a prefix generated by an IPv6 address command. Hosts do not send RA messages, so the command only adds prefixes to RA messages when the EVC is in router mode. This command can also be used to change the defaults used on configured prefixes when all options are not specified.

Changing the prefix defaults will affect prefixes derived from configured IPv6 addresses, as well as prefixes configured using the ***ipv6 nd prefix*** *command.*

Prefixes advertised can be a subset or a superset of the prefixes derived from the IPv6 addresses configured on the EVC. Prefixes for IPv6 addresses configured on a router EVC are automatically eligible to be advertised on that interface using system or configured default values without having to enter a prefix command. To impose additional controls on those prefixes, an entry must be made using this command with the desired settings.

The **default** parameter is used to change the default settings for the IPv6 prefix parameters. Changing these settings can be useful when multiple prefixes are implemented that will use the same set of parameters. When configuring IPv6 prefixes, the prefix default values are only used if no other parameters are specified after specifying the IPv6 prefix and length (for example, **ipv6 nd prefix 2001:DB8::/64**). If additional parameters are specified, any unspecified parameters use the system default values rather than the configured default values. When the default values are changed, any prefix that uses them will also change. Using this command to change prefix default values also affects prefixes derived from configured IPv6 addresses on the EVC.

The optional *<valid lifetime>* parameter specifies the valid lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep this prefix until the valid lifetime expires.

The optional <*preferred lifetime*> parameter specifies the preferred lifetime to advertise for this route in each advertisement. Hosts will reset the lifetime to this value each time the route is advertised, and they will keep the prefix in the preferred state during this time period. After the preferred time period expires, the prefix transitions to the deprecated state where it remains until the valid lifetime expires and the route is removed. The <*preferred lifetime*> value must be set to be shorter than the <*valid lifetime*> value.

The optional **off-link** parameter sets the L flag (on-link flag) value to **0** in RA messages. When the L flag is set to 0, the advertisement makes no statement about on-link or off-link properties of the prefix. When the L flag is set, the prefix is considered on-link and locally reachable by hosts on the link (meaning a router is not needed). Hosts attached to the link will add on-link prefixes to their prefix list or route table. When off-link is not specified, a connected route is added to the route table of this router for this prefix. When off-link is specified, no route is added to the route table. By default, prefixes are advertised as on-link with the L flag set to 1.

The optional **no-rtr-address** parameter sets the R flag (router flag) of the RA to **0** and does not include the full router address in the advertisement. The router address is typically included in the RA to assist in Mobile IP environments. By default, the R flag is set to 1 and the router address is sent in RA messages.

The optional **no-autoconfig** parameter sets the A flag of the RA to **0**, indicating that hosts may not create an address for this prefix using SLAAC. If the A flag is set to **1** (the default setting), hosts perform SLAAC to generate an address based on the prefix. This parameter only affects hosts receiving the RA, it does not effect the operation of the local router.

The optional **no-advertise** parameter specifies that the prefix is excluded from RA messages. By default, the prefix is included in RA messages. The **no-onlink** parameter informs the router that the prefix is not to be used for on-link determination.

By default, all prefixes derived from the EVC's configured IPv6 addresses are advertised using the system default values.

Usage Examples

The following example specifies that the IPv6 prefix **2001:DB8:3F::/48** has an infinite valid and preferred lifetime advertised in RA messages sent from the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 nd prefix 2001:DB8:3F::/48 infinite infinite**

The following example changes the default values and behaviors of prefixes included in RA messages to infinite valid and preferred lifetimes, and specifies that the on- or off-link state of the prefix is not included in the RA and that hosts receiving the RA may not use the prefix for creating an IPv6 address:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 nd prefix default infinite infinite off-link no-autoconfig**

ipv6 nd purge-timer <*value*>

Use the **ipv6 nd purge-timer** command to specify the maximum amount of time an unused Internet Protocol version 6 (IPv6) neighbor entry remains in the neighbor cache. This command is effectual for the system management Ethernet virtual connection (EVC) in either host or router mode. Use the **no** form of this command to return the purging interval to the default value.

Syntax Description

<*value*>	Specifies the neighbor cache entry storage time in minutes. Valid range is **10** to **1440** minutes.

Default Values

By default, idle (STALE) neighbor cache entries are cleared after **1440** minutes (24 hours).

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

This command applies to EVCs in either router or host mode. A neighbor entry is typically purged when neighbor unreachability detection (NUD) is invoked and the neighbor is determined to no longer be reachable. However, NUD is not performed on idle (STALE) neighbor entries, so this command provides a method for purging unused entries after a specified amount of time.

Usage Examples

The following example specifies that idle neighbor entries in the neighbor cache are removed after **800** minutes:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 nd purge-timer 800**

ipv6 nd ra interval

Use the **ipv6 nd ra interval** command to specify the interval between transmission of Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the system management Ethernet virtual connection (EVC) is in router mode. Use the **no** form of this command to return to the default value. Variations of this command include:

ipv6 nd ra interval *<max time>*
ipv6 nd ra interval *<max time> <min time>*
ipv6 nd ra interval msec *<max time>*
ipv6 nd ra interval msec *<max time> <min time>*

Syntax Description

<max time>	Specifies the maximum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **4** to **1800** seconds and **70** to **1800000** ms.
<min time>	Optional. Specifies the minimum interval between RA message transmission. Time can be specified in seconds or milliseconds. Range is **3** seconds to 75 percent of the configured maximum time value in seconds, or **30** ms to 75 percent of the configured maximum time value in ms.
msec	Optional. Specifies that the time values are in milliseconds.

Default Values

By default, the interval is set in seconds and has a maximum interval time of **200** seconds and a minimum interval time of 75 percent of the maximum seconds value, but not less than **3** seconds.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

If this router is used as a default router, the interval between RA messages should not be set to a larger value than the RA lifetime set by the command *ipv6 nd ra lifetime <value> on page 3907*, which has a default value of **1800** seconds.

Usage Examples

The following example specifies that the maximum interval in seconds between RA message transmissions is **300**:

```
(config)#system-management-evc
(config-sys-mgmt-evc)#ipv6 nd ra interval 300
```

ipv6 nd ra lifetime <*value*>

Use the **ipv6 nd ra lifetime** command to specify the router lifetime advertised in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command is only effectual when the system management Ethernet virtual connection (EVC) is in router mode. Use the **no** form of this command to return to the default setting. Variations of this command include:

ipv6 nd ra lifetime <*value*>
ipv6 nd ra lifetime default-route

Syntax Description

<*value*>	Specifies the router lifetime in seconds. Range is **0** to **9000** seconds. A value of **0** indicates this is not a default router. A value other than 0 indicates to other nodes that this router can be used as a default router.
default-route	Specifies the RA lifetime is **0** if no default route exists on any IPv6 interface.

Default Values

By default, the router lifetime is set to **1800** seconds.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.
Release R11.5.0	Command was expanded to include the **default-route** parameter.

Functional Notes

A value other than **0** for a router lifetime should be larger than the router advertisement interval specified in the command *ipv6 nd ra interval on page 3906*.

Usage Examples

In the following example, the router lifetime advertised in RA messages is **3000** seconds:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 nd ra lifetime 3000**

ipv6 nd ra reachable-time *<value>*

Use the **ipv6 nd ra reachable-time** command to specify the value advertised for reachable time in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. This command also specifies the internal base reachable time used by the router. This command is effectual for the system management Ethernet virtual connection (EVC) in either host or router mode. Use the **no** form of this command to return the reachability value to the default setting.

Syntax Description

<value>	Specifies the reachability time in milliseconds. Range is **0** to **3600000** ms. A value of **0** indicates the reachable time is unspecified.

Default Values

By default, the router advertises a reachability time of **0** ms and uses an internal value of **30000** ms.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

This command is effectual for EVCs in either router or host mode. For hosts, this value sets the internal reachable time used by the host if no RAs are received specifying a different value. For routers, the value indicates the amount of time a device is considered reachable after having received a reachability confirmation in neighbor unreachabililty detection (NUD).

Usage Examples

The following example specifies that a reachability time of **50000** ms is advertised in RA messages:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 nd ra reachable-time 50000**

ipv6 nd ra suppress

Use the **ipv6 nd ra suppress** command to specify whether Internet Protocol version 6 (IPv6) router advertisement (RA) messages will be suppressed. This command is only effectual when the system management Ethernet virtual connection (EVC) in router mode. Use the **no** form of this command to begin sending RA messages.

Syntax Description

No subcommands.

Default Values

By default, RA messages are not suppressed. When IPv6 routing is not enabled on the router, or when implemented in a host-only mode, the default setting is to suppress advertisements on all EVC types.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management EVC.

Usage Examples

The following example suppresses RA messages on the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 nd ra suppress**

ipv6 nd router-preference

Use the **ipv6 nd router-preference** command to specify the default router preference value set in Internet Protocol version 6 (IPv6) router advertisement (RA) messages. Setting this preference helps the receivers of RA messages to determine the preference of one router over another as a default router in environments with multiple routers. Use the **no** form of this command to return the preference to the default setting. Variations of this command include:

ipv6 nd router-preference high
ipv6 nd router-preference low
ipv6 nd router-preference medium

Syntax Description

high	Specifies the preference value is high.
low	Specifies the preference value is low.
medium	Specifies the preference value is medium.

Default Values

By default, the router preference is set to medium.

Command History

Release 18.1	Command was introduced.
Release R10.10.0	Command was expanded to include the system management Ethernet virtual connection (EVC).

Usage Examples

The following example specifies that the advertised default router preference is high:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 nd router-preference high**

ipv6 route-cache

Use the **ipv6 route-cache** command to enable Internet Protocol version 6 (IPv6) fast-cache switching on the system management Ethernet virtual connection (EVC). Use the **no** form of this command to disable fast-cache switching and return to process switching mode.

Syntax Description

No subcommands.

Default Values

By default, fast-cache switching is enabled on all Ethernet and virtual Frame Relay subinterfaces. IP route cache is enabled for all virtual Point-to-Point Protocol (PPP) interfaces.

Command History

Release 18.2	Command was introduced.
Release R10.7.0	Command was expanded to include the tunnel interface.
Release R10.10.0	Command was expanded to include the system management EVC.

Functional Notes

Fast switching allows an EVC to provide optimum performance when processing IPv6 traffic.

Usage Examples

The following example enables IPv6 fast switching on the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#ipv6 route-cache**

max-reserved-bandwidth *<value>*

Use the **max-reserved-bandwidth** command to specify the percentage of interface bandwidth reserved for use in user-defined (priority or class-based) queues. The remainder of the interface bandwidth is reserved for system-critical traffic and is not available to user-defined queues. Use the **no** form of this command to restore the default value.

Reserving a portion of the interface bandwidth for system-critical traffic is necessary for proper operation. Specifying the entire interface bandwidth for use in user-defined queues can cause undesirable operation.

Syntax Description

<value>	Specifies the maximum percentage of bandwidth to reserve for quality of service (QoS). This setting is configured as a percentage of the total interface speed. Range is **1** to **100** percent.

Default Values

By default, **max-reserved-bandwidth** is set to **75** percent, which reserves 25 percent of the interface bandwidth for system-critical traffic.

Command History

Release 11.1	Command was introduced.
Release 15.1	Command was expanded to include the bridged virtual interfaces (BVIs).
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet subinterface.
Release R11.1.0	Command was expanded to include the system management Ethernet virtual connection (EVC) and the system control EVC.

Usage Examples

The following example specifies **85** percent of the bandwidth on the system management EVC be available for use in user-defined queues:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#max-reserved-bandwidth 85**

men-pri

Use the **men-pri** command to specify the default value of the S-tag used in the system management Ethernet virtual connection (EVC) communication. Use the **no** form of this command to return to the default setting. Variations of this command include:

men-pri inherit
men-pri <*value*>

Syntax Description

inherit	Specifies that the S-tag priority value is inherited from the customer equipment (CE) virtual local area network (VLAN).
<*value*>	Specifies a priority value for the S-tag. Valid range is **0** to **7**.

Default Values

By default, the S-tag is set to **inherit**.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies that the S-tag has a priority of **5** on the EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#men-pri 5**

qos-policy

Use the **qos-policy** command to apply a previously configured quality of service (QoS) map to incoming or outgoing packets on an interface. Use the **no** form of this command to remove the map from the interface. Variations of this command include:

qos-policy in <*name*>
qos-policy out <*name*>

Syntax Description

<*name*>	Specifies the name of a previously created QoS map (refer to *qos map <name> <number> on page 1673* for more information).
in	Assigns a QoS map to this interface's input.
out	Assigns a QoS map to this interface's output.

Default Values

No default values are necessary for this command.

Command History

Release 9.1	Command was introduced.
Release 15.1	Command was expanded to include the **in** parameter.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the system control Ethernet virtual connection (EVC) and system management EVC.

Functional Notes

When a QoS policy is applied to an interface, it may be disabled if the interface bandwidth is not adequate to support the requested bandwidth on the map set. Once the bandwidth problem is resolved, the map will work again. The bandwidth will be rechecked on any of the following changes:

1. A priority or class-based entry is added to, deleted from, or changed in a QoS map set.
2. The interface bandwidth is changed by the **bandwidth** command on the interface.
3. A QoS policy is applied to an interface.
4. A cross connect is created that includes an interface with a QoS policy.
5. The interface queuing method is changed to fair queue to use weighted fair queuing.
6. The interface operational status changes.
7. The interface bandwidth changes for other reasons (e.g., when asymmetric digital subscriber line (ADSL) finishes training).

In order to prevent the map from being disabled in cases of temporary inadequate bandwidth (e.g., a single link goes down in a dual T1 multilink configuration where the map requests more than one T1's worth of bandwidth), the QoS map uses the maximum theoretical bandwidth on an interface, not the actual bandwidth at that time. This actually helps QoS keep higher priority class-based traffic working better than best-effort traffic when the bandwidth drops.

Usage Examples

The following example applies the QoS map **VOICEMAP** to the system management EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#qos-policy out VOICEMAP**

rtp quality-monitoring

Use the **rtp quality-monitoring** command to enable voice quality monitoring (VQM) of the Realtime Transport Protocol (RTP) voice stream packets on this interface. If the global command (**ip rtp quality-monitoring**) is disabled when this command is issued, the system will return the following warning: "Applied but not used, you must globally enable **ip rtp quality-monitoring** to use VQM." Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, VQM is enabled on all wide area network (WAN) and local area network (LAN) interfaces.

Command History

Release 17.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet interface.
Release R11.2.0	Command was expanded to include the system control Ethernet virtual connection (EVC) and system management EVC.

Usage Examples

The following example enables RTP quality monitoring on the system management EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#rtp quality-monitoring**

snmp trap

Use the **snmp trap** command to enable all supported Simple Network Management Protocol (SNMP) traps on the interface. Us the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, all interfaces (except virtual Frame Relay interfaces and subinterfaces) have SNMP traps enabled.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the port channel and virtual local area network (VLAN) interfaces.
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 16.1	Command was expanded to the tunnel interface.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the single-pair high-speed digital subscriber line (SHDSL) interface, Ethernet in the first mile (EFM) group, system management Ethernet virtual connection (EVC) and the system control EVC.

Usage Examples

The following example enables SNMP capability on the system management EVC:

```
(config)#system-management-evc
(config-sys-mgmt-evc)#snmp trap
```

snmp trap link-status

Use the **snmp trap link-status** command to control the Simple Network Management Protocol (SNMP) variable ifLinkUpDownTrapEnable (RFC 2863) to enable (or disable) the interface to send SNMP traps when there is an interface status change. Use the **no** form of this command to disable this trap.

Syntax Description

No subcommands.

Default Values

By default, the ifLinkUpDownTrapEnable object identifier (OID) is enabled for all interfaces except virtual Frame Relay interfaces.

Command History

Release 1.1	Command was introduced.
Release 5.1	Command was expanded to include the Ethernet subinterfaces and Gigabit Ethernet interfaces.
Release 6.1	Command was expanded to include the E1, port channel, T3, and virtual local area network (VLAN) interfaces.
Release 7.1	Command was expanded to the high speed serial interface (HSSI).
Release 8.1	Command was expanded to the asynchronous transfer mode (ATM) interface.
Release 9.1	Command was expanded to the high level data link control (HDLC) interface.
Release 11.1	Command was expanded to the demand interface.
Release 16.1	Command was expanded to the tunnel interface.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the single-pair high-speed digital subscriber line (SHDSL) interface, Ethernet in the first mile (EFM) group, system management Ethernet virtual connection (EVC) and the system control EVC.

Functional Notes

The **snmp trap link-status** command is used to control the RFC 2863 ifLinkUpDownTrapEnable OID (OID number 1.3.6.1.2.1.31.1.1.1.14.0).

Usage Examples

The following example disables the link-status trap on the system management EVC:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#no snmp trap link-status**

s-tag

Use the **s-tag** command to specify the virtual local area network (VLAN) ID used by the service provider for the system management Ethernet virtual connection (EVC). This VLAN ID, the s-tag, is used by the carrier to mark outbound traffic from this EVC in the Metro Ethernet network (MEN). Use the **no** form of this command to return the s-tag value to the default. Variations of this command include:

s-tag <*vlan id*>
s-tag none

Syntax Description

<*vlan id*>	Specifies ID of the service provider VLAN. Valid range is **1** to **4094**.
none	Specifies no S-tag is used.

Default Values

By default, the s-tag is **0**, which indicates the traffic on the EVC is untagged.

Command History

Release A3.01	Command was introduced.
Release R10.10.0	Command was expanded to include the **none** parameter and the system management EVC.

Usage Examples

The following example specifies the s-tag for traffic outbound on the EVC is **20**:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#s-tag 20**

traffic-shape rate *<value>*

Use the **traffic-shape rate** command to specify and enforce an output bandwidth for the system management Ethernet virtual connection (EVC). Variations of this command include:

traffic-shape rate *<value>*
traffic-shape rate *<value>* **count-eth-overhead**
traffic-shape rate *<value>* *<burst>*
traffic-shape rate *<value>* *<burst>* **count-eth-overhead**

Syntax Description

<value>	Specifies the rate (in bits per second) at which the interface should be shaped.
<burst>	Optional. Specifies the allowed burst in bytes. By default, the burst is specified as the rate divided by 5 and represents the number of bytes that would flow within 200 ms.
count-eth-overhead	Optional. Indicates to include the Ethernet header overhead bytes when determining packet size.

Default Values

By default, traffic-shaping rate is disabled.

Command History

Release 10.1	Command was introduced.
Release A3.01	Command was expanded to include the Metro Ethernet Forum (MEF) Ethernet Interface.
Release R11.1.0	Command was expanded to include the **count-eth-overhead** parameter, system management Ethernet virtual connection (EVC) and the system control EVC.

Functional Notes

Traffic shaping can be used to limit an Ethernet segment to a particular rate or to specify use of quality of service (QoS) on Ethernet or VLAN interfaces.

Usage Examples

The following example sets the outbound rate of traffic on the system management EVC to 128 kbps:

(config)**#system-management-evc**
(config-sys-mgmt-evc)**#traffic-shape rate 128000**

vrf forwarding <*name*>

Use the **vrf forwarding** command to assign an Ethernet virtual connection (EVC) to a specific virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the EVC from the named VRF instance and assign it to the unnamed default VRF.

Keep in mind that changing an EVC's VRF association will clear all IP-related settings on that EVC.

Syntax Description

<name>	Specifies the name of the VRF to which to assign the EVC.

Default Values

By default, EVCs are associated with the default VRF that is unnumbered.

Command History

Release 16.1	Command was introduced.
Release 17.8	The keyword **ip** was removed from this command.
Release R10.10.0	Command was expanded to include the system control and system management EVCs.

Functional Notes

VRF instances must be created first before an EVC can be assigned. An EVC can only be assigned to one VRF, but multiple EVCs can be assigned to the same VRF.

An EVC will only forward IP traffic that matches its associated VRF.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured.

Usage Examples

The following example assigns the system control EVC to the VRF instance named **RED**:

(config)**#system-control-evc**
(config-sys-cntrl-evc)**#vrf forwarding RED**

Y.1731 COMMAND SETS

This section includes the following command sets:

ONE-WAY FRAME DELAY MONITORING SESSION COMMAND SET

A one-way frame delay performance monitoring session can be configured to run between any two Y.1731 maintenance entity group (MEG) endpoints (MEPs). This session monitors frame delays in a one way transmission between a source MEP and a target MEP. The source MEP sends a one-way delay measurement message (1DM) frame to the target MEP, which terminates the 1DM and calculates the one-way frame delay. Two timestamps are used for one-way frame delay messaging. The source MEP applies a transmit timestamp to the outgoing 1DM frame and the target MEP applies a receive timestamp upon receiving the 1DM frame.

A local MEP can run several one-way frame delay performance monitoring sessions between itself and the target MEP as long as each session uses a different priority value. This allows the target MEP to simultaneously monitor frame delay performance at different classes of service. If the two MEPs are synchronized based on the time of day, the following measurements can be performed:

- Minimum one-way frame delay
- Maximum one-way frame delay
- Mean one-way frame delay
- Maximum one-way frame delay variation (reference packet)
- Maximum one-way frame delay variation (inter-packet)

The one-way frame delay command set is used to configure the transmit attributes of the one-way frame delay performance monitoring session. The One-way Frame Delay Configuration mode is accessed from the Local MEP Configuration mode (refer to *Y.1731 Local MEP Command Set on page 3950*) using the **frame-delay one-way** <*mep id* | *target mac address*> **priority** <*value*> command. To access this configuration mode, enter the command as follows:

```
(config)#ethernet y1731 meg char-string MEG1 level 3
(config-y1731-meg MEG1)#local-mep 3
MEP 3 created
(config-y1731-mep3)#frame-delay one-way 500 priority 1
(config-y1731-frame-delay)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide:

cross-connect on page 76
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order:

data <data> on page 3924
interval <interval> on page 3925
size <bytes> on page 3926

data <*data*>

Use the **data** command to set the transmit data pattern for the one-way frame delay monitoring session. Use the **no** form of this command to return to the default value.

Syntax Description

<*data*>	Specifies the hexadecimal pattern used to fill the data type-length value (TLV). Valid range is **0x0000** to **0xFFFF**.

Default Values

By default, the data pattern is set to **0x0000**.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example sets the transmit data pattern for the one-way frame delay monitoring session to **0x1111**:

(config-y1731-mep3)**#frame-delay one-way 500 priority 1**
(config-y1731-frame-delay)**#data 0x1111**

interval *<interval>*

Use the **interval** command to specify the time in milliseconds between one-way delay measurement message (1DM) transmissions. Use the **no** form of this command to return to the default value.

Syntax Description

<interval>	Specifies the time in milliseconds between 1DM transmissions. Valid range is **100** to **10000** ms.

Default Values

By default, the interval is set to **1000** ms.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies the interval between 1DM transmissions is **3500** ms:

(config-y1731-mep3)**#frame-delay one-way 500 priority 1**
(config-y1731-frame-delay)**#interval 3500**

size <*bytes*>

Use the **size** command to specify the size of the one-way delay measurement message (1DM) frame. Use the **no** form of this command to return to the default value.

Syntax Description

<*bytes*>	Specifies the size of the 1DM frame. If no size is specified, 1DM frames are zero-padded up to 64 bytes. If the size is specified, a data type-length value (TLV) is used to ensure the 1DM frame is the correct length. Valid range is **0**, or **64** to **2000** bytes.

Default Values

By default, the size is set to **0** bytes.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example sets the size of the 1DM frame to **100** bytes:

(config-y1731-mep3)**#frame-delay one-way 500 priority 1**
(config-y1731-frame-delay)**#size 100**

TWO-WAY FRAME DELAY MONITORING SESSION COMMAND SET

A two-way frame delay performance monitoring session can be configured to run between any two Y.1731 maintenance entity group (MEG) endpoints (MEPs). This session monitors frame delays in a two-way transmission between a source MEP and a target MEP. The source MEP sends a delay measurement message (DMM) to the target MEP, which replies with a delay measurement reply (DMR). Four timestamps are used for two-way frame delay messaging. In this process, the target MEP applies timestamps to the DMR frame indicating its arrival and transmission time. The source MEP then removes the processing time at the target MEP and only measures the time the DMM/DMR frame was on the wire.

A local MEP can run several two-way frame delay performance monitoring sessions between itself and the target MEP as long as each session uses a different priority value. This allows the target MEP to simultaneously monitor frame delay performance at different classes of service. The two-way frame delay monitoring session can monitor the following metrics:

- Minimum two-way frame delay
- Maximum two-way frame delay
- Mean two-way frame delay
- Maximum two-way frame delay variation (reference packet)
- Maximum two-way frame delay variation (inter-packet)

If the two MEPs are synchronized based on the time of day, the following additional measurements can be performed in both egress and ingress directions:

- Minimum one-way frame delay
- Maximum one-way frame delay
- Mean one-way frame delay

The two-way frame delay command set is used to configure the transmit attributes of the two-way frame delay performance monitoring session. The Two-Way Frame Delay Configuration mode is accessed from the Local MEP Configuration mode (refer to *Y.1731 Local MEP Command Set on page 3950*) using the **frame-delay two-way** <*mep id* | *target mac address*> **priority** <*value*> command. To access this configuration mode, enter the command as follows:

```
(config)#ethernet y1731 meg char-string MEG1 level 3
(config-y1731-meg MEG1)#local-mep 3
MEP 3 created
(config-y1731-mep3)#frame-delay two-way 500 priority 1
(config-y1731-frame-delay)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide:

cross-connect on page 76
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order:

bulk-data-export

Use the **bulk-data-export** command to determine which, if any, files are generated by the delay measurement message (DMM) performance monitoring session. The files are used to store two-way frame delay statistics. Use the **no** form of this command to disable the bulk data export feature. Variations of this command include:

bulk-data-export averaged
bulk-data-export none

Syntax Description

averaged	Specifies that statistics generated by each measurement interval are stored. Measurement intervals are specified using the command *measurement-interval on page 3932*.
none	Specifies that no statistics are stored.

Default Values

By default, no statistics are stored.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies that statistics generated by each measurement interval are stored:

(config-y1731-mep3)**#frame-delay two-way 500 priority 1**
(config-y1731-frame-delay)**#bulk-data-export averaged**

data *<data>*

Use the **data** command to set the transmit data pattern for the two-way frame delay monitoring session. Use the **no** form of this command to return to the default value.

Syntax Description

<data>	Specifies the hexadecimal pattern used to fill the data type-length value (TLV). Valid range is **0x0000** to **0xFFFF**.

Default Values

By default, the data pattern is set to **0x0000**.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example sets the transmit data pattern for the two-way frame delay monitoring session to **0x1111**:

(config-y1731-mep3)**#frame-delay two-way 500 priority 1**
(config-y1731-frame-delay)**#data 0x1111**

interval *<interval>*

Use the **interval** command to specify the time in milliseconds between delay measurement message (DMM) transmissions. Use the **no** form of this command to return to the default value.

Syntax Description

<interval>	Specifies the time in milliseconds between DMM transmissions. Valid range is **100** to **10000** ms.

Default Values

By default, the interval is set to **1000** ms.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies the interval between DMM transmissions is **3500** ms:

(config-y1731-mep3)**#frame-delay two-way 500 priority 1**
(config-y1731-frame-delay)**#interval 3500**

measurement-interval

Use the **measurement-interval** command to specify the interval over which two-way frame delay statistics are generated. The statistics calculated for a measurement interval are stored in the averaged data file (refer to the command *bulk-data-export on page 3929*). Use the **no** form of this command to return to the default setting.

measurement-interval <*measurement interval*>
measurement-interval <*measurement interval*> <*repetition time*>
measurement-interval <*measurement interval*> **none**

Syntax Description

<*measurement interval*>	Specifies the number of seconds over which frame delay statistics are generated. If used with the <*repetition-time*> variable, must be in minute intervals (multiples of 60) and less than the repetition time. Valid range is **60** to **86400** seconds.
<*repetition time*>	Specifies the number of seconds between the start time of measurement intervals. The repetition time must be at least as long as the measurement interval and must be in minute intervals (multiples of 60). Valid range is **60** to **86400** seconds.
none	Specifies that the repetition time is equal to the measurement interval.

Default Values

By default, the measurement interval is set to **60** seconds and the repetition time is set to **none**.

Command History

Release R10.10.0	Command was introduced.
Release R11.6.0	Command was expanded to include the <*repetition time*> variable and the **none** parameter.

Usage Examples

The following example specifies the measurement interval is **120** seconds and the repetition time is **240**:

(config-y1731-mep3)**#frame-delay two-way 500 priority 1**
(config-y1731-frame-delay)**#measurement-interval 120 240**

size <*bytes*>

Use the **size** command to specify the size of the delay measurement message (DMM) frame. Use the **no** form of this command to return to the default value.

Syntax Description

<*bytes*>	Specifies the size of the DMM frame. If no size is specified, DMM frames are zero-padded up to 64 bytes. If the size is specified, a data type-length value (TLV) is used to ensure the DMM frame is the correct length. Valid range is **0**, or **64** to **2000** bytes.

Default Values

By default, the size is set to **0** bytes.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example sets the size of the DMM frame to **100** bytes:

(config-y1731-mep3)**#frame-delay two-way 500 priority 1**
(config-y1731-frame-delay)**#size 100**

stop-time

Use the **stop-time** command to specify the duration of the frame delay monitoring session (in seconds). This is how long the frame delay monitoring session will run after the session begins. Use the **no** form of this command to return to the default value. Variations of this command include:

stop-time <*stop-time*>
stop-time forever

Syntax Description

<*stop-time*>	Specifies the duration in seconds of the frame delay monitoring session. Valid range is **0** to **15552000** seconds.
forever	Specifies that the frame delay monitoring session will continue until it is manually stopped.

Default Values

By default, the **stop-time** is set to **forever**.

Command History

Release R11.6.0	Command was introduced.

Usage Examples

The following example specifies a monitoring session duration of **3600** seconds:

(config-y1731-mep3)**#frame-loss synthetic single-ended 500 priority 1**
(config-y1731-frame-delay)**#stop-time 3600**

SINGLE-ENDED FRAME LOSS MONITORING SESSION COMMAND SET

In Y.1731, the Ethernet Loss Measurement Function (ETH-LM) can be used to monitor frame loss across a service by counting in-profile customer frames. This protocol operates in a single-ended mode in which one maintenance entity group (MEG) endpoint (MEP) initiates a session and sends a request to a peer MEP which sends a response. These sessions can be executed between any two MEPs in the same MEG.

During a session, a loss measurement message (LMM) is sent from the source MEP to the target MEP, which replies with a loss measurement reply (LMR). In this process, each MEP maintains a set of two counters that count the frames transmitted towards the target MEP and the frames received from that MEP. These counters increment when in-profile frames (those that are green or received with the drop eligible indicator (DEI) bit set to false) are transmitted and received. Frames counted in this process are only data frames, and not LMM or LMR frames.

A local MEP can run several single-ended frame loss performance monitoring sessions between itself and a target MEP as long as each session uses a different priority value. This allows the MEP to simultaneously monitor frame loss performance at different classes of service.

The Single-Ended Frame Loss Configuration mode is accessed from the Local MEP Configuration mode using the command *frame-loss single-ended on page 3960*. To access this configuration mode, enter the command from the Local MEP Configuration mode as shown in the following example:

```
(config)#ethernet y1731 meg char-string MEG1 level 4
(config-y1731-meg MEG1)#local-mep 3
(config-y1731-mep3)#frame-loss single-ended 500 priority 1
(config-y1731-frame-loss)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide:

cross-connect on page 76
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order:

data <*data*>

Use the **data** command to set the transmit data pattern for the single-ended frame loss monitoring session. Use the **no** form of this command to return to the default value.

Syntax Description

<*data*>	Specifies the hexadecimal pattern used to fill the data type-length value (TLV). Valid range is **0x0000** to **0xFFFF**.

Default Values

By default, the data pattern is set to **0x0000**.

Command History

Release R11.6.0	Command was introduced.

Usage Examples

The following example sets the transmit data pattern for the frame loss monitoring session to **0x1111**:

(config-y1731-mep3)**#frame-loss single-ended 500 priority 1**
(config-y1731-frame-loss)**#data 0x1111**

interval *<interval>*

Use the **interval** command to specify the time in milliseconds between loss measurement message (LMM) transmissions. Use the **no** form of this command to return to the default value.

Syntax Description

<interval>	Specifies the time in milliseconds between LMM transmissions. Valid range is **100** to **900000** ms.

Default Values

By default, the interval is set to **1000** ms.

Command History

Release R11.6.0	Command was introduced.

Usage Examples

The following example specifies the interval between LMM transmissions is **3500** ms:

(config-y1731-mep3)**#frame-loss single-ended 500 priority 1**
(config-y1731-frame-loss)**#interval 3500**

measurement-interval

Use the **measurement-interval** command to specify the interval over which frame loss statistics are generated. Use the **no** form of this command to return to the default setting.

measurement-interval <*measurement interval*>
measurement-interval <*measurement interval*> <*repetition time*>
measurement-interval <*measurement interval*> **none**

Syntax Description

<*measurement interval*>	Specifies the number of seconds over which frame loss statistics are generated. If used with the <*repetition-time*> variable, must be in minute intervals (multiples of 60) and less than the repetition time. Valid range is **60** to **86400** seconds.
<*repetition time*>	Specifies the number of seconds between the start time of measurement intervals. The repetition time must be at least as long as the measurement interval and must be in minute intervals (multiples of 60). Valid range is **60** to **86400** seconds.
none	Specifies that the repetition time is equal to the measurement interval.

Default Values

By default, the measurement interval is set to **60** seconds and the repetition time is set to **none**.

Command History

Release R11.6.0	Command was introduced.

Usage Examples

The following example specifies the measurement interval is **120** seconds and the repetition time is **240**:

(config-y1731-mep3)**#frame-loss single-ended 500 priority 1**
(config-y1731-frame-loss)**#measurement-interval 120 240**

size <*size*>

Use the **size** command to specify the size of the loss measurement message (LMM) frame. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Specifies the size in bytes of the LMM frame. If no size is specified, LMM frames are zero-padded up to 64 bytes. If the size is specified, a data type-length value (TLV) is used to ensure the LMM frame is the correct length. Valid range is **0**, or **64** to **2000** bytes.

Default Values

By default, the size is set to **0** bytes.

Command History

Release R11.6.0	Command was introduced.

Usage Examples

The following example sets the size of the LMM frame to **100** bytes:

(config-y1731-mep3)**#frame-loss single-ended 500 priority 1**
(config-y1731-frame-loss)**#size 100**

stop-time

Use the **stop-time** command to specify the duration of the frame loss monitoring session (in seconds). This is how long the frame loss monitoring session will run after the session begins. Use the **no** form of this command to return to the default value. Variations of this command include:

stop-time <*stop-time*>
stop-time forever

Syntax Description

<*stop-time*>	Specifies the duration in seconds of the frame loss monitoring session. Valid range is **0** to **15552000** seconds.
forever	Specifies that the frame loss monitoring session will continue until it is manually stopped.

Default Values

By default, the **stop-time** is set to **forever**.

Command History

Release R11.6.0	Command was introduced.

Usage Examples

The following example specifies a monitoring session duration of **3600** seconds:

(config-y1731-mep3)**#frame-loss single-ended 500 priority 1**
(config-y1731-frame-loss)**#stop-time 3600**

SINGLE-ENDED SYNTHETIC FRAME LOSS MONITORING SESSION COMMAND SET

In Y.1731, the Ethernet Loss Measurement Function (ETH-SLM) can be used to monitor frame loss across a service by counting synthetic data frames. This protocol operates in a single-ended mode in which one maintenance entity group (MEG) endpoint (MEP) initiates a session and sends a request to a peer MEP which sends a response. These sessions can be executed between any two MEPs in the same MEG.

During a session, a synthetic loss message (SLM) is sent from the source MEP to the target MEP, which replies with a synthetic loss reply (SLR). In this process, each MEP maintains a set of two counters that count the frames transmitted towards the target MEP and the frames received from that MEP. These counters increment when the synthetic frames are transmitted and received. Frames counted in this process are SLM and SLR frames, not actual data frames.

A local MEP can run several single-ended frame loss performance monitoring sessions between itself and a target MEP as long as each session uses a different priority value. This allows the MEP to simultaneously monitor frame loss performance at different classes of service. g measurement interval

The Single-Ended Synthetic Frame Loss Configuration mode is accessed from the Local MEP Configuration mode using the command *frame-loss synthetic single-ended on page 3963*. To access this configuration mode, enter the command from the Local MEP Configuration mode as shown in the following example:

```
(config)#ethernet y1731 meg char-string MEG1 level 4
(config-y1731-meg MEG1)#local-mep 3
(config-y1731-mep3)#frame-loss synthetic single-ended 500 priority 1
(config-y1731-syn-frame-loss)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide:

cross-connect on page 76
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order:

bulk-data-export

Use the **bulk-data-export** command to determine which, if any, files are generated by the synthetic loss message (SLM) performance monitoring session. The files are used to store two-way frame delay statistics. Use the **no** form of this command to disable the bulk data export feature. Variations of this command include:

bulk-data-export averaged
bulk-data-export none

Syntax Description

averaged	Specifies that statistics generated by each measurement interval are stored. Measurement intervals are specified using the command *measurement-interval on page 3947*.
none	Specifies that no statistics are stored.

Default Values

By default, no statistics are stored.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies that statistics generated by each measurement interval are stored:

(config-y1731-mep3)**#frame-loss synthetic single-ended 500 priority 1**
(config-y1731-syn-frame-loss)**#bulk-data-export averaged**

data *<data>*

Use the **data** command to set the transmit data pattern for the single-ended frame loss monitoring session. Use the **no** form of this command to return to the default value.

Syntax Description

<data>	Specifies the hexadecimal pattern used to fill the data type-length value (TLV). Valid range is **0x0000** to **0xFFFF**.

Default Values

By default, the data pattern is set to **0x0000**.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example sets the transmit data pattern for the frame loss monitoring session to **0x1111**:

(config-y1731-mep3)**#frame-loss synthetic single-ended 500 priority 1**
(config-y1731-syn-frame-loss)**#data 0x1111**

interval *<interval>*

Use the **interval** command to specify the time in milliseconds between synthetic loss message (SLM) transmissions. Use the **no** form of this command to return to the default value.

Syntax Description

<interval>	Specifies the time in milliseconds between SLM transmissions. Valid range is **100** to **900000** ms.

Default Values

By default, the interval is set to **1000** ms.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies the interval between SLM transmissions is **3500** ms:

```
(config-y1731-mep3)#frame-loss synthetic single-ended 500 priority 1
(config-y1731-syn-frame-loss)#interval 3500
```

measurement-interval

Use the **measurement-interval** command to specify the interval over which frame loss statistics are generated. The statistics calculated for a measurement interval are stored in the averaged data file (refer to the command *bulk-data-export on page 3944*). Use the **no** form of this command to return to the default setting. Variations of this command include:

measurement-interval <*measurement interval*>
measurement-interval <*measurement interval*> <*repetition time*>
measurement-interval <*measurement interval*> **none**

Syntax Description

<*measurement interval*>	Specifies the number of seconds over which frame loss statistics are generated. If used with the <*repetition-time*> variable, must be in minute intervals (multiples of 60) and less than the repetition time. Valid range is **60** to **86400** seconds.
<*repetition time*>	Specifies the number of seconds between the start time of measurement intervals. The repetition time must be at least as long as the measurement interval and must be in minute intervals (multiples of 60). Valid range is **60** to **86400** seconds.
none	Specifies that the repetition time is equal to the measurement interval.

Default Values

By default, the measurement interval is set to **60** seconds and the repetition time is set to **none**.

Command History

Release R10.10.0	Command was introduced.
Release R11.6.0	Command was expanded to include the <*repetition time*> variable and the **none** parameter.

Usage Examples

The following example specifies the measurement interval is **120** seconds and the repetition time is **240**:

(config-y1731-mep3)**#frame-loss synthetic single-ended 500 priority 1**
(config-y1731-syn-frame-loss)**#measurement-interval 120 240**

size <*size*>

Use the **size** command to specify the size of the synthetic loss message (SLM) frame. Use the **no** form of this command to return to the default value.

Syntax Description

<*size*>	Specifies the size in bytes of the SLM frame. If no size is specified, SLM frames are zero-padded up to 64 bytes. If the size is specified, a data type-length value (TLV) is used to ensure the SLM frame is the correct length. Valid range is **0**, or **64** to **2000** bytes.

Default Values

By default, the size is set to **0** bytes.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example sets the size of the SLM frame to **100** bytes:

(config-y1731-mep3)**#frame-loss synthetic single-ended 500 priority 1**
(config-y1731-syn-frame-loss)**#size 100**

stop-time

Use the **stop-time** command to specify the duration of the frame loss monitoring session (in seconds). This is how long the frame loss monitoring session will run after the session begins. Use the **no** form of this command to return to the default value. Variations of this command include:

stop-time <*stop-time*>
stop-time forever

Syntax Description

<*stop-time*>	Specifies the duration in seconds of the frame loss monitoring session. Valid range is **0** to **15552000** seconds.
forever	Specifies that the frame loss monitoring session will continue until it is manually stopped.

Default Values

By default, the **stop-time** is set to **forever**.

Command History

Release R11.6.0	Command was introduced.

Usage Examples

The following example specifies a monitoring session duration of **3600** seconds:

(config-y1731-mep3)**#frame-loss synthetic single-ended 500 priority 1**
(config-y1731-syn-frame-loss)**#stop-time 3600**

Y.1731 Local MEP Command Set

A maintenance entity group end point (MEP) is a connectivity fault management (CFM) entity that is implemented at the ends of a maintenance entity (ME) which generates and receives CFM protocol data units (PDUs). MEPs drop, pass, or process CFM packets ingressing on the ports to which they are assigned. If the ingressing CFM packets have a lower maintenance level than the MEP, the packets are dropped. If the MEP receives CFM packets that have a higher maintenance level, the packets are passed transparently. CFM packets with a maintenance domain equal to the MEP are processed. MEPs also ensure the continuity of the maintenance association (MA) to which they belong by periodically transmitting continuity check messages (CCMs) to other MEPs in the MA.

To access the Y.1731 local MEP command set, enter the **local-mep** <*id*> command from the Y.1731 MEG configuration mode prompt, and then enter the appropriate Y.1731 application command as follows (refer to the command *local-mep <id> on page 3970*):

```
(config)#ethernet y1731 meg char-string MEG1 level 1
(config-y1731-meg MEG1)#local-mep 3
MEP 3 created
(config-y1731-mep3)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

ccm frame-loss on page 3951
ccm-enabled on page 3952
ccm-enabled track <name> on page 3953
direction on page 3954
force-rdi track <name> on page 3955

ccm frame-loss

Use the **ccm frame-loss** command to configure the method used to calculate frame loss using received continuity check message (CCM) protocol data units (PDUs). Use the **no** form of this command to return to the default setting. Variations of this command include:

ccm frame-loss measurement-interval <*seconds*>
ccm frame-loss sequence-number

Syntax Description

measurement interval <*seconds*>	Specifies the interval over which frame loss statistics are generated. Valid range is **60** to **900** seconds.
sequence-number	Specifies that frame loss is calculated using the sequence number in CCMs.

Default Values

By default, CCMs do not use a sequence number for calculating frame loss measurements, and the default measurement interval is **60** seconds.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example configures frame loss to be calculated using the sequence number in the CCMs:

(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)**#ccm frame-loss sequence-number**

ccm-enabled

Use the **ccm-enabled** command to enable transmission of continuity check message (CCM) frames by the maintenance entity group end point (MEP). Use the **no** form of this command to disable CCMs.

Syntax Description

No subcommands.

Default Values

By default, CCMs are disabled.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example enables transmission of CCM frames:

```
(config-y1731-meg MEG1)#local-mep 3
MEP 3 created
(config-y1731-mep3)#ccm-enabled
```

ccm-enabled track *<name>*

Use the **ccm-enabled track** command to enable transmission of continuity check message (CCM) frames while the specified track is in the PASS state. While the specified track is in the FAIL state, the local MEP will not send CCMs.

Syntax Description

<name>	Specifies the name of the track on which to base CCM frame transmission.

Default Values

By default, CCM transmission is disabled.

Command History

Release R10.11.0	Command was introduced.

Usage Examples

The following example enables transmission of CCM frames on the local MEP when the track **EXAMPLE_TRACK** is in the PASS state:

(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)**#ccm-enabled track EXAMPLE_TRACK**

direction

Use the **direction** command to specify the direction that the active side of the maintenance entity group end point (MEP) will be pointing in relation to the switch. The direction must be specified to activate the MEP. Use the **no** form of this command to return to the default setting. Variations of this command include:

direction down
direction up

Syntax Description

down	Specifies that the MEP will receive and transmit frames on the interface without accessing the switch.
up	Specifies that the MEP will receive and transmit frames towards the switch without accessing the interface.

Default Values

By default, the direction of the MEP is unspecified.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example specifies that the MEP will receive and transmit frames towards the switch without accessing the interface:

(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)**#direction up**

force-rdi track <*name*>

Use the **force-rdi track** command to specify that the maintenance entity group end point (MEP) should force the transmission of remote defect indications (RDIs) while the track is in the PASS state, and should transmit RDIs according to the rules of Y.1731 when the track is in the FAIL state. This connects the MEP's RDI transmission to the administrative state of the user-network interface (UNI) or network-to-network interface (NNI). Use the **no** form of this command to remove the association between the track's state and the MEP's RDI transmission.

Syntax Description

<*name*>	Specifies the name of the track that should control the transmission of RDIs on the MEP.

Default Values

By default, RDIs are transmitted according to the rules of Y.1731.

Command History

Release R11.5.0	Command was added.

Usage Examples

The following example specifies that the RDI transmission of MEP **3** should be controlled by the track **GIG_3_OPER_STATUS**:

(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)**#force-rdi track GIG_3_OPER_STATUS**

frame-delay one-way

Use the **frame-delay one-way** command to configure a Y.1731 one-way frame delay performance monitoring session between maintenance entity group (MEG) endpoints (MEPs). Use the **no** form of this command to disable the frame delay monitoring session. Variations of this command include:

frame-delay one-way measurement-interval
frame-delay one-way <*mep id* > **priority** <*value*>
frame-delay one-way <*target mac address*> **priority** <*value*>
frame-delay one-way multicast priority <*value*>

Syntax Description

measurement-interval	Specifies the interval over which frame delay statistics are generated. Valid range is **60** to **900** seconds.
<*mep id*>	Specifies the MEP ID of the target MEP. Valid MEP ID range is **1** to **8191**.
<*target mac address*>	Specifies the medium access control (MAC) address of the target MEP. Enter MAC addresses in hexadecimal format, for example: **xx:xx:xx:xx:xx:xx**.
multicast	Specifies the session is configured for multicast.
priority <*value*>	Optional. Specifies the virtual local area network (VLAN) priority of the target MEP. Valid range is **0** to **7**.

Default Values

By default, no one-way frame delay monitoring sessions are configured. If a session is configured, by default it has a measurement interval of **60** seconds.

Command History

Release R10.10.0	Command was introduced.
Release R11.10.0	Command was expanded to include the **multicast** parameter.

Usage Examples

The following example configures a one-way frame delay monitoring session for MEP **100** with a priority of **3**:

(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)**#frame-delay one-way 100 priority 3**

frame-delay two-way

Use the **frame-delay two-way** command to configure a Y.1731 two-way frame delay performance monitoring session between maintenance entity group (MEG) endpoints (MEPs). Use the **no** form of this command to disable the frame delay monitoring session. Variations of this command include:

frame-delay two-way <*mep id*> **priority** <*value*>
frame-delay two-way <*target mac address*> **priority** <*value*>
frame-delay two-way multicast priority <*value*>

Syntax Description

<*mep id*>	Specifies the MEP ID of the target MEP. Valid MEP ID range is **1** to **8191**.
<*target mac address*>	Specifies the medium access control (MAC) address of the target MEP. Enter MAC addresses in hexadecimal format, for example: **xx:xx:xx:xx:xx:xx**.
multicast	Specifies the session is configured for multicast.
priority <*value*>	Optional. Specifies the virtual local area network (VLAN) priority of the target MEP. Valid range is **0** to **7**.

Default Values

By default, no two-way frame delay monitoring sessions are configured. If a session is configured, by default it has a measurement interval of **60** seconds.

Command History

Release R10.10.0	Command was introduced.
Release R11.10.0	Command was expanded to include the **multicast** parameter.

Usage Examples

The following example configures a two-way frame delay monitoring session for MEP **100** with a priority of **3**:

(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)**#frame-delay two-way 100 priority 3**

frame-delay two-way file-save averaged

Use the **frame-delay two-way file-save averaged** command to specify that averaged two-way frame delay (ETH-DM) measurement interval data is saved to performance monitoring logs. Use the **no** form of this command to disable saving data to the performance monitoring logs.

Syntax Description

No subcommands.

Default Values

By default, the ETH-DM measurement interval data is not saved to the performance monitoring logs.

Command History

Release 11.6.0	Command was introduced.

Functional Notes

By default, each time a new measurement interval occurs during a Y.1731 performance monitoring session, ETH-DM, ETH-LM, and ETH-SLM, the data from the previous interval is overwritten. The performance monitoring file save feature allows performance monitoring logs to be stored in memory in a series of hour-long log files. The unit records session data to the current log file at user-specified intervals. At the end of the user-specified log lifetime, the logs are rotated out in a first-in first-out fashion; the oldest files are deleted to make room for the new files. Each performance monitoring session type is stored in a separate file in the user-specified directory. The file is automatically named by the unit using the following format:

<*device serial*>**_<DM | LM | SLM>.Data_**<*date and time*>**.pm.xz[.current]**

Parameter	Description
<*device serial*>	Specifies the serial number of the unit.
DM	Specifies that the file is a single-ended (two-way) frame delay log.
LM	Specifies that the file is a single-ended frame loss log.
SLM	Specifies that the file is a single-ended synthetic frame loss log.
<*date and time*>	Specifes the date and time at which the log ends in the format **YYYY-MM-DD_hh.mm.ss**, for example: **2014-12-30_14:00:00**. This specifies the last time interval that the file will be written.
.pm.xz	Specifies the file extension of the log file.
.current	Appended to files that are still in use and could have data written to them.

The following example is a sample ETH-SLM file name that is no longer writable:

LBADTN340767_SLM.Data_2014-12-04_15.00.00.pm.xz

The following example is a sample ETH-LM file name of a file to which the unit is currently writing:

LBADTN340767_LM.Data_2014-12-04_15.00.00.pm.xz.current

If the file directory for the log files is changed, the files in the previous save directory will not be deleted for log rotation. Log rotation only occurs for files in the currently-specified save directory.

If any of the following conditions occur during a measurement interval, the measurement will be considered suspect, and it will be marked with a suspect flag:

- There is loss of continuity (LOC) during a measurement interval. If the LOC alarm is raised in the maintenance entity group end point (MEP) by continuity check messages (CCMs) during a measurement interval, the suspect flag will be raised for that measurement interval.
- The clock is adjusted by more than 10 seconds. If the system clock is adjusted by more than 10 seconds during a measurement interval, the suspect flag will be raised.
- The performance monitoring session is started during a measurement interval. If the session starts during a measurement interval (for example, a performance monitoring session is initiated at 3:00 with a measurement interval of 5 minutes, and the start time is set to 3 minutes after 3:00) then the suspect flag will be raised for that measurement interval.
- The performance session is stopped during a measurement interval. If the session stops during a measurement interval (for example, a performance monitoring session was initiated at 3:00 with a measurement interval of 5 minutes, and the stop time is set to 3 minutes after 3:00) then the suspect flag will be raised for that measurement interval.
- The Ethernet virtual circuit (EVC) status transitions to **Not Running** during a measurement interval. If the EVC over which the performance monitoring session is conducted transitions to a **Not Running** state during a measurement interval, the suspect flag will be raised for that measurement interval.
- The MEP transitions to an **Unavailable** or **Out of Service** state during a measurement interval. If the MEP goes to an **Unavailable** or **Out of Service** state during a measurement interval, the suspect flag will be raised for that measurement interval.

Usage Examples

The following example specifies that averaged ETH-DM measurement interval data should be saved to the performance monitoring logs:

(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)**#frame-delay two-way file-save averaged**

frame-loss single-ended

Use the **frame-loss single-ended** command to monitor frame loss across maintenance entity group (MEG) endpoints (MEPs) by counting in-profile customer frames. Use the **no** form of this command to disable the monitoring feature. Variations of this command include:

frame-loss single-ended <*mep id*> **priority** <*value*>
frame-loss single-ended <*target mac address*> **priority** <*value*>
frame-loss single-ended multicast priority <*value*>

Syntax Description

<*mep id*>	Specifies the MEP ID of the target MEP. Valid MEP ID range is **1** to **8191**.
<*target mac address*>	Specifies the medium access control (MAC) address of the target MEP. Enter MAC addresses in hexadecimal format, for example: **xx:xx:xx:xx:xx:xx**.
multicast	Specifies the session is configured for multicast.
priority <*value*>	Optional. Specifies the virtual local area network (VLAN) priority of the target MEP. Valid range is **0** to **7**.

Default Values

By default, no frame loss monitoring sessions are configured.

Command History

Release R11.6.0	Command was introduced.
Release R11.10.0	Command was expanded to include the **multicast** parameter.

Usage Examples

The following example configures a frame loss monitoring session for MEP **100** with a priority of **3**:

(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)**#frame-loss single-ended 100 priority 3**

frame-loss single-ended file-save averaged

Use the **frame-loss single-ended file-save averaged** command to specify that averaged single-ended frame loss (ETH-LM) measurement interval data is saved to performance monitoring logs. Use the **no** form of this command to disable saving data to the performance monitoring logs.

Syntax Description

No subcommands.

Default Values

By default, the ETH-LM measurement interval data is not saved to the performance monitoring logs.

Command History

Release 11.6.0	Command was introduced.

Functional Notes

By default, each time a new measurement interval occurs during a Y.1731 performance monitoring session, ETH-DM, ETH-LM, and ETH-SLM, the data from the previous interval is overwritten. The performance monitoring file save feature allows performance monitoring logs to be stored in memory in a series of hour-long log files. The unit records session data to the current log file at user-specified intervals. At the end of the user-specified log lifetime, the logs are rotated out in a first-in first-out fashion; the oldest files are deleted to make room for the new files. Each performance monitoring session type is stored in a separate file in the user-specified directory. The file is automatically named by the unit using the following format:

<*device serial*>**_<DM | LM | SLM>.Data_**<*date and time*>**.pm.xz[.current]**

Parameter	Description
<*device serial*>	Specifies the serial number of the unit.
DM	Specifies that the file is a single-ended (two-way) frame delay log.
LM	Specifies that the file is a single-ended frame loss log.
SLM	Specifies that the file is a single-ended synthetic frame loss log.
<*date and time*>	Specifes the date and time at which the log ends in the format **YYYY-MM-DD_hh.mm.ss**, for example: **2014-12-30_14:00:00**. This specifies the last time interval that the file will be written.
.pm.xz	Specifies the file extension of the log file.
.current	Appended to files that are still in use and could have data written to them.

The following example is a sample ETH-SLM file name that is no longer writable:

LBADTN340767_SLM.Data_2014-12-04_15.00.00.pm.xz

The following example is a sample ETH-LM file name of a file to which the unit is currently writing:

LBADTN340767_LM.Data_2014-12-04_15.00.00.pm.xz.current

If the file directory for the log files is changed, the files in the previous save directory will not be deleted for log rotation. Log rotation only occurs for files in the currently-specified save directory.

If any of the following conditions occur during a measurement interval, the measurement will be considered suspect, and it will be marked with a suspect flag:

- There is loss of continuity (LOC) during a measurement interval. If the LOC alarm is raised in the maintenance entity group end point (MEP) by continuity check messages (CCMs) during a measurement interval, the suspect flag will be raised for that measurement interval.
- The clock is adjusted by more than 10 seconds. If the system clock is adjusted by more than 10 seconds during a measurement interval, the suspect flag will be raised.
- The performance monitoring session is started during a measurement interval. If the session starts during a measurement interval (for example, a performance monitoring session is initiated at 3:00 with a measurement interval of 5 minutes, and the start time is set to 3 minutes after 3:00) then the suspect flag will be raised for that measurement interval.
- The performance session is stopped during a measurement interval. If the session stops during a measurement interval (for example, a performance monitoring session was initiated at 3:00 with a measurement interval of 5 minutes, and the stop time is set to 3 minutes after 3:00) then the suspect flag will be raised for that measurement interval.
- The Ethernet virtual circuit (EVC) status transitions to **Not Running** during a measurement interval. If the EVC over which the performance monitoring session is conducted transitions to a **Not Running** state during a measurement interval, the suspect flag will be raised for that measurement interval.
- The MEP transitions to an **Unavailable** or **Out of Service** state during a measurement interval. If the MEP goes to an **Unavailable** or **Out of Service** state during a measurement interval, the suspect flag will be raised for that measurement interval.

Usage Examples

The following example specifies that averaged ETH-LM measurement interval data should be saved to the performance monitoring logs:

(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)**#frame-loss single-ended file-save averaged**

frame-loss synthetic single-ended

Use the **frame-loss synthetic single-ended** command to monitor frame loss across maintenance entity group (MEG) endpoints (MEPs) by counting synthetic data frames. Use the **no** form of this command to disable the monitoring feature. Variations of this command include:

frame-loss synthetic single-ended <*mep id*> **priority** <*value*>
frame-loss synthetic single-ended <*target mac address*> **priority** <*value*>
frame-loss synthetic single-ended multicast priority <*value*>

Syntax Description

<*mep id*>	Specifies the MEP ID of the target MEP. Valid MEP ID range is **1** to **8191**.
<*target mac address*>	Specifies the medium access control (MAC) address of the target MEP. Enter MAC addresses in hexadecimal format, for example: **xx:xx:xx:xx:xx:xx**.
multicast	Specifies the session is configured for multicast.
priority <*value*>	Optional. Specifies the virtual local area network (VLAN) priority of the target MEP. Valid range is **0** to **7**.

Default Values

By default, no frame loss monitoring sessions are configured.

Command History

Release R10.10.0	Command was introduced.
Release R11.10.0	Command was expanded to include the **multicast** parameter.

Usage Examples

The following example configures a frame loss monitoring session for MEP **100** with a priority of **3**:

(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)**#frame-loss synthetic single-ended 100 priority 3**

frame-loss synthetic single-ended file-save averaged

Use the **frame-loss synthetic single-ended file-save averaged** command to specify that averaged single-ended synthetic frame loss (ETH-SLM) measurement interval data is saved to performance monitoring logs. Use the **no** form of this command to disable saving data to the performance monitoring logs.

Syntax Description

No subcommands.

Default Values

By default, the ETH-SLM measurement interval data is not saved to the performance monitoring logs.

Command History

Release 11.6.0	Command was introduced.

Functional Notes

By default, each time a new measurement interval occurs during a Y.1731 performance monitoring session, ETH-DM, ETH-LM, and ETH-SLM, the data from the previous interval is overwritten. The performance monitoring file save feature allows performance monitoring logs to be stored in memory in a series of hour-long log files. The unit records session data to the current log file at user-specified intervals. At the end of the user-specified log lifetime, the logs are rotated out in a first-in first-out fashion; the oldest files are deleted to make room for the new files. Each performance monitoring session type is stored in a separate file in the user-specified directory. The file is automatically named by the unit using the following format:

*<device serial>***_<DM | LM | SLM>.Data_***<date and time>***.pm.xz[.current]**

Parameter	Description
<device serial>	Specifies the serial number of the unit.
DM	Specifies that the file is a single-ended (two-way) frame delay log.
LM	Specifies that the file is a single-ended frame loss log.
SLM	Specifies that the file is a single-ended synthetic frame loss log.
<date and time>	Specifes the date and time at which the log ends in the format **YYYY-MM-DD_hh.mm.ss**, for example: **2014-12-30_14:00:00**. This specifies the last time interval that the file will be written.
.pm.xz	Specifies the file extension of the log file.
.current	Appended to files that are still in use and could have data written to them.

The following example is a sample ETH-SLM file name that is no longer writable:

LBADTN340767_SLM.Data_2014-12-04_15.00.00.pm.xz

The following example is a sample ETH-LM file name of a file to which the unit is currently writing:

LBADTN340767_LM.Data_2014-12-04_15.00.00.pm.xz.current

> NOTE *If the file directory for the log files is changed, the files in the previous save directory will not be deleted for log rotation. Log rotation only occurs for files in the currently-specified save directory.*

If any of the following conditions occur during a measurement interval, the measurement will be considered suspect, and it will be marked with a suspect flag:

- There is loss of continuity (LOC) during a measurement interval. If the LOC alarm is raised in the maintenance entity group end point (MEP) by continuity check messages (CCMs) during a measurement interval, the suspect flag will be raised for that measurement interval.
- The clock is adjusted by more than 10 seconds. If the system clock is adjusted by more than 10 seconds during a measurement interval, the suspect flag will be raised.
- The performance monitoring session is started during a measurement interval. If the session starts during a measurement interval (for example, a performance monitoring session is initiated at 3:00 with a measurement interval of 5 minutes, and the start time is set to 3 minutes after 3:00) then the suspect flag will be raised for that measurement interval.
- The performance session is stopped during a measurement interval. If the session stops during a measurement interval (for example, a performance monitoring session was initiated at 3:00 with a measurement interval of 5 minutes, and the stop time is set to 3 minutes after 3:00) then the suspect flag will be raised for that measurement interval.
- The Ethernet virtual circuit (EVC) status transitions to **Not Running** during a measurement interval. If the EVC over which the performance monitoring session is conducted transitions to a **Not Running** state during a measurement interval, the suspect flag will be raised for that measurement interval.
- The MEP transitions to an **Unavailable** or **Out of Service** state during a measurement interval. If the MEP goes to an **Unavailable** or **Out of Service** state during a measurement interval, the suspect flag will be raised for that measurement interval.

Usage Examples

The following example specifies that averaged ETH-SLM measurement interval data should be saved to the performance monitoring logs:

(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)**#frame-loss synthetic single-ended file-save averaged**

priority *<value>*

Use the **priority** command to specify the priority given to connectivity fault management (CFM) frames and linktrace messages transmitted by the maintenance entity group end point (MEP). Use the **no** form of this command to return the priority to the default value.

Syntax Description

<value>	Specifies the priority. Range is **0** to **7**.

Default Values

By default, the priority value is **7**.

Command History

Release 17.4	Command was introduced.
Release R10.10.0	Command was expanded to include the Y.1731 local MEP.

Usage Examples

The following example specifies a priority of **3** for CFM frames and linktrace messages transmitted by this MEP:

(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)**#priority 3**

set interface

Use the **set interface** command to associate an interface or Ethernet in the first mile (EFM) group with the maintenance entity group end point (MEP). Use the no form of this command to remove the specified association. Variations of this command include:

set interface efm-group <*slot/group*>
set interface gigabit-ethernet <*slot/port*>

Syntax Description

efm-group <*slot/group*>	Associates the specified EFM group with the MEP.
gigabit-ethernet <*slot/port*>	Associates the specified Gigabit Ethernet interface with the MEP.

Default Values

No default values are necessary for this command.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example associates Gigabit Ethernet interface **1/1** with the MEP:

(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)**#set interface gigabit-ethernet 1/1**

Y.1731 MEG COMMAND SET

A maintenance entity group (MEG) object, as defined by Y.1731, includes different maintenance entities (MEs) that satisfy the following conditions: MEs in a MEG exist in the same administrative boundary, MEs in a MEG have the same MEG level, and MEs in a MEG belong to the same point-to-point or multipoint Ethernet connection. A MEG is a collection of MEs, and an ME refers to the direct connection between two MEG end points (MEPs) in a MEG. A MEP forms an ME with every other MEP in the same MEG. The MEG's MEG level attribute is used by all MEPs created within it.

The minimum attributes required to create or access a MEG are the MEG ID and MEG level after which the MEG attributes can be edited to make ready for operation. The reason why both MEG ID and MEG Level must be used to create the MEG is to allow MEGs with the same name but different MEG levels to be unique. This may be required if the administrator needs to interoperate with devices not under their control which use the same MEG ID but operate at different MEG Levels.

MEG groups are created and configured using the **ethernet y1731 meg** command from the Global Configuration mode as follows:

```
>enable
#configure terminal
(config)#ethernet y1731 meg char-string MEG1 level 1
(config-y1731-meg MEG1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

ccm interval

Use the **ccm interval** command to specify the interval at which the local maintenance entity group end point (MEP) will transmit continuity check messages (CCMs) and the interval at which it expects to receive CCMs from each peer in the MEG. Use the **no** form of this command to return the CCM interval to the default value. Variations of this command include:

ccm interval 1-minute
ccm interval 1-second
ccm interval 10-minutes
ccm interval 10-seconds
ccm interval 100-milliseconds

Syntax Description

1-minute	Specifies a 1 minute CCM interval.
1-second	Specifies a 1 second CCM interval.
10-minutes	Specifes a 10 minute CCM interval.
10-seconds	Specifies a 10 second CCM interval.
100-milliseconds	Specifies a 100 millisecond CCM interval.

Default Values

By default, the CCM interval is 1 minute.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example configures the MEG with a CCM interval of 1 second:

(config)**#ethernet y1731 meg char-string MEG1 level 1**
(config-y1731-meg MEG1)**#ccm interval 1-second**

local-mep *<id>*

Use the **local-mep** command to create a maintentance entity group end point (MEP) and access the Local MEP Configuration mode. Use the **no** form of this command to remove the MEP.

Syntax Description

<id>	Specifies the MEP identifier (ID) of the local MEP. Valid range is **1** to **8191**.

Default Values

By default, no MEPs are configured.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example creates a local MEP with a MEP ID of **3** on **MEG1**:

(config)**#ethernet y1731 meg char-string MEG1 level 1**
(config-y1731-meg MEG1)**#local-mep 3**
MEP 3 created
(config-y1731-mep3)#

mep database clear

Use the **mep database clear** command to clear the discovered remote maintentance entity group end point (MEP) from the MEP database. Variations of this command include:

mep database clear
mep database clear *<id>*

Syntax Description

<id>	Specifies the remote MEP (RMEP) identifier (ID) to remove from the MEP database. Valid range is **1** to **8191**.

Default Values

No default values are necessary for this command.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example clears all discovered RMEPs from the MEP database:

(config)**#ethernet y1731 meg char-string MEG1 level 1**
(config-y1731-meg MEG1)**#mep database clear**

mep database lock

Use the **mep database lock** command to lock the discovered remote maintentance entity group end point (MEP) into the MEP database. Variations of this command include:

mep database lock
mep database lock <*id*>

Syntax Description

<*id*>	Specifies the remote MEP (RMEP) identifier (ID) to lock into the MEP database. Valid range is **1** to **8191**.

Default Values

No default values are necessary for this command.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example locks all discovered RMEPs into the MEP database:

(config)**#ethernet y1731 meg char-string MEG1 level 1**
(config-y1731-meg MEG1)**#mep database lock**

mep database rule

Use the **mep database rule** command to configure the rules for adding new entries into the remote maintentance entity group end point (MEP) database. Variations of this command include:

mep database rule auto-discovery
mep database rule auto-learning
mep database rule configured-only

Syntax Description

auto-discovery	Specifies that when continuity check messages (CCMs) are received from remote MEPs (RMEPs), they are added as discovered RMEPs in the MEP database.
auto-learning	Specifies that when continuity check messages (CCMs) are received from remote MEPs (RMEPs), they are added as static RMEPs in the MEP database.
configured-only	Specifies that CCMs must match the configured static RMEP entries.

Default Values

No default values are necessary for this command.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example allows new RMEPs to be added as discovered RMEPs in the MEP database:

(config)**#ethernet y1731 meg char-string MEG1 level 1**
(config-y1731-meg MEG1)**#mep database rule auto-discovery**

remote-mep *<id>*

Use the **remote mep** command to add a maintentance entity group end point (MEP) to the list of expected continuity check message (CCM) sources. Use the no form of this command to remove a MEP from the list.

Syntax Description

<id>	Specifies the remote MEP (RMEP) identifier (ID) to add to the list of expected CCM sources. Valid range is **1** to **8191**.

Default Values

By default, no RMEPs are configured as CCM sources.

Command History

Release R10.10.0	Command was introduced.

Usage Examples

The following example configures RMEP **25** as an expected CCM source:

(config)**#ethernet y1731 meg char-string MEG1 level 1**
(config-y1731-meg MEG1)**#remote-mep 25**

service

Use the **service** command to specify the service type and service value of traffic on the maintenance entity group (MEG). Variations of this command include:

service single-tagged ce-vlan-id <*tag*>
service single-tagged s-tag <*tag*>
service double-tagged s-tag <*tag*> **ce-vlan-id** <*tag*>

Syntax Description

single-tagged	Specifies that the L2 header of the Y.1731 packets to be processed should contain either a customer edge virtual local area network (CE-VLAN) identifier (ID) tag or a service tag (s-tag) with the specified value.
double-tagged	Specifies that the L2 header of the Y.1731 packets to be processed should contain both a CE-VLAN ID tag and an s-tag with the specified values.
ce-vlan-id <*vlan tag*>	Specifies the CE-VLAN ID of traffic on the MEG. Valid range is **1** to **4094**.
s-tag <*s-tag*>	Specifies the s-tag of traffic on the MEG. Valid range is **1** to **4094**.

Default Values

No default values are necessary for this command.

Command History

Release R10.10.0	Command was introduced.
Release R11.5.0	The **double-tagged** parameter was added.

Functional Notes

This feature is used together with the Y.1731 EtherType, level, and local and remote maintenance entity group end point (MEP) ID to identify Y.1731 packets that should be processed by the maintenance point (MP).

Usage Examples

The following example specifies that packets should contain an **s-tag** with a value of **54**:

(config)**#ethernet y1731 meg char-string MEG1 level 1**
(config-y1731-meg MEG1)**#service single-tagged s-tag 54**

The following example specifies that packets should contain an **s-tag** with a value of **54** and a CE-VLAN ID of **12**:

(config)**#ethernet y1731 meg char-string MEG1 level 1**
(config-y1731-meg MEG1)**#service double-tagged s-tag 54 ce-vlan-id 12**

ROUTING PROTOCOL COMMAND SETS

The routing protocol command sets are divided into the following sections:

BGP COMMAND SETS

This section includes the following command sets:

AS PATH LIST COMMAND SET

To activate the Autonomous System (AS) Path List Configuration mode, enter the **ip as-path-list** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ip as-path-list MyList
(config-as-path-list)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

deny <value> on page 3979
permit <value> on page 3980

deny *<value>*

Use the **deny** command to add an entry to the community list that denies Border Gateway Protocol (BGP) routes containing the specified community number in the community attribute. Use the **no** form of this command to remove the statement from the community list.

Syntax Description

<value>	Denies routes that contain this value in their community attribute. This is a numeric value that can be an integer from **1** to **4294967295** or string in the form ***aa:nn***, where ***aa*** is the autonomous system (AS) number and ***nn*** is the community number. Multiple community number parameters can be present in the command.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example creates a community list named **MyList** to deny BGP routes that match the AS path attributes **30:22**:

(config)**#ip as-path-list MyList**
(config-as-path-list)**#deny 30:22**

permit <*value*>

Use the **permit** command to add an entry to the community list that allows only Border Gateway Protocol (BGP) routes containing the specified community number in the community attribute. Use the **no** form of this command to remove the statement from the community list.

Syntax Description

<*value*>	Permits routes that contain this value in their community attribute. This is a numeric value that can be an integer from **1** to **4294967295** or string in the form ***aa:nn***, where ***aa*** is the autonomous system (AS) number and ***nn*** is the community number. Multiple community number parameters can be present in the command.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example creates a community list named **MyList** to permit BGP routes that match the AS path attributes **30:22**:

(config)**#ip as-path-list MyList**
(config-as-path-list)**#permit 30:22**

BGP COMMAND SET

BGP is an Exterior Gateway Protocol (EGP) that is used within the Internet and multinational organizations. EGP is one of two different types of dynamic routing protocols. The other protocol is Interior Gateway Protocol (IGP). The difference between the two protocols is that IGPs (for example, Routing Information Protocol (RIP), Open Shortest Path First (OSPF)) operate within an autonomous system (AS), whereas EGPs allow routes to be exchanged between different autonomous systems. Typically, an AS is defined by the boundaries of an organization. As an EGP, BGP routes must regulate traffic between networks controlled by organizations with different policies. BGP is designed to allow administrators to customize a policy for route exchange. The following are some characteristics of BGP that make it an appropriate protocol for connecting different autonomous systems:

- BGP can filter both the routes it receives and those that it sends according to bit length, thereby minimizing the number of routes exchanged.
- BGP uses policies to determine best routes rather than per-hop counts used in RIP or link states used in OSPF. Each AS can set their own policy.
- BGP routers communicate only with manually configured neighbors.
- You can configure different policies for route exchange with different neighbors.
- Multiple virtual routing and forwarding (Multi-VRF) BGP allows each VRF instance from the service provider its own BGP session within the router, thus extending the VRF instance from the service provider to the router.

In AOS firmware release 18.03.00, Multi-VRF BGP functionality was incorporated into AOS. This release allows BGP configuration to occur on different VRF instances, and changes the hierarchical structure of BGP within AOS, as well as the configuration steps necessary for BGP configuration. In addition, in AOS firmware release R10.1.0, support for multiprotocol BGP and Internet Protocol version 6 (IPv6) BGP were added.

The following are new features of BGP included with Multi-VRF BGP.

Address families (AFs) are used in BGP to maintain a separation between Internet protocol types within a VRF instance. With the advent of Multi-VRF BGP in 18.03.00, AOS implemented the use of AFs into the BGP hierarchical structure. An AF is a configuration structure that can reside at the default VRF instance and within a nondefault VRF instance. Creating an address family enables processing of that address family within a VRF, and it provides a place for AF-specific configuration.

In addition to the use of AFs, Multi-VRF BGP also allows the recognition and configuration of VRF instances specific to BGP functionality within the router. This allows the VRF constructs from the service provider to be incorporated into the customer router.

Multi-VRF is an application of the typical BGP functionality. As the name suggests, Multi-VRF BGP extends traditional service provider multi-VRF functionality of BGP to the customer edge router. This type of feature is typically used in Layer 3 virtual private network (VPN) applications where the VPN is extended to the customer device using Multi-VRF. Multi-VRF BGP allows the customer edge router to dynamically exchange customer VPN routers to and through the provider's VPN *cloud*, thus eliminating the reliance on the provider to manage static routes. Multi-VRF takes place on the link between the service provider's routers and the customer edge equipment.

In Multi-VRF BGP the concepts of the address family and VRF instances are incorporated into the BGP configuration structure. VRF instances are in themselves not tied to a specific protocol, and therefore, control of multiple protocols within a single VRF is accomplished using an AF. Multi-VRF BGP also uses the concepts of AFs to provide specific BGP configuration to a single BGP policy, and maintain control over multiple BGP policies within a single AF.

In Multi-VRF BGP, the hierarchical structure of BGP configuration is as follows:

```
Global BGP settings (affecting all of BGP for this router)
!
VRF BGP settings (affecting only the default VRF)
Neighbor #1 Definition
    Neighbor #1 common settings (common to all peering with neighbor #1)
    exit
!
Address Family for the default VRF
    AF BGP settings (affecting only this AF)
    Neighbor #1 Reference
        Neighbor #1 AF-specific settings
        exit
    exit
!
VRF name1
    VRF BGP settings (affecting only this vRF)
    Neighbor #2 Definition
        Neighbor #2 common settings (common to all peering with neighbor #2)
        exit
!
Address Family for VRF name1
    AF BGP settings (affecting this AF)
    Neighbor #2 Reference
        Neighbor #2 settings specific to this AF
        exit
    exit
exit
```

Because the structure of BGP changed with the AOS 18.03.00 release, there are several sections of BGP configuration commands. The following are the BGP configuration command sections for AOS products, and are applicable to both the default and nondefault VRF instances:

- *BGP Command Set on page 3981*
- *BGP Address Family Command Set on page 4001*
- *BGP AF Neighbor Command Set on page 4022*
- *BGP Neighbor Command Set on page 4041*

To enable BGP in AOS products, and activate the BGP Configuration mode, enter the **router bgp** command at the Global Configuration mode prompt followed by the AS number of the local system of which this BGP router is a member. To enter the BGP Configuration mode for the default VRF, enter the command as follows:

```
>enable
#configure terminal
(config)#router bgp 100
(config-bgp)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83

All other commands for this command set are described in this section in alphabetical order.

address-family on page 3984
bgp on page 3986
bgp default local-preference <value> on page 3988
bgp fast-external-failover on page 3990
bgp log-neighbor-changes on page 3992
bgp router-id <ipv4 address> on page 3994
hold-timer <value> on page 3996
neighbor on page 3998
vrf <name> on page 4000

address-family

Use the **address-family** command to configure the Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) Border Gateway Protocol (BGP) address family (AF) for the default or nondefault virtual routing and forwarding (VRF) instances on the AOS device. This command also enters the AF's configuration mode. Use the **no** version of this command to remove the AF from the BGP configuration. Variations of this command include:

address-family ipv4
address-family ipv6

Syntax Description

ipv4	Creates an IPv4 BGP AF.
ipv6	Creates an IPv6 BGP AF.

Default Values

By default, the AF is not configured on either the default or nondefault VRF instance.

Command History

Release 18.3	Command was introduced.
Release R10.1.0	Command was expanded to include IPv6 functionality.

Functional Notes

The **address-family** command can be used to create an AF on either the default or nondefault VRF instance. If the AF is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#**

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example creates an IPv4 AF on the default VRF instance and enters the AF's configuration mode:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)#

The following example creates an IPv4 AF on the nondefault VRF instance named **RED1** and enters the AF's configuration mode:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)#

bgp

Use the **bgp** command to instruct AOS on how to handle multi-exit discriminators (MEDs) for all Border Gateway Protocol (BGP) routes from the same autonomous system (AS) on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to disable this feature. Variations of this command include:

bgp always-compare-med
bgp compare-med
bgp deterministic-med
bgp ignore-med

Syntax Description

always-compare-med	Configures AOS to always compare MEDs for all paths for a route, regardless of the AS through which the paths pass.
compare-med	Configures AOS to compare MEDs for all received routes.
deterministic-med	Configures AOS to compare the MEDs for all routes received from different neighbors within the same AS.
ignore-med	Configures AOS to disregard MEDs for all received routes.

Default Values

By default, AOS compares the MED attributes for routes from the same AS.

Command History

Release 11.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Functional Notes

The **bgp** command can be used to specify MED behavior on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables MED options on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#bgp compare-med**

The following example enables MED options on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#bgp compare-med**

bgp default local-preference <*value*>

Use the **bgp default local-preference** command to change the local preference for all Border Gateway Protocol (BGP) routes on either the default or nondefault virtual routing and forwarding (VRF) instances. The local preference is an attribute (LOCAL_PREF) that indicates a degree of preference for a route relative to other routes in the local autonomous system (AS). BGP neighbors can send the local preference value as an attribute of a route in an UPDATE message. Local preference only applies to routes within the local AS. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the local preference value. Valid range is **0** to **4294967295**.

Default Values

By default, the local preference is set to **100**.

Command History

Release 11.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Functional Notes

The **bgp default local-preference** command can be used to specify the local preference on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example changes the default local preference to **200** for the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#bgp default local-preference 200**

The following example changes the default local preference to **200** for the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#bgp default local-preference 200**

bgp fast-external-failover

Use the **bgp fast-external-failover** command to enable the fast-external-failover feature for Border Gateway Protocol (BGP) on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this command is enabled.

Command History

Release 8.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Functional Notes

The **bgp fast-external-failover** command can be used to enable fast-external-failover on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

When enabled, if the link interface over which the router is communicating with a BGP peer goes down, the BGP session with that peer is immediately cleared. When failover is disabled and the link goes down, the session is maintained until the BGP hold timer expires.

Usage Examples

The following example enables fast-external-failover on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#bgp fast-external-failover**

The following example enables fast-external-failover on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#bgp fast-external-failover**

bgp log-neighbor-changes

Use the **bgp log-neighbor-changes** command to control the logging of Border Gateway Protocol (BGP) neighbor state changes on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, BGP neighbor changes are not logged.

Command History

Release 8.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Functional Notes

The **bgp log-neighbor-changes** command can be used to log BGP neighbor activity on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

This command controls logging of BGP neighbor state changes (up/down) and resets. This information is useful for troubleshooting and determining network stability.

Usage Examples

The following example enables logging of BGP neighbor state changes on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#bgp log-neighbor-changes**

The following example enables logging of BGP neighbor state changes on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#bgp log-neighbor-changes**

bgp router-id *<ipv4 address>*

Use the **bgp router-id** command to specify the Internet Protocol version 4 (IPv4) address that the router should use as its Border Gateway Protocol (BGP) router ID. This command can be applied to either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to return to the default setting.

Syntax Description

<ipv4 address>	Designates the IPv4 address this router should use as its BGP router ID. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no router ID is configured. The default action is detailed in *Functional Notes* below.

Command History

Release 8.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Functional Notes

The **bgp router-id** command can be used to specify the IPv4 address used for the router ID on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

The **bgp router-id** command allows an IPv4 address to be specified for use as the BGP router ID. If no IPv4 address is configured at BGP startup, it uses the highest IPv4 address configured on a loopback interface. If no loopback interfaces are configured, it uses the highest IPv4 address configured on any interface that is active. If the specified router ID is changed, existing sessions with BGP neighbors are reset.

Usage Examples

The following example configures IPv4 address **10.0.0.1** as the BGP router ID on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#bgp router-id 10.0.0.1**

The following example configures IPv4 address **10.0.0.1** as the BGP router ID on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#bgp router-id 10.0.0.1**

hold-timer <*value*>

Use the **hold-timer** command to set the default hold time for all neighbors in the Border Gateway Protocol (BGP) process on either the default or nondefault virtual routing and forwarding (VRF) instance.

Syntax Description

<*value*>	Specifies a time interval (in seconds) within which a keepalive must be received from a peer before that peer is declared dead. Range is **0** to **65535** seconds.

Default Values

By default, the hold time is **180** seconds.

Command History

Release 8.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Functional Notes

The **hold-timer** command can be used to specify the hold timer for BGP neighbors on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have configured the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Using the **hold-timer** command in BGP configuration mode sets the default hold time for all neighbors in that BGP process. Using the **hold-timer** command in BGP Neighbor Configuration mode sets the hold time for only that neighbor. The peers will negotiate and use the lowest configured setting. The keepalive interval will be set to one-third of the negotiated hold time.

Usage Examples

The following example sets a hold time of **120** seconds for a specific neighbor, with an understood keepalive interval of **40** seconds on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#hold-timer 120**

The following example sets a hold time of **120** seconds for a specific neighbor, with an understood keepalive interval of **40** seconds on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#hold-timer 120**

neighbor

Use the **neighbor** command to create a Border Gateway Protocol (BGP) neighbor, specify an Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) address, and enter the BGP Neighbor configuration mode. Refer to *BGP Neighbor Command Set on page 4041* for more information on neighbor-specific configuration parameters. This command can be used for either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the configured neighbors. Variations of this command include:

neighbor <*ipv4 address*>
neighbor <*ipv4 address*> **mef-ethernet** <*slot/port*>
neighbor <*ipv4 address*> **system-control-evc**
neighbor <*ipv4 address*> **system-management-evc**
neighbor <*ipv6 address*>
neighbor <*ipv6 address*> **mef-ethernet** <*slot/port*>
neighbor <*ipv6 address*> **system-control-evc**
neighbor <*ipv6 address*> **system-management-evc**

Syntax Description

<*ipv4 address*>	Specifies the IPv4 address for the neighbor. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*ipv6 address*>	Specifies the IPv6 address for the neighbor. IPv6 addresses should be expressed in dotted decimal notation (for example, **2001:DB8:1::1**).
mef-ethernet <*slot/port*>	Optional. Specifies the neighbor is the Metro Ethernet Forum (MEF) Ethernet interface.
system-control-evc	Optional. Specifies the neighbor is a member of the system control Ethernet virtual connection (EVC).
system-management-evc	Optional. Specifies the neighbor is a member of the system management EVC.

Default Values

By default, there are no configured BGP neighbors.

Command History

Release 11.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 functionality.
Release R10.10.0	Command was expanded to include the system control and system management EVCs.
Release R10.11.0	Command was expanded to include the MEF Ethernet interface.

Functional Notes

The **neighbor** command can be used to specify the BGP neighbors on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures an IPv4 BGP neighbor with an IPv4 address of **10.10.10.1** on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#neighbor 10.10.10.1**
(config-bgp-neighbor)#

The following example configures an IPv4 BGP neighbor with an IPv4 address of **10.10.10.1** on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.10.10.1**

The following example configures an IPv4 BGP neighbor with an address of **10.10.10.1** on the nondefault VRF instance named **RED1** and specifies this neighbor is a member of the system control EVC:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.10.10.1 system-control-evc**

vrf *<name>*

Use the **vrf** command to associate a specific virtual routing and forwarding (VRF) instance with Border Gateway Protocol (BGP) configurations and enter the BGP Configuration mode on the nondefault VRF instance. This command allows you to configure the BGP settings for the specified VRF instance. Use the **no** form of this command to remove the association between the named VRF instance and the BGP configuration.

Syntax Description

<name>	Specifies the name of the VRF instance to associate with BGP.

Default Values

By default, BGP configurations are associated with the default (unnamed) VRF instance.

Command History

Release 17.1	Command was introduced.
Release 18.3	Command was added to BGP and Dynamic Host Control Protocol (DHCP) version 4 (DHCPv4) and version 6 (DHCPv6).
Release R11.2.0	Command was added to network monitoring

Functional Notes

VRF instances must be created first before they can be assigned to BGP configuration. Create the VRF instance using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance. For example, to configure the IPv4 BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example creates the VRF instance named **RED1** and enters the BGP configuration mode for the nondefault VRF:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)#

BGP ADDRESS FAMILY COMMAND SET

In AOS firmware release 18.03.00, Multiple virtual routing and forwarding (VRF) Border Gateway Protocol (BGP) functionality was incorporated into AOS. This release allows BGP configuration to occur on different VRF instances, and changes the hierarchical structure of BGP within AOS as well as the configuration steps necessary for BGP configuration. In addition, in AOS firmware release R10.1.0, multiprotocol BGP and BGP for Internet Protocol version 6 (IPv6) were added.

The following are new features of BGP included with Multi-VRF BGP, multiprotocol BGP, and BGP for IPv6.

Address families (AFs) are used in BGP to maintain a separation between Internet protocol types within a VRF instance. With the advent of Multi-VRF BGP in 18.03.00, AOS implemented the use of AFs into the BGP hierarchical structure. An AF is a configuration structure that can reside at the default VRF instance and within a nondefault VRF instance. Creating an address family enables processing of that address family within a VRF, and it provides a place for AF-specific configuration.

In addition to the use of AFs, Multi-VRF BGP also allows the recognition and configuration of VRF instances specific to BGP functionality within the router. This allows the VRF constructs from the service provider to be incorporated into the customer router.

Multi-VRF is an application of the typical BGP functionality. As the name suggests, Multi-VRF BGP extends traditional service provider multi-VRF functionality of BGP to the customer edge router. This type of feature is typically used in Layer 3 virtual private network (VPN) applications where the VPN is extended to the customer device using multi-VRF. Multi-VRF BGP allows the customer edge router to dynamically exchange customer VPN routers to and through the provider's VPN *cloud*, thus eliminating the reliance on the provider to manage static routes. Multi-VRF takes place on the link between the service provider's routers and the customer edge equipment.

In Multi-VRF BGP the concepts of the address family and VRF instances are incorporated into the BGP configuration structure. VRF instances are in themselves not tied to a specific protocol, and therefore, control of multiple protocols within a single VRF is accomplished using an AF. Multi-VRF BGP also uses the concepts of AFs to provide specific BGP configuration to a single BGP policy, and maintain control over multiple BGP policies within a single AF.

In Multi-VRF BGP, the hierarchical structure of BGP configuration is as follows:

```
Global BGP settings (affecting all of BGP for this router)
!
VRF BGP settings (affecting only the default VRF)
Neighbor #1 Definition
    Neighbor #1 common settings (common to all peering with neighbor #1)
    exit
!
Address Family for the default VRF
    AF BGP settings (affecting only this AF)
    Neighbor #1 Reference
```

```
        Neighbor #1 AF-specific settings
        exit
    exit
!
VRF name1
    VRF BGP settings (affecting only this vRF)
    Neighbor #2 Definition
        Neighbor #2 common settings (common to all peering with neighbor #2)
        exit
!
Address Family for VRF name1
    AF BGP settings (affecting this AF)
    Neighbor #2 Reference
        Neighbor #2 settings specific to this AF
        exit
    exit
exit
```

Because the structure of BGP changed with the AOS 18.03.00 release, there are several sections of BGP configuration commands. The following are the BGP configuration command sections for AOS products, and are applicable to both the default and nondefault VRF instances:

- *BGP Command Set on page 3981*
- *BGP Address Family Command Set on page 4001*
- *BGP AF Neighbor Command Set on page 4022*
- *BGP Neighbor Command Set on page 4041*

Once you have enabled BGP in AOS products, you can enter the AF Configuration mode by entering the **address-family** command at the BGP Configuration mode prompt. To enter the IPv4 BGP AF Configuration mode for the default VRF, enter the command as follows:

```
>enable
#configure terminal
(config)#router bgp 100
(config-bgp)#address-family ipv4
(config-bgp-ipv4)#
```

To enter the IPv6 BGP AF Configuration mode for the default VRF, enter the command as follows:

```
>enable
#configure terminal
(config)#router bgp 100
(config-bgp)#address-family ipv6
(config-bgp-ipv6)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83

All other commands for this command set are described in this section in alphabetical order.

distance bgp <external> <internal> <local> on page 4004
maximum-paths <value> on page 4006
neighbor on page 4008
network <ipv4 address> mask <subnet mask> on page 4010
network <ipv6 address/prefix-length> on page 4012
redistribute connected on page 4014
redistribute ospf on page 4016
redistribute rip on page 4018
redistribute static on page 4020

distance bgp *<external> <internal> <local>*

Use the **distance bgp** command to set the administrative distance for both Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6) Border Gateway Protocol (BGP) address family (AF) routes on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to return to the default setting. Variations of this command include:

distance bgp *<external>*
distance bgp *<external> <internal>*
distance bgp *<external> <internal> <local>*

Syntax Description

<external>	Sets the administrative distance for BGP routes learned via external Border Gateway Protocol (eBGP) sessions. Range is **1** to **255**.
<internal>	Optional. Sets the administrative distance for BGP routes learned via internal Border Gateway Protocol (iBGP) sessions. Range is **1** to **255**.
<local>	Optional. Sets the administrative distance for BGP routes learned via the network command and redistribution. Range is **1** to **255**.

Default Values

By default, external is set to **20**, internal to **200**, and local to **200**. Normally, these default settings should not be changed.

Command History

Release 8.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 functionality.

Functional Notes

The **distance** command can be used to allow a BGP AF on either the default or nondefault VRF instance to select the best route when there are multiple routes to the same network. If the AF is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP AF settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP AF characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

This command sets the administrative distance for BGP routes. The administrative distance is a local variable that allows a router to choose the best route when there are multiple paths to the same network. Routes with lower administrative distances are preferable.

Usage Examples

The following example gives external BGP routes an administrative distance of **30**, internal BGP routes an administrative distance of **200**, and local routes an administrative distance of **240** for the IPv4 BGP AF on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#distance bgp 30 200 240**

The following example gives external BGP routes an administrative distance of **30**, internal BGP routes an administrative distance of **200**, and local routes an administrative distance of **240** for the IPv4 BGP AF on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#distance bgp 30 200 240**

maximum-paths *<value>*

Use the **maximum-paths** command to specify the number of equal cost parallel routes (shared paths) learned by the Border Gateway Protocol (BGP) address family (AF) that can be exported to the route table. When IP load sharing is enabled, traffic is balanced to a specific destination across up to six equal paths. This command can be used for a BGP AF on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the number of equal cost parallel routes learned by BGP AFs that can be exported to the route table. Valid range is **1** to **6**.

Default Values

By default, a single path can exist in the route table.

Command History

Release 11.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 functionality.

Functional Notes

The **maximum-paths** command can be used to specify the number of paths for a BGP AF on either the default or nondefault VRF instance to select the best route when there are multiple routes to the same network. If the AF is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP AF settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP AF characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures the IPv4 BGP AF on the default VRF instance to export **4** parallel paths to the route table:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#maximum-paths 4**

The following example configures the IPv4 BGP AF on the nondefault VRF instance named **RED1** to export **4** parallel paths to the route table:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#maximum-paths 4**

neighbor

Use the **neighbor** command to create a Border Gateway Protocol (BGP) address family (AF) neighbor, specify an Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) address, and enter the BGP AF Neighbor Configuration mode. Refer to *BGP AF Neighbor Command Set on page 4022* for more information on AF neighbor-specific configuration parameters. This command can be used for either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the configured neighbors. Variations of this command include:

neighbor <*ipv4 address*>
neighbor <*ipv4 address*> **mef-ethernet** <*slot/port*>
neighbor <*ipv4 address*> **system-control-evc**
neighbor <*ipv4 address*> **system-management-evc**
neighbor <*ipv6 address*>
neighbor <*ipv6 address*> **mef-ethernet** <*slot/port*>
neighbor <*ipv6 address*> **system-control-evc**
neighbor <*ipv6 address*> **system-management-evc**

Syntax Description

<*ipv4 address*>	Specifies the IPv4 address for the BGP AF neighbor. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*ipv6 address*>	Specifies the IPv6 address for the BGP AF neighbor. IPv6 addresses should be expressed in colon hexadecimal format (for example, **2001:DB8:1::1**).
mef-ethernet <*slot/port*>	Optional. Specifies the BGP AF neighbor is the Metro Ethernet Forum (MEF) Ethernet interface.
system-control-evc	Optional. Specifies the BGP AF neighbor is a member of the system control Ethernet virtual connection (EVC).
system-management-evc	Optional. Specifies the BGP AF neighbor is a member of the system management EVC.

Default Values

By default, there are no configured BGP AF neighbors.

Command History

Release 11.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 addressing.
Release R10.10.0	Command was expanded to include the system control and system management EVCs.
Release R10.11.0	Command was expanded to include the MEF Ethernet interface.

Functional Notes

The **neighbor** command can be used to specify the BGP AF neighbors on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures an IPv4 BGP AF neighbor with an IPv4 address of **10.10.10.1** on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#neighbor 10.10.10.1**

The following example configures an IPv4 BGP AF neighbor with an IPv4 address of **10.10.10.1** on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.10.10.1**

network *<ipv4 address>* **mask** *<subnet mask>*

Use the **network mask** command to allow the Border Gateway Protocol (BGP) address family (AF) to advertise local networks that remote sites should be able to access. This command can be used for an Internet Protocol version 4 (IPv4) BGP AF on the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the configured network.

Syntax Description

<ipv4 address>	Specifies the network address for the neighbor that AOS will advertise over BGP. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks must be expressed in dotted decimal notation (for example, **255.255.255.0**).

Default Values

By default, there are no configured BGP networks.

Command History

Release 11.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Functional Notes

The **network** command can be used to specify the advertised routes for BGP AF neighbors on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example adds the **10.10.10.1** network with a subnet mask of **255.255.255.0** to the IPv4 BGP AF on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#network 10.10.10.1 mask 255.255.255.0**

The following example adds the **10.10.10.1** network with a subnet mask of **255.255.255.0** to the IPv4 BGP AF on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#network 10.10.10.1 mask 255.255.255.0**

network *<ipv6 address/prefix-length>*

Use the **network** command to allow the Border Gateway Protocol (BGP) address family (AF) to advertise local networks that remote sites should be able to access. This command can be used for an Internet Protocol version 6 (IPv6) BGP AF on the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to remove the configured network.

Syntax Description

<ipv6 address/prefix-length>	Specifies the IPv6 address and subnet for the neighbor that AOS will advertise over BGP. IPv6 addresses and prefixes should be expressed in colon hexadecimal format (for example, **2001:DB8:0:3F3B::/64**).

Default Values

By default, there are no configured BGP networks.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

The **network** command can be used to specify the advertised routes for BGP AF neighbors on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv6 BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher as-4byte 44:356**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv6**
(config-bgp-vrf-ipv6)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example adds the **2001:DB8:0:3F3B::/64** network to the IPv6 BGP AF on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv6**
(config-bgp-ipv6)**#network 2001:DB8:0:3F3B::/64**

The following example adds the **2001:DB8:0:3F3B::/64** network to the IPv6 BGP AF on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher as-4byte 44:356**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv6**
(config-bgp-vrf-ipv6)**#network 2001:DB8:0:3F3B::/64**

redistribute connected

Use the **redistribute connected** command to pass routes from one network to another, regardless of the routing protocol implemented on the routing domain. Using the **connected** keyword allows the propagation of routes connected to other interfaces using the Border Gateway Protocol (BGP) routing protocol for either the Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) BGP address family (AF) on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to disable the propagation of the specified route type. Variations of this command include:

redistribute connected
redistribute connected metric <*value*>
redistribute connected route-map <*name*>

Syntax Description

metric <*value*>	Optional. Specifies the hop count to use for advertising redistributed connected routes in the BGP AF.
route-map <*name*>	Optional. Specifies the route map filter to use for advertising redistributed connected routes in the BGP AF.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 functionality.

Functional Notes

The **redistribute connected** command can be used to specify the hop count for advertised routes for BGP AF neighbors on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

BGP does not blindly broadcast out of all interfaces. Instead, the network statement tells which networks to include in BGP updates. The **redistribute connected** command simply covers all connected networks.

Usage Examples

The following example passes the connected routes found in the route table to other networks running the BGP routing protocol from the IPv4 BGP AF on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#redistribute connected**

The following example passes the connected routes found in the route table to other networks running the BGP routing protocol from the IPv4 BGP AF on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#redistribute connected**

redistribute ospf

Use the **redistribute ospf** command to redistribute routes from one protocol to another, regardless of the routing protocol implemented on the routing domain. Using the **ospf** keyword allows the propagation of Open Shortest Path First (OSPF) routes into Border Gateway Protocol (BGP) for both Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6) BGP address families (AFs) on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to disable the propagation of the specified route type. Variations of this command include:

redistribute ospf
redistribute ospf <*process id*>
redistribute ospf <*process id*> **include-connected**
redistribute ospf <*process id*> **metric** <*value*>
redistribute ospf <*process id*> **no-include-connected**
redistribute ospf <*process id*> **route-map** <*map*>

After specifying the process id, the other parameters can be entered in any order. Use the ***?*** *after each specified subcommand for a valid list of arguments and settings.*

Syntax Description

<*process id*>	Optional. Specifies the OSPFv2 or OSPFv3 routing process from which BGP AF routes will be redistributed. The process ID is locally significant to the device, and must be unique among OSPF processes of the same version on the device. Valid range is **1** to **65535**.
include-connected	Optional. Used for OSPFv3 and IPv6 BGP AFs to specify that prefixes of the interface running this source protocol are included in the route redistribution.
no-include-connected	Optional. Used for OSPFv2 and IPv4 BGP AFs to specify that prefixes of the interface running this source protocol are not automatically included in the route redistribution.
metric <*value*>	Optional. Specifies the hop count to use for advertising redistributed OSPF routes in the BGP AF. When used with a process ID, it applies to IPv6 BGP AF only.
route-map <*map*>	Optional. Specifies the route map filter to use for advertising redistributed OSPF routes in the BGP AF.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Release R10.5.0	Command was expanded to include the <*process id*> and **include-connected** parameters. Command was also expanded to include IPv6 functionality.
Release R11.3.0	Command was expanded to include the <*process id*> parameter for OSPFv2 and the **no-include-connected** parameter.

Functional Notes

The **redistribute ospf** command can be used to specify the hop count for advertised OSPF routes for BGP AF neighbors on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Redistributing OSPF routes imports those routes into BGP without specifying those subnets with a network statement. The OSPF routes imported this way are not covered by a network command.

If **redistribute ospf** is enabled and no metric value is specified, the value defaults to **0**.

Usage Examples

The following example imports OSPF routes into the IPv4 BGP AF on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#redistribute ospf**

The following example imports OSPF routes into the IPv4 BGP AF on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#redistribute ospf**

redistribute rip

Use the **redistribute rip** command to redistribute routes from one protocol to another, regardless of the routing protocol implemented on the routing domain. Using the **rip** keyword allows the propagation of Routing Information Protocol (RIP) routes into Border Gateway Protocol (BGP) for the Internet Protocol version 4 (IPv4) BGP address family (AF) on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to disable the propagation of the specified route type. Variations of this command include:

redistribute rip
redistribute rip metric <*value*>
redistribute rip route-map <*name*>

Syntax Description

metric <*value*>	Optional. Specifies the hop count to use for advertising redistributed RIP routes in the BGP AF.
route-map <*name*>	Optional. Specifies the route map filter to use for advertising redistributed RIP routes in the BGP AF.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Functional Notes

The **redistribute rip** command can be used to specify the hop count for advertised RIP routes for BGP AF neighbors on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Redistributing RIP routes imports those routes into BGP. The RIP routes imported this way are not covered by a network command.

If **redistribute rip** is enabled and no metric value is specified, the value defaults to **0**.

Usage Examples

The following example imports RIP routes into the IPv4 BGP AF on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#redistribute rip**

The following example imports RIP routes into the IPv4 BGP AF on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#redistribute rip**

redistribute static

Use the **redistribute static** command to pass routes from one network to another, regardless of the routing protocol implemented on the routing domain. Using the **static** keyword allows the propagation of static routes into the Border Gateway Protocol (BGP) routing protocol for both the Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) BGP address family (AF) on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to disable the propagation of the specified route type. Variations of this command include:

redistribute static
redistribute static metric <*value*>
redistribute static route-map <*name*>

The gateway network for the static route must participate in BGP by using the network command for the gateway network.

Syntax Description

metric <*value*>	Optional. Specifies the hop count to use for advertising redistributed static routes in the BGP AF.
route-map <*name*>	Optional. Specifies the route map filter to use for advertising redistributed static routes in the BGP AF.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 functionality.

Functional Notes

The **redistribute static** command can be used to specify the hop count for advertised static routes for BGP AF neighbors on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**

(config-bgp-vrf-ipv4)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Redistributing static routes allows other network devices to learn about routes without requiring manual input to each device on the network.

Usage Examples

The following example passes the static routes found in the route table to other networks running the BGP routing protocol from the IPv4 BGP AF on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#redistribute static**

The following example passes the static routes found in the route table to other networks running the BGP routing protocol from the IPv4 BGP AF on the nondefault VRF instance named **RED1**:

config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#redistribute static**

BGP AF NEIGHBOR COMMAND SET

In AOS firmware release 18.03.00, Multiple virtual routing and forwarding (VRF) Border Gateway Protocol (BGP) functionality was incorporated into AOS. This release allows BGP configuration to occur on different VRF instances, and changes the hierarchical structure of BGP within AOS as well as the configuration steps necessary for BGP configuration. In addition, in AOS firmware release R10.1.0, support for multiprotocol BGP and Internet Protocol version 6 (IPv6) BGP were added.

The following are new features of BGP included with Multi-VRF BGP.

Address families (AFs) are used in BGP to maintain a separation between Internet protocol types within a VRF instance. With the advent of Multi-VRF BGP in 18.03.00, AOS implemented the use of AFs into the BGP hierarchical structure. An AF is a configuration structure that can reside at the default VRF instance and within a nondefault VRF instance. Creating an address family enables processing of that address family within a VRF, and it provides a place for AF-specific configuration.

In addition to the use of AFs, Multi-VRF BGP also allows the recognition and configuration of VRF instances specific to BGP functionality within the router. This allows the VRF constructs from the service provider to be incorporated into the customer router.

Multi-VRF is an application of the typical BGP functionality. As the name suggests, Multi-VRF BGP extends traditional service provider multi-VRF functionality of BGP to the customer edge router. This type of feature is typically used in Layer 3 virtual private network (VPN) applications where the VPN is extended to the customer device using multi-VRF. Multi-VRF BGP allows the customer edge router to dynamically exchange customer VPN routers to and through the provider's VPN *cloud*, thus eliminating the reliance on the provider to manage static routes. Multi-VRF takes place on the link between the service provider's routers and the customer edge equipment.

In Multi-VRF BGP the concepts of the address family and VRF instances are incorporated into the BGP configuration structure. VRF instances are in themselves not tied to a specific protocol, and therefore, control of multiple protocols within a single VRF is accomplished using an AF. Multi-VRF BGP also uses the concepts of AFs to provide specific BGP configuration to a single BGP policy, and maintain control over multiple bGP policies within a single AF.

In Multi-VRF BGP, the hierarchical structure of BGP configuration is as follows:

```
Global BGP settings (affecting all of BGP for this router)
!
VRF BGP settings (affecting only the default VRF)
Neighbor #1 Definition
    Neighbor #1 common settings (common to all peering with neighbor #1)
    exit
!
Address Family for the default VRF
    AF BGP settings (affecting only this AF)
    Neighbor #1 Reference
        Neighbor #1 AF-specific settings
```

```
        exit
    exit
!
VRF name1
    VRF BGP settings (affecting only this vRF)
    Neighbor #2 Definition
        Neighbor #2 common settings (common to all peering with neighbor #2)
        exit
!
Address Family for VRF name1
    AF BGP settings (affecting this AF)
    Neighbor #2 Reference
        Neighbor #2 settings specific to this AF
        exit
    exit
exit
```

Because the structure of BGP changed with the AOS 18.03.00 release, there are several sections of BGP configuration commands. The following are the BGP configuration command sections for AOS products, and are applicable to both the default and nondefault VRF instances:

- *BGP Command Set on page 3981*
- *BGP Address Family Command Set on page 4001*
- *BGP AF Neighbor Command Set on page 4022*
- *BGP Neighbor Command Set on page 4041*

Once you have enabled BGP in AOS products, you can enter the AF Neighbor Configuration mode by entering the **neighbor** command at the BGP AF Configuration mode prompt. To enter the IPv4 BGP AF Neighbor Configuration mode for the default VRF, enter the command as follows:

```
>enable
#configure terminal
(config)#router bgp 100
(config-bgp)#address-family ipv4
(config-bgp-ipv4)#neighbor 10.20.1.1
(config-bgp-ipv4-neighbor)#
```

To enter the IPv6 BGP AF Neighbor Configuration mode for the default VRF, enter the command as follows:

```
>enable
#configure terminal
(config)#router bgp 100
(config-bgp)#address-family ipv6
(config-bgp-ipv6)#neighbor 2001:DB8:1::1
(config-bgp-ipv6-neighbor)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

advertisement-interval <value> on page 4025
as-path-list <name> on page 4027
distribute-list on page 4029
next-hop-self on page 4031
prefix-list <name> on page 4033
route-map <name> on page 4035
send-community standard on page 4037
soft-reconfiguration inbound on page 4039

advertisement-interval *<value>*

Use the **advertisement-interval** command to configure AOS to specify how long the Border Gateway Protocol (BGP) process waits before sending updates to this neighbor. This command can be used for both the Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6) BGP address family (AF) neighbor on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the advertisement interval in seconds. Range is **0** to **600** seconds.

Default Values

By default, the advertisement interval is **30** seconds for external BGP AF neighbors and **5** seconds for internal BGP AF neighbors.

Command History

Release 8.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 functionality.

Functional Notes

The **advertisement-interval** command can be used to specify the wait time for a BGP AF neighbor on either the default or nondefault VRF instance. If the AF neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP AF neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP AF neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

The **advertisement-interval** command sets the minimum interval between sending updates to the specified neighbor.

Usage Examples

The following example configures the BGP process to wait at least **100** seconds before sending updates to this IPv4 AF neighbor on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#neighbor 192.22.73.101**
(config-bgp-ipv4-neighbor)**#advertisement-interval 100**

The following example configures the BGP process to wait at least **100** seconds before sending updates to this IPv4 AF neighbor on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)**#advertisement-interval 100**

as-path-list *<name>*

Use the **as-path-list** command to assign a predefined autonomous system (AS) path list to a Border Gateway Protocol (BGP) Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) address family (AF) neighbor. This list is then used to filter inbound and/or outbound BGP route updates. This command can be used for a BGP AF neighbor on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to discontinue use of the list. Variations of this command include:

as-path-list <*name*> **in**
as-path-list <*name*> **out**

Syntax Description

<name>	Assigns an AS path list to this BGP AF neighbor.
in	Specifies the filtering of all inbound BGP route updates.
out	Specifies the filtering of all outbound BGP route updates.

Default Values

By default, no AS path lists are specified for filtering.

Command History

Release 9.3	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 functionality.

Functional Notes

The **as-path-list** command can be used to specify the AS path list for a BGP AF neighbor on either the default or nondefault VRF instance. If the AF neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP AF neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP AF neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Before they can be assigned to a neighbor, AS path lists must first be defined using the command *ip classless on page 1348*.

Usage Examples

The following example uses the **no15** AS path list to filter all inbound BGP route updates for the IPv4 BGP AF neighbor on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#neighbor 192.22.73.101**
(config-bgp-ipv4-neighbor)**#as-path-list no15 in**

The following example uses the **no15** AS path list to filter all inbound BGP route updates for the IPv4 BGP AF neighbor on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)**#as-path-list no15 in**

distribute-list

Use the **distribute-list** command to add route filtering functionality by assigning inbound and outbound Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6) access control lists (ACLs) to a BGP address family (AF) neighbor on either the default or nondefault virtual routing and forwarding (VRF) instance. Only one inbound/outbound pair of ACLs can be configured for a particular AF neighbor. Use the **no** form of this command to disable filtering. Variations of this command include:

distribute-list <*ipv4 acl name*> **in**
distribute-list <*ipv4 acl name*> **out**
distribute-list <*ipv6 acl name*> **in**
distribute-list <*ipv6 acl name*> **out**

For a complete list of all extended and standard ACL configuration commands, refer to the *IPv6 Access Control List Command Set on page 4296* or *IPv4 Access Control List Command Set on page 4252*.

Syntax Description

<ipv4 acl name>	Specifies an IPv4 ACL name. This is a standard IPv4 ACL against which the contents of the incoming/outgoing routing updates are matched.
<ipv6 acl name>	Specifies an IPv6 ACL name. This is a standard IPv6 ACL against which the contents of the incoming/outgoing routing updates are matched.
in	Applies route filtering to inbound data.
out	Applies route filtering to outbound data.

Default Values

By default, distribute-list filtering is disabled.

Command History

Release 12.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 functionality.

Functional Notes

The **distribute-list** command can be used to specify the IPv4 or IPv6 ACL used by a BGP AF neighbor on either the default or nondefault VRF instance. If the AF neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP AF neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP AF neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**

(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example will filter out all network advertisements received by the IPv4 BGP AF neighbor on the default VRF instance via Ethernet interface **0/1** with the exception of the **10.10.10.0** network:

(config)**#ip access-list standard TRUSTED**
(config-std-nacl)**#permit 10.10.10.0 0.0.0.255**
(config-std-nacl)**#exit**
(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#neighbor 192.22.73.101**
(config-bgp-ipv4-neighbor)**#distribute-list TRUSTED in**

The following example will filter out all network advertisements received by the IPv4 BGP AF neighbor on the nondefault VRF instance named **RED1** via Ethernet interface **0/1** with the exception of the **10.10.10.0** network:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)**#distribute-list TRUSTED in**

next-hop-self

Use the **next-hop-self** command to force the NEXT_HOP attribute to be changed to this unit's IP address for each network it advertises to the Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) BGP address family (AF) neighbor on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled and the next autonomous system (AS) is advertised as the NEXT_HOP attribute.

Command History

Release 9.3	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 functionality.

Functional Notes

The **next-hop-self** command can be used to specify the IPv4 address used by a BGP AF neighbor on either the default or nondefault VRF instance. If the AF neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP AF neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP AF neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Internal Gateway Protocols (IGPs), such as Routing Information Protocol (RIP) and Open Shortest Path First (OSPF), always use the source IP address of a routing update as the next-hop address for each network that is placed in the routing table. Conversely, since BGP routes AS-to-AS, the default next hop that is advertised is the next AS. This behavior can present a problem in situations where an internal Border Gateway Protocol (iBGP) router learns about networks outside of its AS through one of its iBGP peers. By default, the next-hop address for the external networks advertised to the iBGP router is the entry

point for the next AS. When the iBGP router receives packets destined for one of the external networks, it performs a recursive lookup of the entries in its own IGP routing table to determine how to reach the BGP next-hop address. Unless the iBGP router has a static route or an entry in its IGP routing table indicating how to reach the edge router in the external AS, packets destined for those networks will be dropped. To remedy this scenario, the iBGP peer must advertise its own IP address as the next-hop address to the external networks. Consider the following example:

In external Border Gateway Protocol (eBGP), routes are normally advertised with a next hop set to the IP address that the receiving peer has configured in its neighbor statement for this router. In the eBGP case where the receiving router is in the same subnet as the current next hop, the current next hop is not changed.

For broadcast multiaccess networks (Ethernet), this provides more efficient routing. For nonbroadcast multiaccess (NBMA) networks, such as Frame Relay with a partial mesh using point-to-multipoint circuits, this rule can cause significant problems. Since the partial mesh is on the same subnet, BGP applies the rule of not changing the next-hop address, rendering routes in certain topologies invalid. This is one case where this command is necessary to solve a problem.

Usage Examples

The following example enables **next-hop-self** for the IPv4 BGP AF neighbor on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#neighbor 192.22.73.101**
(config-bgp-ipv4-neighbor)**#next-hop-self**

The following example enables **next-hop-self** for the IPv4 BGP AF neighbor on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)**#next-hop-self**

prefix-list <*name*>

Use the **prefix-list** command to assign a predefined prefix list to an Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) Border Gateway Protocol (BGP) address family (AF) neighbor on either the default or nondefault virtual routing and forwarding (VRF) instance. The list is then used to filter BGP route updates received and/or sent from/by the specified peer. Use the **no** form of this command to discontinue use of the prefix list. Variations of this command include:

prefix-list <*name*> **in**
prefix-list <*name*> **out**

Syntax Description

<*name*>	Assigns the specified prefix list to this BGP AF neighbor.
in	Specifies that all inbound BGP route updates received from the specified peer be filtered.
out	Specifies that all outbound BGP route updates being sent to the specified peer be filtered.

Default Values

By default, no prefix lists are specified for filtering.

Command History

Release 9.3	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 functionality.

Functional Notes

The **prefix-list** command can be used to specify the prefix list used by a BGP AF neighbor on either the default or nondefault VRF instance. If the AF neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP AF neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP AF neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Before they can be assigned to a BGP AF neighbor, prefix lists must first be defined using the **ip prefix-list** <*name*> **seq** <*number*> or **ipv6 prefix-list** <*name*> **seq** <*number*> command. Refer to the command *ip prefix-list <name> seq <number> on page 1443* or *ipv6 prefix-list <name> seq <number> on page 1556* for more information.

Usage Examples

The following example uses the **MyList** prefix list to filter all BGP updates received by the IPv4 BGP AF neighbor on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#neighbor 192.22.73.101**
(config-bgp-ipv4-neighbor)**#prefix-list MyList in**

The following example uses the **MyList** prefix list to filter all BGP updates received by the IPv4 BGP AF neighbor on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)**#prefix-list MyList in**

route-map <*name*>

Use the **route-map** command to assign a route map to this Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) Border Gateway Protocol (BGP) address family (AF) neighbor. You can apply the route map to BGP AF neighbors on either the default or nondefault virtual routing and forwarding (VRF) instance. The route map is then used to filter or modify inbound and/or outbound BGP route updates. Use the **no** form of this command to return to the default setting. Variations of this command include:

route-map <*name*> **in**
route-map <*name*> **out**

Syntax Description

<*name*>	Assigns the specified route map to this BGP AF neighbor.
in	Specifies the filtering/modification of all inbound BGP route updates.
out	Specifies the filtering/modification of all outbound BGP route updates.

Default Values

By default, no route map is assigned.

Command History

Release 9.3	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 functionality.

Functional Notes

The **route-map** command can be used to specify the route map used by a BGP AF neighbor on either the default or nondefault VRF instance. If the AF neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP AF neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP AF neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Before a route map can be assigned to a BGP neighbor, it must first be defined using the command *route-map on page 1687*.

Usage Examples

The following example assigns a route map to the IPv4 BGP AF neighbor on the default VRF instance for outbound filtering:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#neighbor 192.22.73.101**
(config-bgp-ipv4-neighbor)**#route-map MapName out**

The following example assigns a route map to the IPv4 BGP AF neighbor on the nondefault VRF instance named **RED1** for outbound filtering:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)**#route-map MapName out**

send-community standard

Use the **send-community standard** command to insert a standard Border Gateway Protocol (BGP) community attribute to all outgoing route updates for this Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) BGP address family (AF) neighbor. You can insert a BGP community attribute to the BGP AF neighbor on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, this command is disabled.

Command History

Release 9.3	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 functionality.

Functional Notes

The **send-community standard** command can be used to specify the BGP community used by a BGP AF neighbor on either the default or nondefault VRF instance. If the AF neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP AF neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP AF neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example inserts a standard BGP community attribute to all outgoing route updates for the IPv4 BGP AF neighbor on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#neighbor 192.22.73.101**
(config-bgp-ipv4-neighbor)**#send-community standard**

The following example inserts a standard BGP community attribute to all outgoing route updates for the IPv4 BGP AF neighbor on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)**#send-community standard**

soft-reconfiguration inbound

Use the **soft-reconfiguration inbound** command to enable this unit to store all updates from an Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) Border Gateway Protocol (BGP) address family (AF) neighbor in case the inbound policy is changed. This command can be used for a BGP AF neighbor on either the default or nondefault virtual routing and forwarding (VRF) instance.

Syntax Description

No subcommands.

Default Values

By default, this command is enabled.

Command History

Release 9.3	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.1.0	Command was expanded to include IPv6 functionality.

Functional Notes

The **soft-reconfiguration inbound** command can be used to specify that a BGP AF neighbor on either the default or nondefault VRF instance store all updates. If the AF neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP AF neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the IPv4 BGP AF neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

The **soft-reconfiguration inbound** command allows a network administrator to reconfigure BGP policies without clearing active BGP sessions. Administrators can then institute new policies at any time without forcing the neighbors to re-establish their connection and possibly disrupting traffic.

BGP updates are stored prior to filtering; thus, allowing the **clear bgp soft** command to be used in the absence of route refresh (RFC 2918) capability. The unfiltered table is used when an inbound policy is changed; allowing the router to immediately implement policy changes immediately based on the stored table instead of having to wait on a new table to be built after a hard reset. A soft reset is beneficial over a hard reset because it allows policy updates without disrupting network traffic flow. A hard reset terminates the existing BGP session, effectively removing all routes learned from a neighbor. A new session is then created and all of the routes must be relearned. Due to the fact that this process takes place with a hard reset, a network outage can potentiality occur until the BGP database and route table have been rebuilt.

Refer to *clear bgp on page 107* for more information.

Usage Examples

The following example enables the unit to store BGP updates for the IPv4 BGP AF neighbor on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#address-family ipv4**
(config-bgp-ipv4)**#neighbor 192.22.73.101**
(config-bgp-ipv4-neighbor)**#soft-reconfiguration inbound**

The following example enables the unit to store BGP updates for the IPv4 BGP AF neighbor on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#address-family ipv4**
(config-bgp-vrf-ipv4)**#neighbor 10.20.1.1**
(config-bgp-vrf-ipv4-neighbor)**#soft-reconfiguration inbound**

BGP NEIGHBOR COMMAND SET

Border Gateway Protocol (BGP) differs from many routing protocols because it does not allow a router to automatically search for peers from which to obtain routes. A separate BGP neighbor must be manually configured for each router with which the local router will communicate. Optional filtering policies can be configured for individual neighbors and are used by the router to dictate which routes the BGP interface sends to and accepts from the neighbor. In AOS firmware release 18.03.00, Multi-VRF BGP functionality was incorporated into AOS. This release allows BGP configuration to occur on different VRF instances, and changes the hierarchical structure of BGP within AOS as well as the configuration steps necessary for BGP configuration. In addition, in AOS firmware release R10.1.0, support for multiprotocol BGP and Internet Protocol version 6 (IPv6) BGP were added.

The following are new features of BGP included with Multi-VRF BGP.

Address families (AFs) are used in BGP to maintain a separation between Internet protocol types within a VRF instance. With the advent of Multi-VRF BGP in 18.03.00, AOS implemented the use of AFs into the BGP hierarchical structure. An AF is a configuration structure that can reside at the default VRF instance and within a nondefault VRF instance. Creating an address family enables processing of that address family within a VRF, and it provides a place for AF-specific configuration.

In addition to the use of AFs, Multi-VRF BGP also allows the recognition and configuration of VRF instances specific to BGP functionality within the router. This allows the VRF constructs from the service provider to be incorporated into the customer router.

Multi-VRF is an application of the typical BGP functionality. As the name suggests, Multi-VRF BGP extends traditional service provider multi-VRF functionality of BGP to the customer edge router. This type of feature is typically used in Layer 3 virtual private network (VPN) applications where the VPN is extended to the customer device using multi-VRF. Multi-VRF BGP allows the customer edge router to dynamically exchange customer VPN routers to and through the provider's VPN *cloud*, thus eliminating the reliance on the provider to manage static routes. Multi-VRF takes place on the link between the service provider's routers and the customer edge equipment.

In Multi-VRF BGP the concepts of the address family and VRF instances are incorporated into the BGP configuration structure. VRF instances are in themselves not tied to a specific protocol, and therefore, control of multiple protocols within a single VRF is accomplished using an AF. Multi-VRF BGP also uses the concepts of AFs to provide specific BGP configuration to a single BGP policy, and maintain control over multiple BGP policies within a single AF.

In Multi-VRF BGP, the hierarchical structure of BGP configuration is as follows:

```
Global BGP settings (affecting all of BGP for this router)
!
VRF BGP settings (affecting only the default VRF)
Neighbor #1 Definition
    Neighbor #1 common settings (common to all peering with neighbor #1)
    exit
!
```

```
Address Family for the default VRF
    AF BGP settings (affecting only this AF)
    Neighbor #1 Reference
        Neighbor #1 AF-specific settings
        exit
    exit
!
VRF name1
    VRF BGP settings (affecting only this vRF)
    Neighbor #2 Definition
        Neighbor #2 common settings (common to all peering with neighbor #2)
        exit
!
Address Family for VRF name1
    AF BGP settings (affecting this AF)
    Neighbor #2 Reference
        Neighbor #2 settings specific to this AF
        exit
    exit
exit
```

Because the structure of BGP changed with the AOS 18.03.00 release, there are several sections of BGP configuration commands. The following are the BGP configuration command sections for AOS products, and are applicable to both the default and nondefault VRF instances:

- *BGP Command Set on page 3981*
- *BGP Address Family Command Set on page 4001*
- *BGP AF Neighbor Command Set on page 4022*
- *BGP Neighbor Command Set on page 4041*

To activate the BGP Neighbor Configuration mode, enter the **neighbor** command at the BGP Configuration mode prompt followed by the neighbor's IP address.

The IP address entered in this command must match the address for the interface that the remote router is using as its update source.

The local router must be able to reach the IP address configured as the neighbor ID. View the routing table and verify that it includes a route to this address.

Enter the IPv4 BGP Neighbor Configuration mode from the BGP Configuration mode as follows (for the default VRF instance):

```
>enable
#configure terminal
(config)#router bgp 1
(config-bgp)#neighbor 192.22.73.101
(config-bgp-neighbor)#
```

Enter the IPv6 BGP Neighbor Configuration mode from the BGP Configuration mode as follows (for the default VRF instance):

```
>enable
#configure terminal
(config)#router bgp 1
(config-bgp)#neighbor 2001:DB8:1::1
(config-bgp-neighbor)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

ebgp-multihop <value> on page 4044
hold-timer <value> on page 4046
local-as <value> on page 4048
password <password> on page 4050
remote-as <value> on page 4052
transport connection-mode on page 4054
update-source on page 4056

ebgp-multihop *<value>*

Use the **ebgp-multihop** command to configure the maximum hop count of Border Gateway Protocol (BGP) messages to a neighbor. This command can be applied to either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the maximum hop count of BGP messages to a neighbor. Range is **1** to **255** hops.

Default Values

By default, BGP multihop is set to **1**.

Command History

Release 8.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Functional Notes

The **ebgp-multihop** command can be used to allow a BGP neighbor on a network that is not directly connected on either the default or nondefault VRF instance. If the behavior is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

The **ebgp-multihop** command allows a BGP neighbor to be on a network that is not directly connected. Normally, BGP peers are directly connected. In certain applications, a non-BGP device, such as a firewall or router, can reside between BGP peers. In this case, the **ebgp-multihop** command is required to allow updates to have a time to live (TTL) greater than 1 and to allow received BGP updates to be added to the BGP table when the next-hop address is not directly connected.

Usage Examples

The following example allows a BGP message on the default VRF instance to travel **10** hops to a neighbor:

(config)**#router bgp 100**
(config-bgp)**#neighbor 192.22.73.101**
(config-bgp-neighbor)**#ebgp-multihop 10**

The following example allows a BGP message on the nondefault VRF instance named **RED1** to travel **10** hops to a neighbor:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)**#ebgp-multihop 10**

hold-timer <*value*>

Use the **hold-timer** command to set the default hold time for the Border Gateway Protocol (BGP) neighbor on either the default or nondefault virtual routing and forwarding (VRF) instance.

Syntax Description

<*value*>	Specifies a time interval (in seconds) within which a keepalive must be received from a peer before that peer is declared dead. Range is **0** to **65535** seconds.

Default Values

By default, the hold time is **180** seconds.

Command History

Release 8.1	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Functional Notes

The **hold-timer** command can be used to specify the hold timer for the BGP neighbor on either the default or nondefault VRF instance. If the neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Using the **hold-timer** command in BGP Neighbor Configuration mode sets the hold time for only that neighbor. The peers will negotiate and use the lowest configured setting. The keepalive interval will be set to one-third of the negotiated hold time.

Usage Examples

The following example sets a hold time of **120** seconds for this BGP neighbor, with an understood keepalive interval of **40** seconds, on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#neighbor 10.20.1.1**
(config-bgp-neighbor)**#hold-timer 120**

The following example sets a hold time of **120** seconds for this BGP neighbor, with an understood keepalive interval of **40** seconds, on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)**#hold-timer 120**

local-as <*value*>

Use the **local-as** command to specify an autonomous system (AS) number for the unit to use when communicating with this Border Gateway Protocol (BGP) neighbor. This command can be used for BGP neighbors on either the default or nondefault virtual routing and forwarding (VRF) instances. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the AS number to use when communicating with this neighbor. Must be different than the AS number for this router and the peer router. Only valid for external Border Gateway Protocol (eBGP) connections. Range is **0** to **4294967295**. When **0** is sued, it indicates that the BGP process local AS is used, because **0** is not a valid AS number.

Default Values

By default, the **local-as** value is set to **0**, indicating the router's BGP AS number is used.

Command History

Release 9.3	Command was introduced.
Release 18.1	Command was altered to support 4-byte AS numbers (previously AOS only supported 2-byte numbers).
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Functional Notes

The **local-as** command can be used to specify the AS number for the unit to use when communicating with this BGP neighbor on either the default or nondefault VRF instance. If the neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

The **local-as** command substitutes a different AS number to be used for communicating with this BGP neighbor (other than the one the router is actually a member of). This can be used to satisfy network designs requiring a customer to appear as one AS number when communicating with one Internet service provider (ISP) and another when communicating with another ISP.

Usage Examples

The following example configures this BGP neighbor's AS number on the default VRF instance to be **300**:

(config)**#router bgp 100**
(config-bgp)**#neighbor 192.22.73.101**
(config-bgp-neighbor)**#local-as 300**

The following example configures this BGP neighbor's AS number on the nondefault VRF instance named **RED1** to be **300**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)**#local-as 300**

Technology Review

This router appears (to the peer router) to be in the AS specified with the **local-as** command. Therefore, all routes learned from the peer have this number prepended to the AS path. In network advertisements from routers using the **local-as** command, the router's true AS number (the number specified using the **router bgp as-number** command) is prepended to the AS path attribute, and the local AS (the number specified in the **neighbor local-as** command) is prepended to the AS path attribute. This makes it appear that the path to the network is first through the local AS, and then through the true AS. To further illustrate, consider the following example network.

In this network:

- Router A is in AS 100.
- Router B is in AS 300.
- Router A is an eBGP peer with Router B.
- Router A's connection to Router B specifies a **local-as** of 200.
- Router B is configured to connect to Router A in AS 200.

Therefore:

- To Router B, all aspects of Router A appear as AS 200.
- Networks advertised from Router A to Router B will have the AS path **200 100** prepended to the AS path attribute.
- Router A will add AS 200 to the AS path of networks learned from Router B.

password *<password>*

Use the **password** command to enable message digest 5 (MD5) password authentication on Transmission Control Protocol (TCP) segments exchanged with the Border Gateway Protocol (BGP) peer. This command can be used for BGP neighbors on the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to disable authentication.

Syntax Description

<password>	Specifies the password string to be used for authentication. The password is case sensitive and must not exceed **80** characters.

Default Values

By default, authentication is disabled.

Command History

Release 9.3	Command was introduced.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Functional Notes

The **password** command can be used to specify the authentication password used for TCP communication with this BGP neighbor on either the default or nondefault VRF instance. If the neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Authentication must be configured on both peers using the same password. Every BGP TCP segment sent is authenticated. Configuring authentication causes an existing session to be torn down and re-established using the currently specified authentication.

Usage Examples

The following example enables authentication for this BGP neighbor on the default VRF instance and sets a password of **user1**:

(config)**#router bgp 100**
(config-bgp)**#neighbor 192.22.73.101**
(config-bgp-neighbor)**#password user1**

The following example enables authentication for this BGP neighbor on the nondefault VRF instance named **RED1** and sets a password of **user1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)**#password user1**

remote-as <*value*>

Use the **remote-as** command to specify the Border Gateway Protocol (BGP) autonomous system (AS) to which the neighbor belongs, adding an entry to the BGP neighbor table. This command can be used for BGP neighbors on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the AS number. This number must be different from the AS number of the local router (defined using the command *router bgp <value> on page 1689*). Range is **1** to **4294967295**.

Default Values

By default, no BGP neighbors are defined.

Command History

Release 9.3	Command was introduced.
Release 18.1	Command was altered to support 4-byte AS numbers (previously AOS only supported 2-byte numbers).
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.

Functional Notes

The **remote-as** command can be used to specify the AS number for this BGP neighbor on either the default or nondefault VRF instance. If the neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures a remote AS number of **200** for this neighbor on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#neighbor 192.22.73.101**
(config-bgp-neighbor)**#remote-as 200**

The following example configures a remote AS number of **200** for this neighbor on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)**#remote-as 200**

transport connection-mode

Use the **transport connection-mode** command to specify Border Gateway Protocol (BGP) transport session options for the BGP neighbor. This command can be used for BGP neighbors on the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to return the connection mode to the default value. Variations of this command include:

transport connection-mode active
transport connection-mode passive

Syntax Description

active	Specifies that only active Transmission Control Protocol (TCP) session connections are allowed for this neighbor. Active connections are those that are initiated by the router to establish a TCP connection to the neighbor.
passive	Specifies that only passive TCP session connections are allowed for this neighbor. Passive connections are those in which the router is only allowed to listen for incoming BGP connections without trying to establish a connection.

Default Values

By default, both active and passive connections are supported simultaneously, and a collision detection algorithm is used to determine which TCP session to use should an inbound and outbound connection begin.

Command History

Release 18.3	Command was introduced.

Functional Notes

The **transport connection-mode** command can be used to specify the connection mode for this BGP neighbor on either the default or nondefault VRF instance. If the neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that **active** connections are allowed for this BGP neighbor on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#neighbor 192.22.73.101**
(config-bgp-neighbor)**#transport connection-mode active**

The following example specifies that **active** connections are allowed for this BGP neighbor on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)**#transport connection-mode active**

update-source

Use the **update-source** command to specify which interface's IPv4 address will be used as the source IPv4 address for the Border Gateway Protocol (BGP) Transmission Control Protocol (TCP) connection (when connecting to this peer). This command can be used for BGP neighbors on either the default or nondefault virtual routing and forwarding (VRF) instance. Use the **no** form of this command to return to the default setting. Variations of this command include:

update-source <*interface*>
update-source system-control-evc
update-source system-management-evc

Syntax Description

<*interface*>	Specifies the interface to be used as the source IPv4 address. Specify an interface in the format <*interface type [slot/port	slot/port.subinterface id	interface id	interface id.subinterface id]*>. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**. Type **update-source ?** for a complete list of valid interfaces.
system-control-evc	Specifies the system control Ethernet virtual connection (EVC) is used as the source IPv4 address.
system-management-evc	Specifies the system management EVC is used as the source IPv4 address.

Default Values

By default, the outbound interface's IPv4 address is used for BGP updates.

Command History

Release 9.3	Command was introduced.
Release 14.1	Command was expanded to include the asynchronous transfer mode (ATM) and high level data link control (HDLC) interfaces.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface.
Release 18.3	Command was incorporated into Multi-VRF BGP functionality.
Release R10.4.0	Command was expanded to include the virtual local area network (VLAN) interface.
Release R10.10.0	Command was expanded to include the system control and system management EVCs.
Release R11.3.0	Command was expanded to include the Ethernet in the first mile (EFM) group interface.

Functional Notes

The **update-source** command can be used to specify the source IP address for this BGP neighbor on either the default or nondefault VRF instance. If the neighbor is to be created on a nondefault VRF instance, the VRF instance must first be created using the command *vrf <name> route-distinguisher on page 1989*. Once you have created the nondefault VRF instance, you can configure the BGP neighbor settings for the VRF instance using the command *vrf <name> on page 4000* from the router's BGP Configuration mode. For example, to configure the BGP neighbor characteristics for the nondefault VRF instance **RED1**, enter the following commands:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)#

For more information about VRF and Multi-VRF BGP configuration, refer to the configuration guides *Configuring IPv4 Multi-VRF in AOS* and *Configuring BGP in AOS for Releases 18.03.00/R10.1.0 or Later* available online at https://supportcommunity.adtran.com.

The source interface is most often configured as a loopback interface that is reachable by the peer router. The peer will specify this address in its neighbor commands for this router.

Usage Examples

The following example configures the **loopback 1** interface as the source IPv4 address for this BGP neighbor on the default VRF instance:

(config)**#router bgp 100**
(config-bgp)**#neighbor 192.22.73.101**
(config-bgp-neighbor)**#update-source loopback 1**

The following example configures the **loopback 1** interface as the source IPv4 address for this BGP neighbor on the nondefault VRF instance named **RED1**:

(config)**#vrf RED1 route-distinguisher ip 192.17.250.24:33**
(config)**#router bgp 100**
(config-bgp)**#vrf RED1**
(config-bgp-vrf)**#neighbor 10.20.1.1**
(config-bgp-vrf-neighbor)**#update-source loopback 1**

COMMUNITY LIST COMMAND SET

To activate the Community List Configuration mode, enter the **ip community-list** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ip community-list listname
(config-comm-list)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

deny on page 4059
permit on page 4060

deny

Use the **deny** command to add an entry to the community list that denies Border Gateway Protocol (BGP) routes containing the specified community number in the community attribute. Use the **no** form of this command to remove the statement from the community list. Variations of this command include:

deny <*value*>
deny internet
deny local-as
deny no-advertise
deny no-export

Syntax Description

<*value*>	Denies routes that contain this value in their community attribute. This is a numeric value that can be an integer from **1** to **4294967295** or string in the form ***aa:nn***, where ***aa*** is the autonomous system (AS) number and ***nn*** is the community number. Multiple community number parameters can be present in the command.
internet	Denies routes that contain the reserved community number for the Internet community.
local-as	Denies routes that contain the reserved community number for NO_EXPORT_SUBCONFED. Routes containing this attribute should not be advertised to external BGP peers.
no-advertise	Denies routes that contain the reserved community number for NO_ADVERTISE. Routes containing this attribute should not be advertised to any BGP peer.
no-export	Denies routes that contain the reserved community number for NO_EXPORT. Routes containing this attribute should not be advertised to BGP peers outside a confederation boundary.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example creates a community list named **MyList** to deny BGP routes that have the Internet community number in their community attribute:

(config)**#ip community-list MyList**
(config-comm-list)**#deny no-export**

permit

Use the **permit** command to add an entry to the community list that allows only Border Gateway Protocol (BGP) routes containing the specified community number in the community attribute. Use the **no** form of this command to remove the statement from the community list. Variations of this command include:

permit <*value*>
permit internet
permit local-as
permit no-advertise
permit no-export

Syntax Description

<*value*>	Permits routes that contain this value in their community attribute. This is a numeric value that can be an integer from **1** to **4294967295** or string in the form ***aa:nn***, where ***aa*** is the autonomous system (AS) number and ***nn*** is the community number. Multiple community number parameters can be present in the command.
internet	Permits routes that contain the reserved community number for the Internet community.
local-as	Permits routes that contain the reserved community number for NO_EXPORT_SUBCONFED. Routes containing this attribute should not be advertised to external BGP peers.
no-advertise	Permits routes that contain the reserved community number for NO_ADVERTISE. Routes containing this attribute should not be advertised to any BGP peer.
no-export	Permits routes that contain the reserved community number for NO_EXPORT. Routes containing this attribute should not be advertised to BGP peers outside a confederation boundary.

Default Values

No default values are necessary for this command.

Command History

Release 9.3	Command was introduced.

Usage Examples

The following example permits BGP routes that match the AS path attributes:

(config)**#ip as-path-list listname**
(config-comm-list)**#permit 30:22**

NETWORK MONITORING COMMAND SETS

This section includes the following command sets:

NETWORK MONITOR PROBE COMMAND SET

This section explains the commands available for Network Monitoring Probes. Probes are software agents that send test traffic across a network path. Tracks are standalone objects that can help determine the status of a route based on the success or failure of a probe. The probes can be configured to trigger at particular intervals. There are five types of probes supported by Adtran Operating System (AOS): Internet Control Message Protocol (ICMP) echo, Transmission Control Protocol (TCP) connect, Hypertext Transfer Protocol (HTTP) request, Two-Way Active Measurement Protocol (TWAMP), and ICMP timestamp. Commands common to all the probe types are identified in the following section, as well as isolated commands that only apply to the specific probe types.

Additional configuration commands are available for associating tracks with each probe. These are explained in the *Network Monitor Track Command Set on page 4098*.

To activate the Network Monitor Probe Configuration mode, enter the **probe** command at the Global Configuration mode prompt followed by the probe name. Specify the probe type of **icmp-echo**, **tcp-connect**, **http-request, icmp-timestamp**, and **twamp**. For example:

```
>enable
#configure terminal
(config)#probe probe1 icmp-echo
(config-probe-probe1)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
exit on page 83
interface on page 84
shutdown on page 93

The following commands are applicable to ICMP echo probe types and can be executed after this command:

(config)**#probe** <*probe name*> **icmp-echo**

data <pattern> on page 4069
destination on page 4070
period <value> on page 4076
size <payload length> on page 4079
source-address <ip address> on page 4080
timeout <value> on page 4084
tolerance on page 4085
vrf <name> on page 4088

The following commands are applicable to TCP connect probe types and can be executed after this command:

(config)#**probe** <*probe name*> **tcp-connect**

destination on page 4070
num-packets <value> on page 4075
period <value> on page 4076
source-address <ip address> on page 4080
source-port <port> on page 4081
timeout <value> on page 4084
tolerance on page 4085
vrf <name> on page 4088

The following commands are applicable to HTTP request probe types and can be executed after this command:

(config)#**probe** <*probe name*> **http-request**

absolute-path <name> on page 4065
destination on page 4070
expect regex <expression> on page 4072
expect status <minimum> <maximum> on page 4073
num-packets <value> on page 4075
period <value> on page 4076
raw-string on page 4077
source-address <ip address> on page 4080
source-port <port> on page 4081
timeout <value> on page 4084
tolerance on page 4085
type on page 4087
vrf <name> on page 4088

The following commands are applicable to ICMP timestamp probe types and can be executed after this command:

(config)#**probe** <*probe name*> **icmp-timestamp**

data on page 4068
destination on page 4070
dscp <value> on page 4071
history-depth <value> on page 4074
num-packets <value> on page 4075

num-packets <value> on page 4075
period <value> on page 4076
send-schedule periodic <value> on page 4078
size <payload length> on page 4079
source-address <ip address> on page 4080
threshold on page 4082
timeout <value> on page 4084
tolerance on page 4085
vrf <name> on page 4088

The following commands are applicable to TWAMP probe types and can be executed after this command:

(config)**#probe** <*probe name*> **twamp**

auth-mode open on page 4066
control on page 4067
data on page 4068
destination on page 4070
dscp <value> on page 4071
history-depth <value> on page 4074
num-packets <value> on page 4075
num-packets <value> on page 4075
period <value> on page 4076
send-schedule periodic <value> on page 4078
size <payload length> on page 4079
source-address <ip address> on page 4080
source-port <port> on page 4081
threshold on page 4082
timeout <value> on page 4084
tolerance on page 4085
vrf <name> on page 4088

absolute-path *<name>*

Use the **absolute-path** command to specify the server's root path. Use the **no** form of this command to return to the default setting.

Syntax Description

<name>	Specifies a path name.

Default Values

By default, the path name is the forward slash symbol (**/**).

Command History

Release 13.1	Command was introduced.

Functional Notes

This command can only be executed while in the **probe** *<name>* **http-request** command set.

Usage Examples

The following example sets the absolute path to **/home/index.html**:

(config)**#probe probe1 http-request**
(config-probe-probe1)**#absolute-path/home/index.html**

auth-mode open

Use the **auth-mode open** command to specify the authentication mode the probe must use for communication. Use the **no** form of this command to return to the default setting.

Syntax Description

No subcommands.

Default Values

By default, the authentication mode is **open**.

Command History

Release 17.2	Command was introduced.

Functional Notes

This command can only be executed while in the **probe** <*name*> **twamp** command set.

Usage Examples

The following example sets the authentication mode to **open**:

(config)**#probe probe1 twamp**
(config-probe-probe1)**#auth-mode open**

control

Use the **control** command to specify source and destination ports. Use the **no** form of this command to return to the default setting. Variations of this command include:

control dest-port owamp-control
control dest-port twamp-control
control dest-port <*port*>
control source-port <*port*>

Syntax Description

dest-port	Specifies the type of destination control port.
owamp-control	Specifies the destination One-Way Active Measurement Protocol (OWAMP) control port (861).
twamp-control	Specifies the destination Two-Way Active Measurement Protocol (TWAMP) default control port (862).
<*port*>	Specifies a destination TWAMP control port other than the default port 862. The valid range is **1** to **65535**.
source-port <*port*>	Specifies the TWAMP source control port. The valid range is **0** to **65535**.

Default Values

By default, the source port is **0**, which means that the source port will be dynamically selected by the probe. The default destination port is the TWAMP control port, port **862**.

Command History

Release 17.2	Command was introduced.
Release 17.6	Command was expanded to include the **twamp-control** parameter and default destination port was set to port **862**.

Functional Notes

This command can only be executed while in the **probe** <*name*> **twamp** command set.

Usage Examples

The following example specifies a destination control port for the **probe1** probe:

(config)**#probe probe1 twamp**
(config-probe-probe1)**#control dest-port owamp-control**

data

Use the **data** command to specify the data for padding a measurement packet. Payload data specifies the data used to pad a measurement packet. Payload data can consist of all zeros pattern, a random pattern, or a user-defined pattern. If the payload size is greater than the length of the pattern, the pattern will be repeated. Use the **no** form of this command to return to the default setting. Variations of this command include:

data pattern ascii <*string*>
data pattern hex <*string*>
data random
data zero

Syntax Description

pattern ascii <*string*>	Specifies an ASCII data pattern.
pattern hex <*string*>	Specifies a hexadecimal data pattern.
random	Specifies using a pattern of random numbers.
zero	Specifies using a pattern of zeros.

Default Values

By default, the data pattern is set to **zero**.

Command History

Release 17.2	Command was introduced to function with Two-Way Active Measurement Protocol (TWAMP) and Internet Control Message Protocol (ICMP) timestamp probes only.

Functional Notes

This command can only be executed while in the **probe** <*name*> **twamp** and **probe** <*name*> **icmp-timestamp** command set.

Usage Examples

The following example specifies a data pattern as **random**:

(config)**#probe probe2 twamp**
(config-probe-probe2)**#data random**

data *<pattern>*

Use the **data** command to specify a hexadecimal pattern to repeat in the Internet Control Message Protocol (ICMP) packet data section. Use the **no** form of this command to return to the default setting.

Syntax Description

<pattern>	Specifies a hexadecimal data pattern.

Default Values

By default, the data pattern is a standard ping packet pattern of data values starting with 0x00, incrementing by one for the length of the packet. Refer to *ping on page 48* for more information on ping packet data patterns.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example specifies a data pattern of **0FF0** for **probe1**:

(config)**#probe probe1 icmp-echo**
(config-probe-probe1)**#data 0FF0**

destination

Use the **destination** command to specify the destination host name and port for the probe object. Use the **no** form of this command to remove the setting. Variations of this command include:

destination <*hostname*>
destination <*hostname*> **port** <*number*>
destination interface <*interface*>
destination <*ip address*>
destination <*ip address*> **port** <*number*>

The probe is not operational until a destination is defined.

Syntax Description

<*hostname*>	Specifies the IP host by name.
interface <*interface*>	Specifies an interface's gateway as the destination for an Internet Control Message Protocol (ICMP) probe object. Specify an interface in the format <*interface type [slot/port	slot/port.subinterface id	interface id	interface id.subinterface id]*>. For example, for a Frame Relay interface, use **fr 1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; and for an ATM subinterface, use **atm 1.1**. Type **destination interface ?** for a complete list of valid interfaces.
<*ip address*>	Specifies a valid IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
port <*number*>	Optional. Specifies port number. This feature is not used with icmp-echo probes. The valid range is **1** to **65535**.

Default Values

By default, there is no setting for this command.

Command History

Release 13.1	Command was introduced.
Release R12.3.0	Command expanded to include the **interface** parameter for ICMP probes.

Usage Examples

The following example specifies **www.adtran.com** as the host and **port 21** File Transfer Protocol (FTP) as the destination for the HTTP request probe, **probe1**:

(config)**#probe probe1 http-request**
(config-probe-probe1)**#destination www.adtran.com port 21**

dscp *<value>*

Use the **dscp** command to specify the differentiated services code point (DSCP) value placed in the test packets. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the DSCP value. The range is **0** to **63**.

Default Values

By default, the DSCP value is **0**.

Command History

Release 13.1	Command was introduced.
Release 17.2	Command was added to the Two-Way Active Measurement Protocol (TWAMP) and Internet Control Message Protocol (ICMP) timestamp probes.

Usage Examples

The following example specifies DSCP value to be placed in the probe:

(config)**#probe probe2 icmp-timestamp**
(config-probe-probe2)**#dscp 15**

expect regex *<expression>*

Use the **expect regex** command to configure the probe to expect a regular expression inside the contents of the Hypertext Transfer Protocol (HTTP) response message. If the regular expression does not match anything, the probe fails. Use the **no** form of this command to return to the default setting.

Syntax Description

<expression>	Specifies the expression to display.

Default Values

By default, no regular expression is defined.

Command History

Release 13.1	Command was introduced.

Functional Notes

This command can only be executed while in the **probe** *<name>* **http-request** command set.

Usage Examples

The following example only allows the **probe1** test to pass if the word **success** is found in the HTTP server response message:

(config)**#probe probe1 http-request**
(config-probe-probe1)**#expect regex success**

expect status <*minimum*> <*maximum*>

Use the **expect status** command to configure the probe to expect a specific status code in response to an Hypertext Transfer Protocol (HTTP) request message. If a different status code is returned, the probe fails. Use the **no** form of this command to return to the default setting. Variations of this command include:

expect status <*minimum*>
expect status <*minimum*> <*maximum*>

Syntax Description

<*minimum*>	Specifies a minimum number value for the status code. Valid range is **0** to **999**.
<*maximum*>	Optional. Specifies a maximum number to create a range of status codes. Valid range is **0** to **999**.

Default Values

By default, there is no setting for this command.

Command History

Release 13.1	Command was introduced.

Functional Notes

This command can only be executed while in the **probe** <*name*> **http-request** command set.

Specifying only a minimum value indicates only one value can match the status code. Entering a maximum value indicates a range of possible matches.

Usage Examples

The following example configures **probe1** to expect a status code of **200** (the status of a successful HTTP request):

(config)**#probe probe1 http-request**
(config-probe-probe1)**#expect status 200**

history-depth <*value*>

Use the **history-depth** command to specify the number of probe operation results allowed to be stored in the unit's memory. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the number of probe operation results to keep in the history memory. The range is **1** to **120**.

Default Values

By default, the **history-depth** value is set to **1**.

Command History

Release 17.2	Command was introduced.

Functional Notes

This command can only be executed while in the **probe** <*name*> **icmp-timestamp** or **probe** <*name*> **twamp** command set.

Usage Examples

The following example specifies the number of probe results that can be stored in the unit:

(config)**#probe probe2 icmp-timestamp**
(config-probe-probe2)**#history-depth 30**

num-packets *<value>*

Use the **num-packets** command to specify the number of packets to send and receive during a single probe operation. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the number of packets. Valid range is **1** to **1000** packets.

Default Values

By default, the **num-packets** is set to **10**.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example specifies sending **10** packets during the probe test:

(config)**#probe probe3 twamp**
(config-probe-probe3)**#num-packets 10**

period <*value*>

Use the **period** command to specify the time between probe test attempts. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the time (in seconds) between probe test attempts. Valid range is **1** to **65535** seconds.

Default Values

By default, the period between probe tests is **60** seconds.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example specifies **probe1** to initiate probe tests every **90** seconds:

(config)**#probe probe1 icmp-echo**
(config-probe-probe1)**#period 90**

raw-string

Use the **raw-string** command to enter text to appear in the data portion of a Hypertext Transfer Protocol (HTTP) request. Refer to *ping on page 512* for more details on the output text. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 13.1	Command was introduced.

Functional Notes

This command can only be executed while in the **probe** <*name*> **http-request** command set. The type should be set to RAW. Refer to *tolerance on page 4085* for more information.

The following system variables can be used in the text:

$SYSTEM_NAME = The host name of the system.

$SYSTEM_SERIAL_NUMBER = The serial number of the system.

$SYSTEM_DESCRIPTION = The product name and part number of the system.

$SYSTEM_SOFTWARE_VERSION = The firmware version of the system.

Usage Examples

The following example configures a RAW HTTP request that attempts to access **update.php** on the Web server. This command could be useful if the server administrator creates a PHP script that logs network connectivity information. Additional information (the router name and its uptime) placed after **update.php** is sent to the HTTP server.

```
(config)#probe probe1 http-request
(config-probe-probe1)#raw-string
    GET /update.php?hostname=$SYSTEM_NAME&uptime=$SYSTEM_UPTIME HTTP/1.0
    \r\n
    \r\n
    exit
```

send-schedule periodic <*value*>

Use the **send-schedule periodic** command to specify the amount of time (in milliseconds) between sending individual test packets during the probe. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the time interval between the individual packets. The valid range is **5** to **5000** milliseconds.

Default Values

By default, the time interval is **20** milliseconds.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example specifies a **45** millisecond time interval between the packets during **probe1** test:

(config)**#probe probe1 twamp**
(config-probe-probe1)**#send-schedule periodic 45**

size *<payload length>*

Use the **size** command to specify the length of the probe's test packet payload. Use the **no** form of this command to return to the default setting.

Syntax Description

<payload length>	Specifies size of test packet's payload. Valid range is **0** to **1462** bytes.

Default Values

By default, the payload length is **0** bytes.

Command History

Release 13.1	Command was introduced.
Release 17.2	Command was updated with a new default, range, and description.

Usage Examples

The following example sets the length of the Internet Control Message Protocol (ICMP) echo packet's padding field for **probe1** to **25** bytes:

(config)**#probe probe1 icmp-echo**
(config-probe-probe1)**#size 25**

source-address <*ip address*>

Use the **source-address** command to associate an IP address source for probe traffic. Use the **no** form of this command to remove the source IP address.

Syntax Description

<ip address>	Specifies a valid IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, the IP address of the outbound interface is used.

Command History

Release 13.1	Command was introduced.

Functional Notes

A valid local IP address must be entered for proper functionality.

Usage Examples

The following example configures the source IP address on **probe1**:

(config)**#probe probe1 icmp-echo**
(config-probe-probe1)**#source-address 10.10.10.1**

source-port <*port*>

Use the **source-port** command to specify a port source to use for probe traffic. Use the **no** form of this command to return to the default setting.

Syntax Description

<*port*>	Specifies the port number. Valid range is **0** to **65535**.

Default Values

By default, the port is set to **0** which means that the probe will dynamically select the port number.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example configures the source port on **probe1** as **5000**:

(config)**#probe probe1 http-request**
(config-probe-probe1)**#source-port 5000**

threshold

Use the **threshold** command to specify the criteria for a probe to be declared as passing or failing for the **delay**, **ipdv-abs**, and **packet-loss** values measured by the probe. Any combination of direction and type of threshold can be simultaneously configured and performed during the probe. Use the **no** form of this command to return to the default setting. Variations of this command include the following:

threshold delay [in | out | round-trip] [avg | max | min] *<fail value> <pass value>*
threshold ipdv-abs [in | out | round-trip] [avg | max | min] *<fail value> <pass value>*
threshold packet-loss round-trip [avg | max | min] *<fail value> <pass value>*

Syntax Description

delay	Specifies the thresholds for changing the state of the probe between pass and fail based on the measured delay. The fail and pass value range is **-2147483648** to **2147483647** milliseconds.
ipdv-abs	Specifies the thresholds for changing the state of the probe between pass and fail based on measured interpacket delay variation (IPDV). The fail and pass value range is **0** to **4294967295** milliseconds.
in	Specifies inbound delay or IPDV.
avg	Specifies the inbound average delay or IPDV.
max	Specifies the inbound maximum delay or IPDV.
min	Specifies the inbound minimum delay or IPDV.
out	Specifies outbound delay or IPDV.
avg	Specifies the outbound average delay or IPDV.
max	Specifies the outbound maximum delay or IPDV.
min	Specifies the outbound minimum delay or IPDV.
round-trip	Specifies round trip delay or IPDV.
packet-loss	Specifies the thresholds for changing the state of the probe between pass and fail based on measured packet loss. The fail and pass value range is **1** to **1000** packets.
round-trip	Specifies round trip packet loss.
avg	Specifies the average round trip packet loss.
max	Specifies the maximum round trip packet loss.
min	Specifies the minimum round trip packet loss.
<fail value>	Specifies the probe's failing value. Refer to the specific threshold type above for the valid range.
<pass value>	Specifies the probe's passing value. Refer to the specific threshold type above for the valid range.

Default Values

By default, the **delay** pass and fail value is **2147483647** milliseconds, the **ipdv-abs** pass and fail value is **4294967295** milliseconds, and the **packet-loss** pass and fail value is **1000**. This disables each of these thresholds by default.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example configures the probe to fail if it loses **100** packets and change to pass if packet loss is below **75**:

(config)**#probe probe1 icmp-echo**
(config-probe-probe1)**#threshold packet-loss in max 100 75**

timeout <*value*>

Use the **timeout** command to specify the amount of time to wait for a test result before determining a failure. Use the **no** form of this command to remove the timeout setting.

Syntax Description

<*value*>	Specifies the timeout value in milliseconds. This value must be less than the probe period value (refer to *dscp <value> on page 4071*). Valid range is **1** to **900000** milliseconds.

Default Values

By default, the timeout is **2000** milliseconds, and **10000** milliseconds (10 seconds) for Transmission Control Protocol (TCP) connect probes and **10000** milliseconds (10 seconds) for Hypertext Transfer Protocol (HTTP) request probes.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example configures AOS to wait **90** milliseconds before determining a failure on **probe1**:

(config)**#probe probe1 icmp-echo**
(config-probe-probe1)**#timeout 90**

tolerance

Use the **tolerance** command to configure the tolerance limit for test failures before returning a fail status from the probe. Limits can be specified for consecutive failures or by rate of failure. Tolerance levels can also be different based upon whether the probe is transitioning to the pass or fail state. Use the **no** form of this command to remove tolerance levels from probes. Variations of this command include:

tolerance consecutive fail <*number*>
tolerance consecutive pass <*number*>
tolerance consecutive fail <*number*> **pass** <*number*>
tolerance rate fail <*number*> **of** <*set size*>
tolerance rate pass <*number*> **of** <*set size*>
tolerance rate fail <*number*> **pass** <*number*> **of** <*set size*>

The probe is not operational until tolerance is defined.

Syntax Description

consecutive	Specifies that the probe state transitions occur only after a consecutive number of test results conflict with the current state.
rate	Specifies that the probe state transitions occur after a certain ratio of test results conflict with the current state.
fail <*number*>	Specifies the number of failures that must occur before transitioning the probe to the FAIL state. Valid ranges are **1** to **255** consecutive failures and **1** to **254** failures per set.
pass <*number*>	Specifies the number of passes before transitioning the probe to the PASS state. Valid ranges are **1** to **255** consecutive passes and **1** to **254** passes per set.
of <*set size*>	Specifies test set size for rate configuration. Valid range is **1** to **255**.

Default Values

By default, there are no configured tolerance levels. Therefore, a probe that does not have a defined tolerance will never fail.

When probes are set in **consecutive** mode, any state not explicitly configured has its tolerance value set to **1**.

In **rate** mode, any state not explicitly configured has its tolerance value set to 1+s-t, where ‘s’ is the set size and ‘t’ is the value of the other state.

Command History

Release 14.1	Command was introduced.
Release 15.1	Command revised to include **pass** and **fail** values.
Release 17.2	Command was added to the Two-Way Active Measurement Protocol (TWAMP) and Internet Control Message Protocol (ICMP) timestamp probes.

Functional Notes

This command has been modified from its original form. All tolerance configurations before Revision 15.1 are deprecated, but will be supported for existing units that are upgraded.

Usage Examples

The following example configures probe1 to allow **10** consecutive failures before changing the probe status to FAIL, and requires **5** consecutive passes to change its status to PASS when in the FAIL state:

(config)**#probe probe1 icmp-echo**
(config-probe-probe1)**#tolerance consecutive fail 10 pass 5**

In the following example, the probe is configured for rate tolerance. To move to the FAIL state, 5 of the last 10 tests must fail. Once in this state, **8** of the last **10** tests must pass in order to transition the probe back to PASS:

(config)**#probe probe1 icmp-echo**
(config-probe-probe1)**#tolerance rate fail 5 pass 8 of 10**

type

Use the **type** command to specify a Hypertext Transfer Protocol (HTTP) request type. Use the **no** form of this command to return to the default setting. Variations of this command include:

type get
type head
type raw

Syntax Description

get	Specifies the probe to use HTTP **get** request.
head	Specifies the probe to use HTTP **head** request.
raw	Specifies the probe to use HTTP **raw** request.

Default Values

By default, the probe's HTTP request is set to **get**.

Command History

Release 13.1	Command was introduced.

Functional Notes

This command can only be executed while in the **probe** <*name*> **http-request** command set.

Usage Examples

The following example configures **probe1** to use HTTP request **raw**:

(config)**#probe probe1 http-request**
(config-probe-probe1)**#type raw**

vrf *<name>*

Use the **vrf** command to specify the virtual routing and forwarding (VRF) instance in which the probe operates. Use the **no** form of this command to associate the probe with the default (unnamed) VRF.

Syntax Description

<name>	Specifies the name of the VRF instance. If no VRF is specified, the probe operates within the default (unnamed) VRF instance.

Default Values

By default, probes operate within the default (unnamed) VRF instance.

Command History

Release 17.1	Command was introduced.
Release 18.3	Command was added to Border Gateway Protocol (BGP) and Dynamic Host Control Protocol (DHCP) version 4 (DHCPv4) and version 6 (DHCPv6).
Release R11.2.0	Command was added to network monitoring.

Usage Examples

The following example specifies that the VRF instance **RED** is used for **probe1**:

(config)**#probe probe1 http-request**
(config-probe-probe1)**#vrf RED**

NETWORK MONITOR PROBE RESPONDER COMMAND SET

This section explains the commands available for Network Monitoring Probe Responders. A probe responder is the general term used for a variety of server applications that respond to the network monitor probe types. The Two-Way Active Measurement Protocol (TWAMP) probe responder encompasses the responder side of the TWAMP-Control protocol by responding to TWAMP-Control messages and acting as a remote endpoint for test packets. The Internet Control Message Protocol (ICMP) timestamp probe responder responds to ICMP timestamp request packets so that it can act as a remote endpoint for ICMP timestamp probes. Commands common to all the probe responder types are identified in the following section, as well as isolated commands that only apply to the specific probe responder types.

To activate the Network Monitor Probe Responder Configuration mode, enter the **probe responder** command at the Global Configuration mode prompt followed by the probe type. Specify the probe responder type of **icmp-timestamp**, **twamp**, and **udp-echo**. For example:

```
>enable
#configure terminal
(config)#probe responder twamp
(config-responder-twamp)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

do on page 81
cross-connect on page 76 (applicable to the ICMP timestamp and UDP echo responders only)
exit on page 83
interface on page 84
shutdown on page 93

The following commands are applicable to ICMP timestamp probe responder types and can be executed after this command:

(config)**#probe responder icmp-timestamp**

access-class <name> in on page 4091

The following commands are applicable to TWAMP probe responder types and can be executed after this command:

(config)**#probe responder twamp**

access-class <name> in on page 4091
control source-port on page 4092
control timeout <value> on page 4093
max-sessions <value> on page 4094
port <value> on page 4095

source-interface <interface> on page 4096
test timeout <value> on page 4097

The following commands are applicable to User Datagram Protocol (UDP) echo probe responder types and can be executed after this command:

(config)**#probe responder udp-echo**

access-class <name> in on page 4091
port <value> on page 4095
source-interface <interface> on page 4096

access-class <*name*> in

Use the **access-class in** command to specify an access control list (ACL) to filter access to the responder. Use the **no** form of this command to remove the ACL from the responder. Variations of this command include:

access-class <*name*> **in**
access-class <*name*> **in any-vrf**
access-class <*name*> **in vrf** <*name*>

Syntax Description

access-class <*name*>	Specifies a name of the ACL.
any-vrf	Optional. Specifies that the ACL used by the responder can be located in any virtual routing and forwarding (VRF) instance.
vrf <*name*>	Optional. Specifies a VRF instance in which the ACL used by the responder resides. If no VRF is specified, the default (unnamed) VRF is used.

Default Values

By default, no ACL is configured.

Command History

Release 17.2	Command was introduced.
Release R11.2.0	Command was expanded to include the **any-vrf** and **vrf** <*name*> parameters.

Usage Examples

The following example sets an ACL for the Two-Way Active Measurement Protocol (TWAMP) responder:

(config)**#probe responder twamp**
(config-responder-twamp)**#access-class Anet in**

control source-port

Use the **control source-port** command to specify the Two-Way Active Measurement Protocol (TWAMP) source control port. Use the **no** form of this command to return to the default setting. Variations of this command include:

control source-port owamp-control
control source-port twamp-control
control source-port <*port*>

Syntax Description

owamp-control	Specifies One-Way Active Measurement Protocol (OWAMP) control port (861) as the source port.
twamp-control	Specifies the default TWAMP control port (862) as the source port.
<*port*>	Specifies a source TWAMP control port other than the default port 862. The valid range is **1** to **65535**.

Default Values

By default, the source port is the TWAMP control port, port **862**.

Command History

Release 17.2	Command was introduced.
Release 17.6	Command was expanded to include the **twamp-control** parameter and the default source port was set to port **862**.

Usage Examples

The following example specifies the OWAMP control port as the source control port for the TWAMP responder:

(config)**#probe responder twamp**
(config-responder-twamp)**#control source-port owamp-control**

control timeout <*value*>

Use the **control timeout** command to set the Two-Way Active Measurement Protocol (TWAMP) control session timeout value. Use the **no** form of this command to return to the default value.

Syntax Description

<*value*>	Specifies the timeout interval in seconds. Range is **1** to **65535**.

Default Values

By default, the control timeout value is set to **900**.

Command History

Release 17.6	Command was introduced.

Usage Examples

In the following example, the TWAMP control session is set to timeout after **7200** seconds:

(config)**#probe responder twamp**
(config-responder-twamp)**#control timeout 7200**

max-sessions *<value>*

Use the **max-sessions** command to specify the number of simultaneous Two-Way Active Measurement Protocol (TWAMP) control sessions the responder can handle. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the maximum number of simultaneous TWAMP-control sessions.

Default Values

By default, the maximum sessions is **10**.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example specifies the **max-sessions** value of **5**:

(config)**#probe responder twamp**
(config-responder-twamp)**#max-sessions 5**

port *<value>*

Use the **port** command to specify the User Datagram Protocol (UDP) port to listen for and respond to UDP echo packets. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Specifies the port number. Valid range is **1** to **65535**.

Default Values

By default, the UDP port value is **6**.

Command History

Release 17.2	Command was introduced.

Usage Examples

The following example specifies **port 5055** as the UDP port for the UDP echo responder:

(config)**#probe responder udp-echo**
(config-responder-udp)**#port 5055**

source-interface <*interface*>

Use the **source-interface** command to specify an interface with the primary IP address used as the source address for responder traffic that originated from the unit. Use the **no** form of this command to return to the default setting. Variations of this command include:

source-interface <*interface*>
vrf <*name*> **source-interface** <*interface*>

Syntax Description

<*interface*>	Specify an interface in the format <*interface type [slot/port	slot/port.subinterface id	interface id	interface id.subinterface id	ap	ap/radio	ap/radio.vap]*>. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**.
vrf <*name*>	Optional. Specifies a virtual routing and forwarding (VRF) instance in which the source interface resides. If no VRF is specified, the default (unnamed) VRF is used.

Default Values

By default, the source interface is not configured.

Command History

Release 17.2	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface.
Release R11.2.0	Command was expanded to include the **vrf** parameter.

Usage Examples

The following example configures the source interface as **vlan1**:

(config)**#probe responder twamp**
(config-responder-twamp)#source-interface **vlan1**

test timeout *<value>*

Use the **test timeout** command to set the timeout value associated with the Two-Way Active Management Protocol (TWAMP) probe responder test session. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the timeout interval in seconds. Range is **1** to **65535**.

Default Values

By default, the test session timeout is set to **900** seconds.

Command History

Release 17.6	Command was introduced.

Usage Examples

The following example sets the TWAMP probe responder's timeout interval to **7200** seconds:

(config)**#probe responder twamp**
(config-responder-twamp)**#test timeout 7200**

NETWORK MONITOR TRACK COMMAND SET

This section explains the commands available for Network Monitoring Tracks. Tracks are objects created to monitor network probes for a change in their state. The tracks can be configured to perform a specific action based upon the probe state detected. Association between a track and a probe occurs through referencing the probe in the track's configuration. Once the track is registered with the probe, whenever a change occurs with the probe's state, an event is sent to the track.

Additional configuration commands are available for creating probes. These are explained in the *Network Monitor Probe Command Set on page 4062*.

To activate the Network Monitor Track Configuration mode, enter the **track** command at the Global Configuration mode prompt followed by the name of the track. For example:

```
>enable
#configure terminal
(config)#track track1
(config-track)#
```

The following command is common to multiple command sets and is covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order:

dampening-interval on page 4099
log-changes on page 4100
snmp trap state-change on page 4101
test if on page 4102
test list on page 4108
test list weighted on page 4113
time-schedule <name> on page 4118

dampening-interval

Use the **dampening-interval** command to specify an amount of time to wait before allowing a new probe status change to trigger a new action. Use the **no** form of this command to return to the default setting. Variations of this command include:

dampening-interval <*value*>
dampening-interval fail<*value*>
dampening-interval pass <*value*>

Syntax Description

<*value*>	Specifies the time interval value in seconds. Valid range is **1** to **4294967295** seconds. If neither the **fail** or **pass** subcommand is specified, the value will be used for both conditions.
fail <*value*>	Specifies the delay in seconds following pass-to-fail transitions before a new action can be triggered.
pass <*value*>	Specifies the delay in seconds following fail-to-pass transitions before a new action can be triggered.

Default Values

By default, the interval is set to **1** seconds.

Command History

Release 13.1	Command was introduced.
Release 14.1	Command was expanded to include the **fail** and **pass** criteria.

Usage Examples

The following example sets the dampening interval to **90** seconds for a fail-to-pass transition:

(config)**#track track1**
(config-track)**#dampening-interval pass 90**

log-changes

Use the **log-changes** command to enable logging of status changes. When enabled, probe state transitions are displayed (real time) on the terminal (or Telnet) screen. Unlike **track debug** commands, the **log-changes** command appears in the running configuration and can be saved to persist through a unit restart. Use the **no** form of this command to disable this feature.

Syntax Description

No subcommands.

Default Values

By default, this feature is disabled.

Command History

Release 13.1	Command was introduced.

Usage Examples

The following example enables the logging of status changes:

```
(config)#track track1
(config-track)#log-changes
```

snmp trap state-change

Use the **snmp trap state-change** command to enable the network monitor track to send a Simple Network Management Protocol (SNMP) trap when a change in state occurs. Use the **no** form of this command to disable the trap.

Syntax Description

No subcommands.

Default Values

By default, the state-change trap is disabled.

Command History

Release 18.1	Command was introduced.

Functional Notes

The network monitor track set of traps must also be enabled using the **snmp-server enable traps track** command in the Global Configuration mode. Refer to *snmp-server enable traps on page 1792* for more information.

Additional configuration steps are necessary to configure SNMP traps for this feature to function. Refer to the *SNMP in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables the **snmp trap state-change** for network monitoring:

```
(config)#track track1
(config-track)#snmp trap state-change
```

test if

Use the **test if** command to specify a single object (schedule, probe, or interface) to be tested. Use the **no** form of this command to remove the track test. Variations of this command include:

test if ethernet y1731 meg char-string <*name*> <*level*> <*id*> **loc**
test if ethernet y1731 meg char-string <*name*> <*level*> <*id*> **rdi**
test if ethernet y1731 meg icc-umc <*name*> <*level*> <*id*> **loc**
test if ethernet y1731 meg icc-umc <*name*> <*level*> <*id*> **rdi**
test if interface <*interface*> **downspeed** <*speed*>
test if interface <*interface*> **ip-routing**
test if interface <*interface*> **ipv6-routing**
test if interface <*interface*> **line-protocol**
test if interface <*interface*> **upspeed** <*speed*>
test if interface system-control-evc downspeed <*speed*>
test if interface system-control-evc ip-routing
test if interface system-control-evc ipv6-routing
test if interface system-control-evc line-protocol
test if interface system-control-evc upspeed <*speed*>
test if interface system-management-evc ip-routing
test if interface system-management-evc ipv6-routing
test if interface system-management-evc line-protocol
test if ip ffe entries less-than <*number*>
test if ip ffe <*ingress interface*> **entries less-than** <*number*>
test if ipv6 ffe entries less-than <*number*>
test if ipv6 ffe <*ingress interface*> **entries less-than** <*number*>
test if probe <*name*>
test if schedule <*name*>
test if voice user <*extension*> **registered**

test if not ethernet y1731 meg char-string <*name*> <*level*> <*id*> **loc**
test if not ethernet y1731 meg char-string <*name*> <*level*> <*id*> **rdi**
test if not ethernet y1731 meg icc-umc <*name*> <*level*> <*id*> **loc**
test if not ethernet y1731 meg icc-umc <*name*> <*level*> <*id*> **rdi**
test if not interface <*interface*> **downspeed** <*speed*>
test if not interface <*interface*> **ip-routing**
test if not interface <*interface*> **ipv6-routing**
test if not interface <*interface*> **line-protocol**
test if not interface <*interface*> **upspeed** <*speed*>
test if not interface system-control-evc downspeed <*speed*>
test if not interface system-control-evc ip-routing
test if not interface system-control-evc ipv6-routing
test if not interface system-control-evc line-protocol
test if not interface system-control-evc upspeed <*speed*>
test if not interface system-management-evc ip-routing
test if not interface system-management-evc ipv6-routing

test if not interface system-management-evc line-protocol
test if not ip ffe entries less-than <*number*>
test if not ip ffe <*ingress interface*> **entries less-than** <*number*>
test if not ipv6 ffe entries less-than <*number*>
test if not ipv6 ffe <*ingress interface*> **entries less-than** <*number*>
test if not probe <*name*>
test if not schedule <*name*>
test if not voice user <*extension*> **registered**

Syntax Description

ethernet y1731 meg	Specifies a Y.1731 maintenance endpoint (MEP) as the object to be tested.
char-string <*name*>	Specifies a Y.1731 maintenance entity group (MEG) name using a character string format. Maximum length is **45** ASCII characters.
icc-umc <*name*>	Specifies a Y.1731 MEG name using the ITU-CarrierCode Unique MEG ID Code MEG (ICC-UMC) format. Maximum length is **13** ASCII characters.
<*level*>	Specifies the MEG level. Valid range is **0** to **7**.
<id>	Specifies the MEP ID. Valid range is **1** to **8191**.
loc	Specifies that the track will inspect the specified MEP for indication of loss of continuity (LOC). The test will report TRUE if the specified MEP reports an LOC condition.
rdi	Specifies that the track will inspect the specified MEP for remote defect indication (RDI). The test will report TRUE if the specified MEP reports an RDI condition.
interface <*interface*>	Specifies an interface as the object to be tested. Specify an interface in the format <*interface type [slot/port	slot/port.subinterface id	interface id	interface id.subinterface id]*>. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a virtual local area network interface, use **vlan 1**. Type **test if interface ?** for a complete list of valid interfaces.
downspeed <*speed*>	Specifies the downstream speed (in kilobits per second) will be tested. The downstream speed is the receive speed of an interface from the perspective of the unit. The test will report TRUE if the interface downstream speed is greater than or equal to the specified downstream speed.
ip-routing	Specifies the interface's ability to perform Internet Protocol version 4 (IPv4) routing will be tested.
ipv6-routing	Specifies the interface's ability to perform Internet Protocol version 6 (IPv6) routing will be tested.
line-protocol	Specifies the line-protocol state of an interface will be tested.

upspeed <*speed*>	Specifies the upstream speed (in kilobits per second) will be tested. The upstream speed is the transmit speed of an interface from the perspective of the unit. The test will report TRUE if the interface upstream speed is greater than or equal to the specified downstream speed.
interface system-control-evc	Specifies the system control Ethernet virtual connection (EVC) is the object to be tested.
interface system-management-evc	Specifies the system management EVC is the object to be tested.
ip ffe entries less-than	Tests that the number of RapidRoute flow entries is less than the specified number for IPv4.
ipv6 ffe entries less-than	Tests that the number of RapidRoute flow entries is less than the specified number for IPv6.
<*number*>	The specified maximum number of RapidRoute flow entries for the test. Valid range is **1** to **500000** entries.
<*ingress interface*>	Optional. Specifies that only a single ingress interface is tested for RapidRoute entries. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id]>*. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a virtual local area network interface, use **vlan 1**. Type **test if ip ffe ?** for a complete list of valid interfaces.
not	Optional. Negates the test results when specifying a single object (schedule, probe, or interface) to be tested.
probe <*name*>	Specifies the name of the probe.
schedule <*name*>	Specifies the name of the schedule.
voice user <*extension*> **registered**	Tests the SIP registration status of the specified voice user.

Network monitoring probes and their associated names are created using the command *probe on page 1666**. Schedules and their associated names are created using the command* *schedule <name> on page 1695**. For more information about interfaces, refer to the command* *interface on page 84**.*

Default Values

By default, a track is not associated with any probes or interfaces.

Functional Notes

The **test if** command specifies a conditional test where the track state (pass or fail) is dependent upon the state of the object (probe, schedule, or interface) being tested. For example, the track will PASS if the schedule or probe is in an ACTIVE or PASS state. Conversely, the track will FAIL if the schedule or probe is in an INACTIVE or FAIL state.

The **test if not** command specifies a conditional test where the track state (pass or fail) is dependent upon the state of the object (probe, schedule, or interface) being tested. The **not** keyword indicates that the track state will negate the result of the object test. For example, the track will FAIL if the schedule or probe is in an ACTIVE or PASS state. Conversely, the track will PASS if the schedule or probe is in an INACTIVE or FAIL state.

An interface is IP routing if its line-protocol state is up and if it has a valid, nonzero IP address. This means that interfaces using Dynamic Host Configuration Protocol (DHCP) or negotiated Point-to-Point Protocol (PPP) will not pass until their primary IP address is dynamically configured.

Command History

Release 15.1	Command was introduced.
Release 16.1	Command was expanded to include the **interface** parameter.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface.
Release R10.7.0	Command was expanded to include the **ipv6-routing** parameter.
Release R10.10.0	Command was expanded to include the system control EVC.
Release R10.11.0	Command was expanded to include the **ethernet y1731 meg**, **downspeed**, and **upspeed** parameters, as well as the Ethernet in the first mile (EFM) group interface.
Release R11.2.0	Command was expanded to include the High-level Data Link Control (HDLC) interface.
Release R11.5.0	Command was expanded to include the switchport interface, Gigabit Ethernet switchport interface, and 10-Gigabit Ethernet switchport interface.
Release R11.10.0	Command was expanded to include the **ip ffe entries less-than**, **ipv6 ffe entries less-than** and **voice user** <*extension*> **registered** parameters.

Usage Examples

The following example demonstrates the use of the **test if probe** command to specify a single object to test:

(config)**#track PINGTEST**
(config-track)**#test if probe PINGREMOTE**

The following example demonstrates the logic of the **test if not** command used with schedule tracking:

(config)**#track DELAY**
(config-track)**#test if not schedule DELAY-AFTER-BOOT**

The inverse logic of this command means that track DELAY will pass only if the schedule DELAY-AFTER-BOOT is inactive.

The explanation that follows uses a real-world example to provide insight into the example above:

A customer has a primary Ethernet wide area network (WAN) interface, as well as a dial-on-demand interface enabled on an AOS unit. The demand interface is intended as a backup for the primary Ethernet interface. During router initialization and bootup, the Ethernet interface negotiates an IPv4 address and default route from a DHCP server. Due to this negotiation process, the active state of the Ethernet interface lags behind that of the demand interface. As a result, the Ethernet interface appears down and the demand interface dials out to back up the connection. The customer would like to prevent the demand interface from dialing out before the Ethernet connection has had a chance to obtain its DHCP settings and become active. It is determined that 180 seconds is a sufficient amount of time to allow for the Ethernet interface to become active.

The following bullets describe the setup via command line interface (CLI) to accomplish the customer's goals:

- A schedule called DELAY-AFTER-BOOT is created and specified to become active 180 seconds after the AOS unit has booted up.
- A track named DELAY is created.
- Track DELAY is associated with the schedule DELAY-AFTER-BOOT via the following command:

  (config-track-DELAY)**#test if not schedule DELAY-AFTER-BOOT**

  The inverse logic of this command means that track DELAY will pass only if the schedule DELAY-AFTER-BOOT is inactive. Therefore, this track will pass only during the first 180 seconds following bootup of the AOS unit.
- A default route to null interface 0 is created and associated with track DELAY. This default route will only be inserted into the routing table when track DELAY is in the pass state. The administrative distance for the default route to null interface 0 is 10 and is set to be lower than the administrative distance for the demand interface default route (200).

Output from the **show run** command summarizes the CLI configuration:

```
#show run
(some output omitted)…
.schedule DELAY-AFTER-BOOT
!! Schedule is Inactive for first 180 seconds, then Active thereafter
 relative start-after 180
!
track DELAY
 log-changes
 test if not schedule DELAY-AFTER-BOOT
 no shutdown
!
!!! Below is a default route to null 0 with an admin distance of
!!! 10 that is tracked by DELAY and a default route to demand 1
!!! with admin distance of 200
ip route 0.0.0.0 0.0.0.0 null 0 10 track DELAY
ip route 0.0.0.0 0.0.0.0 demand 1 200
```

Since track DELAY is in a pass state during the first 180 seconds after the AOS unit has booted up, the default route to null interface 0 will be in effect and all traffic using the default route in the route table will be routed to null interface 0. The demand interface will not be activated during the first 180 seconds because the default route to null interface 0 has a lower administrative distance than the demand interface default route.

As soon as a default route has been assigned to the primary Ethernet WAN interface, the route will appear in the routing table with an administrative distance of 1 (which is lower than the administrative distance of 10 for the null interface). Due to the lower administrative distance, all traffic using the default route in the route table will switch to the default route associated with the primary Ethernet interface.

180 seconds after bootup, the schedule DELAY-AFTER-BOOT becomes active. Subsequently, track DELAY fails. The default route to null interface 0 is removed from the routing table and will not be placed in the route table again as long as the AOS unit is up. The two default routes that remain are the current default route to the primary WAN Ethernet interface (administrative distance is 1) and the backup default route to the demand interface (administrative distance is 200).

The following example uses the **test if interface** command to specify testing the IPv4 routing capability of an Ethernet interface:

```
(config)#track track1
(config-track-track1)#test if interface ethernet 0/1 ip-routing
```

To view the results of the test, use the **do show track track1** command:

```
(config-track-track1)#do show track track1
 Current State: FAIL     (Admin: UP)
 Testing:
   interface eth 0/1 ip-routing (FAIL)
 Dampening Interval: 1 seconds
 Time in current state: 0 days, 0 hours, 0 minutes, 4 seconds
 Track State Changes: 1
 Tracking:
```

test list

Use the **test list** command to enter the Boolean Track Test List command set, which is used to specify multiple objects (schedules, probes, or interfaces) to be tested. Use the **no** form of this command to remove the test list. Variations of this command include:

test list and
test list or

The following additional subcommands are available once you have entered the Boolean Track Test List Configuration mode:

if ethernet y1731 meg char-string <*name*> <*level*> <*id*> **loc**
if ethernet y1731 meg char-string <*name*> <*level*> <*id*> **rdi**
if ethernet y1731 meg icc-umc <*name*> <*level*> <*id*> **loc**
if ethernet y1731 meg icc-umc <*name*> <*level*> <*id*> **rdi**
if interface <*interface*> **downspeed** <*speed*>
if interface <*interface*> **ip-routing**
if interface <*interface*> **ipv6-routing**
if interface <*interface*> **line-protocol**
if interface <*interface*> **upspeed** <*speed*>
if interface system-control-evc downspeed <*speed*>
if interface system-control-evc ip-routing
if interface system-control-evc ipv6-routing
if interface system-control-evc line-protocol
if interface system-control-evc upspeed <*speed*>
if interface system-management-evc ip-routing
if interface system-management-evc ipv6-routing
if interface system-management-evc line-protocol
if ip ffe entries less-than <*number*>
if ip ffe <*ingress interface*> **entries less-than** <*number*>
if ipv6 ffe entries less-than <*number*>
if ipv6 ffe <*ingress interface*> **entries less-than** <*number*>
if probe <*name*>
if schedule <*name*>
if voice user <*extension*> **registered**

if not ethernet y1731 meg char-string <*name*> <*level*> <*id*> **loc**
if not ethernet y1731 meg char-string <*name*> <*level*> <*id*> **rdi**
if not ethernet y1731 meg icc-umc <*name*> <*level*> <*id*> **loc**
if not ethernet y1731 meg icc-umc <*name*> <*level*> <*id*> **rdi**
if not interface <*interface*> **downspeed** <*speed*>
if not interface <*interface*> **ip-routing**
if not interface <*interface*> **ipv6-routing**
if not interface <*interface*> **line-protocol**
if not interface <*interface*> **upspeed** <*speed*>
if not interface system-control-evc downspeed <*speed*>

if not interface system-control-evc ip-routing
if not interface system-control-evc ipv6-routing
if not interface system-control-evc line-protocol
if not interface system-control-evc upspeed <*speed*>
if not interface system-management-evc ip-routing
if not interface system-management-evc ipv6-routing
if not interface system-management-evc line-protocol
if not ip ffe entries less-than <*number*>
if not ip ffe <*ingress interface*> **entries less-than** <*number*>
if not ipv6 ffe entries less-than <*number*>
if not ipv6 ffe <*ingress interface*> **entries less-than** <*number*>
if not probe <*name*>
if not schedule <*name*>
if not voice user <*extension*> **registered**

When using any command under the Boolean AND/OR track test list, it is important to remember how the logic will affect every object in the track test list.

Syntax Description

and	Specifies the relationship between all objects placed in this list. The logical AND relationship means that all objects in this list must be in the PASS state for the track test list to pass, or at least one object must be in a FAIL state for the track test list to fail.
or	Specifies the relationship between all objects placed in this list. The logical OR relationship means that only one of the objects in this list must be in the PASS state for the track test list to pass, and all objects in a FAIL state for the track test list to fail.
if	Specifies a single conditional test to be added to the test track list.
if not	Specifies a single conditional test to be added to the test track list. The **not** keyword indicates that the individual track state will negate the result of the object test.
ethernet y1731 meg	Specifies a Y.1731 maintenance endpoint (MEP) as the object to be tested.
char-string <*name*>	Specifies a Y.1731 maintenance entity group (MEG) name using a character string format. Maximum length is **45** ASCII characters.
icc-umc <*name*>	Specifies a Y.1731 MEG name using the ITU-CarrierCode Unique MEG ID Code MEG (ICC-UMC) format. Maximum length is **13** ASCII characters.
<*level*>	Specifies the MEG level. Valid range is **0** to **7**.
<id>	Specifies the MEP ID. Valid range is **1** to **8191**.

loc	Specifies that the track will inspect the specified MEP for indication of loss of continuity (LOC). The test will report TRUE if the specified MEP reports an LOC condition.
rdi	Specifies that the track will inspect the specified MEP for remote defect indication (RDI). The test will report TRUE if the specified MEP reports an RDI condition.
interface <*interface*>	Specifes an interface in the format <*interface type [slot/port	slot/port.subinterface id	interface id	interface id.subinterface id]*>. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a virtual local area network interface, use **vlan 1**. Type **if interface ?** for a complete list of valid interfaces.
downspeed <*speed*>	Specifies the downstream speed (in kilobits per second) will be tested. The downstream speed is the receive speed of an interface from the perspective of the unit. The test will report TRUE if the interface downstream speed is greater than or equal to the specified downstream speed.
ip-routing	Specifies the interface's ability to perform Internet Protocol version 4 (IPv4) routing will be tested.
ipv6-routing	Specifies the interface's ability to perform Internet Protocol version 6 (IPv6) routing will be tested.
line-protocol	Specifies the line-protocol state of an interface will be tested.
upspeed <*speed*>	Specifies the upstream speed (in kilobits per second) will be tested. The upstream speed is the transmit speed of an interface from the perspective of the unit. The test will report TRUE if the interface upstream speed is greater than or equal to the specified downstream speed.
interface system-control-evc	Specifies the system control Ethernet virtual connection (EVC) is added to the test track list.
interface system-management-evc	Specifies the system management EVC is added to the test track list.
ip ffe entries less-than	Tests that the number of RapidRoute flow entries is less than the specified number for IPv4.
ipv6 ffe entries less-than	Tests that the number of RapidRoute flow entries is less than the specified number for IPv6.
<*number*>	The specified maximum number of RapidRoute flow entries for the test. Valid range is **1** to **500000** entries.
<*ingress interface*>	Optional. Specifies that only a single ingress interface is tested for RapidRoute entries. Specify an interface in the format <*interface type [slot/port	slot/port.subinterface id	interface id	interface id.subinterface id]*>. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a virtual local area network interface, use **vlan 1**. Type **if ip ffe ?** for a complete list of valid interfaces.

probe <*name*>	Specifies the name of the probe.
schedule <*name*>	Specifies the name of the schedule.
voice user <*extension*> **registered**	Tests the SIP registration status of the specified voice user.

Network monitoring probes and their associated names are created using the command *probe on page 1666**. Schedules and their associated names are created using the command* *schedule <name> on page 1695**. For more information about interfaces, refer to the command* *interface on page 84**.*

Default Values

By default, a track list does not exist.

Command History

Release 15.1	Command was introduced.
Release 16.1	Command was expanded to include the **interface** parameter.
Release R10.7.0	Command was expanded to include the **ipv6-routing** parameter.
Release R10.10.0	Command was expanded to include the system control EVC.
Release R10.11.0	Command was expanded to include the **ethernet y1731 meg**, **downspeed**, and **upspeed** parameters, as well as the Ethernet in the first mile (EFM) group interface.
Release R11.2.0	Command was expanded to include the High-level Data Link Control (HDLC) interface.
Release R11.5.0	Command was expanded to include the switchport interface, Gigabit Ethernet switchport interface, and 10-Gigabit Ethernet switchport interface.
Release R11.10.0	Command was expanded to include the **ip ffe entries less-than**, **ipv6 ffe entries less-than** and **voice user** <*extension*> **registered** parameters.

Functional Notes

There is no limit to how many probes, schedules, or interfaces can be tested within a single test list. However, only one type (AND, OR, or weighted) of test list can exist on a track at any given time.

An interface is IPv4 routing if its line-protocol state is up and if it has a valid, nonzero IPv4 address. This means that interfaces using Dynamic Host Configuration Protocol (DHCP) or negotiated Point-to-Point Protocol (PPP) will not pass until their primary IPv4 address is dynamically configured.

Usage Examples

The following example demonstrates use of the **test list and** command to create a Boolean track test list where ALL tests must PASS in order for the track to PASS. The test list for track LB contains two probe tests, LB and LB2.

(config)**#track LB**
(config-track)**#test list and**
(config-track-test)**#if probe LB**
(config-track-test)**#if probe LB2**
(config-track-test)**#exit**
(config-track)**#no shutdown**

The **show track LB** command is executed to see whether track LB is in a PASS state:

#show track LB
Current State: PASS (Admin: UP)
Testing:
probe LB (PASS)
AND probe LB2 (PASS)
Dampening Interval: 1 seconds
Time in current state: 0 days, 0 hours, 0 minutes, 29 seconds
Track State Changes: 2
Tracking:

Currently, track LB is in a PASS state. Due to the AND Boolean logic for this test list, track LB is in a PASS state because the test probe statements within the test list (probe LB and LB2) are also BOTH in a PASS state.

Now, probe LB has been forced to fail for demonstration purposes in this example. Output from the **show track LB** command shows track LB in a FAIL state.

(config-loop 1)**#do show track LB**

Current State: FAIL (Admin: UP)
Testing:
probe LB (FAIL)
AND probe LB2 (PASS)
Dampening Interval: 1 seconds
Time in current state: 0 days, 0 hours, 0 minutes, 10 seconds
Track State Changes: 3
Tracking:

Probe LB is now in a FAIL state. As a result, track LB is also in a FAIL state.

*If the test list in this example had specified the OR Boolean logic (using the **test list or** command), then track LB would have passed even though one of the test probes was in the FAIL state.*

test list weighted

Use the **test list weighted** command to enter the Weighted Track Test List Configuration mode, which is used to specify multiple objects (schedules, probes, or interfaces) to be tested. Objects listed in a weighted track test are assigned a specific weight value. The total weight of all the objects in the list is compared to a user-specified threshold to determine whether the track passes or fails. Use the **no** form of this command to remove the test list.

The following additional subcommands are available once you have entered the Weighted Track Test List Configuration mode:

if ethernet y1731 meg char-string <*name*> <*level*> <*id*> **loc weight** <*value*>
if ethernet y1731 meg char-string <*name*> <*level*> <*id*> **rdi weight** <*value*>
if ethernet y1731 meg icc-umc <*name*> <*level*> <*id*> **loc weight** <*value*>
if ethernet y1731 meg icc-umc <*name*> <*level*> <*id*> **rdi weight** <*value*>
if interface <*interface*> **downspeed** <*speed*> **weight** <*value*>
if interface <*interface*> **ip-routing weight** <*value*>
if interface <*interface*> **ipv6-routing weight** <*value*>
if interface <*interface*> **line-protocol weight** <*value*>
if interface <*interface*> **upspeed** <*speed*> **weight** <*value*>
if interface system-control-evc downspeed <*speed*> **weight** <*value*>
if interface system-control-evc ip-routing weight <*value*>
if interface system-control-evc ipv6-routing weight <*value*>
if interface system-control-evc line-protocol weight <*value*>
if interface system-control-evc upspeed <*speed*> **weight** <*value*>
if ip ffe entries less-than <*number*> **weight** <*value*>
if ip ffe <*ingress interface*> **entries less-than** <*number*> **weight** <*value*>
if ipv6 ffe entries less-than <*number*> **weight** <*value*>
if ipv6 ffe <*ingress interface*> **entries less-than** <*number*> **weight** <*value*>
if probe <*name*> **weight** <*value*>
if schedule <*name*> **weight** <*value*>

if voice user <*extension*> **registered weight** <*value*>
if not ethernet y1731 meg char-string <*name*> <*level*> <*id*> **loc weight** <*value*>
if not ethernet y1731 meg char-string <*name*> <*level*> <*id*> **rdi weight** <*value*>
if not ethernet y1731 meg icc-umc <*name*> <*level*> <*id*> **loc weight** <*value*>
if not ethernet y1731 meg icc-umc <*name*> <*level*> <*id*> **rdi weight** <*value*>
if not interface <*interface*> **downspeed** <*speed*> **weight** <*value*>
if not interface <*interface*> **ip-routing weight** <*value*>
if not interface <*interface*> **ipv6-routing weight** <*value*>
if not interface <*interface*> **line-protocol weight** <*value*>
if not interface <*interface*> **upspeed** <*speed*> **weight** <*value*>
if not interface system-control-evc downspeed <*speed*> **weight** <*value*>
if not interface system-control-evc ip-routing weight <*value*>
if not interface system-control-evc ipv6-routing weight <*value*>
if not interface system-control-evc line-protocol weight <*value*>

if not schedule <*name*> **weight** <*value*>
if not voice user <*extension*> **registered weight** <*value*>
threshold <*number*>
threshold pass <*number*> **fail** <*number*>

Syntax Description

if	Specifies a single conditional test to be added to the test track list.
if not	Specifies a single conditional test to be added to the test track list. The **not** keyword indicates that the individual track state will negate the result of the object test.
ethernet y1731 meg	Specifies a Y.1731 maintenance endpoint (MEP) as the object to be tested.
char-string <*name*>	Specifies a Y.1731 maintenance entity group (MEG) name using a character string format. Maximum length is **45** ASCII characters.
icc-umc <*name*>	Specifies a Y.1731 MEG name using the ITU-CarrierCode Unique MEG ID Code MEG (ICC-UMC) format. Maximum length is **13** ASCII characters.
<*level*>	Specifies the MEG level. Valid range is **0** to **7**.
<id>	Specifies the MEP ID. Valid range is **1** to **8191**.
loc	Specifies that the track will inspect the specified MEP for indication of loss of continuity (LOC). The test will report TRUE if the specified MEP reports an LOC condition.
rdi	Specifies that the track will inspect the specified MEP for remote defect indication (RDI). The test will report TRUE if the specified MEP reports an RDI condition.
interface <*interface*>	Specifies an interface to add to the track test list. Specify interfaces in the format <*interface type [slot/port* | *slot/port.subinterface id* | *interface id* | *interface id.subinterface id]*>. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a virtual local area network interface, use **vlan 1**. Type **if interface ?** for a complete list of valid interfaces.
downspeed <*speed*>	Specifies the downstream speed (in kilobits per second) will be tested. The downstream speed is the receive speed of an interface from the perspective of the unit. The test will report TRUE if the interface downstream speed is greater than or equal to the specified downstream speed.
ip-routing	Specifies the interface's ability to perform Internet Protocol version 4 (IPv4) routing will be tested.

ipv6-routing	Specifies the interface's ability to perform Internet Protocol version 6 (IPv6) routing will be tested.
line-protocol	Specifies the line-protocol state of an interface will be tested.
upspeed <*speed*>	Specifies the upstream speed (in kilobits per second) will be tested. The upstream speed is the transmit speed of an interface from the perspective of the unit. The test will report TRUE if the interface upstream speed is greater than or equal to the specified downstream speed.
interface system-control-evc	Specifies the system control Ethernet virtual connection (EVC) is added to the test track list.
ip ffe entries less-than	Tests that the number of RapidRoute flow entries is less than the specified number for IPv4.
ipv6 ffe entries less-than	Tests that the number of RapidRoute flow entries is less than the specified number for IPv6.
<*number*>	The specified maximum number of RapidRoute flow entries for the test. Valid range is **1** to **500000** entries.
<*ingress interface*>	Optional. Specifies that only a single ingress interface is tested for RapidRoute entries. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id]>*. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a virtual local area network interface, use **vlan 1**. Type **if ip ffe ?** for a complete list of valid interfaces.
probe <*name*>	Specifies the name of the probe or schedule.
schedule <*name*>	Specifies the name of the schedule.
threshold <*number*>	Specifies a baseline weight for state transitions. Range is **1** to **4294967295**.
fail <*number*>	Optional. Specifies the number that will change the state of the track test list to fail. Range is **1** to **4294967295**.
pass <*number*>	Optional. Specifies the number which, if reached or exceeded, will change the state of the track test list to pass. Range is **1** to **4294967295**.
voice user <*extension*> **registered**	Tests the SIP registration status of the specified voice user
weight <*value*>	Specifies the weight value to use if this test is successful. Range is **1** to **65535**.

Network monitoring probes and their associated names are created using the command *probe on page 1666**. Schedules and their associated names are created using the command* *schedule <name> on page 1695**. For more information about interfaces, refer to the command* *interface on page 84**.*

Default Values

By default, a track list does not exist.

Command History

Release 15.1	Command was introduced.
Release 16.1	Command was expanded to include the **interface** parameter.
Release R10.7.0	Command was expanded to include the **ipv6-routing** parameter.
Release R10.10.0	Command was expanded to include the system control EVC.
Release R10.11.0	Command was expanded to include the **ethernet y1731 meg**, **downspeed**, and **upspeed** parameters, as well as the Ethernet in the first mile (EFM) group interface.
Release R11.2.0	Command was expanded to include the High-level Data Link Control (HDLC) interface.
Release R11.5.0	Command was expanded to include the switchport interface, Gigabit Ethernet switchport interface, and 10-Gigabit Ethernet switchport interface.
Release R11.10.0	Command was expanded to include the **ip ffe entries less-than**, **ipv6 ffe entries less-than** and **voice user** <*extension*> **registered** parameters.

Functional Notes

There is no limit to how many probes, schedules, or interfaces can be tested within a single test list. However, only one type (AND, OR, or weighted) of test list can exist on a track at any given time.

An interface is IPv4 routing if its line-protocol state is up and if it has a valid, nonzero IPv4 address. This means that interfaces using Dynamic Host Configuration Protocol (DHCP) or negotiated Point-to-Point Protocol (PPP) will not pass until their primary IPv4 address is dynamically configured.

Usage Examples

The following example demonstrates use of the **test list weighted** command. The list contains three probe tests and each test has been assigned a different weight value (10, 20, and 30). When a probe test passes, its weight is added to the sum of the weights from other successful tests contained within the Weighted Track Test List. The pass threshold in this example is set to 35. The sum of all the weights must meet or exceed the value of 35 before the Weighted Track Test List will transition to a PASS state. The fail threshold in this example is set to 25. Therefore, if the sum of all the weights falls below the value of 25, the Weighted Track Test List will transition to a FAIL state.

(config)**#track LB-test**
(config-track)**#test list weighted**
(config-track-test)**#if probe LB weight 10**
(config-track-test)**#if probe LB2 weight 20**
(config-track-test)**#if probe LB3 weight 30**
(config-track-test)**#threshold pass 35 fail 25**
(config-track-test)**#exit**
(config-track)**#no shutdown**

The **show track LB-test** command is executed to see whether track LB-test is in a PASS state:

#show track LB-test
Current State: PASS (Admin: UP)
Testing:
+10 if probe LB (PASS)
+20 if probe LB2 (PASS)
+30 if probe LB3 (PASS)
Total = 60 currently, < 25 changes state to FAIL
Dampening Interval: 1 seconds
Time in current state: 2 days, 5 hours, 21 minutes, 13 seconds
Track State Changes: 0
Tracking:

Currently, all probe test commands are in the PASS state. Therefore, the sum of the assigned weights equals 60. The value of 60 exceeds the specified pass threshold of 35. As a result, the current state of the track is PASS.

Probe LB and probe LB3 have been forced to fail for demonstration purposes in this example. Output from the **show track LB-test** command shows track LB-test to be in a FAIL state.

(config-loop 1)**#do show track LB-test**
Current State: FAIL (Admin: UP)
Testing:
+10 if probe LB (FAIL)
+20 if probe LB2 (PASS)
+30 if probe LB3 (FAIL)
Total = 20 currently, >= 35 changes state to PASS
Dampening Interval: 1 seconds
Time in current state: 0 days, 0 hours, 0 minutes, 33 seconds
Track State Changes: 1
Tracking:

Only probe LB2 is in the PASS state. Therefore, the sum of the assigned weights equals 20. The value of 20 falls below the FAIL threshold of 25. As a result, the current state of the track is now FAIL.

time-schedule <*name*>

Use the **time-schedule** command to specify the time period a track has an effect. While the specified schedule is active, the track follows the state of its associated probe. Use the no form of this command to remove the time schedule from this track. Refer to the command *schedule <name> on page 1695* for more information on creating and modifying a schedule. Variations of this command include:

time-schedule <*name*> **pass**
time-schedule <*name*> **fail**

Syntax Description

<*name*>	Specifies the name of the time schedule to apply.
pass	Specifies that the track status is PASS when the schedule is inactive.
fail	Specifies that the track status is FAIL when the schedule is inactive.

Default Values

By default, no time schedule is assigned to the track. Therefore, the track always follows the state of its associated probe.

Command History

Release 14.1	Command was introduced.
Release 15.1	Command was expanded to allow specification of the track state when the schedule is inactive.

Usage Examples

The following example specifies that **schedule1** will be used to determine when **track1** follows the state of its probe:

(config)**#track track1**
(config-track)**#time-schedule schedule1 pass**

OSPFv2 and OSPFv3 Command Sets

This section includes the following command sets:

ROUTER OSPFV2 COMMAND SET

Open Shortest Path First version 2 (OSPFv2) is an Internet Protocol version 4 (IPv4) routing protocol defined in RFC 2328. The purpose of this protocol is to share the paths to destination networks among peer gateways or routers. The scope of operation for OSPF is designed to be within one autonomous system (AS). A single AS includes all routers normally under a single administrative control, rather than under the control of many autonomous systems, as with the Internet. OSPF is a hierarchical routing protocol, meaning it was developed to enable preplanning for large networks in a top-down fashion. This hierarchical structure allows a large network to be subdivided into smaller areas, which creates the ability to represent an entire area with a single network address, provides granular control over sensitive areas, creates smaller routing tables, reduces link-state exchanges, creates fewer shortest path first (SPF) calculations, and allows for larger internetworks. For more information about OSPF, refer to the technical note *Understanding OSPF*, available online at https://supportcommunity.adtran.com.

To activate the OSPF Configuration mode, enter the **router ospf** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#router ospf
(config-ospf)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

area <area id> default-cost <value> on page 4122
area <area id> range <ipv4 address> <subnet mask> on page 4123
area <area id> stub on page 4124
auto-cost reference-bandwidth <value> on page 4125
default-information originate on page 4126
default-metric <value> on page 4127
distance <number> on page 4128
distribute-list <ipv4 acl name> out on page 4130
distribute-list route-map <name> in on page 4131
maximum-paths <value> on page 4132
network <ipv4 address> <wildcard mask> area <area id> on page 4133

area <*area id*> default-cost <*value*>

Use the **area default-cost** command to assign a cost of the default summary route sent into a stub area or not-so-stubby-area (NSSA). Use the **no** form of this command to delete the assigned cost.

Syntax Description

<*area id*>	Specifies an identifier for this area either as an integer (range is **0** to **4294967295**) or an IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*value*>	Specifies the default summary route cost. Range is **0** to **166777214**.

Default Values

By default, the summary route cost is set to **0**. There is no default for the area ID.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example defines a default cost of **85** to a specific area:

(config)**#router ospf**
(config-ospf)**#area 192.22.72.0 default-cost 85**

area *<area id>* **range** *<ipv4 address> <subnet mask>*

Use the **area range** command to configure area route summarizations and to determine whether an Internet Protocol version 4 (IPv4) address range is advertised to the networks. Use the **no** form of this command to disable this feature. Variations of this command include:

area *<area id>* **range** *<ipv4 address>* *<subnet mask>* **advertise**
area *<area id>* **range** *<ipv4 address>* *<subnet mask>* **not-advertise**

Syntax Description

<area id>	Specifies the identifier for this area. Specifies as an integer (range is **0** to **4294967295**) or an IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<ipv4 address>	Specifies the IPv4 address of the advertised summary route. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
advertise	Specifies that the address range will be advertised to other networks.
not-advertise	Specifies that the address range will not be advertised to other networks.

Default Values

By default, open shortest path first (OSPF) is not enabled.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example defines an address range for a specific area that allows the unit to advertise this range to other networks:

(config)**#router ospf**
(config-ospf)**#area 11.0.0.0 range 11.0.0.0 255.0.0.0 advertise**

area <*area id*> stub

Use the **area stub** command to configure an area as a stub area. Use the **no** form of this command to disable stub-designation for areas defined as stubs using this command. Variations of this command include:

area <*area id*> **stub**
area <*area id*> **stub no-summary**

Syntax Description

<*area id*>	Specifies the identifier for this area. Specifies as an integer (range is **0** to **4294967295**) or an IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
no-summary	Optional. Designates the area as a total stub area. No summary link advertisements will be sent by the area border router (ABR) into the stub area.

Default Values

By default, open shortest path first (OSPF) is not enabled.

Command History

Release 3.1	Command was introduced.

Technology Review

It is important to coordinate configuration of all routers and access servers in the stub area. The **area stub** command must be configured for each of those pieces of equipment. Use the **area router configuration** command with the **area default-cost** command to specify the cost of a default internal router sent into a stub area by an ABR. Refer to *area <area id> default-cost <value> on page 4122* for related information.

Usage Examples

The following example configures **area 2** as a stub area:

(config)**#router ospf**
(config-ospf)**#area 2 stub**

auto-cost reference-bandwidth <*value*>

Use the **auto-cost reference-bandwidth** command to assign a different interface cost to an interface. It may be necessary to assign a higher number to high-bandwidth links. This value is used in open shortest path first (OSPF) metric calculations. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Sets the default reference bandwidth rate in Mbps. Range is **1** to **4294967** Mbps.

Default Values

By default, the rate is set to **100**.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example sets the auto cost reference bandwidth to **1000** Mbps:

(config)**#router ospf**
(config-ospf)**#auto-cost reference-bandwidth 1000**

default-information originate

Use the **default-information originate** command to cause an autonomous system boundary router (ASBR) to generate a default route. It must have its own default route before it generates one unless the **always** keyword is used. Use the **no** form of this command to return to the default setting. Variations of this command include:

default-information originate
default-information originate always
default-information originate always metric <*value*>
default-information originate always metric <*value*> **metric-type** <*type*>
default-information originate always metric <*value*> **metric-type** <*type*> **tag** <*value*>

*The optional parameters can be entered in any order. Use the **?** after each specified subcommand for a valid list of arguments and settings.*

Syntax Description

always	Optional. Specifies to always advertise default route.
metric <*value*>	Optional. Configures the metric value. Range is **0** to **16777214**.
metric-type <*type*>	Optional. Configures the metric type. Select from type **1** or **2**.
tag <*value*>	Optional. Specifies the route tag for the default external route being injected. Route tags can be used to implement routing policies using route maps. For example, they can be used to control route redistribution to prevent routing loops when configuring multipoint route redistribution (i.e., routes are redistributed from protocol A into protocol B, then back into protocol A). Route tags only apply to external (Type 5) LSAs. Range is **1** to **4294967295**.

Default Values

By default, the metric value is set to **10** and the metric type is set to **2**.

Command History

Release 3.1	Command was introduced.
Release R11.3.0	Command syntax changed from **default-information-originate** to **default-information originate**.
Release R11.4.0	Command was expanded to include the **tag** parameter.

Usage Examples

The following example configures a router to always advertise default routes and assigns the default router a metric value of **10000** and a metric type of **2**:

(config)**#router ospf**
(config-ospf)**#default-information originate always metric 10000 metric-type 2**

default-metric *<value>*

Use the **default-metric** command to set a metric value for redistributed routes. Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Sets the default metric value. Range is **0** to **4294967295**.

Default Values

By default, **default-metric** value is set at **20**.

Command History

Release 3.1	Command was introduced.

Functional Notes

The metric value defined using the **redistribute** command overrides the **default-metric** command's metric setting. Refer to *redistribute ospf on page 4215* for related information.

Usage Examples

The following example shows a router using both Routing Information Protocol (RIP) and open shortest path first (OSPF) routing protocols. The example advertises RIP-derived routes using the OSPF protocol and assigns the RIP-derived routes an OSPF metric of **10**.

(config)**#router ospf**
(config-ospf)**#default-metric 10**
(config-ospf)**#redistribute rip**

distance <*number*>

Use the **distance** command to overwrite the open shortest path first (OSPF) route administrative distance. This can be the same for all OSPF routes or different based on the route type. Use the **no** form of this command to set the OSPF administrative distance to the default value. Variations of this command include:

distance <*number*>
distance ospf external <*number*>
distance ospf intra-area <*number*>
distance ospf inter-area <*number*>

Syntax Description

<*number*>	Specifies the administrative distance to use when adding OSPF routes into the route table. Range is **0** to **255**.
ospf external	Specifies using a unique administrative distance for route paths between different autonomous systems (ASs).
ospf intra-area	Specifies using a unique administrative distance for route paths between a source and destination in the same routing area.
ospf inter-area	Specifies using a unique administrative distance for route paths between a source and destination in different areas.

Default Values

By default, **110** is the administrative distance for OSPF routes.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following example configures external OSPF routes to use an administrative distance of **20** while other OSPF routes continue to use the default value of **110**:

(config)**#router ospf**
(config-ospf)**#distance ospf external 20**

Technology Review

An AS is a set of routers under common administration control that usually use a common routing strategy. Each AS is composed of routing areas, which are groups of adjoining networks and attached hosts. Intra-area routing occurs when the source and destination hosts are in the same area; inter-area routing occurs when the source and destination hosts are in different areas; and external routing occurs when communication is between different ASs.

Administrative distance is a feature that routers employ in order to select the most reliable path when there are two or more routes to the same destination from two different routing protocols. Administrative distance defines the reliability of a routing protocol by assigning a value (the smaller the value, the more trustworthy the protocol) that is then used by the router to organize routing protocols according to reliability.

distribute-list <*ipv4 acl name*> out

Use the **distribute-list out** command to apply an Internet Protocol version 4 (IPv4) access control list (ACL) to routes that are redistributed into the OSPFv2 network. Use the **no** form of this command to disable filtering.

For a complete list of all standard IPv4 ACL configuration commands, refer to the *IPv4 Access Control List Command Set on page 4252*.

Syntax Description

<ipv4 acl name>	Specifies an IPv4 ACL name. This is a standard IPv4 ACL against which the redistributed routes are matched.

Default Values

By default, distribute-list filtering is disabled.

Command History

Release R11.4.0	Command was introduced.

Functional Notes

The **distribute-list** *<ipv4 acl name>* **out** command allows you to filter what traffic gets redistributed into the OSPFv2 network. For example, if the OSPFv2 process is configured to redistribute Routing Information Protocol (RIP) routes (using the command *redistribute on page 4134*), and RIP has a route to 10.22.8.0 /24, OSPFv2 would normally generate a Type 5 external LSA to distribute the route through the autonomous system (AS). However, if an ACL is applied that blocks the 10.22.8.0 /24 prefix, the external LSA will not be generated, and the route will not be distributed through the AS.

Usage Examples

The following example filters routes redistributed into the OSPFv2 process based on the ACL **RIP**:

(config)**#router ospf**
(config-ospf)**#distribute-list RIP out**

distribute-list route-map <*name*> in

Use the **distribute-list route-map in** command to apply a route map to filter the routes added by OSPFv2 to the route table. Use the **no** form of this command to disable filtering.

Syntax Description

<*name*>	Specifies a route map name.

Default Values

By default, distribute-list filtering is disabled.

Command History

Release R11.4.0	Command was introduced.

Functional Notes

The **distribute-list route-map** <*name*> **in** command allows you to filter what OSPFv2 is allowed to add to the route table. For example, if OSPF calculations determine that a route to 10.22.8.0 /24 should be added to the route table, the route map matching rules are applied to the prefix to determine whether the route should be added to the route table. This command does not affect the distribution of link-state advertisements (LSAs) or the link-state (LS) database (every router in the same area should still have the same database for that area).

Usage Examples

The following example filters routes added to the OSPFv2 route table based on the route map **OSPFMAP**:

(config)**#router ospf**
(config-ospf)**#distribute-list route-map OSPFMAP in**

maximum-paths *<value>*

Use the **maximum-paths** command to specify the number of parallel routes (shared paths) open shortest path first (OSPF) can inject into the route table. When IP load sharing is enabled, traffic is balanced to a specific destination across up to six equal paths. Use the **no** form of this command to return to the default value.

Syntax Description

<value>	Specifies the number of routes OSPF can insert into the route table. Valid range is **1** to **6**.

Default Values

By default, the **maximum-paths** value is **4**.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the maximum number of multipath routes OSPF can insert in the route table to **5**.

(config)**#router ospf**
(config-ospf)**#maximum-paths 5**

network *<ipv4 address> <wildcard mask>* **area** *<area id>*

Use the **network area** command to enable routing on an IP stack and to define area IDs for the interfaces on which open shortest path first (OSPF) will run. Use the **no** form of this command to disable OSPF routing for interfaces defined using this command.

Syntax Description

<ipv4 address>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<wildcard mask>	Specifies the wildcard mask that corresponds to a range of IPv4 addresses (network). Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).
<area id>	Specifies the identifier for this area. Specifies as an integer (range is **0** to **4294967295**) or an IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

No default values are necessary for this command.

Command History

Release 3.1	Command was introduced.

Functional Notes

In order for OSPF to operate on an interface, the *primary* address for the interface must be included in the **network area** command. Assigning an interface to an OSPF area is done using the **network area** command. There is no limit to the number of **network area** commands used on a router. If the address ranges defined for different areas overlap, the first area in the **network area** command list is used and all other overlapping portions are disregarded. Try to avoid overlapping to avoid complications.

Usage Examples

In the following example, the OSPF routing process is enabled and two OSPF areas are defined:

(config)**#router ospf**
(config-ospf)**#network 192.22.72.101 0.0.0.255 area 0**
(config-ospf)**#network 10.0.0.0 0.255.255.255 area 10.0.0.0**

redistribute

Use the **redistribute** command to redistribute routes from a specified source into the Open Shortest Path First version 2 (OSPFv2) process. A router that performs redistribution becomes an OSPFv2 autonomous system boundary router (ASBR), because it is sourcing routes from outside the OSPFv2 autonomous system (AS). The specified source from which routes are redistributed must be in the same virtual routing and forwarding (VRF) as the OSPFv2 instance being configured. This command can be entered multiple times (at most, once for each source). Reentering the command with the same source replaces any existing command with that source. Use the **no** form of this command to remove the redistribution from the specified source. Variations of this command include:

redistribute bgp
redistribute bgp metric <*value*>
redistribute bgp metric-type <*type*>
redistribute bgp route-map <*name*>
redistribute bgp subnets
redistribute bgp tag <*value*>
redistribute connected
redistribute connected metric <*value*>
redistribute connected metric-type <*type*>
redistribute connected route-map <*name*>
redistribute connected subnets
redistribute connected tag <*value*>
redistribute ospf <*process id*>
redistribute ospf <*process id*> **metric** <*value*>
redistribute ospf <*process id*> **metric-type** <*type*>
redistribute ospf <*process id*> **no-include-connected**
redistribute ospf <*process id*> **route-map** <*name*>
redistribute ospf <*process id*> **tag** <*value*>
redistribute rip
redistribute rip metric <*value*>
redistribute rip metric-type <*type*>
redistribute rip route-map <*name*>
redistribute rip subnets
redistribute rip tag <*value*>
redistribute static
redistribute static metric <*value*>
redistribute static metric-type <*type*>
redistribute static route-map <*name*>
redistribute static subnets
redistribute static tag <*value*>

*The optional parameters can be entered in any order. Use the **?** after each specified subcommand for a valid list of arguments and settings.*

Syntax Description

bgp	Specifies that Border Gateway Protocol (BGP) routes are being redistributed.
connected	Specifies that connected routes are being redistributed.
metric <*value*>	Optional. Specifies an OSPF metric value to be assigned to routes learned via BGP.
metric-type <*type*>	Optional. Specifies a type **1** or type **2** external route as the external link type. If not specified, the default is **2**.
ospf <*process id*>	Specifies the OSPF process from which to redistribute routes. Valid process ID range is **1** to **65535**.
no-include-connected	Optional. Specifies that prefixes of the interface running this source protocol are not automatically included in the route redistribution.
rip	Specifies that Routing Information Protocol (RIP) routes are being redistributed.
route-map <*name*>	Optional. Specifies a route map that is applied to routes being redistributed by this command. A route map can impose granular control on routes being redistributed.
static	Specifies that static routes are being redistributed.
subnets	Optional. Specifies subnet redistribution when redistributing routes into OSPF.
tag <*value*>	Optional. Specifies the route tag for the redistributed routes. Route tags can be used to implement routing policies using route maps. For example, they can be used to control route redistribution to prevent routing loops when configuring multipoint route redistribution (i.e., routes are redistributed from protocol A into protocol B, then back into protocol A). Route tags only apply to external (Type 5) LSAs. Range is **1** to **4294967295**.

Default Values

By default, this command is disabled.

Command History

Release 3.1	Command was introduced.
Release 10.1	Subcommands were added.
Release 14.1	Command was expanded to include the route map filtering.
Release R11.3.0	Command was expanded to include the **ospf** and **no-include-connected** parameters.
Release R11.4.0	Command was expanded to include the **tag** parameter.

Functional Notes

Redistributing routes imports those routes into OSPF without the interfaces in question actually participating in OSPF. The routes imported this way are not covered by a network command and do not send/receive OSPF traffic. This allows OSPF to learn and distribute routes to networks that do not participate in OSPF.

Usage Examples

The following example imports BGP routes into OSPF:

(config)**#router ospf**
(config-ospf)**#redistribute bgp**

rfc1583compatibility

Use the **rfc1583compatability** command to specify that the algorithm defined in RFC 1583 is used to determine autonomous system (AS) external routes. Use the **no** form of this command to specify that the algorithm defined in RFC 2328 is used to determine AS external routes.

Syntax Description

No subcommands.

Default Values

By default, RFC 1583 compatibility is enabled.

Command History

Release R11.4.0	Command was introduced.

Functional Notes

With the introduction of RFC 2328, the algorithm used to determine the cost of AS external routes was changed to help minimize the occurrence of routing loops.

This command should be set identically on all routers in the OSPFv2 network. Otherwise, the summary route from area boundary routers (ABRs) using RFC 1583 will be preferentially chosen because the summary routes they advertise will have a lower cost.

Usage Examples

The following example specifies that the algorithm defined in RFC 2328 is used to determine AS external routes:

(config)**#router ospf 5**
(config-ospf)**#no rfc1583compatibility**

router-id *<ipv4 address>*

Use the **router-id** command to specify the value to be used by the Open Shortest Path First version 2 (OSPFv2) process as the router ID. Use the **no** form of this command to return the router ID for this OSPFv2 process to the default value.

Syntax Description

<ipv4 address>	Specifies a 32-bit value, represented in IPv4 address format, that is used by this specific OSPFv2 instance as the router ID. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). Valid IPv4 address range is **0.0.0.1** to **255.255.255.255**.

Default Values

The default router ID value is determined by algorithm (refer to *Functional Notes* below).

Command History

Release R11.3.0	Command was introduced.

Functional Notes

An OSPFv2 router ID is selected using a well-defined algorithm that is also used for Border Gateway Protocol (BGP) router IDs. The default router ID value is chosen by first looking at the configured router ID (if there is one), then the highest value IPv4 address assigned to a loopback interface in the same virtual routing and forwarding (VRF) instance that is not already in use as an OSPFv2 router ID (if there is one). Then, the highest value IPv4 address assigned to a non-loopback interface that is not already in use as an OSPFv2 router ID interface in the same VRF instance.

When defining an IPv4 address for the router ID, keep in mind that the value must be unique among router IDs in use by other OSPFv2 processes on the local system. If a value is specified that is already in use, an error message is displayed, and the command is rejected. Though the value uses an IPv4 address in general format, it does not actually use the IPv4 address.

Usage Examples

The following example specifies a router ID for the OSPFv2 process **5**:

(config)**#router ospf 5**
(config-ospf)**#router-id 10.10.10.2**

summary-address *<ipv4 address> <subnet mask>*

Use the **summary-address** command to control address summarization of routes that are redistributed into open shortest path first (OSPF) from other sources (for example, Routing Information Protocol (RIP)-to-OSPF, static-to-OSPF, etc.). Variations of this command include:

summary-address *<ipv4 address> <subnet mask>*
summary-address *<ipv4 address> <subnet mask>* **not-advertise**
summary-address *<ipv4 address> <subnet mask>* **tag**

*The optional parameters can be entered in any order. Use the **?** after each specified subcommand for a valid list of arguments and settings.*

Syntax Description

<ipv4 address>	Specifies a valid IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).
not-advertise	Optional. Causes suppression of routes that match the specified IPv4 address and subnet mask.
tag *<value>*	Optional. Specifies the route tag for the summarized route. Route tags can be used to implement routing policies using route maps. For example, they can be used to control route redistribution to prevent routing loops when configuring multipoint route redistribution (i.e., routes are redistributed from protocol A into protocol B, then back into protocol A). Route tags only apply to external (Type 5) LSAs. Range is **1** to **4294967295**.

Default Values

By default, this command is disabled.

Command History

Release 3.1	Command was introduced.
Release R11.4.0	Command was expanded to include the **tag** parameter.

Usage Examples

The following example suppresses advertisement of the routes that match the specified IPv4 address and subnet mask:

(config)**#router ospf**
(config-ospf)**#summary-address 11.0.0.0 255.0.0.0 not-advertise**

timers spf <*delay*> <*hold*>

Use the **timers spf** command to configure the shortest path first (SPF) calculation and hold intervals. Use the **no** form of this command to return to the default setting. Variations of this command include:

timers spf <*delay*>
timers spf <*delay*> <*hold*>

Syntax Description

<*delay*>	Specifies the time in seconds between open shortest path first's (OSPF's) receipt of topology changes and the beginning of SPF calculations.
<*hold*>	Specifies the time in seconds between consecutive SPF calculations. Range is **10** to **1800** seconds.

Default Values

By default, the SPF delay is **5** seconds and the hold interval is set to **10** seconds.

Command History

Release 3.1	Command was introduced.

Usage Examples

The following example defines a delay of **10** seconds and a hold time of **30** seconds:

(config)**#router ospf**
(config-ospf)**#timers spf 10 30**

ROUTER OSPFV3 COMMAND SET

Open Shortest Path First version 3 (OSPFv3) is the newest version of OSPF and includes Internet Protocol version 6 (IPv6) support by using IPv6 messages to calculate IPv6 routes. Dual stack networks can use an OSPFv2 instance to support IPv4 connectivity and an OSPFv3 instance to support IPv6 connectivity. OSPFv3 functions by allowing routers to resolve paths through the network using OSPFv3 messages sent over IPv6 packets. OSPFv3 functions in a similar manner to OSPFv2, with a few crucial exceptions. In OSPFv3 for IPv6, authentication has been removed from the OSPF protocol. When running over IPv6, OSPF relies on the IP Encapsulating Security Payload (ESP) and IP Authentication Header (AH) protocols to ensure integrity and authentication or confidentiality of routing exchanges (refer to RFC 4552). In addition, all addressing semantics have been removed from OSPF packet headers in OSPFv3. All addressing information is contained in the various link state advertisements (LSA) types only. In OSPFv3, neighboring routers are always identified by router ID, rather than by an IPv4 address as with OSPFv2. In OSPFv2, unknown LSAs were discarded. In OSPFv3, however, the protocol allows a mixture of router capabilities on a single link, so these LSAs are not discarded but rather can be handled more flexibly.

Another major difference between OSPFv2 and OSPFv3 is that in OSPFv3, the concept of address families is introduced. Address families use entirely separate OSPF processes for each family. Each process maps its messages to or from the wire using a different instance ID. OSPFv3 address families are configured once routing for the address family is enabled at the global level. Configuration commands for OSPFv3 address families are discussed in *Router OSPFv3 IPv6 Address Family on page 4153*.

There are many additional differences between OSPFv2 and OSPFv3 operation and configuration. For more information about OSPFv3 configuration, refer to the configuration guide *Configuring IPv6 in AOS*, available online at http://supportforums.adtran.com.

To activate the OSPF Configuration mode, enter the **router ospfv3** <*process id*> command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#router ospfv3 5
(config-ospfv3)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
exit on page 83

All other commands for this command set are described in this section in alphabetical order.

address-family ipv6 unicast on page 4143
area <area id> authentication ipsec spi <spi> on page 4144
area <area id> default-cost <value> on page 4146
area <area id> encryption ipsec spi <spi> on page 4147
area <area id> stub on page 4149

address-family ipv6 unicast

Use the **address-family ipv6 unicast** command to specify an address family for the Open Shortest Path First version 3 (OSPFv3) process, and to enter the address family's configuration mode. Once an address family is created, it is permanently associated with the parent OSPFv3 process until the process itself is removed. Therefore, there is not a **no** version of this command.

Syntax Description

No subcommands.

Default Values

By default, no address family exists.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example creates an IPv6 address family for the OSPFv3 process **5**:

```
(config)#router ospfv3 5
(config-ospfv3)#address-family ipv6 unicast
```

area <*area id*> authentication ipsec spi <*spi*>

Use the **area authentication ipsec spi** command to enable authentication of all Open Shortest Path First version 3 (OSPFv3) messages that are sent or received on each interface in the specified area and to specify the authentication type. This command allows you to specify OSPFv3 authentication at the area level, which eases configuration and management when the same security settings are desired at multiple interfaces. It also allows the same security parameter index (SPI) to be used at multiple interfaces, which is not possible when specifying OSPFv3 authentication at the interface level. Use the **no** form of this command to remove IP security (IPsec) authentication of OSPFv3 messages in the area. Variations of this command include:

area <*area id*> **authentication ipsec spi** <*spi*> **md5** <*key*>
area <*area id*> **authentication ipsec spi** <*spi*> **sha1** <*key*>

Syntax Description

area <*area id*>	Specifies the ID of the area on which authentication is used. The area is specified as an integer (range is **1** to **967295**) or an IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
ipsec	Specifies that IPsec authentication is used on the interface for OSPFv3 SAs.
spi <*spi*>	Specifies the security parameter index (SPI) for the SA. The value specified must not be in used by another IPsec function on the system, or an error message is generated. If the same SPI is already in use in the same OSPFv3 area, entering this command with the same value will overwrite the current configuration. Valid SPI range is **256** to **4294967295**.
md5 <*key*>	Specifies that Message-Digest 5 (**md5**) is used for authentication. Keys are specified as 32 hexadecimal characters.
sha1 <*key*>	Specifies that secure-Hash 1 (**sha1**) is used for authentication. Keys are specified as 40 hexadecimal characters.

Default Values

By default, there is no authentication for OSPFv3 messages in an area.

Command History

Release R10.7.0	Command was introduced.

Functional Notes

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures OSPFv3 messages in area **10** with an SPI of **100** and **md5** as the authentication method:

(config)**#router ospfv3 5**
(config-ospfv3)**#area 10 authentication ipsec spi 100 md5 NeWtStpsswdKEY**

area <*area id*> default-cost <*value*>

Use the **area default-cost** command to assign a cost of the default summary route sent into a stub area or not-so-stubby-area (NSSA). Use the **no** form of this command to delete the assigned cost.

Syntax Description

<*area id*>	Specifies an identifier for this area either as an integer (range is **1** to **967295**) or an IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*value*>	Specifies the default summary route cost. Range is **0** to **166777214**.

Default Values

By default, the summary route cost is set to **0**. There is no default for the area ID.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example defines a default cost of **85** to a specific area:

(config)**#router ospfv3 5**
(config-ospfv3)**#area 192.22.72.0 default-cost 85**

area <*area id*> encryption ipsec spi <*spi*>

Use the **area encryption ipsec spi** command to specify a symmetrical, bidirectional Open Shortest Path First version 3 (OSPFv3) security association (SA) that uses encapsulating security payload (ESP) for encryption and authentication of all OSPFv3 messages that are sent or received on each interface in the specified area. This command allows you to specify OSPFv3 security at the area level, which eases configuration and management when the same security settings are desired at multiple interfaces. It also allows the same security parameter index (SPI) to be used at multiple interfaces, which is not possible when specifying OSPFv3 protection at the interface level. Use the **no** form of this command to remove IP security (IPsec) protection of OSPFv3 messages in the area. Variations of this command include:

area <*area id*> **encryption ipsec spi** <*spi*> **esp** <*encryption type*> <*encryption key*> <*authentication type*> <*authentication key*>

area <*area id*> **encryption ipsec spi** <*spi*> **esp null** <*authentication type*> <*authentication key*>

Syntax Description

area <*area id*>	Specifies the ID of the area on which encryption and authentication is used. The area is specified as an integer (range is **1** to **967295**) or an IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
ipsec	Specifies that IPsec encryption is used on the interface for OSPFv3 SAs.
spi <*spi*>	Specifies the security parameter index (SPI) for the SA. The value specified must not be in used by another IPsec function on the system, or an error message is generated. If the same SPI is already in use in the same OSPFv3 area, entering this command with the same value will overwrite the current configuration. Valid SPI range is **256** to **4294967295**.
esp	Specifies that ESP is used.
null	Specifies that OSPFv3 messages on this interface are not encrypted when used in the **ospfv3 encryption null** format (even when encryption is specified by the OSPFv3 area configuration). When used in the **ospfv3 encryption ipsec spi** <*spi*> **esp null** format, **null** indicates that messages on the interface will not be encrypted, but will be authenticated.
<*encryption type*>	Specifies the type of algorithm used to encrypt OSPFv3 messages. Valid values for encryption are: **3des** uses triple data encryption standard (DES). **aes-cbc** uses advanced encryption standard (AES) with cipher block chaining (CBC). Select from **aes-cbc 128**, **aes-cbc 192**, or **aes-cbc 256**. **des** uses DES.
<*encryption key*>	Specifies the hexadecimal encryption key. The size of the encryption key is determined by the respective encryption algorithm, as follows: **3des** uses a **48** character key size. **aes-cbc 128** uses a **32** character key size. **aes-cbc 192** uses a **48** character key size.

aes-cbc 256 uses a **64** character key size.

des uses a **16** character key size.

<authentication type> Specifies the algorithm used for authenticating OSPFv3 messages. Valid values for authentication are Message-Digest 5 (**md5**) and Secure-Hash 1 (**sha1**) algorithms.

<authentication key> Specifies the hexadecimal authentication key. The size of the authentication key is determined by the respective authentication algorithm, as follows:

md5 uses a **32** character key size.

sha1 uses a **40** character key size.

Default Values

By default, there is no security for OSPFv3 messages in an area.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

This commands specifies OSPFv3 security at the area level. After this command has been entered, and the security associations (SAs) are in place, if the command is reentered with different settings, an attempt is made to create the new SA. If SA creation fails, an error message is displayed, the command is not accepted into the running configuration on the device, and the original command and SAs remain in place. When OSPFv3 protection is specified at multiple locations that affect the same interface, one protection set is selected to protect all OSPFv3 instances on that interface. The set is chosen using the following rules processed in this order:

1. The protection configured at the interface level (including null), then everything else
2. The protection configured at the IPv6 address family instance, then everything else
3. The protection configured at the IPv4 address family instance, then everything else (IPv4 address family is not supported as of AOS firmware release R10.5.0).
4. No protection.

For more information about configuring OSPFv3, refer to the configuration guide *Configuring IPv6 in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example configures OSPFv3 messages in area **10** with an SPI of **100**, no encryption, and **md5** as the authentication method:

```
(config)#router ospfv3 5
(config-ospfv3)#area 10 encryption ipsec spi 100 esp null md5 NeWtStpsswdKEY
```

area <*area id*> stub

Use the **area stub** command to configure an area as a stub or total stub area. When an area is specified as a stub, the area border router withholds inter-area-router link state advertisements (LSAs) and autonomous system (AS)-external LSAs, and instead injects a default summary route. When an area is a total stub, the area border router also withholds inter-area-prefix LSAs. The cost for the injected route is defined by the command *area <area id> default-cost <value> on page 4146*. Use the **no** form of this command to return the area to the default area type. Variations of this command include:

area <*area id*> **stub**
area <*area id*> **stub no-summary**

Syntax Description

<area id>	Specifies the identifier for this area. Area IDs are specified as an integer (range is **1** to **967295**) or an IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
no-summary	Optional. Designates the area as a total stub area.

Default Values

By default, the area type is normal, and is not specified as a stub.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example configures area **10** as a total stub area:

(config)**#router ospfv3 5**
(config-ospfv3)**#area 10 stub no-summary**

auto-cost reference-bandwidth <*value*>

Use the **auto-cost reference-bandwidth** command to specify the reference value used to calculate the Open Shortest Path First version 3 (OSPFv3) cost of an interface. In OSPFv3, the cost of an interface is the reference value divided by the interface's bandwidth. Certain conditions require a change to the system's reference value, such as an increase in interface speeds. This command allows the reference value to be customized for specific network requirements. All OSPFv3 participants in the network should use the same reference value. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Sets the default reference bandwidth rate in Mbps. This rate is used to calculate the OSPFv3 cost on the AOS device's OSPFv3 interfaces. Range is **1** to **4294967** Mbps.

Default Values

By default, the rate is set to **100** Mbps.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example sets the auto cost reference bandwidth to **1000** Mbps:

(config)**#router ospfv3 5**
(config-ospfv3)**#auto-cost reference-bandwidth 1000**

router-id *<ipv4 address>*

Use the **router-id** command to specify the value to be used by the Open Shortest Path First version 3 (OSPFv3) process as the router ID. Use the **no** form of this command to return the router ID for this OSPFv3 process to the default value.

Syntax Description

<ipv4 address>	Specifies a 32-bit value, represented in IPv4 address format, that is used by this specific OSPFv3 instance as the router ID. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). Valid IPv4 address range is **0.0.0.1** to **255.255.255.255**.

Default Values

The default router ID value is determined by algorithm (refer to *Functional Notes* below).

Command History

Release R10.5.0	Command was introduced.

Functional Notes

An OSPFv3 router ID is selected using a well-defined algorithm that is also used for Border Gateway Protocol (BGP) router IDs. The default router ID value is chosen by first looking at the configured router ID (if there is one), then the highest value IPv4 address assigned to a loopback interface in the same virtual routing and forwarding (VRF) instance that is not already in use as an OSPFv3 router ID (if there is one). Then, the highest value IPv4 address assigned to a non-loopback interface that is not already in use as an OSPFv3 router ID interface in the same VRF instance.

When defining an IPv4 address for the router ID, keep in mind that the value must be unique among router IDs in use by other OSPFv3 processes on the local system. If a value is specified that is already in use, an error message is displayed, and the command is rejected. Though the value uses an IPv4 address in general format, it does not actually use the IPv4 address.

Usage Examples

The following example specifies a router ID for the OSPFv3 process **5**:

(config)**#router ospfv3 5**
(config-ospfv3)**#router-id 10.10.10.2**

timers spf <*delay*>

Use the **timers spf** command to configure the Open Shortest Path First version 3 (OSPFv3) shortest path first (SPF) calculation and hold interval timers. Use the **no** form of this command to return the timers to the default settings. Variations of this command include:

timers spf <*delay*>
timers spf <*delay*> <*hold*>

Syntax Description

<*delay*>	Specifies the time in seconds between receipt of OSPFv3 topology changes and the beginning of SPF calculations. Valid range is **0** to **65535** seconds.
<*hold*>	Optional. Specifies the time in seconds between consecutive SPF calculations. Range is **0** to **65535** seconds.

Default Values

By default, the SPF delay is **5** seconds and the hold interval is **10** seconds.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example defines an SPF delay timer of **10** seconds:

(config)**#router ospfv3 5**
(config-ospfv3)**#timers spf 10**

ROUTER OSPFV3 IPV6 ADDRESS FAMILY

In Open Shortest Path First version 3 (OSPFv3), the concept of address families is introduced. Address families use entirely separate OSPFv3 processes for each family. Each OSPFv3 process maps its messages to or from the wire using a different instance ID. The instance ID is a field in the OSPF header with a value from **0** to **255**. The value itself conveys no information, other than the instance number; however, the instance ID adheres to a range of values that convey address family information (refer to RFC 5838). The table below outlines the address family information associated with each instance ID value.

Instance ID Range	Address Family	Default Value
0 to 31	IPv6 Unicast	0
32 to 63	IPv6 Multicast	32
64 to 95	IPv4 Unicast	64
96 to 127	IPv4 Multicast	96
128 to 255	Unassigned	

*As of AOS firmware release R10.5.0, only IPv6 unicast address families are supported for OSPFv3. This configuration is backward compatible with non-address family capable OSPFv3 devices that support only IPv6, as long as those devices use the instance ID for the **Base IPv6 Unicast AF** (value of **0**). The AOS unit only accepts OSPF messages that do not set the address family bit when the instance ID is 0.*

Before an OSPFv3 process address family can be created, routing for the address family must be enabled at the global level (using the command *ipv6 unicast-routing on page 1564*). Before an OSPFv3 process can be enabled at an interface, routing for the address family must be enabled at that interface (using the command **ipv6** or a variation of the **ipv6 address** command). Globally disabling routing for an address family does not remove existing OSPFv3 commands associated with that address family. Disabling an address family at an interface removes OSPFv3 commands associated with that address family at the interface.

Because an OSPFv3 process supports one address family, and only one instance of an address family is allowed at an interface, all **ospfv3** <*process id*> commands entered at a given interface must have the same value for the process ID. In addition, OSPFv3 for a given process ID must be globally enabled before **ospfv3** <*process id*> commands can be entered at the interface.

For more information about OSPFv3 configuration, refer to the configuration guide *Configuring IPv6 in AOS*, available online at http://supportforums.adtran.com

To create an OSPFv3 address family, and enter the address family configuration mode, enter the **address-family ipv6 unicast** command from the OSPFv3 Configuration mode as follows:

```
(config)#router ospfv3 5
(config-ospfv3)#address-family ipv6 unicast
(config-ospfv3-ipv6)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
exit on page 83

All other commands for this command set are described in this section in alphabetical order.

area <area id> range <ipv6 address/prefix-length> on page 4155
default-information originate on page 4156
default-metric <value> on page 4158
distance <number> on page 4159
duplicate-routerid-detection on page 4161
maximum-paths <value> on page 4162
redistribute on page 4163
summary-prefix <ipv6 address/prefix-length> on page 4166

area *<area id>* **range** *<ipv6 address/prefix-length>*

Use the **area range** command to control the route summarization between Open Shortest Path First version 3 (OSPFv3) areas (inter-area prefixes of type 3 link-state advertisements (LSAs)). Use the **no** form of this command to remove the specified summarization, and return to advertisement of individual summary prefixes between areas. Variations of this command include:

area *<area id>* **range** *<ipv6 address/prefix-length>*
area *<area id>* **range** *<ipv6 address/prefix-length>* **advertise**
area *<area id>* **range** *<ipv6 address/prefix-length>* **not-advertise**

Syntax Description

<area id>	Specifies the identifier of the area of which the router is a member, and which contains the prefixes being summarized. Specify area IDs as an integer (range is **1** to **967295**) or an IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<ipv6 address/prefix-length>	Specifies the IPv6 prefix and length to be advertised. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
advertise	Optional. Specifies that the summary will be advertised to other OSPFv3 areas.
not-advertise	Optional. Specifies that the summary will not be advertised to other OSPFv3 areas.

Default Values

By default, route summarization is disabled. When enabled, OSPFv3 route summaries are advertised by default.

Command History

Release 3.1	Command was introduced.
Release R10.5.0	Command was expanded to include OSPFv3 functionality and the OSPFv3 IPv6 address family.

Functional Notes

Operation of this command is the same as the existing OSPFv2 command (*area <area id> range <ipv4 address> <subnet mask> on page 4123*), with the exception that the range is specified as an Internet Protocol version 6 (IPv6) prefix and length, rather than an IPv4 address with subnet and mask.

Usage Examples

The following example configures route summarization between OSPFv3 areas:

(config-ospfv3)**#address-family ipv6 unicast**
(config-ospfv3-ipv6)**#area 10 range 2001:DB8::1/64 not-advertise**

default-information originate

Use the **default-information originate** command to specify that a default external route is injected into the Open Shortest Path First version 3 (OSPFv3) process. A router that injects an external default route becomes an OSPFv3 autonomous system border router (ASBR) because it sources routes from outside the OSPFv3 autonomous system (AS). Use the **no** form of this command to remove the external default route. Variations of this command include:

default-information originate
default-information originate always
default-information originate metric <*value*>
default-information originate metric-type 1
default-information originate metric-type 2

Syntax Description

always	Optional. Specifies that the injected default route is always advertised.
metric <*value*>	Optional. Assigns an OSPFv3 metric value to the route being injected into OSPFv3. Valid metric range is **0** to **16777214**.
metric-type 1	Optional. Specifies the external metric type for the route being injected into OSPFv3. Metric type **1** specifies that when external routes are assigned a metric they begin with the metric value specified by this command, and add the cost of the OSPF path as they are advertised throughout the AS.
metric-type 2	Optional. Specifies the external metric type for the route being injected into OSPFv3. Metric type **2** is not affected by the OSPF path cost, and retains the original metric values.

Default Values

By default, no external routes are injected into OSPFv3. When an external route is injected, by default it will use **metric-type 2**, and will have a metric value that is the same as the default metric set by the command *default-metric <value> on page 4158*. If the default metric command is not configured, the injected route will have a default metric of **10** (refer to *Functional Notes* below).

Command History

Release 3.1	Command was introduced.
Release R10.5.0	Command was expanded to include OSPFv3 functionality and the OSPFv3 IPv6 address family.

Functional Notes

If the metric is not specified, then the **default-metric** command is used for the default route metric (refer to *default-metric <value> on page 4158*). If the **default-metric** command is not configured, then a metric of **10** is used. If the metric is specified as **0** using the **default-information originate** command, it means that the metric is set to an unconfigured value, and the **default-metric** command setting is used.

Usage Examples

The following example specifies that an external route is injected into OSPFv3 using the default metric value of **10** and the default metric type of **2**:

(config-ospfv3)**#address-family ipv6 unicast**
(config-ospfv3-ipv6)**#default-information originate always**

default-metric *<value>*

Use the **default-metric** command to specify the metric value used for Open Shortest Path First version 3 (OSPFv3) redistributed routes when the value is not otherwise specified. The metric for redistributed routes can be specified using the command *redistribute on page 4163* or using a route map. When the value is not set in one of the locations, the default metric is used. This setting does not affect the metric of the default route injected using the command *default-information originate on page 4156*, although this value is used if the metric is not specified in the **default-information originate** command. Use the **no** form of this command to return the default metric to the default value.

Syntax Description

<value>	Specifies the OSPFv3 metric value assigned to the route being injected into OSPFv3. Valid range is **0** to **6777214**.

Default Values

By default, the default metric is set to **20**.

Command History

Release 3.1	Command was introduced.
Release R10.5.0	Command was expanded to include OSPFv3 functionality and the OSPFv3 IPv6 address family.

Usage Examples

The following example changes the default metric to **30**:

```
(config-ospfv3)#address-family ipv6 unicast
(config-ospfv3-ipv6)#default-metric 30
```

distance <*number*>

Use the **distance** command to specify the administrative distance for Open Shortest Path First version 3 (OSPFv3) routes. The distance can be set once for all OSPFv3 route types or individually for each route type. Use the **no** form of this command to return the administrative distance to the default value. Variations of this command include:

distance <*number*>
distance ospf external <*number*>
distance ospf inter-area <*number*>
distance ospf intra-area <*number*>

Syntax Description

<*number*>	Specifies the administrative distance to use when adding OSPFv3 routes into the route table. Range is **0** to **255**.
ospf intra-area	Optional. Specifies using a unique administrative distance for route paths between a source and destination in the same routing area.
ospf inter-area	Optional. Specifies using a unique administrative distance for route paths between a source and destination in different areas.
ospf external	Optional. Specifies using a unique administrative distance for route paths between different autonomous systems.

Default Values

By default, **110** is the administrative distance for OSPFv3 routes.

Command History

Release 15.1	Command was introduced.
Release R10.5.0	Command was expanded to include OSPFv3 functionality and the OSPFv3 address family.

Usage Examples

The following example changes the administrative distance of all OSPFv3 routes to **150**:

(config-ospfv3)**#address-family ipv6 unicast**
(config-ospfv3-ipv6)**#distance 150**

Technology Review

An autonomous system (AS) is a set of routers under common administration control that usually use a common routing strategy. Each AS is composed of routing areas, which are groups of adjoining networks and attached hosts. Intra-area routing occurs when the source and destination hosts are in the same area; inter-area routing occurs when the source and destination hosts are in different areas; and external routing occurs when communication is between different ASs.

Administrative distance is a feature that routers employ in order to select the most reliable path when there are two or more routes to the same destination from two different routing protocols. Administrative distance defines the reliability of a routing protocol by assigning a value (the smaller the value, the more trustworthy the protocol) that is then used by the router to organize routing protocols according to reliability.

duplicate-routerid-detection

Use the **duplicate-routerid-detection** command to enable the ability to detect when a duplicate router ID is found in the Open Shortest Path First version 3 (OSPFv3) link state database. When enabled, if a received link state advertisement (LSA) contains the router ID of the OSPFv3 process to which the LSA belongs, a warning event is displayed. Use the **no** form of this command to disable duplicate router ID detection.

Syntax Description

No subcommands.

Default Values

By default, duplicate router ID detection is disabled.

Command History

Release R10.5.0	Command was introduced.

Usage Examples

The following example enables duplicate router ID detection for the OSPFv3 address family:

```
(config-ospfv3)#address-family ipv6 unicast
(config-ospfv3-ipv6)#duplicate-routerid-detection
```

maximum-paths *<value>*

Use the **maximum-paths** command to specify the maximum number of equal cost routes to a given prefix that Open Shortest Path First version 3 (OSPFv3) can enter into the route table. Use the **no** form of this command to return the maximum paths value to the default setting.

Syntax Description

<value>	Specifies the maximum number of equal cost OSPFv3 routes allowed. Valid range is **1** to **6**.

Default Values

By default, the **maximum-paths** value is **4**.

Command History

Release 11.1	Command was introduced.
Release R10.5.0	Command was expanded to include OSPFv3 functionality and the OSPFv3 IPv6 address family.

Usage Examples

The following example sets the maximum number of equal cost routes to **5**:

(config-ospfv3)**#address-family ipv6 unicast**
(config-ospfv3-ipv6)**#maximum-paths 5**

redistribute

Use the **redistribute** command to redistribute routes from a specified source into the Open Shortest Path First version 3 (OSPFv3) process. A router that performs redistribution becomes an OSPFv3 ASBR, because it is sourcing routes from outside the OSPFv3 AS. The specified source from which routes are redistributed must be in the same virtual routing and forwarding (VRF) instance, and of the same address family as the OSPFv3 instance being configured. This command can be entered multiple times (at most, once for each source). Reentering the command with the same source replaces any existing command with that source. Use the **no** form of this command to remove the redistribution from the specified source. Variations of this command include:

redistribute bgp
redistribute bgp metric <*value*>
redistribute bgp metric-type 1
redistribute bgp metric-type 2
redistribute bgp route-map <*map*>
redistribute connected
redistribute connected metric <*value*>
redistribute connected metric-type 1
redistribute connected metric-type 2
redistribute connected route-map <*map*>
redistribute ospf <*process id*>
redistribute ospf <*process id*> **include-connected**
redistribute ospf <*process id*> **metric** <*value*>
redistribute ospf <*process id*> **metric-type 1**
redistribute ospf <*process id*> **metric-type 2**
redistribute ospf <*process id*> **route-map** <*map*>
redistribute static
redistribute static metric <*value*>
redistribute static metric-type 1
redistribute static metric-type 2
redistribute static route-map <*map*>

Syntax Description

bgp	Specifies that Border Gateway Protocol (BGP) routes are being redistributed.
connected	Specifies that connected routes are being redistributed.
ospf <*process id*>	Specifies the OSPF process from which to redistribute routes. Valid process ID range is **1** to **65535.**
include-connected	Optional. Specifies that all connected routes corresponding with the OSPF process are redistributed. In addition, routes on interfaces participating in the OSPF process are also redistributed.
static	Specifies that static routes are being redistributed.
metric <*value*>	Optional. Assigns an OSPFv3 metric value to the route being redistributed into OSPFv3. Valid metric range is **0** to **16777214**.

metric-type 1	Optional. Specifies the external metric type for the route being redistributed into OSPFv3. Metric type **1** specifies that when external routes are assigned a metric they begin with the metric value specified by this command, and add the cost of the OSPF path as they are advertised throughout the autonomous system.
metric-type 2	Optional. Specifies the external metric type for the route being redistributed into OSPFv3. Metric type **2** is not affected by the OSPF path cost, and retains the original metric values.
route-map *<map>*	Optional. Specifies a route map that is applied to routes being redistributed by this command. A route map can impose granular control on routes being redistributed.

Default Values

By default, no routes are redistributed into OSPFv3. When a route is redistributed, by default it will use **metric-type 2**, and will have a metric value that is the same as the default metric set by the command *default-metric <value> on page 4158*. If the default metric command is not configured, the injected route will have a default metric of **10** (refer to *Functional Notes* below).

Command History

Release 3.1	Command was introduced.
Release 14.1	Command was expanded to include the **bgp** keyword and route map filtering.
Release R10.5.0	Command was expanded to include the OSPFv3 functionality and the OSPFv3 IPv6 address family.
Release R10.8.0	Command was expanded to include the **ospf** and **include-connected** parameters.

Functional Notes

The optional parameters of this command can be entered in any order.

When using redistribution, keep in mind the following:

- OSPFv3 settings, such as metric and metric types, that are specified in a route map entry override those settings in the **redistribution** command for the routes that match the route map entry.
- When using the command *summary-prefix <ipv6 address/prefix-length> on page 4166*, individual routes that are summarized, as well as the resulting summary, bypass route maps in **redistribute** commands.
- By default, no route map is used.

If the metric is not specified, then the **default-metric** command is used for the default route metric (refer to *default-metric <value> on page 4158*). If the **default-metric** command is not configured, then a metric of **10** is used. If the metric is specified as **0** using the **default-information originate** command, it means that the metric is set to an unconfigured value, and the **default-metric** command setting is used.

Usage Examples

The following example redistributes all routes from BGP:

(config-ospfv3)#**address-family ipv6 unicast**
(config-ospfv3-ipv6)#**redistribute bgp**

summary-prefix *<ipv6 address/prefix-length>*

Use the **summary-prefix** command to control route summarization and route advertisement that is redistributed into this Open Shortest Path First version 3 (OSPFv3) process (external prefixes of type 5 link state advertisements (LSAs)). Use the **no** form of this command to remove the specified route summary, and return to advertising the individual prefixes that are being redistributed. Variations of this command include:

summary-prefix *<ipv6 address/prefix-length>*
summary-prefix *<ipv6 address/prefix-length>* **not-advertise**

Syntax Description

<ipv6 address/prefix-length>	Specifies the IPv6 prefix and length to be advertised. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
not-advertise	Optional. Specifies that the summary is not advertised to other OSPFv3 areas.

Default Values

By default, the cost applied to the summary route is that of the lowest cost route in the set it summarizes.

Command History

Release R10.5.0	Command was introduced.

Functional Notes

The command can be entered multiple times to summarize different prefixes. Individual routes being summarized, as well as the resulting summary prefix, bypass route maps specified in the *redistribute on page 4163* commands. In addition, if multiple summaries exist where one summary subsumes another, the prefix with the shortest length is used.

Usage Examples

The following example creates a route summary:

(config-ospfv3)**#address-family ipv6 unicast**
(config-ospfv3-ipv6)**#summary-prefix 2001:DB8::1/64**

ROUTING COMMAND SETS

This section includes the following command sets:

ROUTE MAP COMMAND SET

The Route Map Command Set contains commands used to match attributes within a route for the purpose of filtering. This section also contains set commands that are optionally used to apply attributes to the routes that are being filtered.

To activate the Route Map Configuration mode, enter the **route-map** command at the Global Configuration mode prompt. Refer to the command *route-map on page 1687* for additional information.

For example:

```
>enable
#configure terminal
(config)#route-map MyMap permit 100
(config-route-map)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
description <text> on page 80
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

match as-path <name> on page 4170
match community <name> on page 4171
match ip address <name> on page 4172
match ip address prefix-list <name> on page 4173
match ip dscp on page 4174
match ip precedence on page 4178
match ipv6 address <ipv6 acl name> on page 4180
match ipv6 address prefix-list <name> on page 4181
match length <minimum> <maximum> on page 4182
match metric <value> on page 4183
match tag <number> on page 4184
set as-path prepend on page 4185
set comm-list <name> delete on page 4186
set community on page 4187
set default interface on page 4189
set interface <interface> on page 4190

match as-path *<name>*

Use the **match as-path** command to configure the route map to route traffic based on the autonomous system (AS) path list name. Use the **no** form of this command to discontinue matching.

Syntax Description

<name>	Specifies the name of the AS path list you want to match.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example instructs the route map named **MYMAP** to match the AS path list named **TESTPATH**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#match as-path TESTPATH**

match community <*name*>

Use the **match community** command to configure the route map to route traffic based on a specified community. Use the **no** form of this command to discontinue matching. Variations of this command include:

match community <*name*>
match community <*name*> **exact-match**

Syntax Description

<*name*>	Specifies the name of the community you want to match.
exact-match	Optional. Specifies that the route map must match the community name exactly.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example instructs the route map named **MYMAP** to match the community named **MYCOMMUNITY**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#match community MYCOMMUNITY**

match ip address <*name*>

Use the **match ip address** command to configure the route map to route traffic based on the access control list (ACL) name defined with the **ip access-list** command. Refer to *ip access-list standard <ipv4 acl name> on page 1346* for more information. Use the **no** form of this command to discontinue matching.

Syntax Description

<name>	Specifies the name of the ACL to match.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example instructs the route map named **MYMAP** to match the IP address ACL named **MYLIST**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#match ip address MYLIST**

match ip address prefix-list *<name>*

Use the **match ip address prefix-list** command to configure the route map to route traffic based on a prefix list route filter. The name of the prefix list is defined with the **ip prefix-list** command. Refer to *ip prefix-list <name> description "<text>" on page 1442* for more information. Use the **no** form of this command to discontinue matching.

Syntax Description

<name>	Specifies matching the IP address based on the prefix list name.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example instructs the route map named **MYMAP** to match the IP address prefix list named **MYLIST**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#match ip address prefix-list MYLIST**

match ip dscp

Use the **match ip dscp** command to configure the route map to route traffic based on the differentiated services code point (DSCP) value in the IP header of the packet. Use the **no** form of this command to discontinue matching. Variations of this command include:

match ip dscp <*value*>
match ip dscp af*xx*
match ip dscp cs*x*
match ip dscp default
match ip dscp ef

Syntax Description

<*value*>	Specifies the DSCP numeric value. Valid range is **0** to **63**.
af*xx*	Specifies the assured forwarding (AF) class and subclass. Select from: 11 (001010), 12 (001100), 13 (001110), 21 (010010), 22 (010100), 23 (010110), 31 (011010), 32 (011100), 33 (011110), 41 (100010), 42 (100100), or 43 (100110).
cs*x*	Specifies the class selector (CS) value. Valid range is **1** to **7**.
default	Specifies the default IP DSCP value (000000).
ef	Specifies marking for expedited forwarding (EF).

Default Values

No default values are necessary for this command.

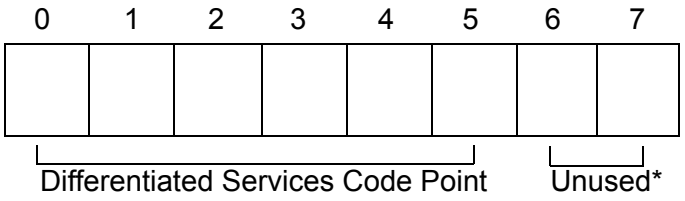
Command History

Release 11.1	Command was introduced.

Functional Notes

The differentiated services (DiffServ or DS) model was created in RFC 2474 and RFC 2475 to build on the original type of service (ToS) field by creating a six-bit sequence (combining the precedence value with the delay, throughput, and reliability bits). This six-bit sequence increased the number of available values from 8 to 64. The DiffServ model introduced a new concept to quality of service (QoS) in the IP network environment: per-hop behaviors (PHBs). The PHB premise is that equipment using the DiffServ model have an agreed upon set of rules (PHB types) for handling certain network traffic. Though the RFC explicitly defines what each PHB should be capable of, it does not restrict vendor-specific implementation of the PHBs. Each vendor is free to decide how their network product implements the various defined PHBs.

According to RFC 2474, the DS field contains the following bits:



* The previously unused bits in the DS field are now used for congestion control and are not discussed in this document.

Equipment following the DiffServ model (DS-compliant nodes) must use the entire six-bit DSCP value to determine the appropriate PHB. The PHBs are defined as the following:

- Default PHB
- Class selector PHB
- Assured forwarding PHB (RFC 2597)
- Expedited forwarding PHB (RFC 2598)

Default PHB

All DS-compliant nodes must provide a default PHB to offer best-effort forwarding service. For default PHBs, the DSCP value is 0. Any packet that does not contain a standardized DSCP should be mapped to the Default PHB and handled accordingly.

Class Selector PHB

In the class selector PHB, the first three bits in the DSCP value are used for backwards compatibility to systems implementing IP precedence. In this scenario, all but the first three bits of the DS field are set to 0. This compatibility requires DS-compliant nodes to provide the same data services as are provided by nodes implementing IP precedence. The following table is a comparison of IP precedence values to their corresponding DSCP values.

IP Precedence Value (bits)	DSCP Value (bits)
0 (000)	0 (000000)
1 (001)	8 (001000)
2 (010)	16 (010000)
3 (011)	24 (011000)
4 (100)	32 (100000)
5 (101)	40 (101000)
6 (110)	48 (110000)
7 (111)	56 (111000)

Assured Forwarding PHB

The flexibility of DiffServ allows for more developed subclasses of service within each main class using the last three bits of the DSCP. As defined in RFC 2597, the assured forwarding PHB creates four main classes of service:

Class	DSCP Bits
AF1	001XX0
AF2	010XX0
AF3	011XX0
AF4	100XX0
X indicates a do not care value.	

The first three bits of the DSCP specify the class and the last bit is always zero. Each class is separated into subclasses using the two remaining bits in the DSCP (bits 3 and 4). The subclasses are divided based on the likelihood that packets in the class are dropped in the event of network congestion. The higher the value for bits 3 and 4, the greater the likelihood that the packets will be dropped.

Bit 3	Bit 4	Drop Precedence
0	1	Low
1	0	Medium
1	1	High

The following table lists the assured forwarding PHB subclasses and their corresponding DSCP bits and values.

Class	Subclass	DSCP Bits	DSCP Value
AF1	1	001010	10
	2	001100	12
	3	001110	14
AF2	1	010010	18
	2	010100	20
	3	010110	22
AF3	1	011010	26
	2	011100	28
	3	011110	30
AF4	1	100010	34
	2	100100	36
	3	100110	38

Expedited Forwarding PHB

RFC 2598 created a new DiffServ PHB intended to provide the best service possible on an IP network. Packets using the expedited forwarding PHB markings should provide service to reduce latency, jitter, and dropped packets, and be guaranteed bandwidth during the entire end-to-end transmission journey through the network. The DSCP value for the expedited forwarding PHB is 46 (DSCP bits are 101110).

Usage Examples

The following example instructs the route map named **MYMAP** to match the IP header with a DSCP AF Class 1, Subclass 2 (**af12**):

(config)**#route-map MYMAP permit 100**
(config-route-map)**#match ip dscp af12**

match ip precedence

Use the **match ip precedence** command to configure the route map to route traffic based on the precedence value in the IP header of the packet. Use the **no** form of this command to discontinue matching. Variations of this command include:

match ip precedence <*value*>
match ip precedence critical
match ip precedence flash
match ip precedence flash-override
match ip precedence immediate
match ip precedence internet
match ip precedence network
match ip precedence priority
match ip precedence routine

Syntax Description

<*value*>	Specifies matching the IP precedence (in numeric value). Valid range is **0** to **7** in ascending order of importance.
routine	Specifies matching the IP precedence **routine**. (Numeric value of 0.)
priority	Specifies matching the IP precedence **priority**. (Numeric value of 1.)
immediate	Specifies matching the IP precedence **immediate**. (Numeric value of 2.)
flash	Specifies matching the IP precedence **flash**. (Numeric value of 3.)
flash-override	Specifies matching the IP precedence **flash-override**. (Numeric value of 4.)
critical	Specifies matching the IP precedence **critical**. (Numeric value of 5.)
internet	Specifies matching the IP precedence **internet**. (Numeric value of 6.) This level is reserved for internal network use.
network	Specifies matching the IP precedence **network**. (Numeric value of 7.) This level is reserved for internal network use.

Default Values

No default values are necessary for this command.

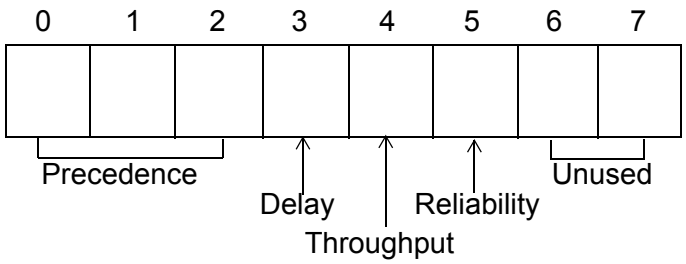
Command History

Release 11.1	Command was introduced.

Functional Notes

RFC 791 created a single octet (labeled type of service (ToS)) to help with the difficulty of trying to provide quality of service (QoS) handling in IP networks.

According to RFC 791, the ToS field contains the following bits:



The three-bit IP precedence values (0 through 7) are specified as:

111	Network Control Packets
110	Internetwork Control Packets
101	Critical Traffic
100	Flash Override
011	Flash
010	Immediate Servicing
001	Priority Traffic
000	Routine Data

The IP precedence values provide network routers with information about the kind of traffic contained in the IP packet. Based on the IP precedence values, some networks (when supported) can offer special handling to certain packets. In addition, providing IP precedence values to critical traffic (such as route information) ensures that critical packets will always be delivered regardless of network congestion. This traffic is often critical to network and internetwork operation. In general, the higher the IP precedence value, the more important the traffic and the better handling it should receive in the network. It is important to remember that not all equipment in the public IP network will be configured to recognize and handle IP precedence values. While it is a good idea to set the values for critical traffic, it does not guarantee special handling.

In addition to the IP precedence values, RFC 791 specifies bits for delay, throughput, and reliability to help balance the needs of particular traffic types when traveling on the IP network infrastructure. When these bits are set to 0, they are handled with normal operation. When set to 1, each bit specifies premium handling for that parameter. For example, a 1 in the delay position indicates that the traffic is delay sensitive and care should be taken to minimize delay. A 1 in the throughput position indicates that the traffic has higher bandwidth requirements that should be met. A 1 in the reliability position indicates that the traffic is sensitive to delivery issues and care should be taken to ensure proper delivery with all packets of this type. These extra bits are rarely used because it is quite difficult to balance the cost and benefits of each parameter (especially when more than one bit is set to 1).

Usage Examples

The following example instructs the route map named **MyMap** to match the IP precedence value of **critical**:

(config)**#route-map MyMap permit 100**
(config-route-map)**#match ip precedence critical**

match ipv6 address *<ipv6 acl name>*

Use the **match ipv6 address** command to configure the route map to route traffic based on the Internet Protocol version 6 (IPv6) access control list (ACL) name defined with the **ipv6 access-list** command. Refer to *ipv6 access-list standard <ipv6 acl name> on page 1502* for more information. Use the **no** form of this command to discontinue matching.

Syntax Description

<ipv6 acl name>	Specifies the name of the IPv6 ACL to match.

Default Values

No default values are necessary for this command.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example instructs the route map named **MYMAP** to match the IPv6 address ACL named **MYLIST**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#match ipv6 address MYLIST**

match ipv6 address prefix-list *<name>*

Use the **match ipv6 address prefix-list** command to configure the route map to route traffic based on an Internet Protocol version 6 (IPv6) prefix list route filter. The name of the prefix list is defined with the command *ipv6 prefix-list <name> seq <number> on page 1556*. Use the **no** form of this command to discontinue matching.

Syntax Description

<name>	Specifies matching the IPv6 address based on the IPv6 prefix list name.

Default Values

No default values are necessary for this command.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example instructs the route map named **MYMAP** to match the IPv6 address prefix list named **MYLIST**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#match ipv6 address prefix-list MYLIST**

match length *<minimum> <maximum>*

Use the **match length** command to configure the route map to route traffic based on the packet length. Use the **no** form of this command to discontinue matching.

Syntax Description

<minimum>	Specifies the minimum packet length you want to match. Valid range is **1** to **4294967295**.
<maximum>	Specifies the maximum packet length you want to match. Valid range is **1** to **4294967295**.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example instructs the route map named **MYMAP** to match packets with a minimum length of **1** and a maximum length of **200**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#match length 1 200**

match metric <*value*>

Use the **match metric** command to configure the route map to route traffic based on a specified metric value. Use the **no** form of this command to discontinue matching.

Syntax Description

<*value*>	Specifies the metric value you want to match. Valid range is **1** to **4294967295**.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example instructs the route map named **MYMAP** to match the metric value **100**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#match metric 100**

match tag <*number*>

Use the **match tag** command to configure the route map to filter traffic based on a route's tag value. Use the **no** form of this command to discontinue matching.

match tag <*number*>
match tag <*number*> <*number*>

Syntax Description

<*number*>	Specifies the desired route tag value to match. If more than one value is specified, the match command will pass if any value matches. Valid range is **1** to **65535**.

Default Values

No default values are necessary for this command.

Command History

Release 15.1	Command was introduced.

Functional Notes

More than one value may be specified as a tag to be matched.

Usage Examples

The following example instructs the route map named **MYMAP** to match a route tag of 100 or 200:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#match tag 100 200**

Technical Review

The command *ip route on page 1447* is related to the **match tag** command in that it includes an optional parameter to set the route tag value for local static routes.

Virtual private network (VPN) reverse-route injection (RRI) routes can also have a tag applied.

set as-path prepend

Use the **set as-path prepend** command to prepend a number to the autonomous system (AS) path to influence the best-path selection process by making the AS path appear further away. Use the **no** form of this command to disable this feature. Variations of this command include:

set as-path prepend <*number*>
set as-path prepend last-as <*number*>

Syntax Description

<*number*>	Specifies a number to be prepended to the AS path value as an autonomous number. Valid range is **1** to **65535**.
last-as <*number*>	Specifies a number to be prepended to the last AS path number. Valid range is **1** to **10**.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example prepends the number **2** to the last AS path number:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set as-path prepend last-as 2**

set comm-list <*name*> delete

Use the **set comm-list delete** command to specify a list of communities to delete. Use the **no** form of this command to disable this feature.

Syntax Description

<name>	Specifies the name of the IP community list that contains the list of community strings to delete.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Functional Notes

A community list must be defined using the **ip community-list** command before the **set comm-list delete** command can be used. Refer to *community-list <name> on page 1236* for information on configuring a community list.

Usage Examples

The following example deletes the community list named **LISTNAME**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set comm-list LISTNAME delete**

set community

Use the **set community** command to modify the community attribute for all paths serviced by the route map. Use the **no** form of this command to disable this feature. Variations of this command include:

set community <*value*>
set community <*value*> **add**
set community <*value*> **internet**
set community <*value*> **local-as**
set community <*value*> **no-advertise**
set community <*value*> **no-export**
set community none

Syntax Description

<*value*>	Sets the community attribute to the specified community number for routes serviced by this route map. This is a numeric value that can be an integer from **1** to **4294967295** or string in the form ***aa:nn***, where the value of ***aa*** is the autonomous system (AS) number and the value of ***nn*** is the community number. Multiple community-number parameters can be present in the command.
add	Appends the listed community number to the end of the community attribute for routes serviced by this route map.
internet	Sets the community attribute to the INTERNET community number for routes serviced by this route map.
local-as	Sets the community attribute to the NO_EXPORT_SUBCONFED community number for routes serviced by this route map. Routes containing this attribute should not be advertised to external Border Gateway Protocol (BGP) peers.
no-advertise	Sets the community attribute to the NO_ADVERTISE community number for routes serviced by this route map. Routes containing this attribute should not be advertised to any BGP peer.
no-export	Sets the community attribute to the NO_EXPORT community number for routes serviced by this route map. Routes containing this attribute should not be advertised to BGP peers outside a confederation boundary.
none	Removes all communities from BGP routes serviced by this route map.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example sets the community number for BGP routes to the Internet community:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set community internet**

set default interface

Use the **set default interface** command to specify a default interface to redirect traffic to the specified interface if there is no specific routing information for the traffic. If more than one interface is specified, the router uses the first available interface from the list. Use the **no** form of this command to remove the default interface. Variations of this command include:

set default interface <*interface*>
set default interface efm-group <*slot/port.subint*>
set default interface null 0

Syntax Description

<*interface*>	Specifies the default interface. Specify an interface in the format <*interface type [slot/port	slot/port.subinterface id	interface id	interface id.subinterface id	ap	ap/radio	ap/radio.vap]*>. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **set default interface ?** for a list of valid interface types.
efm-group <*slot/port.subint*>	Specifies an Ethernet in the first mile (EFM) group interface. Interface number is specified in <*slot/port.subinterface id*>.
null 0	Redirects traffic to the specified interface regardless of available routing information.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface.
Release R11.2.0	Command was expanded to include Ethernet in the first mile (EFM) group.
Release R11.4.0	Command was expanded to include the Gigabit Ethernet interface.
Release R13.7.0	Command was expanded to include the VLAN interface.

Usage Examples

The following example sets the default interface as **ppp 1** interface:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set default interface ppp 1**

set interface <*interface*>

Use the **set interface** command to specify an output interface for the packet. Multiple interfaces can be specified. The router forwards the packet along the first usable interface. Use the **no** form of this command to cancel output from the specified interface. Variations of this command include:

set interface <*interface*>
set interface efm-group <*slot/port.subint*>

Syntax Description

<*interface*>	Sets output interface type for the packet. Specify an interface in the format <*interface type [slot/port	slot/port.subinterface id	interface id	interface id.subinterface id	ap	ap/radio	ap/radio.vap]*>. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **set interface ?** for a list of valid interfaces.
efm-group <*slot/port.subint*>	Specifies an Ethernet in the first mile (EFM) group interface. Interface number is specified in <*slot/port.subinterface id*>.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface.
Release R11.2.0	Command was expanded to include Ethernet in the first mile (EFM) group.
Release R11.4.0	Command was expanded to include the Gigabit Ethernet interface.
Release R13.7.0	Command was expanded to include the VLAN interface.

Usage Examples

The following example sets the output interface as Point-to-Point Protocol (PPP) 1:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set interface ppp 1**

set ip default next-hop *<interface>*

Use the **set ip default next-hop** command to set the next-hop IP address to the specified interface's address for all routes serviced by the route map that do not have explicit routing information available. Use the **no** form of this command to remove the configured default next hop.

Syntax Description

<interface>	Specifies the default interface. Specify an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **set default next-hop ?** for a list of valid interface types.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the default next-hop interface to the **ppp 1** interface:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set ip default next-hop ppp 1**

set ip df

Use the **set ip df** command to identify the packet as *don't fragment* (DF). Use the **no** form of this command to remove this designation.

Syntax Description

No subcommands.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example designates the packet as DF:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set ip df**

set ip dscp

Use the **set ip dscp** command to configure the route map to set the differentiated services code point (DSCP) value in the IP header of the packet for traffic serviced by this route map. For more details on DSCP values, refer to the command *match ip dscp on page 4174*. Use the **no** form of this command to remove the specified DSCP value. Variations of this command include:

set ip dscp <*value*>
set ip dscp af*xx*
set ip dscp cs*x*
set ip dscp default
set ip dscp ef

Syntax Description

<*value*>	Specifies the DSCP numeric value. Valid range is **0** to **63**.
af*xx*	Specifies the assured forwarding (AF) class and subclass. Select from: 11 (001010), 12 (001100), 13 (001110), 21 (010010), 22 (010100), 23 (010110), 31 (011010), 32 (011100), 33 (011110), 41 (100010), 42 (100100), or 43 (100110).
cs*x*	Specifies the class selector (CS) value. Valid range is **1** to **7**.
default	Specifies the default IP DSCP value (000000).
ef	Specifies marking for expedited forwarding (EF).

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example instructs the route map named **MYMAP** to set the IP header with a DSCP AF Class 1, Subclass 2 (**af12**):

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set ip dscp af12**

set ip next-hop *<ip address>*

Use the **set ip next-hop** command to set the next-hop IP address to the specified address for all routes serviced by the route map. Use the **no** form of this command to remove the configured next-hop address.

Syntax Description

<ip address>	Specifies a valid IP address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). More than one address can be entered, and the router uses the first available route from the list.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the ip next-hop interface to **10.10.11.254** in the header of the route map named **MYMAP**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set ip next-hop 10.10.11.254**

set ip precedence

Use the **set ip precedence** command to configure the route map to set the precedence value in the IP header of the packet for traffic serviced by the route map. For more details on IP precedence values, refer to the command *match ip precedence on page 4178*. Use the **no** form of this command to remove the specified IP precedence value. Variations of this command include:

set ip precedence <*value*>
set ip precedence critical
set ip precedence flash
set ip precedence flash-override
set ip precedence immediate
set ip precedence internet
set ip precedence network
set ip precedence priority
set ip precedence routine

Syntax Description

<*value*>	Specifies matching the IP precedence (in numeric value). Valid range is **0** to **7** in ascending order of importance.
routine	Specifies matching the IP precedence **routine**. (Numeric value of 0.)
priority	Specifies matching the IP precedence **priority**. (Numeric value of 1.)
immediate	Specifies matching the IP precedence **immediate**. (Numeric value of 2.)
flash	Specifies matching the IP precedence **flash**. (Numeric value of 3.)
flash-override	Specifies matching the IP precedence **flash-override**. (Numeric value of 4.)
critical	Specifies matching the IP precedence **critical**. (Numeric value of 5.)
internet	Specifies matching the IP precedence **internet**. (Numeric value of 6.) This level is reserved for internal network use.
network	Specifies matching the IP precedence **network**. (Numeric value of 7.) This level is reserved for internal network use.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets an IP precedence value of **critical** in the IP header of the route map named **MYMAP**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set ip precedence critical**

set ipv6 next-hop <*ipv6 address*>

Use the **set ipv6 next-hop** command to set the next-hop Internet Protocol version 6 (IPv6) address to the specified address for all routes serviced by the route map. Use the **no** form of this command to remove the configured next-hop address.

Syntax Description

<ipv6 address>	Specifies a valid IPv6 address. IPv6 addresses should be expressed in colon hexadecimal notation (**X:X:X:X::X**), for example, **2001:DB8:1::1**. More than one address can be entered, and the router uses the first available route from the list.

Default Values

No default values are necessary for this command.

Command History

Release R10.1.0	Command was introduced.

Usage Examples

The following example sets the IPv6 address of the next hop to **2001:DB8:1::1** in the header of the route map named **MYMAP**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set ipv6 next-hop 2001:DB8:1::1**

set local-preference *<value>*

Use the **set local-preference** command to restrict traffic to a local autonomous system (AS). Use the **no** form of this command to cancel the local preference.

Syntax Description

<value>	Sets the local preference value. Valid range is **0** to **4294967295**.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example sets the local preference for **MYMAP** to a value of **100**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set local-preference 100**

set metric *<value>*

Use the **set metric** command to specify a metric value for the route map. Use the **no** form of this command to cancel the metric value.

Syntax Description

<value>	Sets the metric value. Valid range is **0** to **4294967295**.

Default Values

No default values are necessary for this command.

Command History

Release 10.1	Command was introduced.

Usage Examples

The following example sets the metric value for **MYMAP** to **100**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set metric 100**

set metric-type

Use the **set metric-type** command to set the open shortest path first (OSPF) metric type for the route map. Use the **no** form of this command to return to the default value. Variations of this command include:

set metric-type type-1
set metric-type type-2

Syntax Description

type-1	Specifies intra-area metric.
type-2	Specifies inter-area metric.

Default Values

By default, the metric type is set to **type 1**.

Command History

Release 14.1	Command was introduced.

Usage Examples

The following example sets the metric-type value for **MYMAP** to **type 2**:

(config)**#route-map MYMAP permit 100**
(config-route-map)**#set metric-type type-2**

set tag <*value*>

Use the **set tag** command to set the open shortest path first (OSPF) route tag for the route map. This command applies the specified route tag to any route matched by the route map. Use the **no** form of this command to cancel the route tag.

Syntax Description

<*value*>	Specifies the route tag value. Valid range is **0** to **4294967295**.

Default Values

By default, no route tag is set.

Command History

Release R11.4.0	Command was introduced.

Usage Examples

The following example sets the route tag value for **OSPFMAP** to **555**:

(config)**#route-map OSPFMAP permit 100**
(config-route-map)**#set tag 555**

ROUTER PIM SPARSE COMMAND SET

To activate the Router (Protocol-Independent Multicast (PIM) Sparse) Configuration mode, enter the **router pim-sparse** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#router pim-sparse
(config-pim-sparse)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

join-prune-msg-interval <value> on page 4202
rp-address <ip address> on page 4203
spt-threshold on page 4204

join-prune-msg-interval <*value*>

Use the **join-prune-msg-interval** command to set a timing rate for protocol-independent multicast (PIM) sparse join/prune messages. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the PIM sparse join/prune message interval. Valid range: **10** to **65534** seconds.

Default Values

By default, the message interval is set to **60** seconds.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the interval for **50** seconds:

(config)**#router pim-sparse**
(config-pim-sparse)**#join-prune-msg-interval 50**

rp-address <*ip address*>

Use the **rp-address** command to specify a static IP address for the rendezvous point (RP) router. The **access-group** keyword is used to limit the multicast group addresses to which the RP applies. Use the **no** form of this command to remove a static IP address for the RP router. Variations of this command include:

rp-address <*ip address*>
rp-address <*ip address*> **access-group** <*name*>

Syntax Description

<*ip address*>	Specifies the IP address for the RP. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
access-group <*name*>	Optional. Specifies the particular access group to which the RP applies.

Default Values

No default values are necessary for this command.

Command History

Release 11.1	Command was introduced.

Functional Notes

The **access-group** keyword is used to limit the multicast group addresses to which the RP applies. If more than one RP is configured for a given multicast group address, then a hash algorithm determines the appropriate hierarchy (as shown below). The results of the hash algorithm can be seen with the **show ip pim-sparse rp-map** command.

The hash algorithm is defined in RFC 2117 section 3.7 as follows:

For each RP address C(i) in the RP-Set, whose Group-prefix covers G, compute a value:

Value(G,M,C(i))=(1103515245 * ((1103515245 * (G&M)+12345) XOR C(i)) + 12345) mod 2^31

where M is a hash-mask included in Bootstrap messages.This hash-mask allows a small number of consecutive groups (e.g., **4**) to always hash to the same RP. For instance, hierarchically encoded data can be sent on consecutive group addresses to get the same delay and fate-sharing characteristics.

The candidate with the highest resulting value is then chosen as the RP for that group, and its identity and hash value are stored with the entry created.

Ties between C-RPs having the same hash value are broken in advantage of the highest address.

Usage Examples

The following example specifies an IP address of **172.22.5.100** for the RP:

(config)**#router pim-sparse**
(config-pim-sparse)**#rp-address 172.22.5.100**

spt-threshold

Use the **spt-threshold** command to change the protocol-independent multicast (PIM) sparse shortest path tree (SPT) threshold, which specifies the number of packets the router sends using the rendezvous point (RP) before switching to the SPT. Use the **no** form of this command to return to the default setting. Variations of this command include:

spt-threshold <*value*>
spt-threshold infinity

Syntax Description

<*value*>	Optional. Specifies the number of packets the routing switch sends using the RP before switching to the SPT. Valid range is **1** to **4294967295** packets.
infinity	Optional. Causes all sources to use the shared RP tree.

Default Values

By default, the SPT threshold is set to **1** packet.

Command History

Release 11.1	Command was introduced.

Usage Examples

The following example sets the SPT threshold at **five** packets:

(config)**#router pim-sparse**
(config-pim-sparse)**#spt-threshold 5**

ROUTER RIP COMMAND SET

To activate the Router (Routing Information Protocol (RIP)) Configuration mode, enter the **router rip** command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#router rip
(config-rip)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

auto-summary on page 4206
default-metric <value> on page 4207
distance <number> on page 4208
distribute-list <name> on page 4209
network <ip address> <subnet mask> on page 4211
passive-interface <interface> on page 4212
redistribute bgp on page 4213
redistribute connected on page 4214
redistribute ospf on page 4215
redistribute static on page 4217
timeout-timer <value> on page 4218
update-timer <value> on page 4219
version on page 4220

auto-summary

Use the **auto-summary** command to have Routing Information Protocol (RIP) version 2 summarize subnets to the classful boundaries. Use the **no** form of this command to disable this summarization.

Syntax Description

No subcommands.

Default Values

By default, **auto-summary** is disabled.

Command History

Release 3.1	Command was introduced.

Functional Notes

Use this command if you are subdividing a classful network into many subnets and these subnets are to be advertised over a slow link (64k or less) to a router that can only reach the classful network via the router you are configuring.

Usage Examples

The following example configures the router to not automatically summarize network numbers:

(config)**#router rip**
(config-rip)**#no auto-summary**

default-metric *<value>*

Use the **default-metric** command to set the default metric value for the Routing Information Protocol (RIP). Use the **no** form of this command to return to the default setting.

Syntax Description

<value>	Sets the default metric value in Mbps. Range is **1** to **4294967295** Mbps.

Default Values

By default, this value is set at **0**.

Command History

Release 3.1	Command was introduced.

Functional Notes

The metric value defined using the **redistribute** command overrides the **default-metric** command's metric setting. Refer to *redistribute ospf on page 4215* for related information.

Usage Examples

The following example shows a router using both RIP and open shortest path first (OSPF) routing protocols. The example advertises OSPF-derived routes using RIP and assigns the OSPF-derived routes a RIP metric of **10**.

(config)**#router rip**
(config-rip)**#default-metric 10**
(config-rip)**#redistribute ospf**

distance <*number*>

Use the **distance** command to set the administrative distance for Routing Information Protocol (RIP) routes that are added to the route table. Use the **no** form of this command to set the RIP administrative distance to the default value.

Syntax Description

<*number*>	Specifies the new administrative distance. Range is **0** to **255**.

Default Values

By default, the administrative distance for RIP routes is set to **120**.

Command History

Release 15.1	Command was introduced.

Usage Examples

The following configuration sets the administrative distance to **109**, which gives RIP routes a lower administrative distance than open shortest path first (OSPF) routes:

(config)**#router rip**
(config-rip)**#distance 109**

Technical Review

Administrative distance is a feature that routers employ in order to select the most reliable path when there are two or more routes to the same destination from two different routing protocols. Administrative distance defines the reliability of a routing protocol by assigning a value (the smaller the value, the more trustworthy the protocol) that is then used by the router to organize routing protocols according to reliability.

distribute-list <*name*>

Use the **distribute-list** command to add route filtering functionality by assigning inbound and outbound access control lists (ACLs) on either a per-interface or global basis. Only one inbound/outbound pair of ACLs can be configured for a particular interface. Use the **no** form of this command to disable the filtering. Variations of this command include:

distribute-list <*name*> **in**
distribute-list <*name*> **in** <*interface*>
distribute-list <*name*> **out**
distribute-list <*name*> **out** <*info source*>

Syntax Description

<*name*>	Specifies an ACL name. This is a standard IP ACL against which the contents of the incoming/outgoing routing updates are matched.
in	Applies route filtering to inbound data.
in <*interface*>	Optional. Specifies the interface in which to apply the ACL. Specify an interface in the format <*interface type [slot/port* | *slot/port.subinterface id* | *interface id* | *interface id.subinterface id* | *ap* | *ap/radio* | *ap/radio.vap]*>. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **distribute-list list1 in ?** for a complete list of applicable interfaces.
out	Applies route filtering to outbound data.
out <*info source*>	Optional. Specifies the source of the routing information. The source can be an interface or a routing process (**connected**, **ospf**, **rip**, or **static**). Type **distribute list** <*name*> **out ?** for a list of available options.

Default Values

By default, distribute-list filtering is disabled.

Command History

Release 12.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface.
Release A5.01	Command was epxanded to include the Gigabit Ethernet interface.

Usage Examples

The following example filters out all network advertisements received via Ethernet interface **0/1** with the exception of the **10.10.10.0** network:

(config)**#router rip**
(config-rip)**#version 2**
(config-rip)**#network 192.168.1.0 255.255.255.0**
(config-rip)**#distribute-list list_1 in eth 0/1**
(config-rip)**#exit**
(config)**#ip access-list standard list_1**
(config-std-nacl)**#permit 10.10.10.0 0.0.0.255**

network *<ip address> <subnet mask>*

Use the **network** command to enable Routing Information Protocol (RIP) on the specified network. Use the **no** form of this command to remove a network from the list.

Syntax Description

<ip address>	Specifies the IP address of the network on which RIP will be enabled. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<subnet mask>	Specifies the subnet mask that corresponds to a range of IP addresses (network). Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**).

Default Values

By default, RIP is not enabled.

Command History

Release 1.1	Command was introduced.

Functional Notes

AOS will only allow processing (sending and receiving) RIP messages on interfaces with IP addresses that are contained in the networks listed using this command. All RIP messages received on interfaces not listed using this command will be discarded. To allow for receiving and participating in RIP, but not for transmitting, use the **passive-interface** command (refer to *passive-interface <interface> on page 4212*).

Usage Examples

The following example enables RIP on the **102.22.72.252 /30**, **192.45.2.0 /24**, and **10.200.0.0 /16** networks:

(config)**#router rip**
(config-rip)**#network 102.22.72.252 255.255.255.252**
(config-rip)**#network 192.45.2.0 255.255.255.0**
(config-rip)**#network 10.200.0.0 255.255.0.0**

passive-interface *<interface>*

Use the **passive-interface** command to disable the transmission of routing updates on the specified interface. Use the **no** form of this command to enable the transmission of routing updates on an interface.

Syntax Description

<interface>	Specifies an interface in the format *<interface type [slot/port | slot/port.subinterface id | interface id | interface id.subinterface id | ap | ap/radio | ap/radio.vap]>*. For example, for a T1 interface, use **t1 0/1**; for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; for an ATM subinterface, use **atm 1.1**; and for a wireless virtual access point, use **dot11ap 1/1.1**. Type **passive-interface ?** for a complete list of valid interfaces.

Default Values

By default, Routing Information Protocol (RIP) is not enabled.

Command History

Release 1.1	Command was introduced.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.

Functional Notes

All routing updates received on that interface will still be processed (and advertised to other interfaces), but no updates will be transmitted to the network connected to the specified interface. Multiple **passive-interface** commands may be used to create a customized list of interfaces.

Usage Examples

The following example disables routing updates on the Frame Relay link (labeled **1.17**) and the Point-to-Point Protocol (PPP) link (labeled **1**):

(config)**#router rip**
(config-rip)**#passive-interface frame-relay 1.17**
(config-rip)**#passive-interface ppp 1**

redistribute bgp

Use the **redistribute bgp** command to redistribute routes from one protocol to another, regardless of the routing protocol implemented on the routing domain. Using the **bgp** keyword allows the propagation of Border Gateway Protocol (BGP) routes into Routing Information Protocol (RIP). Use the **no** form of this command to disable the propagation of the specified route type. Variations of this command include:

redistribute bgp
redistribute bgp metric <*value*>
redistribute bgp route-map <*name*>

Syntax Description

metric <*value*>	Optional. Specifies the hop count to use for advertising redistributed BGP routes in RIP.
route-map <*name*>	Optional. Specifies the route map filter to use for advertising redistributed BGP routes in RIP.

Default Values

By default, this command is disabled.

Command History

Release 14.1	Command was introduced.

Functional Notes

Redistributing BGP routes imports those routes into RIP without the interfaces in question actually participating in RIP. The BGP routes imported this way are not covered by a network command and are learned via BGP. This allows RIP to distribute routes for networks that are not participating in this RIP network.

If **redistribute bgp** is enabled and no metric value is specified, the value defaults to **0**. The metric value defined using the **redistribute bgp metric** command overrides the **default-metric** command's metric setting. Refer to *default-metric <value> on page 4207* for more information.

Usage Examples

The following example imports BGP routes into RIP:

(config)**#router rip**
(config-rip)**#redistribute bgp**

redistribute connected

Use the **redistribute connected** command to pass routes from one network to another, regardless of the routing protocol implemented on the routing domain. Using the **connected** keyword allows the propagation of routes connected to other interfaces using the Routing Information Protocol (RIP). Use the **no** form of this command to disable the propagation of the specified route type. Variations of this command include:

redistribute connected
redistribute connected metric <*value*>
redistribute connected route-map <*name*>

Syntax Description

metric <*value*>	Optional. Specifies the hop count to use for advertising redistributed routes in RIP.
route-map <*name*>	Optional. Specifies the route map filter to use for advertising redistributed routes in RIP.

Default Values

By default, this command is disabled.

Command History

Release 3.1	Command was introduced.
Release 14.1	Command was expanded to include the route map filtering.

Functional Notes

Redistributing connected routes imports those routes into RIP without the interfaces in question actually participating in RIP. The connected routes imported this way are not covered by a network command and do not send/receive RIP traffic.

Usage Examples

The following example passes the connected routes found in the route table to other networks running the RIP routing protocol:

(config)**#router rip**
(config-rip)**#redistribute connected**

redistribute ospf

Use the **redistribute ospf** command to redistribute routes from one protocol to another, regardless of the routing protocol implemented on the routing domain. Using the **ospf** keyword allows the propagation of open shortest path first (OSPF) routes into Routing Information Protocol (RIP). Use the **no** form of this command to disable the propagation of the specified route type. Variations of this command include:

redistribute ospf
redistribute ospf <*process id*>
redistribute ospf <*process id*> **metric** <*value*>
redistribute ospf <*process id*> **no-include-connected**
redistribute ospf <*process id*> **route-map** <*name*>

After specifying the process id, the other parameters can be entered in any order. Use the ***?*** *after each specified subcommand for a valid list of arguments and settings.*

Syntax Description

<*process id*>	Optional. Specifies the OSPFv2 routing process from which RIP routes will be redistributed. The process ID is locally significant to the device, and must be unique among OSPFv2 processes on the device. Valid range is **1** to **65535**.
metric <*value*>	Optional. Specifies the hop count to use for advertising redistributed OSPF routes in RIP.
no-include-connected	Optional. Specifies that prefixes of the interface running this source protocol are not automatically included in the route redistribution.
route-map <*name*>	Optional. Specifies the route map filter to use for advertising redistributed OSPF routes in RIP.

Default Values

By default, this command is disabled.

Command History

Release 3.1	Command was introduced.
Release 14.1	Command was expanded to include the route map filtering.
Release R11.3.0	Command was expanded to include the <*process id*> and **no-include-connected** parameters.

Functional Notes

Redistributing OSPF routes imports those routes into RIP without the interfaces in question actually participating in RIP. The OSPF routes imported this way are not covered by a network command and do not send/receive RIP traffic. This allows RIP to distribute routes for networks that are not participating in this RIP network.

If **redistribute ospf** is enabled and no metric value is specified, the value defaults to **0**. The metric value defined using the **redistribute ospf metric** command overrides the **default-metric** command's metric setting. Refer to *default-metric <value> on page 4207* for more information.

Usage Examples

The following example imports OSPF routes into RIP:

(config)**#router rip**
(config-rip)**#redistribute ospf**

redistribute static

Use the **redistribute static** command to pass routes from one network to another, regardless of the routing protocol implemented on the routing domain. Using the **static** keyword allows the propagation of static routes to other interfaces using the Routing Information Protocol (RIP). Use the **no** form of this command to disable the propagation of the specified route type. Variations of this command include:

redistribute static
redistribute static metric <*value*>
redistribute static route-map <*name*>

The gateway network for the static route must participate in RIP by using the network command for the gateway network.

Syntax Description

metric <*value*>	Optional. Specifies the hop count to use for advertising redistributed static routes in RIP.
route-map <*name*>	Optional. Specifies the route map filter to use for advertising redistributed static routes in RIP.

Default Values

By default, this command is disabled.

Command History

Release 1.1	Command was introduced.
Release 14.1	Command was expanded to include the route map filtering.

Functional Notes

Redistributing static routes allows other network devices to learn about routes without requiring manual input to each device on the network.

Usage Examples

The following example passes the static routes found in the route table to other networks running the RIP routing protocol:

(config)**#router rip**
(config-rip)**#redistribute static**

timeout-timer <*value*>

Use the **timeout-timer** command to set the timeout timer value for a route when it is learned via Routing Information Protocol (RIP). Each time a RIP update for that route is received, the timeout timer is reset to this value. If no updates for that route are received in the specified number of seconds and the timeout timer expires, the route is considered invalid, and it will be removed from the route table. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Sets the timeout timer value. Valid range is **5** to **4294967295** seconds.

Default Values

By default, this value is set at **180** seconds.

Command History

Release 11.1	Command was introduced.

Functional Notes

Note that the timeout timer value cannot be set to a value less than the **update-timer** value. It is recommended that this timer be set to a value that is three times the value of the **update-timer** (refer to *update-timer <value> on page 4219*).

Usage Examples

The following example configures the router to mark routes invalid if no RIP updates for those routes are received within **120** seconds:

(config)**#router rip**
(config-rip)**#timeout-timer 120**

update-timer <*value*>

Use the **update-timer** command to set the value of the Routing Information Protocol (RIP) update interval timer. The RIP update interval is the number of seconds that must elapse between RIP update packet transmissions. Use the **no** form of this command to return to the default setting.

Syntax Description

<*value*>	Specifies the number of seconds allowed to elapse between RIP update packet transmissions. Valid range is **5** to **4294967295** seconds.

Default Values

By default, this value is set at **30** seconds.

Command History

Release 11.1	Command was introduced.

Functional Notes

Note that the **timeout-timer** value cannot be set to a value less than the **update-timer** value. It is recommended that the **timeout-timer** be set to a value that is three times the value of the **update-timer**. (Refer to *timeout-timer <value> on page 4218* for more information.)

Usage Examples

The following example sets the rate at which RIP update messages are transmitted from the router to **20** seconds.

(config)**#router rip**
(config-rip)**#update-timer 20**

version

Use the **version** command to specify (globally) the Routing Information Protocol (RIP) version used on all IP interfaces. This global configuration is overridden using the configuration commands **ip rip send version** and **ip rip receive version**. Use the **no** form of this command to return to the default value. Variations of this command include:

version 1
version 2

Syntax Description

1	Specifies RIP version **1** be used globally.
2	Specifies RIP version **2** be used globally.

Default Values

By default, RIP is not enabled.

Command History

Release 1.1	Command was introduced.

Usage Examples

The following example specifies RIP version **2** as the global RIP version:

(config)**#router rip**
(config-rip)**#version 2**

VRRPv3 Command Set

Virtual Router Redundancy Protocol version 3 (VRRPv3) is a standard protocol that allows multiple physical routers to act as a single virtual router on an Ethernet network. The virtual router is comprised of two or more physical routers running VRRPv3, and acts as a single virtual router for hosts on a shared local area network (LAN). This functionality provides seamless redundancy to networked end-host devices, and allows the forwarding of host traffic if a router or interface port fails within the network. VRRPv3 is defined in RFC 3768, and functions similarly to IPv4 VRRPv2, with the primary difference being the support of both IPv4 and IPv6. For more information about the implementation of VRRPv3, refer to the configuration guide *VRRPv3 in AOS*, available online at https://supportcommunity.adtran.com.

To enable VRRPv3, and enter the virtual router instance's configuration mode, enter the **vrrpv3** <*vrid*> **address-family [ipv4 | ipv6]** command from the interface's configuration mode. For example, to enable VRRPv3, create a virtual router ID of **15**, and specify VRRPv3 with IPv6, enter the command as follows:

```
(config)#interface ethernet 0/1
(config-eth 0/1)#vrrpv3 15 address-family ipv6
(config-if-vrrpv3 15)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

exit on page 83
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

address <ipv4 address> on page 4222
address <ipv6 address> on page 4223
description <text> on page 4225
match-address on page 4226
preempt on page 4227
priority <level> on page 4228
startup-delay <delay> on page 4229
timers advertise <interval> on page 4230
track <name> on page 4231

address *<ipv4 address>*

Use the **address** *<ipv4 address>* command to assign an IPv4 address to the virtual router. Using the **no** form of this command removes the address from the virtual router's configuration. Variations of this command include:

address *<ipv4 address>*
address *<ipv4 address>* **primary**
address *<ipv4 address>* **secondary**

Syntax Description

<ipv4 address>	Specifies the IPv4 address for the virtual router. IPv4 addresses should be expressed in decimal dotted notation, for example, **10.10.10.1**, and must include a subnet mask.
primary	Specifies the IPv4 address is the primary address for the virtual router.
secondary	Specifies the IPv4 address is the secondary address for the virtual router.

Default Values

By default, no IPv4 addresses are assigned to the virtual router instance.

Command History

Release R10.11.0	Command was introduced.

Functional Notes

This command is for use with IPv4 VRRPv3.

The primary address must be configured before the virtual router will become active, and before any secondary addresses can be added. The primary address is the only address that can be an owner address (the configured router IPv4 address for the interface).

Usage Examples

The following example creates an IPv4 virtual router instance with an assigned address of **10.10.10.1 255.255.255.0**:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#vrrpv3 15 address-family ipv4**
(config-if-vrrpv3 15)**#address 10.10.10.1 255.255.255.0 primary**

address *<ipv6 address>*

Use the **address** *<ipv6 link-local address>* command to assign a link-local IPv6 address to the virtual router. Use the **no** form of this command to remove the IPv6 address from the virtual router. Variations of this command include:

address *<ipv6 link-local address>* **primary**
address generate primary
address *<ipv6 global-address>* **secondary**

Syntax Description

<ipv6 link-local address>	Specifies the link-local address to assign to the virtual router. A link-local IPv6 address is specified in the format **FE80::**<*bits*>. The <*bits*> are the lower 64 bits of the link-local IPv6 address, and since link-local addresses have no prefix, the bits entered form the entire IPv6 address.
primary	Specifies this is the primary IPv6 address for the virtual router.
generate primary	Optional. Specifies that a default virtual link-local address is assigned to the virtual router. Default link-local addresses are created based on a computation from the virtual interface ID (VRID) and the virtual medium access control (MAC) address associated with the VRID.
<ipv6 global-address>	Specifies the IPv6 global address to assign to the virtual router. Specify IPv6 addresses in colon hexadecimal format, for example, **2001:DB8::1**.
secondary	Specifies the address is the IPv6 global address.

Default Values

By default, no IPv6 addresses are assigned to the virtual router instance.

Command History

Release R10.11.0	Command was introduced. This command replaces the **vrrpv3** <*number*> **link-local** command on the interface.

Functional Notes

This command is for use with IPv6 VRRPv3. IPv6 must be enabled on the interface before IPv6 VRRPv3 can be configured.

A virtual link-local address must be configured before the VRRPv3 router becomes active. Only one virtual link-local address can be specified per virtual router. The IPv6 global address can be specified using the **secondary** keyword with the *<ipv6 global-address>* parameter.

Usage Examples

The following example creates an IPv6 virtual router instance with an assigned default link-local address:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6**
(config-eth 0/1)**#vrrpv3 15 address-family ipv6**
(config-if-vrrpv3 15)**#address generate primary**

description *<text>*

Use the **description** command to add a text description to the Virtual Router Redundancy Protocol version 3 (VRRPv3) group. Use the **no** form of this command to remove the description from the virtual router's configuration.

Syntax Description

<text>	Specifies the text string used to describe the virtual router instance.

Default Values

By default, no text description of the virtual router exists.

Command History

Release R10.11.0	Command was introduced. This command replaces the **vrrpv3** *<number>* **description** *<text>* command on the interface.

Usage Examples

The following example adds a description to the virtual router instance:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#vrrpv3 15 address-family ipv4**
(config-if-vrrpv3 15)**#description RemoteRoutersA**

match-address

Use the **match-address** command to specify that IPv4 or IPv6 Virtual Router Redundancy Protocol version 3 (VRRPv3) virtual routers will match secondary IP addresses when receiving packets from nearby virtual routers. Use the **no** form of this command to disable secondary address matching.

Syntax Description

No subcommands.

Default Values

By default, secondary address matching is enabled for VRRPv3.

Command History

Release R10.11.0	Command was introduced.

Functional Notes

This command is available for both IPv4 and IPv6 VRRPv3.

Secondary address matching is used to verify configuration consistency between neighboring virtual routers. Primary address matching is always enforced, regardless of whether secondary address matching is enabled.

Usage Examples

The following example enables secondary address matching for the virtual router:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#vrrpv3 15 address-family ipv4**
(config-if-vrrpv3 15)**#match-address**

preempt

Use the **preempt** command to specify that a virtual router can preempt the current master router. Use the **no** form of this command to disable preemption. Variations of this command include:

preempt
preempt delay minimum <*delay*>

Syntax Description

delay minimum <*delay*>	Optional. Specifies that the router waits a specified amount of time before attempting to preempt the master router. Valid range is **0** to **255** seconds.

Default Values

By default, a virtual router preempts with no additional delay.

Command History

Release R10.11.0	Command was introduced. This command replaces the **vrrpv3** <*number*> **preempt** command on the interface.

Functional Notes

Whenever a Virtual Router Redundancy Protocol version 3 (VRRPv3) router with a higher actual priority level than the current master is added to a virtual router group, it attempts to take over or preempt the master router if preemption is enabled. This behavior may be desired, for example, when the new router is more powerful than the existing master router.

When VRRPv3 transitions occur between master and backup devices, security related configurations can be affected and security policies may need to be adjusted. For example, preemption might need to be disabled to prevent loss of state or session, particularly in use of long-term Transmission Control Protocol (TCP) connections, such as Telnet or Secure Socket Layer (SSL).

Using the **no** form of this command disables preemption, unless the master router is the link-local address owner, in which case it will always preempt, and this command is ignored.

Usage Examples

The following example enables a preempt after **30** seconds:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#vrrpv3 15 address-family ipv4**
(config-if-vrrpv3 15)**#preempt delay minimum 30**

priority <*level*>

Use the **priority** command to specify the virtual router instance priority. Use the **no** form of this command to return the virtual router priority to the default value.

Syntax Description

<*level*>	Specifies the configured priority level for the virtual router. Valid range is **1** to **254**.

Default Values

By default, the virtual router's priority is **100**, unless it is the owner of the virtual link-local address, in which case the priority default is **255**.

Command History

Release R10.11.0	Command was introduced. This command replaces the **vrrpv3** <*number*> **priority** <*level*> command on the interface.

Functional Notes

It is possible for VRRPv3 to operate based on default priority level settings. However, it is important to understand and verify the election process to ensure the desired VRRPv3 router is ultimately selected as the master. The virtual router master is selected using an election process based on the priority level setting of each VRRPv3 router. There are two types of priority levels: configured and actual. The configured priority level is the numerical value originally assigned to the VRRPv3 router. The actual priority level is a value that takes into account any adjustments resulting from a track event. The VRRPv3 router with the highest actual priority level is the virtual router master. If there is a tie, the actual priority level will be used along with the interface link-local address to determine the master.

If the virtual link-local address of the virtual router is the same as the interface address on the VRRPv3 router (the link-local address owner), then the default priority level will be **255**. This is the highest priority level and means that when the link-local address owner is available, it will be the virtual router master.

Usage Examples

The following example configures a virtual router priority of **200**:

(config)**#interface eth 0/1**
(config-eth 0/1)**#vrrpv3 15 address-family ipv4**
(config-if-vrrpv3 15)**#priority 200**

startup-delay <*delay*>

Use the **startup-delay** command to specify that the virtual router waits a specified amount of time before running the Virtual Router Redundancy Protocol version 3 (VRRPv3) state machine after initial activation. Use the **no** form of this command to return to the default value.

Syntax Description

<*delay*>	Specifies the delay (in seconds) that the virtual router waits to run VRRPv3. Valid range is **0** to **255** seconds.

Default Values

By default, the startup delay is set to **35** seconds.

Command History

Release R10.11.0	Command was introduced. This command replaces the **vrrpv3** <*number*> **startup-delay** <*delay*> command on the interface.

Functional Notes

Startup delay can prevent inadvertent declarations of multiple VRRPv3 masters while waiting for potentially slower interfaces to begin passing advertisement traffic.

If the virtual router receives an advertisement from an external master during the delay period, it assumes that the network path is open, cancels the timer, and transitions to the appropriate backup or master state.

Usage Examples

The following example creates a virtual router with a startup delay of **100** seconds:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#vrrpv3 15 address-family ipv4**
(config-if-vrrpv3 15)**#startup-delay 100**

timers advertise <*interval*>

Use the **timers advertise** command to specify the interval between Virtual Router Redundancy Protocol version 3 (VRRPv3) advertisements sent by the master router. Use the **no** form of this command to return the advertisement interval to the default value.

Syntax Description

<*interval*>	Specifies the time, in seconds, between sent advertisements. Valid range is **1** to **40** seconds.

Default Values

By default, advertisements are sent every **1** second.

Command History

Release R10.11.0	Command was introduced. This command replaces the **vrrpv3** <*number*> **timers advertise** <*interval*> command on the interface.

Functional Notes

All VRRPv3 routers in a virtual router group must use the same advertisement interval.

Usage Examples

The following example changes the advertisement interval to **5** seconds:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#vrrpv3 15 address-family ipv4**
(config-if-vrrpv3 15)**#timers advertise 5**

track <*name*>

Use the **track** command to track objects associated with the virtual router. Use the **no** form of this command to remove the track reference and its configuration from the virtual router. Variations of this command include:

track <*name*>
track <*name*> **decrement** <*value*>

Syntax Description

<*name*>	Specifies the name of the track to apply to the virtual router.
decrement <*value*>	Optional. Specifies the amount to decrement the router's priority level if the track transitions to a FAIL state. Valid range is **1** to **254**.

Default Values

By default, tracks are not associated with virtual routers. If a track is associated with a virtual router, its priority decrements by **10** if the track transitions to a FAIL state.

Command History

Release R10.11.0	Command was introduced. This command replaces the **vrrpv3** <*number*> **track** <*name*> command on the interface.

Functional Notes

Object tracking can be used to change the priority level of a VRRPv3 router. One purpose of object tracking for VRRPv3 is to detect failure of the interface or main path connected to the master router. The object that is tracked is typically an interface towards the far end of the main path. Depending on the object type specified, as long as the line protocol for the interface is up, the track will remain in a PASS state and nothing will change. However, if the line protocol for an interface goes down, the track will transition to a FAIL state. This transition will cause the priority level of the VRRPv3 router to be decremented by the numerical amount specified (or the default amount).

If a VRRPv3 router owns the virtual router link-local address, then the VRRPv3 router's priority level cannot be decremented as a result of the **track** command. Therefore, if object tracking is used to monitor paths and effectively decrement priority levels in case of interface or path failure, then it is important that no VRRPv3 router own the virtual router link-local address.

A track must be created before this command can be used. For detailed information about creating tracks, refer to the configuration guide *Configuring Network Monitor in AOS*, available online at https://supportcommunity.adtran.com.

Usage Examples

The following example specifies that the virtual router is associated with **TRACK1** and will decrement its priority by **20** if the track changes to a FAIL state:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#vrrpv3 15 address-family ipv4**
(config-if-vrrpv3 15)**#track TRACK1 decrement 20**

SECURITY AND SERVICES COMMAND SETS

The security and services command sets are divided into the following sections:

ACCESS CONTROL LISTS AND ACCESS CONTROL POLICIES COMMAND SETS

This section includes the following command sets:

HARDWARE ACL AND ACCESS MAP COMMAND SET

Hardware access control lists (ACLs) are access lists that function by comparing incoming frames to specific criteria at the hardware level. These hardware ACLs function in the same way typical IP ACLs do at the software level. The difference is that hardware ACLs filter incoming traffic through the switch chip at wire speeds, rather than through software packet filtering processes.

It is beneficial to understand the basic functioning of ACLs in AOS before working with hardware ACLs. All ACLs, whether hardware or software, by themselves do not perform any action. Rather, they are lists of criteria to which all incoming frames are compared. These lists provide the methods for many of the configurable filtering and security features of AOS to logically inspect each frame, compare it to the criteria in the ACL, and behave accordingly.

ACLs list criteria for incoming frames that begin with either the keyword **permit** or **deny**. **Permit** indicates that frames matching the specific criteria are selected and handled according to the configuration of the AOS feature using the ACL. **Deny** indicates that frames matching the specific criteria are not selected and are handled accordingly. Each ACL's criteria are compared to the frame in the order in which it was entered. This means that the order of criteria for permitting or denying frames is one to one with the order in which the criteria were entered into the ACL's configuration. As frames come into the unit, they are compared to the ACL criteria from top-to-bottom. If a frame does not match the criteria specified by the first entry, then it is compared to the criteria in the next entry. When the frame is found to match an entry's specified criteria, then the frame is either categorized as **permit** or **deny** and the comparison of the ACL entries abruptly stops. At this point, the feature using the ACL takes the appropriate action.

There are many uses for ACLs, and many ways to configure ACLs. If you would like more information about ACL basic configuration and uses in AOS, refer to the configuration guide *Hardware ACLs in AOS* available online at https://supportcommunity.adtran.com. Specific commands for configuring ACLs are also included in this guide in the section *IPv4 Access Control List Command Set on page 4252*.

Hardware ACLs and Hardware Access Maps

Hardware ACLs can filter frames based either on IP information or on medium access control (MAC) address information. IP hardware ACLs support filtering traffic on source and destination IP addresses, Transmission Control Protocol (TCP) and User Datagram Protocol (UDP), and TCP or UDP port numbers. MAC hardware ACLs filter traffic based on source and destination MAC addresses. All hardware ACLs filter only the incoming traffic, comparing the traffic to the list of criteria cited in the ACL.

As with all ACLs, the hardware ACL by itself performs no action. In order for the hardware ACL to function, a hardware access map must be created and applied to a virtual local area network (VLAN) interface. Access maps are the feature that uses the ACL and performs the action on the incoming traffic. Each access map can either forward or discard incoming frames acting on a single IP hardware ACL, a single MAC hardware ACL, or both. When both an IP and MAC hardware ACL are used by the access map, the two ACLs are linked by **and** logic. **And** logic indicates to the access map that *both* ACLs must conclude that the frame be forwarded for the access map to forward it. As with all other ACLs, the information entered into the hardware ACLs is order dependent. The order in which criteria is listed in the ACL configuration is the order in which the frames will be compared to the criteria.

Once the access map has been created and associated with a hardware ACL, it must be applied to a virtual local area network (VLAN) for the ACL to be fully functional. Access maps can be applied to a single VLAN or a range of VLANs, however, only one access map can be applied to a VLAN at a time.

To create an IP hardware ACL and enter the ACL's configuration, enter the command *ip hw-access-list extended <name> on page 1404* from the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ip hw-access-list extended Trusted
        Configuring New IP Hardware Extended ACL "Trusted"
(config-ext-ip-hw-nacl)#
```

TTo create an extended MAC hardware ACL and enter the ACL's configuration, enter the command **mac hw-access-list extended** <*name*> from the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#mac hw-access-list extended Untrusted
        Configuring New MAC Hardware Extended ACL "Untrusted"
(config-ext-mac-hw-nacl)#
```

To create a standard MAC hardware ACL and enter the ACL's configuration, enter the command **mac hw-access-list standard** <*name*> from the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#mac hw-access-list standard Untrusted
        Configuring New MAC Hardware Standard ACL "Untrusted"
(config-std-mac-hw-nacl)#
```

To create a hardware access map and enter the map's configuration, enter the command *hw-access-map <name> on page 1337* from the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#hw-access-map Map1
(config-hw-access-map)#
```

Technology Review

Hardware access maps and ACLs regulate traffic through the routed network. When designing your traffic flow configuration, it is important to keep the following in mind:

- A hardware ACL serves as a traffic selector, defining exactly which frames should take the given action.
- A hardware access map defines the action to take on the frames selected by the ACL.
- A hardware ACL is inactive until it is assigned to an active hardware access map.

- A hardware access map is inactive until it is assigned to a VLAN interface.

> NOTE *For more information on both hardware ACLs and hardware access maps, refer to the Hardware ACLs in AOS configuration guide available online at* https://supportcommunity.adtran.com.

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76

The following are commands used to configure an **IP** hardware ACL. **IP** hardware ACL configuration includes creating a remark for the ACL, specifying an ACL action, a protocol, a packet source, a source port, a packet destination, and a destination port. These commands are described in this section in alphabetical order:

deny <protocol> <source> <source port> <destination> <destination port> on page 4238
permit <protocol> <source> <source port> <destination> <destination port> on page 4240
remark <text> on page 4242

The following are commands used to configure an extended or standard **MAC** hardware ACL. **MAC** hardware ACL configuration includes creating a remark for the ACL, specifying the ACL action, a source MAC address, and a destination MAC address. These commands are described in this section in alphabetical order:

deny mac <source> <destination> on page 4243
permit mac <source> <destination> on page 4245
remark <text> on page 4242

The following are commands used to configure a hardware access map. Access map configuration includes specifying which hardware ACL(s) the map will use and the relationship between those ACLs, and applying the access map to a VLAN or VLANs. These commands are described in this section in alphabetical order:

forward ip <acl name> on page 4247
forward mac <acl name> on page 4249
vlans <vlan id> on page 4251

deny *<protocol> <source> <source port> <destination> <destination port>*

Use the **deny** command to configure the IP hardware access control list (ACL) to deny specified packets to enter the system. Use the **no** form of this command to remove the deny parameter from the ACL. Variations of this command include:

deny *<protocol> <source> <source port> <destination> <destination port>*
deny *<protocol> <source> <source port> <destination> <destination port>* **log**

Syntax Description

<protocol>	Specifies the data protocol as **ip**, **tcp**, or **udp**.	
<source>	Specifies the source used for packet matching. Sources can be expressed in one of three ways: 1. Using the keyword **any** to match any IP address. 2. Using **host** *<ip address>* to specify a single host address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). 3. Using the *<ip address> <wildcard mask>* format to match all IP addresses in a range. The wildcard mask corresponds to a range of IP addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).	
<source port>	Optional. The source port is used only when *<protocol>* is **tcp** or **udp**. The following keywords and port numbers/names are supported for the *<source port>* field:	
	eq *<port>*	Matches only packets equal to the specified port number. Range is **0** to **65535**.
	range *<min> <max>*	Matches only packets that contain a port number in the specified range. Range is **0** to **65535**.
<destination>	Specifies the destination used for packet matching. Destinations can be expressed in one of three ways: 1. Using the keyword **any** to match any IP address. 2. Using **host** *<ip address>* to specify a single host address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). 3. Using the *<ip address> <wildcard mask>* format to match all IP addresses in a range. The wildcard mask corresponds to a range of IP addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).	
<destination port>	Optional. The destination port is used only when *<protocol>* is **tcp** or **udp**. The following keywords and port numbers are supported for the *<destination port>* field:	
	eq *<port>*	Matches only packets equal to the specified port number. Range is **0** to **65535**.

	range <*min*> <*max*>	Matches only packets that contain a port number in the specified range. Range is **0** to **65535**.
log		Optional. Enables logging of any packets that match the hardware ACL entry.

Default Values

By default, all AOS security features are disabled, and there are no configured hardware ACLs.

Command History

Release 17.6	Command was introduced.

Functional Notes

Hardware ACLs are used as frame selectors by the hardware access maps; by themselves they do nothing. Hardware ACLs are composed of an ordered list of entries with an implicit **deny any** at the end of each list. A hardware ACL with no entries includes an implicit **permit any**. An ACL entry contains two parts: an action (**permit** or **deny**) and a frame pattern. A **permit** ACL matches frames (meeting the specified pattern) and allows them to enter the network. A **deny** ACL advances AOS to the next ACL entry.

ACL criteria are compared to the incoming frame in the order in which they were entered or from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Changing hardware ACL or hardware access map configuration or application causes new information to be reinstalled on the hardware. It is possible to run out of hardware resources depending on how many resources are needed to apply the desired change. If there are not enough hardware resources to install the new criteria in the hardware, an error message is displayed. You can view the amount of hardware resources available using the command *show hw-filter-resource on page 672*.

Usage Examples

The following example creates an IP hardware ACL **Untrusted** to deny packets from any source destined for IP address **192.168.20.0**:

(config)**#ip hw-access-list extended Untrusted**
(config-ext-ip-hw-nacl)**#deny ip any host 192.168.20.0**

The following example creates an entry in the **Untrusted** IP hardware ACL that denies any UDP packets from being forwarded to the UDP ports that range between **1080** and **1150**:

(config)**#ip hw-access-list extended Untrusted**
(config-ext-nacl)**#deny udp any any range 1080 1150**

permit *<protocol> <source> <source port> <destination> <destination port>*

Use the **permit** command to configure the IP hardware access control list (ACL) to permit specified packets to enter the system. Use the **no** form of this command to remove the permit parameter from the ACL. Variations of this command include:

permit <*protocol*> <*source*> <*source port*> <*destination*> <*destination port*>
permit <*protocol*> <*source*> <*source port*> <*destination*> <*destination port*> **log**

Syntax Description

<*protocol*>	Specifies the data protocol as **ip**, **tcp**, or **udp**.	
<*source*>	Specifies the source used for packet matching. Sources can be expressed in one of three ways: 1. Using the keyword **any** to match any IP address. 2. Using **host** <*ip address*> to specify a single host address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). 3. Using the <*ip address*> <*wildcard mask*> format to match all IP addresses in a range. The wildcard mask corresponds to a range of IP addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).	
<*source port*>	Optional. The source port is used only when <*protocol*> is **tcp** or **udp**. The following keywords and port numbers/names are supported for the <*source port*> field:	
	eq <*port*>	Matches only packets equal to the specified port number. Range is **0** to **65535**.
	range <*min*> <*max*>	Matches only packets that contain a port number in the specified range. Range is **0** to **65535**.
<*destination*>	Specifies the destination used for packet matching. Destinations can be expressed in one of three ways: 1. Using the keyword **any** to match any IP address. 2. Using **host** <*ip address*> to specify a single host address. IP addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). 3. Using the <*ip address*> <*wildcard mask*> format to match all IP addresses in a range. The wildcard mask corresponds to a range of IP addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).	
<*destination port*>	Optional. The destination port is used only when <*protocol*> is **tcp** or **udp**. The following keywords and port numbers are supported for the <*destination port*> field:	
	eq <*port*>	Matches only packets equal to the specified port number. Range is **0** to **65535**.

	range <*min*> <*max*>	Matches only packets that contain a port number in the specified range. Range is **0** to **65535**.
log		Optional. Enables logging of any packets that match the hardware ACL entry.

Default Values

By default, all AOS security features are disabled, and there are no configured hardware ACLs.

Command History

Release 17.6	Command was introduced.

Functional Notes

Hardware ACLs are used as frame selectors by the hardware access maps; by themselves they do nothing. Hardware ACLs are composed of an ordered list of entries with an implicit **deny any** at the end of each list. A hardware ACL with no entries includes an implicit **permit any**. An ACL entry contains two parts: an action (**permit** or **deny**) and a frame pattern. A **permit** ACL matches frames (meeting the specified pattern) and allows them to enter the network. A **deny** ACL advances AOS to the next ACL entry.

ACL criteria are compared to the incoming frame in the order in which they were entered or from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Changing hardware ACL or hardware access map configuration or application causes new information to be reinstalled on the hardware. It is possible to run out of hardware resources depending on how many resources are needed to apply the desired change. If there are not enough hardware resources to install the new criteria in the hardware, an error message is displayed. You can view the amount of hardware resources available using the command *show hw-filter-resource on page 672*.

Usage Examples

The following example creates an IP hardware ACL **Trusted** to permit packets from any source destined for IP address **192.168.20.0**:

(config)**#ip hw-access-list extended Trusted**
(config-ext-ip-hw-nacl)**#permit ip any host 192.168.20.0**

The following example creates an entry in the **Trusted** IP hardware ACL that permits any UDP packets to be forwarded to the UDP ports that range between **1080** and **1150**:

(config)**#ip hw-access-list extended Trusted**
(config-ext-nacl)**#permit udp any any range 1080 1150**

remark *<text>*

Use the **remark** command to associate a descriptive tag with a hardware access control list (ACL). Use the **no** form of this command to remove the descriptive tag.

Syntax Description

<text>	Specifies a descriptive tag for the ACL. Tags can be up to **80** alphanumeric characters. For example, **This list blocks all outbound Web traffic**.

Default Values

By default, all AOS security features are disabled, and there are no configured hardware ACLs.

Command History

Release 17.6	Command was introduced.
Release R11.5.0	Command was expanded to include standard medium access control (MAC) ACLs.

Usage Examples

The following example specifies a description for IP hardware ACL **Matchall**:

(config)**#ip hw-access-list extended Matchall**
(config-ext-ip-hw-nacl)**#remark Allows all IP traffic from remote location.**

The following example specifies a description for an extended MAC hardware ACL **Matchall**:

(config)**#mac hw-access-list extended Matchall**
(config-ext-mac-hw-nacl)**#remark Allows all IP traffic from remote location.**

deny mac *<source> <destination>*

Use the **deny mac** command to configure the standard or extended medium access control (MAC) hardware access control list (ACL) to deny specified frames to enter the system. Use the **no** form of this command to remove the deny parameters from the ACL. Variations of this command include:

deny mac <*source*>
deny mac <*source*> <*destination*>
deny mac <*source*> <*destination*> **log**

Syntax Description

<*source*>	Specifies the source used for frame matching. Sources can be expressed in one of three ways: 1. Using the keyword **any** to match any MAC address. 2. Using **address** <*mac address*> to specify a single host address. IP addresses should be expressed in dotted decimal notation (for example, **08:00:69:02:06:CB**). 3. Using the <*mac address*> <*wildcard mask*> format to match all IP addresses in a range. The wildcard mask corresponds to a range of IP addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).
<*destination*>	Applies only to extended MAC ACLs. Specifies the destination used for frame matching. Destinations can be expressed in one of three ways: 1. Using the keyword **any** to match any MAC address. 2. Using **address** <*mac address*> to specify a single host address. IP addresses should be expressed in dotted decimal notation (for example, **08:00:69:02:06:CB**). 3. Using the <*mac address*> <*wildcard mask*> format to match all IP addresses in a range. The wildcard mask corresponds to a range of IP addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).
log	Optional. Enables logging of any frames that match the hardware ACL entry.

Default Values

By default, all AOS security features are disabled, and there are no configured hardware ACLs.

Command History

Release 17.6	Command was introduced.
Release R11.5.0	Command was expanded to include standard MAC ACLs.

Functional Notes

Hardware ACLs are used as frame selectors by the hardware access maps; by themselves they do nothing. Hardware ACLs are composed of an ordered list of entries with an implicit **deny any** at the end of each list. A hardware ACL with no entries includes an implicit **permit any**. An ACL entry contains two parts: an action (**permit** or **deny**) and a frame pattern. A **permit** ACL matches frames (meeting the specified pattern) and allows them to enter the network. A **deny** ACL advances AOS to the next access list entry.

ACL criteria are compared to the incoming frame in the order in which they were entered or from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Changing hardware ACL or hardware access map configuration or application causes new information to be reinstalled on the hardware. It is possible to run out of hardware resources depending on how many resources are needed to apply the desired change. If there are not enough hardware resources to install the new criteria in the hardware, an error message is displayed. You can view the amount of hardware resources available using the command *show hw-filter-resource on page 672*.

Usage Examples

The following example specifies that the extended MAC hardware ACL **Untrusted** deny traffic from MAC address **08:00:69:02:01:FC** with a destination of MAC address **08:00:69:02:06:CB**. Traffic that matches this description will be logged.

(config)**#mac hw-access-list extended Untrusted**
(config-ext-mac-hw-nacl)**#deny address 08:00:69:02:01:FC address 08:00:69:02:06:CB log**

permit mac *<source> <destination>*

Use the **permit mac** command to configure the extended or standard medium access control (MAC) hardware access control list (ACL) to permit specified frames to enter the system. Use the **no** form of this command to remove the permit parameters from the ACL. Variations of this command include:

permit mac <*source*>
permit mac <*source*> <*destination*>
permit mac <*source*> <*destination*> **log**

Syntax Description

<*source*>	Specifies the source used for frame matching. Sources can be expressed in one of three ways: 1. Using the keyword **any** to match any MAC address. 2. Using **address** <*mac address*> to specify a single host address. IP addresses should be expressed in dotted decimal notation (for example, **08:00:69:02:06:CB**). 3. Using the <*mac address*> <*wildcard mask*> format to match all IP addresses in a range. The wildcard mask corresponds to a range of IP addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).
<*destination*>	Applies only to extended MAC ACLs. Specifies the destination used for frame matching. Destinations can be expressed in one of three ways: 1. Using the keyword **any** to match any MAC address. 2. Using **address** <*mac address*> to specify a single host address. IP addresses should be expressed in dotted decimal notation (for example, **08:00:69:02:06:CB**). 3. Using the <*mac address*> <*wildcard mask*> format to match all IP addresses in a range. The wildcard mask corresponds to a range of IP addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).
log	Optional. Enables logging of any frames that match the hardware ACL entry.

Default Values

By default, all AOS security features are disabled, and there are no configured hardware ACLs.

Command History

Release 17.6	Command was introduced.
Release R11.5.0	Command was expanded to include standard MAC ACLs.

Functional Notes

Hardware ACLs are used as frame selectors by the hardware access maps; by themselves they do nothing. Hardware ACLs are composed of an ordered list of entries with an implicit **deny any** at the end of each list. A hardware ACL with no entries includes an implicit **permit any**. An ACL entry contains two parts: an action (**permit** or **deny**) and a frame pattern. A **permit** ACL matches frames (meeting the specified pattern) and allows them to enter the network. A **deny** ACL advances AOS to the next access list entry.

ACL criteria are compared to the incoming frame in the order in which they were entered or from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Changing hardware ACL or hardware access map configuration or application causes new information to be reinstalled on the hardware. It is possible to run out of hardware resources depending on how many resources are needed to apply the desired change. If there are not enough hardware resources to install the new criteria in the hardware, an error message is displayed. You can view the amount of hardware resources available using the command *show hw-filter-resource on page 672*.

Usage Examples

The following example specifies that the extended MAC hardware ACL **Trusted** permit traffic from any MAC address destined for MAC address **08:00:69:02:06:CB**. Traffic that matches this description will be logged.

(config)**#mac hw-access-list extended Trusted**
(config-ext-mac-hw-nacl)**#permit any address 08:00:69:02:06:CB log**

forward ip <*acl name*>

Use the **forward ip** command to specify which IP hardware access control list (ACL) the hardware access map will use to determine which frames to forward. Use the **no** form of this command removes this action from the access map. Variations of this command include:

forward ip <*acl name*>
forward ip <*acl name*> **and mac** <*acl name*>

Syntax Description

<*acl name*>	Specifies the hardware ACL the access map will use when determining which traffic to forward.
mac <*acl name*>	Specifies the medium access control (MAC) hardware ACL that the access map will use in conjunction with the IP hardware ACL to determine which traffic to forward.
and	Specifies that the relationship between the IP and MAC ACLs is such that the access map will forward traffic only if both ACLs indicate that it should be forwarded.

Default Values

By default, all AOS security features are disabled, and there are no configured hardware access maps.

Command History

Release 17.6	Command was introduced.

Functional Notes

Hardware access maps can only forward traffic. This action can be performed based on the criteria outlined in a single IP hardware ACL, a single MAC hardware ACL, or both. Like the hardware ACLs, the hardware access map will match traffic in top-down order. Use the **forward ip** command if the first criteria for the access map is to match traffic based on IP information.

Specifying **and** indicates to the access map that both ACLs must conclude the frame should be forwarded for the access map to forward it.

If you configure the access map to reference a nonexistent IP or MAC hardware ACL, the ACL will be created. Note that this newly created ACL will have **permit any** as the default entry because no other entries are present.

Hardware access maps are not active until they are applied to a virtual local area network (VLAN). For instructions on how to apply an access map to a VLAN, refer to *vlans <vlan id> on page 4251*.

Changing hardware ACL or hardware access map configuration or application causes new information to be reinstalled on the hardware. It is possible to run out of hardware resources depending on how many resources are needed to apply the desired change. If there are not enough hardware resources to install the new criteria in the hardware, an error message is displayed. You can view the amount of hardware resources available using the command *show hw-filter-resource on page 672*.

Usage Examples

In the following example, the access map **Map1** is configured to operate on both an IP hardware ACL (**Trusted)** and a MAC hardware ACL (**Untrusted**), specifying that both must agree that a frame should be forwarded before the access list will forward it.

(config)**#hw-access-map Map1**
(config-hw-access-map)**#forward ip Trusted and mac Untrusted**

forward mac *<acl name>*

Use the **forward mac** command to specify which medium access control (MAC) hardware access control list (ACL) the hardware access map will use to determine which frames to forward. Use the **no** form of this command removes this action from the access map. Variations of this command include:

forward mac *<acl name>*
forward mac *<acl name>* **and ip** *<acl name>*

Syntax Description

<acl name>	Specifies the hardware ACL the access map will use when determining which traffic to forward.
ip *<acl name>*	Specifies the IP hardware ACL that the access map will use in conjunction with the MAC hardware ACL to determine which traffic to forward.
and	Specifies that the relationship between the MAC and IP ACLs is such that the access map will forward traffic only if both ACLs indicate that it should be forwarded.

Default Values

By default, all AOS security features are disabled, and there are no configured hardware access maps.

Command History

Release 17.6	Command was introduced.

Functional Notes

Hardware access maps can only forward traffic. This action can be performed based on the criteria outlined in a single IP hardware ACL, a single MAC hardware ACL, or both. Like the hardware ACLs, the hardware access map will match traffic in top-down order. Use the **forward mac** command if the first criteria for the access map is to match traffic based on MAC addresses.

Specifying **and** indicates to the access map that both ACLs must conclude the frame should be forwarded for the access map to forward it.

If you configure the access map to reference a nonexistent IP or MAC hardware ACL, the ACL will be created. Note that this newly created ACL will have **permit any** as the default entry because no other entries are present.

Hardware access maps are not active until they are applied to a virtual local area network (VLAN). For instructions on how to apply an access map to a VLAN, refer to *vlans <vlan id> on page 4251*.

Changing hardware ACL or hardware access map configuration or application causes new information to be reinstalled on the hardware. It is possible to run out of hardware resources depending on how many resources are needed to apply the desired change. If there are not enough hardware resources to install the new criteria in the hardware, an error message is displayed. You can view the amount of hardware resources available using the command show hw-filter-resource on page 672.

Usage Examples

In the following example, the access map **Map1** is configured to operate on both a MAC hardware ACL (**Trusted)** and an IP hardware ACL (**Untrusted**), specifying that both must agree that a frame should be forwarded before the access list will forward it.

(config)**#hw-access-map Map1**
(config-hw-access-map)**#forward mac Trusted and ip Untrusted**

vlans <*vlan id*>

Use the **vlans** command to apply a hardware access map to a virtual local area network (VLAN) interface. Access maps can be applied to a single VLAN, a list of VLANs, or a range of VLANs. Use the **no** form of this command to remove the access map from the specified VLAN(s).

Syntax Description

<vlan id>	Specifies the VLAN(s) to which the access map is applied. Enter the single VLAN ID for the map to apply to a single VLAN. Enter multiple VLAN IDs separated by commas to apply the map to a list of VLANs (for example: **1,2,7,9**). Enter multiple VLANs separated by dashes or commas to apply the map to a range of VLANs (for example: **1-5,7-9**).

Default Values

By default, access maps are not applied to any VLAN interfaces.

Command History

Release 17.6	Command was introduced.

Functional Notes

Once an access map has been created and associated with a hardware access control list (ACL), it must be applied to a VLAN for the ACL or access map to be fully functional. Access maps can be applied to a single VLAN or a range of VLANs, however, only one access map can be applied to a VLAN at a time. If you attempt to apply a second access map to a VLAN, an error is displayed.

Changing hardware ACL or hardware access map configuration or application causes new information to be reinstalled on the hardware. It is possible to run out of hardware resources depending on how many resources are needed to apply the desired change. If there are not enough hardware resources to install the new criteria in the hardware, an error message is displayed. You can view the amount of hardware resources available using the command *show hw-filter-resource on page 672*.

Usage Examples

The following example specifies that the access map **Map1**, which uses IP hardware ACL **Trusted** and **MAC** hardware ACL **Untrusted**, is applied to VLANs **1**,**2**, and **15-30**.

(config)**#hw-access-map Map1**
(config-hw-access-map)**#forward ip Trusted and mac Untrusted**
(config-hw-access-map)**#vlans 1,2,15-30**

IPv4 Access Control List Command Set

An Internet Protocol version 4 (IPv4) access control list (ACL) is an ordered list of entries used as packet selectors by an IPv4 access control policy (ACP) in the Adtran Operating System (AOS) command line interface (CLI). ACLs and ACPs work together to regulate IPv4 traffic through the routed network.

There are two types of IPv4 ACLs within AOS: **standard** and **extended**. A **standard** IPv4 ACL allows source IPv4 address packet patterns only. An **extended** IPv4 ACL may specify patterns using most fields in the IPv4 header and the Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) header. This configuration command set details the configuration of both a standard and an extended IPv4 ACL.

IPv6 ACLs are also supported by AOS, but are explained separately in this document. Refer to IPv6 Access Control List Command Set on page 4296 for more information on configuring IPv6 ACLs.

To create a **standard** IPv4 ACL and activate the Standard IPv4 ACL Configuration mode, enter the **ip access-list standard** <*name*> command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ip access-list standard MATCHALL
(config-std-nacl)#
```

To create an **extended** IPv4 ACL and activate the Extended IPv4 ACL Configuration Mode, enter the **ip access-list extended** <*name*> command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ip access-list extended MATCHALL
(config-ext-nacl)#
```

*An IPv4 ACL will remain inactive until it is assigned to an **active** IPv4 ACP. For more information on configuring and activating IPv4 ACPs, refer to the IPv4 Access Control Policy Command Set on page 4278.*

Technology Review

IPv4 ACPs and IPv4 ACLs regulate traffic through the routed network. When designing your traffic flow configuration, it is important to keep the following in mind:

- An IPv4 ACL serves as a packet selector, defining exactly which packets should take the given action.
- An IPv4 ACP defines the action to take on the packets selected by the ACL.
- An IPv4 ACL is inactive until it is assigned to an active ACP.
- An IPv4 ACP is inactive until it is assigned to an interface.

IPv4 Access Control Policies (ACPs)

IPv4 ACPs are used to allow, discard, or manipulate (using network address translation (NAT)) data for each physical interface. Each IPv4 ACP consists of an action (**allow**, **discard**, **nat**) and a selector (IPv4 ACL). In a sense, the IPv4 ACPs answer the question, “What should I do?” while the IPv4 ACLs answer the question, “On which packets?”

When packets are received on an interface with an IPv4 ACP applied, the ACP is used to determine whether the data is processed or discarded. Both IPv4 ACLs and IPv4 ACPs are order dependent. When a packet is evaluated, the matching engine begins with the first entry in the list and progresses through the entries until it finds a match. The first entry that matches is executed. The IPv4 ACP has an implicit **discard** at the end of the list. Typically, the most specific entries should be at the top and the most general at the bottom.

IPv4 Access Control Lists (ACLs)

IPv4 ACLs are used as packet selectors by IPv4 ACPs. They must be assigned to an IPv4 ACP in order to be active.

IPv4 ACP must use an IPv4 ACL. You cannot apply an IPv4 ACL to an IPv6 ACP, or vice-versa. In addition, all IPv4 ACLs and IPv4 ACPs must have a different name than any configured IPv6 ACLs or IPv6 ACPs.

IPv4 ACLs are composed of an ordered list of entries. Each entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** action is used to allow packets (meeting the specified pattern) to enter the router system. A **deny** action is used to disregard packets (that do not match the pattern) and proceed to the next entry on the IPv4 ACP. The IPv4 ACL has an implicit **deny** at the end of the list.

The AOS provides two types of IPv4 ACLs: **standard** and **extended**. A **standard** IPv4 ACL allows source IPv4 address packet patterns only. An **extended** IPv4 ACL may specify patterns using most fields in the IPv4 header and the Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) header.

Creating and Assigning IPv4 ACLs and IPv4 ACPs

Creating IPv4 ACPs and IPv4 ACLs to regulate traffic through the routed network is a four-step process:

Step 1:
Enable the security features of AOS using the **ip firewall** command. Refer to the command *ip firewall on page 1367* for more information.

Step 2:
Create an IPv4 ACP that uses a configured IPv4 ACL by issuing the **ip policy-class** command. AOS IPv4 ACPs are used to allow, discard, or manipulate (using NAT) data for each physical interface. Each IPv4 ACP consists of an action (**allow**, **discard**, **nat**) and a selector (IPv4 ACL). When packets are received on an interface, the configured IPv4 ACPs are applied to determine whether the data will be processed or discarded.

Step 3:
Create an IPv4 ACL to permit or deny specified traffic by using either the **ip access-list extended** or **ip access-list standard** command. Standard IPv4 ACLs match based on the source IPv4 address of the packet. Extended IPv4 ACLs match based on the source and destination of the packet. Refer to the command *ip access-list extended <ipv4 acl name> on page 1344* or the command *ip access-list standard <ipv4 acl name> on page 1346* for more information. Sources can be expressed in one of four ways:

1. Using the keyword **any** to match any IPv4 address.

2. Using **host** *<ipv4 address>* to specify a single host address.

3. Using the *<ipv4 address>* *<wildcard>* format to match all IPv4 addresses in a range. Wildcard masks work in reverse logic from subnet masks. When broken out into binary form, a 0 indicates which bits of the IPv4 address to consider, a 1 indicates which bits are disregarded. For example, specifying 255 in any octet of the wildcard mask equates to a “don’t care” for that octet in the IPv4 address. Additionally, a 30-bit mask would be represented with the wildcard string 0.0.0.3, a 28-bit mask with 0.0.0.15, a 24-bit mask with 0.0.0.255, and so forth.

4. Using the keyword **hostname** to match based on a domain naming system (DNS) name. DNS servers must be configured or host names must be locally defined for this function to work.

Step 4:
Apply the created IPv4 ACP to an interface. To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** *<ipv4 acp name>*. The following example assigns ACP **UNTRUSTED** to the Ethernet 0/1 interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip access-policy UNTRUSTED**

For more information about configuring ACLs, ACPs, and the AOS Firewall, refer to the IPv4 Firewall configuration guide available at https://supportcommunity.adtran.com.

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
exit on page 83
interface on page 84

The following are commands used to configure an **extended** IPv4 ACL. **Extended** IPv4 ACL configuration includes specifying an IPv4 ACL action, a protocol, a packet source, a source port, a packet destination, and a destination port. These commands are described in this section in alphabetical order.

deny <protocol> <source> <source port> <destination> <destination port> on page 4256
deny icmp <source> <destination> on page 4260

The following are commands for configuring a **standard** IPv4 ACL. **Standard** IPv4 ACL configuration includes specifying an IPv4 ACL action and a packet source. These commands are described in this section in alphabetical order.

deny *<protocol> <source> <source port> <destination> <destination port>*

Use the **deny** command to configure the Internet Protocol version 4 (IPv4) extended access control list (ACL) to deny specified packets entry into the routing system. Use the **no** form of this command to remove the deny parameter from the ACL. Variations of this command include:

deny *<protocol> <source> <source port> <destination> <destination port>*
deny *<protocol> <source> <source port> <destination> <destination port>* **log**
deny *<protocol> <source> <source port> <destination> <destination port>* **track** *<name>*
deny ip *<source> <source port> <destination> <destination port>* **fragments**

Syntax Description

<protocol> Specifies the data protocol **ip**, **tcp**, **udp**, **ahp**, **esp**, **gre**, or a specific protocol. Range is **0** to **255**.

<source> Specifies the source used for packet matching. Sources can be expressed in one of four ways:

1. Using the keyword **any** to match any IPv4 address.
2. Using **host** *<ip address>* to specify a single host address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
3. Using the *<ip address> <wildcard mask>* format to match all IPv4 addresses in a range. The wildcard mask corresponds to a range of IPv4 addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).
4. Using the keyword **hostname** *<hostname>* to match based on a DNS name. The unit must be configured with DNS servers for this function to work. Using **vrf** *<name>* in conjunction with the **hostname** parameter associates a nondefault VRF with the DNS host name for the source. The VRF is required if the router's DNS server is on a nondefault VRF. This parameter can only be used with the **hostname** source.

<source port> Optional. The source port is used only when *<protocol>* is **tcp** or **udp**. The following keywords and port numbers/names are supported for the *<source port>* field:

any	Matches any destination port.
eq *<port number/name>*	Matches only packets equal to specified port number.
gt *<port number/name>*	Matches only packets with a port number greater than the specified port number.
lt *<port number/name>*	Matches only packets with a port number less than the specified port number.
neq *<port number/name>*	Matches only packets that are not equal to the specified port number.
range *<begin port number/name> <end port number/name>*	Matches only packets that contain a port number in the specified range.

<port number>	Specifies the port number used by Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) to pass information to upper layers using the following syntax: <***0-65535***>. All ports below 1024 are considered well-known ports, and are controlled by the Internet Assigned Numbers Authority (IANA). All ports above 1024 are dynamically assigned ports that include registered ports for vendor-specific applications.
<port name>	The following UDP port numbers can be specified using the associated names: **biff** (Port 512) **bootpc** (Port 68) **bootps** (Port 67) **discard** (Port 9) **dnsix** (Port 195) **domain** (Port 53) **echo** (Port 7) **isakmp** (Port 500) **mobile-ip** (Port 434) **nameserver** (Port 42) **netbios-dgm** (Port 138) **netbios-ns** (Port 137) **netbios-ss** (Port 139) **ntp** (Port 123) **pim-auto-rp** (Port 496) **rip** (Port 520) **snmp** (Port 161) **snmptrap** (Port 162) **sunrpc** (Port 111) **syslog** (Port 514) **tacacs** (Port 49) **talk** (Port 517) **tftp** (Port 69) **time** (Port 37) **who** (Port 513) **xdmcp** (Port 177) The following TCP port numbers can be specified using the associated names: **bgp** (Port 179) **chargen** (Port 19) **cmd** (Port 514) **daytime** (Port 13) **discard** (Port 9) **domain** (Port 53) **echo** (Port 7) **exec** (Port 512) **finger** (Port 79) **ftp** (Port 21) **gopher** (Port 70) **hostname** (Port 101) **ident** (Port 113) **lpd** (Port 515) **nntp** (Port 119) **pim-auto-rp** (Port 496) **pop2** (Port 109) **pop3** (Port 110) **smtp** (Port 25) **sunrpc** (Port 111) **tacacs** (Port 49) **talk** (Port 517) **tftp** (Port 69) **telnet** (Port 23) **time** (Port 37) **uucp** (Port 540)

	irc (Port 194)	**whois** (Port 43)
	klogin (Port 543)	**www** (Port 80)
	kshell (Port 544)	
	login (Port 513)	

<destination> Specifies the destination used for packet matching. Destinations can be expressed in one of four ways:

1. Using the keyword **any** to match any IPv4 address.
2. Using **host** *<ip address>* to specify a single host address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
3. Using the *<ip address>* *<wildcard mask>* format to match all IPv4 addresses in a range. The wildcard mask corresponds to a range of IPv4 addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).
4. Using the keyword **hostname** *<hostname>* to match based on a DNS name. The unit must be configured with DNS servers for this function to work. Using **vrf** *<name>* in conjunction with the **hostname** parameter associates a nondefault VRF with the DNS host name for the source. The VRF is required if the router's DNS server is on a nondefault VRF. This parameter can only be used with the **hostname** source.

<destination port> Optional. Specifies the destination port. Only valid when *<protocol>* is **tcp** or **udp.** The same keywords and port numbers/names used for the *<source port>* field are valid for the *<destination port>* field. Refer to previously listed *<source port>* for more details.

fragments Optional. Indicates that the IPv4 ACL entry will only be matched by non-initial fragments. This parameter is only available using the **ip** protocol.

log Optional. Enables logging of any packets that match the IPv4 ACL entry.

track *<name>* Optional. Makes the IPv4 ACL entry dependent upon a track.

Default Values

By default, all AOS IPv4 security features are disabled, and there are no configured IPv4 ACLs.

Command History

Release 2.1	Command was introduced.
Release 16.1	Command was expanded to include the **log**, **track**, and **vrf** parameters.
Release R11.10.2	Command was expanded to include the **fragments** parameter.

Functional Notes

IPv4 Access control lists (ACLs) are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv4 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv4 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** IPv4 ACL is used to match packets (meeting the specified pattern) to enter the router system. A **deny** IPv4 ACL advances AOS to the next access policy entry. AOS provides two types of IPv4 ACLs: standard and extended. Standard IPv4 ACLs match based on the source of the packet. Extended IPv4 ACLs match based on the source and destination of the packet.

IPv4 ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the abovementioned commands without specifying a VRF will only affect the default unnamed VRF.

IPv4 ACLs match non-initial fragments in the following manner:

- Non-initial fragments can match entries with the **fragments** keyword, provided the other Layer 3 information specified in the entry matches the packet.
- Non-initial fragments can match entries with the **ip** protocol specified, provided the other Layer 3 information specified in the entry matches the packet.
- Non-initial fragments are implicitly permitted by access groups if the fragments did not match an explicit entry in the ACL.

Usage Examples

The following example creates an ACL **DenyIKE** to deny all Internet key exchange (IKE) (UDP Port 500) packets from the 190.72.22.0 /24 network:

(config)**#ip access-list extended DenyIKE**
(config-ext-nacl)**#deny udp 190.72.22.0 0.0.0.255 eq 500 any eq 500**

The following example creates an entry in the **Untrusted** IPv4 ACL to deny ip packets from host name **www.adtran.com** using the nondefault VRF **RED** to resolve the DNS host name with any destination:

(config)**#ip access-list extended Untrusted**
(config-ext-nacl)**#deny ip hostname www.adtran.com vrf RED any**

deny icmp <*source*> <*destination*>

Use the **deny icmp** command to configure the extended Internet Protocol version 4 (IPv4) access control list (ACL) to deny specified Internet Control Message Protocol (ICMP) packets entry into the routing system. This command provides traffic matching based on the packet's IPv4 header field and ICMP-specific fields. Use the **no** form of this command to remove the deny parameter from the IPv4 ACL. Variations of this command include:

deny icmp <*source*> <*destination*>
deny icmp <*source*> <*destination*> <*message name*>
deny icmp <*source*> <*destination*> <*message type*> <*message code*>

Syntax Description

<*source*>

Specifies the source used for IPv4 packet matching. Sources can be expressed in one of four ways:

1. Using the keyword **any** to match any IPv4 address.
2. Using **host** <*ipv4 address*> to specify a single host address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
3. Using the <*ip address*> <*wildcard mask*> format to match all IPv4 addresses in a range. The wildcard mask corresponds to a range of IPv4 addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).
4. Using the keyword **hostname** <*hostname*> to match based on a DNS name. The unit must be configured with DNS servers for this function to work. Using **vrf** <*name*> in conjunction with the **hostname** parameter associates a nondefault VRF with the DNS host name for the source. The VRF is required if the router's DNS server is on a nondefault VRF. This parameter can only be used with the **hostname** source.

<*destination*>

Specifies the destination used for packet matching. Destinations can be expressed in one of five ways:

1. Using the keyword **any** to match any IPv4 address.
2. Using **host** <*ip address*> to specify a single host address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
3. Using the <*ip address*> <*wildcard mask*> format to match all IPv4 addresses in a range. The wildcard mask corresponds to a range of IPv4 addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).
4. Using the keyword **hostname** <*hostname*> to match based on a DNS name. The unit must be configured with DNS servers for this function to work. Using **vrf** <*name*> in conjunction with the **hostname** parameter associates a nondefault VRF with the DNS host name for the source. The VRF is required if the router's DNS server is on a nondefault VRF. This parameter can only be used with the **hostname** source.

<message name> Optional. Specifies the ICMP message type used for matching ICMP packets. ICMP message names are specified using one of the following keywords:

administratively-prohibited	Indicates the destination is unreachable because it is administratively prohibited.
alternate-address	Indicates the destination has an alternate address.
conversion-error	Indicates an error in datagram conversion.
dod-host-prohibited	Indicates the host is prohibited.
dod-net-prohibited	Indicates the network is prohibited.
echo	Indicates an echo (ping) message.
echo-reply	Indicates an echo reply message.
host-isolated	Indicates the host is isolated.
host-redirect	Indicates the host is redirected.
host-tos-redirect	Indicates the host is redirected for type of service (TOS).
host-tos-unreachable	Indicates the host is unreachable for TOS.
host-unknown	Indicates the host is unknown.
host-unreachable	Indicates the host is unreachable.
information-reply	Indicates an information reply.
information-request	Indicates an information request.
log	Indicates the log matches against this entry.
mask-reply	Indicates an address mask reply.
mask-request	Indicates an address mask request.
mobile-redirect	Indicates a mobile host redirect.
net-redirect	Indicates a network redirect.
net-tos-redirect	Indicates a network redirect for TOS.
net-tos-unreachable	Indicates the network is unreachable for TOS.
net-unreachable	Indicates the network is unreachable.
network-unknown	Indicates the network is unknown.

option-missing	Indicates a parameter that is required is missing.
packet-too-big	Indicates the packet is too large. Fragmentation is needed and the DF should be set.
port-unreachable	Indicates the destination is unreachable because the port is unreachable.
precedence-unreachable	Indicates the precedence is cut off.
protocol-unreachable	Indicates the protocol is unreachable.
reassembly-timeout	Indicates a timeout for reassembly.
redirect	Indicates a redirect message.
router-advertisement	Indicates a router advertisement message.
router-solicitation	Indicates an router solicitation message.
source-quench	Indicates a source quench.
source-route-failed	Indicates the source route failed.
timestamp-reply	Indicates a timestamp reply.
timestamp-request	Indicates a timestamp request.
traceroute	Indicates a traceroute.
track	Indicates this ACL entry is dependent upon a track.
ttl-exceeded	Indicates the time-to-live (TTL) value has been exceeded.
unreachable	Indicates the destination is unreachable.

<message type>	Optional. Specifies the ICMP message type for matching ICMP packets. When you specify an ICMP message type, you must also specify an ICMP message code. Message types range from **0** to **127** for error messages and from **128** to **255** for informational messages.
<message code>	Optional. Specifies the ICMP message code for matching ICMP packets. You must specify the message code when you specify the ICMP message type. Message code range is **0** to **255**.

Default Values

By default, all AOS IPv4 security features are disabled, and there are no configured IPv4 ACLs.

Command History

Release R11.1.0	Command was introduced.

Functional Notes

IPv4 ACLs are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv4 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv4 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** ACL is used to match packets (meeting the specified pattern) and allow them to enter the router system or specify that the feature using the ACL should apply its action to this traffic. A **deny** ACL advances AOS to the next ACP entry, discards the traffic, or specifies that the feature using the ACL should not apply its action to this traffic. AOS provides two types of IPv4 ACLs: standard and extended. Standard IPv4 ACLs match based on the source of the packet. Extended IPv4 ACLs match based on the source and destination of the packet.

ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Usage Examples

The following example creates an extended IPv4 ACL named **Untrustedv4** IPv4 ACL that denies any IPv4 traffic from a source with the address **10.10.10.1**, headed to a destination of **10.10.10.4**, and an ICMP message type of **echo-reply**:

(config)**#ipv4 access-list extended Untrustedv4**
(config-ext6-nacl)**#deny icmp 10.10.10.1 10.10.10.4 echo-reply**

permit *<protocol> <source> <source port> <destination> <destination port>*

Use the **permit** command to configure the extended Internet Protocol version 4 (IPv4) access control list (ACL) to permit specified packets entry into the routing system. Use the **no** form of this command to remove the permit permission from the IPv4 ACL. Variations of this command include:

permit *<protocol> <source> <source port> <destination> <destination port>*
permit *<protocol> <source> <source port> <destination> <destination port>* **log**
permit *<protocol> <source> <source port> <destination> <destination port>* **track** *<name>*
permit ip *<source> <source port> <destination> <destination port>* **fragments**

Syntax Description

<protocol> Specifies the IPv4 data protocol **ip**, **tcp**, **udp**, **ahp**, **esp**, **gre**, or a specific protocol. Range is **0** to **255**.

<source> Specifies the source used for IPv4 packet matching. Sources can be expressed in one of four ways:

1. Using the keyword **any** to match any IPv4 address.
2. Using **host** *<ip address>* to specify a single host address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
3. Using the *<ip address> <wildcard mask>* format to match all IPv4 addresses in a range. The wildcard mask corresponds to a range of IPv4 addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).
4. Using the keyword **hostname** *<hostname>* to match based on a DNS name. The unit must be configured with DNS servers for this function to work. Using **vrf** *<name>* in conjunction with the **hostname** parameter associates a nondefault VRF with the DNS host name for the source. The VRF is required if the router's DNS server is on a nondefault VRF. This parameter can only be used with the **hostname** source.

<source port> Optional. The source port is used only when *<protocol>* is **tcp** or **udp**. The following keywords and port numbers/names are supported for the *<source port>* field:

any	Matches any destination port.
eq *<port number/name>*	Matches only packets equal to specified port number.
gt *<port number/name>*	Matches only packets with a port number greater than the specified port number.
lt *<port number/name>*	Matches only packets with a port number less than the specified port number.
neq *<port number/name>*	Matches only packets that are not equal to the specified port number.
range *<begin port number/name> <endport number/name>*	Matches only packets that contain a port number in the specified range.

<port number>	Specifies the port number used by Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) to pass information to upper layers using the following syntax: <***0-65535***>. All ports below 1024 are considered well-known ports, and are controlled by the Internet Assigned Numbers Authority (IANA). All ports above 1024 are dynamically assigned ports that include registered ports for vendor-specific applications.
<port name>	The following UDP port numbers can be specified using the associated names: **biff** (Port 512) **bootpc** (Port 68) **bootps** (Port 67) **discard** (Port 9) **dnsix** (Port 195) **domain** (Port 53) **echo** (Port 7) **isakmp** (Port 500) **mobile-ip** (Port 434) **nameserver** (Port 42) **netbios-dgm** (Port 138) **netbios-ns** (Port 137) **netbios-ss** (Port 139) **ntp** (Port 123) **pim-auto-rp** (Port 496) **rip** (Port 520) **snmp** (Port 161) **snmptrap** (Port 162) **sunrpc** (Port 111) **syslog** (Port 514) **tacacs** (Port 49) **talk** (Port 517) **tftp** (Port 69) **time** (Port 37) **who** (Port 513) **xdmcp** (Port 177) The following TCP port numbers can be specified using the associated names: **bgp** (Port 179) **chargen** (Port 19) **cmd** (Port 514) **daytime** (Port 13) **discard** (Port 9) **domain** (Port 53) **echo** (Port 7) **exec** (Port 512) **finger** (Port 79) **ftp** (Port 21) **gopher** (Port 70) **hostname** (Port 101) **ident** (Port 113) **lpd** (Port 515) **nntp** (Port 119) **pim-auto-rp** (Port 496) **pop2** (Port 109) **pop3** (Port 110) **smtp** (Port 25) **sunrpc** (Port 111) **tacacs** (Port 49) **talk** (Port 517) **tftp** (Port 69) **telnet** (Port 23) **time** (Port 37) **uucp** (Port 540)

		irc (Port 194)	**whois** (Port 43)
		klogin (Port 543)	**www** (Port 80)
		kshell (Port 544)	
		login (Port 513)	

<destination> Specifies the destination used for IPv4 packet matching. Destinations can be expressed in one of five ways:

1. Using the keyword **any** to match any IPv4 address.
2. Using **host** *<ip address>* to specify a single host address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
3. Using the *<ip address>* *<wildcard mask>* format to match all IPv4 addresses in a range. The wildcard mask corresponds to a range of IPv4 addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).
4. Using the keyword **hostname** *<hostname>* to match based on a DNS name. The unit must be configured with DNS servers for this function to work. Using **vrf** *<name>* in conjunction with the **hostname** parameter associates a nondefault VRF with the DNS host name for the source. The VRF is required if the router's DNS server is on a nondefault VRF. This parameter can only be used with the **hostname** source.

<destination port> Optional. Specifies the destination port. Only valid when *<protocol>* is **tcp** or **udp.** The same keywords and port numbers/names used for the *<source port>* field are valid for the *<destination port>* field. Refer to previously listed *<source port>* for more details.

fragments Optional. Indicates that the IPv4 ACL entry will only be matched by non-initial fragments. This parameter is only available using the **ip** protocol.

log Optional. Enables logging of any packets that match the IPv4 ACL entry.

track *<name>* Optional. Makes the IPv4 ACL entry dependent upon a track.

Default Values

By default, all AOS security features are disabled, and there are no configured IPv4 ACLs.

Command History

Release 2.1	Command was introduced.
Release 16.1	Command was expanded to include the **log**, **track**, and **vrf** parameters.
Release R11.10.2	Command was expanded to include the **fragments** parameter.

Functional Notes

IPv4 Access control lists (ACLs) are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv4 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv4 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** IPv4 ACL is used to match packets (meeting the specified pattern) to enter the router system. A **deny** IPv4 ACL advances AOS to the next access policy entry. AOS provides two types of IPv4 ACLs: standard and extended. Standard IPv4 ACLs match based on the source of the packet. Extended IPv4 ACLs match based on the source and destination of the packet.

IPv4 ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the abovementioned commands without specifying a VRF will only affect the default unnamed VRF.

IPv4 ACLs match non-initial fragments in the following manner:

- Non-initial fragments can match entries with the **fragments** keyword, provided the other Layer 3 information specified in the entry matches the packet.
- Non-initial fragments can match entries with the **ip** protocol specified, provided the other Layer 3 information specified in the entry matches the packet.
- Non-initial fragments are implicitly permitted by access groups if the fragments did not match an explicit entry in the ACL.

Usage Examples

The following example creates an IPv4 ACL **AllowIKE** to allow all Internet key exchange (IKE) (UDP Port 500) packets from the 190.72.22.0 /24 network:

(config)**#ip access-list extended AllowIKE**
(config-ext-nacl)**#permit udp 190.72.22.0 0.0.0.255 eq 500 any eq 500**

The following example creates an entry in the **MatchAll** IPv4 ACL to permit ip packets from host name **www.adtran.com** using the nondefault VRF **RED** to resolve the DNS host name with any destination:

(config)**#ip access-list extended MatchAll**
(config-ext-nacl)**#permit ip hostname www.adtran.com vrf RED any**

permit icmp <*source*> <*destination*>

Use the **permit icmp** command to configure the extended Internet Protocol version 4 (IPv4) access control list (ACL) to permit specified Internet Control Message Protocol (ICMP) packets entry into the routing system. This command provides traffic matching based on the packet's IPv4 header field and ICMP-specific fields. Use the **no** form of this command to remove the permit parameter from the IPv4 ACL. Variations of this command include:

permit icmp <*source*> <*destination*>
permit icmp <*source*> <*destination*> <*message name*>
permit icmp <*source*> <*destination*> <*message type*> <*message code*>

Syntax Description

<*source*>

Specifies the source used for IPv4 packet matching. Sources can be expressed in one of four ways:

1. Using the keyword **any** to match any IPv4 address.
2. Using **host** <*ipv4 address*> to specify a single host address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
3. Using the <*ip address*> <*wildcard mask*> format to match all IPv4 addresses in a range. The wildcard mask corresponds to a range of IPv4 addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).
4. Using the keyword **hostname** <*hostname*> to match based on a DNS name. The unit must be configured with DNS servers for this function to work. Using **vrf** <*name*> in conjunction with the **hostname** parameter associates a nondefault VRF with the DNS host name for the source. The VRF is required if the router's DNS server is on a nondefault VRF. This parameter can only be used with the **hostname** source.

<*destination*>

Specifies the destination used for packet matching. Destinations can be expressed in one of five ways:

1. Using the keyword **any** to match any IPv4 address.
2. Using **host** <*ip address*> to specify a single host address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
3. Using the <*ip address*> <*wildcard mask*> format to match all IPv4 addresses in a range. The wildcard mask corresponds to a range of IPv4 addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**).
4. Using the keyword **hostname** <*hostname*> to match based on a DNS name. The unit must be configured with DNS servers for this function to work. Using **vrf** <*name*> in conjunction with the **hostname** parameter associates a nondefault VRF with the DNS host name for the source. The VRF is required if the router's DNS server is on a nondefault VRF. This parameter can only be used with the **hostname** source.

<message name> Optional. Specifies the ICMP message type used for matching ICMP packets. ICMP message names are specified using one of the following keywords:

administratively-prohibited	Indicates the destination is unreachable because it is administratively prohibited.
alternate-address	Indicates the destination has an alternate address.
conversion-error	Indicates an error in datagram conversion.
dod-host-prohibited	Indicates the host is prohibited.
dod-net-prohibited	Indicates the network is prohibited.
echo	Indicates an echo (ping) message.
echo-reply	Indicates an echo reply message.
host-isolated	Indicates the host is isolated.
host-redirect	Indicates the host is redirected.
host-tos-redirect	Indicates the host is redirected for type of service (TOS).
host-tos-unreachable	Indicates the host is unreachable for TOS.
host-unknown	Indicates the host is unknown.
host-unreachable	Indicates the host is unreachable.
information-reply	Indicates an information reply.
information-request	Indicates an information request.
log	Indicates the log matches against this entry.
mask-reply	Indicates an address mask reply.
mask-request	Indicates an address mask request.
mobile-redirect	Indicates a mobile host redirect.
net-redirect	Indicates a network redirect.
net-tos-redirect	Indicates a network redirect for TOS.
net-tos-unreachable	Indicates the network is unreachable for TOS.
net-unreachable	Indicates the network is unreachable.
network-unknown	Indicates the network is unknown.

option-missing	Indicates a parameter that is required is missing.
packet-too-big	Indicates the packet is too large. Fragmentation is needed and the DF should be set.
port-unreachable	Indicates the destination is unreachable because the port is unreachable.
precedence-unreachable	Indicates the precedence is cut off.
protocol-unreachable	Indicates the protocol is unreachable.
reassembly-timeout	Indicates a timeout for reassembly.
redirect	Indicates a redirect message.
router-advertisement	Indicates a router advertisement message.
router-solicitation	Indicates an router solicitation message.
source-quench	Indicates a source quench.
source-route-failed	Indicates the source route failed.
timestamp-reply	Indicates a timestamp reply.
timestamp-request	Indicates a timestamp request.
traceroute	Indicates a traceroute.
track	Indicates this ACL entry is dependent upon a track.
ttl-exceeded	Indicates the time-to-live (TTL) value has been exceeded.
unreachable	Indicates the destination is unreachable.

<message type>	Optional. Specifies the ICMP message type for matching ICMP packets. When you specify an ICMP message type, you must also specify an ICMP message code. Message types range from **0** to **127** for error messages and from **128** to **255** for informational messages.
<message code>	Optional. Specifies the ICMP message code for matching ICMP packets. You must specify the message code when you specify the ICMP message type. Message code range is **0** to **255**.

Default Values

By default, all AOS IPv4 security features are disabled, and there are no configured IPv4 ACLs.

Command History

Release R11.1.0	Command was introduced.

Functional Notes

IPv4 ACLs are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv4 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv4 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** ACL is used to match packets (meeting the specified pattern) and allow them to enter the router system or specify that the feature using the ACL should apply its action to this traffic. A **deny** ACL advances AOS to the next ACP entry, discards the traffic, or specifies that the feature using the ACL should not apply its action to this traffic. AOS provides two types of IPv4 ACLs: standard and extended. Standard IPv4 ACLs match based on the source of the packet. Extended IPv4 ACLs match based on the source and destination of the packet.

ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Usage Examples

The following example creates an extended IPv4 ACL named **Untrustedv4** IPv4 ACL that permits any IPv4 traffic from a source with the address **10.10.10.1**, headed to a destination of **10.10.10.4**, and an ICMP message type of **echo-reply**:

(config)**#ipv4 access-list extended Untrustedv4**
(config-ext6-nacl)**#permit icmp 10.10.10.1 10.10.10.4 echo-reply**

remark *<remark>*

Use the **remark** command to associate a descriptive tag with an extended Internet Protocol version 4 (IPv4) access control list (ACL). Use the **no** form of this command to remove the descriptive tag.

Syntax Description

<remark>	Specifies a descriptive tag for the IPv4 ACL. Tags can be up to **80** alphanumeric characters enclosed in quotation marks. For example, “This list blocks all outbound Web traffic.”

Default Values

By default, all AOS security features are disabled, and there are no configured IPv4 ACLs.

Command History

Release 2.1	Command was introduced.

Usage Examples

The following example specifies a description for extended IPv4 ACL **matchall**:

(config)**#ip access-list extended matchall**
(config-ext-nacl)**#remark “allows all ip traffic from remote location”**

deny *<source>*

Use the **deny** command to configure the standard Internet Protocol version 4 (IPv4) access control list (ACL) to deny specified packets entry into the routing system. Use the **no** form of this command to remove the deny parameter from the IPv4 ACL. Variations of this command include:

deny <*source*>
deny <*source*> **log**
deny <*source*> **track** <*name*>

Syntax Description

<*source*>	Specifies the source used for IPv4 packet matching. Sources can be expressed in one of four ways: 1. Using the keyword **any** to match any IPv4 address. 2. Using **host** <*ip address*> to specify a single host address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). 3. Using the <*ip address*> <*wildcard mask*> format to match all IPv4 addresses in a range. The wildcard mask corresponds to a range of IPv4 addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**). 4. Using the keyword **hostname** <*hostname*> to match based on a DNS name. The unit must be configured with DNS servers for this function to work. Using **vrf** <*name*> in conjunction with the **hostname** parameter associates a nondefault VRF with the DNS host name for the source. The VRF is required if the router's DNS server is on a nondefault VRF. This parameter can only be used with the **hostname** source.
log	Optional. Enables logging of any packets that match the IPv4 ACL entry.
track <*name*>	Optional. Makes the IPv4 ACL entry dependent upon a track.

Default Values

By default, all AOS security features are disabled, and there are no configured IPv4 ACLs.

Command History

Release 2.1	Command was introduced.
Release 16.1	Command was expanded to include the **log**, **track**, and **vrf** parameters.

Functional Notes

IPv4 Access control lists (ACLs) are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv4 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv4 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** IPv4 ACL is used to match packets (meeting the specified pattern) to enter the router system. A **deny** IPv4 ACL advances AOS to the next access policy entry. AOS provides two types of IPv4 ACLs: standard and extended. Standard IPv4 ACLs match based on the source of the packet. Extended IPv4 ACLs match based on the source and destination of the packet.

IPv4 ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the abovementioned commands without specifying a VRF will only affect the default unnamed VRF.

Usage Examples

The following example creates an IPv4 ACL **UnTrusted** to deny all packets from the 190.72.22.248 /30 network:

(config)**#ip access-list standard UnTrusted**
(config-std-nacl)**#deny 190.72.22.248 0.0.0.3**

permit <*source*>

Use the **permit** command to configure the standard Internet Protocol version 4 (IPv4) access control list (ACL) to permit specified packets entry into the routing system. Use the **no** form of this command to remove the permit permission from the IPv4 ACL. Variations of this command include:

permit <*source*>
permit <*source*> **log**
permit <*source*> **track** <*name*>

Syntax Description

<*source*>	Specifies the source used for IPv4 packet matching. Sources can be expressed in one of four ways: 1. Using the keyword **any** to match any IPv4 address. 2. Using **host** <*ip address*> to specify a single host address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**). 3. Using the <*ip address*> <*wildcard mask*> format to match all IPv4 addresses in a range. The wildcard mask corresponds to a range of IPv4 addresses (network) or a specific host. Wildcard masks are expressed in dotted decimal notation (for example, **0.0.0.255**). 4. Using the keyword **hostname** <*hostname*> to match based on a DNS name. The unit must be configured with DNS servers for this function to work. Using **vrf** <*name*> in conjunction with the **hostname** parameter associates a nondefault VRF with the DNS host name for the source. The VRF is required if the router's DNS server is on a nondefault VRF. This parameter can only be used with the **hostname** source.
log	Optional. Enables logging of any packets that match the IPv4 ACL entry.
track <*name*>	Optional. Makes the IPv4 ACL entry dependent upon a track.

Default Values

By default, all AOS security features are disabled, and there are no configured IPv4 ACLs.

Command History

Release 2.1	Command was introduced.
Release 16.1	Command was expanded to include the **log**, **track**, and **vrf** parameters.

Functional Notes

IPv4 Access control lists (ACLs) are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv4 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv4 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** IPv4 ACL is used to match packets (meeting the specified pattern) to enter the router system. A **deny** IPv4 ACL advances AOS to the next access policy entry. AOS provides two types of IPv4 ACLs: standard and extended. Standard IPv4 ACLs match based on the source of the packet. Extended IPv4 ACLs match based on the source and destination of the packet.

IPv4 ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

VRF on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the abovementioned commands without specifying a VRF will only affect the default unnamed VRF.

Usage Examples

The following example creates an IPv4 ACL **Trusted** to permit all packets from the 190.72.22.248 /30 network:

(config)**#ip access-list standard Trusted**
(config-std-nacl)**#permit 190.72.22.248 0.0.0.3**

remark *<remark>*

Use the **remark** command to associate a descriptive tag with a standard Internet Protocol version 4 (IPv4) access control list (ACL). Use the **no** form of this command to remove the descriptive tag.

Syntax Description

<remark>	Specifies a descriptive tag for the IPv4 ACL. Tags can be up to **80** alphanumeric characters enclosed in quotation marks. For example, “This list blocks all outbound Web traffic.”

Default Values

By default, all AOS security features are disabled, and there are no configured IPv4 ACLs.

Command History

Release 2.1	Command was introduced.

Usage Examples

The following example specifies a description for standard IPv4 ACL **matchall**:

(config)**#ip access-list extended matchall**
(config-std-nacl)**#remark “allows all ip traffic from remote location”**

IPv4 Access Control Policy Command Set

An Internet Protocol version 4 (IPv4) access control policy (ACP) defines a policy class containing IPv4 access control lists (ACLs) in the Adtran Operating System (AOS) command line interface (CLI). The IPv4 ACP is a named policy with multiple action entries.

IPv6 ACPs are also supported by AOS, but are explained separately in this document. Refer to *IPv6 Access Control Policy Command Set on page 4326* for more information on configuring IPv6 ACPs.

To create an IPv4 ACP and activate the Access Control Policy Configuration mode, enter the **ip policy-class** <*ipv4 acp name*> command at the Global Configuration mode prompt. For example:

```
>enable
#config terminal
(config)#ip policy-class PRIVATE
(config-policy-class)#
```

> NOTE
> *Configured IPv4 ACPs will only be active if the **ip firewall** command has been entered at the Global Configuration mode prompt to enable the AOS security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

> CAUTION
> *Before applying an IPv4 ACP to an interface, verify your Telnet or secure shell (SSH) connection will not be affected by the policy. If an IPv4 ACP is applied to the interface you are connecting through and it does not allow Telnet or SSH traffic, your connection will be lost.*

Technology Review

IPv4 ACPs and IPv4 ACLs regulate traffic through the routed network. When designing your traffic flow configuration, it is important to keep the following in mind:

- An IPv4 ACL serves as a packet selector, defining exactly which packets should take the given action.
- An IPv4 ACP defines the action to take on the packets selected by the IPv4 ACL.
- An IPv4 ACL is inactive until it is assigned to an active IPv4 ACP.
- An IPv4 ACP is inactive until it is assigned to an interface.

IPv4 Access Control Policies (ACPs)

IPv4 ACPs are used to allow, discard, or manipulate (using network address translation (NAT)) data for each physical interface. Each IPv4 ACP consists of an action (**allow**, **discard**, **nat**) and a selector (IPv4 ACL). In a sense, the IPv4 ACPs answer the question, “What should I do?” while the IPv4 ACLs answer the question, “On which packets?”

When packets are received on an interface with an IPv4 ACP applied, the IPv4 ACP is used to determine whether the data is processed or discarded. Both IPv4 ACLs and IPv4 ACPs are order dependent. When a packet is evaluated, the matching engine begins with the first entry in the list and progresses through the entries until it finds a match. The first entry that matches is executed. The IPv4 ACP has an implicit **discard** at the end of the list. Typically, the most specific entries should be at the top and the most general at the bottom.

IPv4 Access Control Lists (ACLs)

IPv4 ACLs are used as packet selectors by IPv4 ACPs. They must be assigned to an IPv4 ACP in order to be active.

IPv4 ACP must use an IPv4 ACL. You cannot apply an IPv4 ACL to an IPv6 ACP, or vice-versa. In addition, all IPv4 ACLs and IPv4 ACPs must have a different name than any configured IPv6 ACLs or IPv6 ACPs.

IPv4 ACLs are composed of an ordered list of entries. Each entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** action is used to allow packets (meeting the specified pattern) to enter the router system. A **deny** action is used to disregard packets (that do not match the pattern) and proceed to the next entry on the IPv4 ACP. The IPv4 ACL has an implicit **deny** at the end of the list.

The AOS provides two types of IPv4 ACLs: **standard** and **extended**. A **standard** IPv4 ACL allows source IPv4 address packet patterns only. An **extended** IPv4 ACL may specify patterns using most fields in the IPv4 header and the Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) header.

Creating and Assigning IPv4 ACLs and IPv4 ACPs

Creating IPv4 ACPs and IPv4 ACLs to regulate traffic through the routed network is a four-step process:

Step 1:
Enable the security features of AOS using the **ip firewall** command. Refer to the command *ip firewall on page 1367* for more information.

Step 2:
Create an IPv4 ACP that uses a configured IPv4 ACL by issuing the **ip policy-class** command. AOS IPv4 ACPs are used to allow, discard, or manipulate (using NAT) data for each physical interface. Each IPv4 ACP consists of an action (**allow**, **discard**, **nat**) and a selector (IPv4 ACL). When packets are received on an interface, the configured IPv4 ACPs are applied to determine whether the data will be processed or discarded.

Step 3:
Create an IPv4 ACL to permit or deny specified traffic by using either the **ip access-list extended** or **ip access-list standard** command. Standard IPv4 ACLs match based on the source IPv4 address of the packet. Extended IPv4 ACLs match based on the source and destination of the packet. Refer to the command *ip access-list extended <ipv4 acl name> on page 1344* or the command *ip access-list standard <ipv4 acl name> on page 1346* for more information. Sources can be expressed in one of four ways:

1. Using the keyword **any** to match any IPv4 address.

2. Using **host** <*ipv4 address*> to specify a single host address.

3. Using the <*ipv4 address*> <*wildcard*> format to match all IPv4 addresses in a range. Wildcard masks work in reverse logic from subnet masks. When broken out into binary form, a 0 indicates which bits of the IPv4 address to consider, a 1 indicates which bits are disregarded. For example, specifying 255 in any octet of the wildcard mask equates to a “don’t care” for that octet in the IPv4 address. Additionally, a 30-bit mask would be represented with the wildcard string 0.0.0.3, a 28-bit mask with 0.0.0.15, a 24-bit mask with 0.0.0.255, and so forth.

4. Using the keyword **hostname** to match based on a domain naming system (DNS) name. DNS servers must be configured or host names must be locally defined for this function to work.

Step 4:
Apply the created IPv4 ACP to an interface. To assign an IPv4 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ip access-policy** <*ipv4 acp name*>. The following example assigns ACP **UNTRUSTED** to the Ethernet 0/1 interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ip access-policy UNTRUSTED**

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

allow list on page 4281
allow reverse list on page 4283
discard list on page 4285
nat destination list on page 4287
nat destination list <ipv4 acl name> pool <pool name> on page 4289
nat source list on page 4291
nat source list <ipv4 acl name> pool <pool name> on page 4294

allow list

Use the **allow list** command to specify an Internet Protocol version 4 (IPv4) access control list (ACL) to determine which packets are allowed to enter the interface to which the IPv4 access control policy (ACP) is assigned, and create a firewall association in the firewall. All associations created by the **allow list** command are subject to the built-in firewall timers (refer to *ip policy-timeout on page 1439*). Variations of this command include:

allow list *<ipv4 acl name>*
allow list *<ipv4 acl name>* **policy** *<ipv4 acp name>*
allow list *<ipv4 acl name>* **policy** *<ipv4 acp name>* **stateless**
allow list *<ipv4 acl name>* **self**
allow list *<ipv4 acl name>* **self stateless**
allow list *<ipv4 acl name>* **stateless**

Syntax Description

<ipv4 acl name>	Specifies the IPv4 ACL against which to check traffic before allowing packets to enter the interface. All packets not matched by the IPv4 ACL will be processed by the next IPv4 ACP entry or implicitly discarded if no further IPv4 ACP entries exist.
policy *<ipv4 acp name>*	Optional. Specifies the destination IPv4 ACP against which to match traffic. The firewall attempts to match the specified IPv4 ACP with the IPv4 ACP that is applied to the packet's egress interface as determined by the routing table or policy-based routing configuration. If there is a match, the firewall will process the packet. If there is no match, the firewall will process the packet based on the next IPv4 ACP entry or implicitly discard it if no further IPv4 ACP entries exist.
self	Optional. Allows packets to pass that are permitted by the IPv4 ACL and destined for any local interface on the unit. These packets are terminated by the unit and are not routed or forwarded to other destinations. Using the **self** keyword is helpful when opening up remote administrative access to the unit (Telnet, secure shell (SSH), Internet Control Message Protocol (ICMP), Web-based graphical user interface (GUI)).
stateless	Optional. Enables bypassing of stateful firewall processing and application-level gateways (ALGs). Use for trusted traffic or traffic that the firewall is incorrectly blocking as a perceived attack. Stateless processing is helpful when passing traffic over virtual private network (VPN) tunnels. Traffic sent over VPN tunnels is purposely selected and encrypted; there is no need for additional inspection of the traffic by the firewall. VPN configurations created using the VPN Wizard in the GUI use stateless processing by default.

Default Values

By default, all AOS security features are disabled and there are no configured IPv4 ACP entries.

Command History

Release 2.1	Command was introduced.

Usage Examples

The following example configures the IPv4 ACP name **UNTRUSTED** to allow any traffic that matches the IPv4 ACL named **INWEB** to enter the router system:

(config)**#ip policy-class UNTRUSTED**
(config-policy-class)**#allow list INWEB**

allow reverse list

Use the **allow reverse list** command to specify an Internet Protocol version 4 (IPv4) access control list (ACL) to determine which packets are allowed to enter the interface to which the IPv4 access control policy (ACP) is assigned, and create a firewall association in the firewall. The **allow reverse list** command is identical in function to the **allow list** command with the exception of the **reverse** keyword. The **reverse** keyword instructs the firewall to use the source information as the destination information and vice versa when attempting matches against the specified IPv4 ACL. This command is most useful when the IPv4 ACP is applied to an interface terminating a virtual private network (VPN) tunnel. The **allow reverse list** allows the reuse of the IPv4 ACL defined as the VPN selector. Variations of this command include:

allow reverse list *<ipv4 acl name>*
allow reverse list *<ipv4 acl name>* **policy** *<ipv4 acp name>*
allow reverse list *<ipv4 acl name>* **policy** *<ipv4 acp name>* **stateless**
allow reverse list *<ipv4 acl name>* **self**
allow reverse list *<ipv4 acl name>* **self stateless**
allow reverse list *<ipv4 acl name>* **stateless**

Syntax Description

<ipv4 acl name>	Specifies the IPv4 ACL against which to check traffic before allowing packets to enter the interface. All packets not matched by the IPv4 ACL will be processed by the next IPv4 ACP entry or implicitly discarded if no further IPv4 ACP entries exist.
policy *<ipv4 acp name>*	Optional. Specifies the destination IPv4 ACP against which to match traffic. The firewall attempts to match the specified IPv4 ACP with the IPv4 ACP that is applied to the packet's egress interface as determined by the routing table or policy-based routing configuration. If there is a match, the firewall will process the packet. If there is no match, the firewall will process the packet based on the next IPv4 ACP entry or implicitly discard it if no further IPv4 ACP entries exist.
self	Optional. Allows packets to pass that are permitted by the IPv4 ACL and destined for any local interface on the unit. These packets are terminated by the unit and are not routed or forwarded to other destinations. Using the **self** keyword is helpful when opening up remote administrative access to the unit (Telnet, secure shell (SSH), Internet Control Message Protocol (ICMP), Web-based graphical user interface (GUI)).
stateless	Optional. Enables bypassing of stateful firewall processing and application-level gateways (ALGs). Use for trusted traffic or traffic that the firewall is incorrectly blocking as a perceived attack. Stateless processing is helpful when passing traffic over VPN tunnels. Traffic sent over VPN tunnels is purposely selected and encrypted; there is no need for additional inspection of the traffic by the firewall. VPN configurations created using the VPN Wizard in the GUI use stateless processing by default.

Default Values

By default, all AOS security features are disabled and there are no configured IPv4 ACP entries.

Command History

Release 2.1	Command was introduced.

Usage Examples

The following example configures the IPv4 ACP named **UNTRUSTED** to allow any traffic that matches the IPv4 ACL named **INWEB** (with source and destination information reversed) to enter the router system:

(config)**#ip policy-class UNTRUSTED**
(config-policy-class)**#allow reverse list INWEB**

discard list

Use the **discard list** command to specify an Internet Protocol version 4 (IPv4) access control list (ACL) to determine which packets are discarded after entering the interface to which the IPv4 access control policy (ACP) is assigned. Packets matched by the IPv4 ACL will be discarded, and no further IPv4 ACP entries will be inspected. All packets not matched by the IPv4 ACL will be processed by the next IPv4 ACP entry or implicitly discarded if no further IPv4 ACP entries exist. Variations of this command include:

discard list <*ipv4 acl name*>
discard list <*ipv4 acl name*> **policy** <*ipv4 acp name*>
discard list <*ipv4 acl name*> **self**

Syntax Description

<*ipv4 acl name*>	Specifies the IPv4 ACL against which to check traffic before discarding the packet. All packets not matched by the IPv4 ACL will be processed by the next IPv4 ACP entry or implicitly discarded if no further IPv4 ACP entries exist.
policy <*ipv4 acp name*>	Optional. Specifies the destination IPv4 ACP against which to match traffic. The firewall attempts to match the specified IPv4 ACP with the IPv4 ACP that is applied to the packet's egress interface as determined by the routing table or policy-based routing configuration. If there is a match, the firewall will discard the packet. If there is no match, the firewall will process the packet based on the next IPv4 ACP entry or implicitly discard it if no further IPv4 ACP entries exist.
self	Optional. Discards packets that are matched by the IPv4 ACL and destined for any local interface on the unit. These packets, had they been allowed, would be terminated by the unit and not routed or forwarded to other destinations. Using the **self** keyword is helpful when forbidding certain access to the unit.

Default Values

By default, all AOS security features are disabled and there are no configured IPv4 ACP entries.

Command History

Release 2.1	Command was introduced.

Functional Notes

AOS IPv4 ACPs are used to allow, discard, or manipulate (using network address translation (NAT)) data for each physical interface. Each IPv4 ACP consists of an action (**allow**, **discard**, **nat**) and a selector (IPv4 ACL). When packets are received on an interface, the configured IPv4 ACPs are applied to determine whether the data will be processed or discarded.

*An implicit discard exists at the end of every IPv4 ACP. Specifying a **discard list** is unnecessary in most applications and should be used with caution. A **discard list** can adversely affect certain functions of a unit (virtual private network (VPN), routing protocols, etc.). Specifying an empty IPv4 ACL or a nonexistent IPv4 ACL in an IPv4 ACP will result in an implicit permit.*

Usage Examples

The following example configures the IPv4 ACP named **UNTRUSTED** to discard any traffic that matches the IPv4 ACL named **INWEB**:

(config)**#ip policy-class UNTRUSTED**
(config-policy-class)**#discard list INWEB**

nat destination list

Use the **nat destination list** command to translate the destination Internet Protocol version 4 (IPv4) address to a specified IPv4 address, and creates a firewall association in the firewall. The translation is applied only to those packets permitted by the specified IPv4 access control list (ACL) and entering the interface to which the IPv4 access control policy (ACP) is assigned. All firewall associations are subject to the built-in firewall timers (refer to *ip policy-timeout on page 1439*). Variations of this command include:

nat destination list <*ipv4 acl name*> **address** <*ipv4 address*> **no-alg**
nat destination list <*ipv4 acl name*> **address** <*ipv4 address*> **port** <*port number*>
nat destination list <*ipv4 acl name*> **address** <*ipv4 address*> **port** <*port number*> **no-alg**
nat destination list <*ipv4 acl name*> **address vrf** <*ipv4 address*> <*vrf name*>
nat destination list <*ipv4 acl name*> **address vrf** <*ipv4 address*> <*vrf name*> **no-alg**
nat destination list <*ipv4 acl name*> **address vrf** <*ipv4 address*> <*vrf name*> **port** <*port number*>
nat destination list <*ipv4 acl name*> **address vrf** <*ipv4 address*> <*vrf name*> **port** <*port number*> **no-alg**

Syntax Description

<*ipv4 acl name*>	Specifies the IPv4 ACL against which to check traffic before allowing packets to enter the interface. All packets not matched by the IPv4 ACL will be processed by the next IPv4 ACP entry or implicitly discarded if no further IPv4 ACP entries exist.
address <*ipv4 address*>	Specifies the address of the private IPv4 host to which the translated packets are destined. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
address vrf <*ipv4 address*> <*vrf name*>	Specifies the virtual routing and forwarding (VRF) instance corresponding to the specified post-NAT destination address.
no-alg	Optional. Allows packets matching the IPv4 ACP entry to traverse the firewall without being processed by the application-level gateways (ALGs). This parameter, along with the appropriate IPv4 ACL, prevents specific destinations from being processed by the ALGs.
port <*port number*>	Optional. Translates the original destination port to a user-specified port.

Default Values

By default, all AOS security features are disabled and there are no configured IPv4 ACP entries.

Command History

Release 2.1	Command was introduced.
Release 16.1	Command was expanded to include the **no-alg** parameter.
Release 17.1	Command was expanded to include the **vrf** parameter.
Release A4.01	Syntax for the **address vrf** parameter was altered.

Functional Notes

AOS IPv4 ACPs are used to allow, discard, or manipulate (using network address translation (NAT)) data for each physical interface. Each IPv4 ACP consists of an action (**allow**, **discard**, **nat**) and a selector (ACL). When packets are received on an interface, the configured IPv4 ACPs are applied to determine whether the data will be processed or discarded.

*An implicit discard exists at the end of every IPv4 ACP. Specifying a **discard list** is unnecessary in most applications and should be used with caution. A **discard list** can adversely affect certain functions of a unit (VPN, routing protocols, etc.). Specifying an empty IPv4 ACL or a nonexistent IPv4 ACL in an IPv4 ACP will result in an implicit permit.*

The optional **vrf** <*vrf name*> parameter specifies the VRF instance. The VRF does not have to be the same VRF from which the packet originated. VRF on an AOS product allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the abovementioned commands without specifying a VRF indicates that the specified address corresponds to the default unnamed VRF.

Usage Examples

The following example enables NAT for traffic that matches the IPv4 ACL **INWEB** and changes the destination address to **192.168.0.253**:

(config)**#ip policy-class UNTRUSTED**
(config-policy-class)**#nat destination list INWEB address 192.168.0.253**

nat destination list *<ipv4 acl name>* pool *<pool name>*

Use the **nat destination list pool** command to translate the destination Internet Protocol version 4 (IPv4) address to an address within the specified pool of addresses, translating a global to local address association. The translation is applied only to those packets permitted by the specified IPv4 access control list (ACL), and entering the interface to which the IPv4 access control policy (ACP) is assigned, and to those packets whose destination IPv4 address falls within the global range of the network address translation (NAT) pool. All firewall associations are subject to the built-in firewall timers (refer to *ip policy-timeout on page 1439*). Variations of this command include:

nat destination list *<ipv4 acl name>* **pool** *<pool name>*
nat destination list *<ipv4 acl name>* **pool** *<pool name>* **no-alg**

Syntax Description

<ipv4 acl name>	Specifies the IPv4 ACL against which to check traffic before allowing packets to enter the interface. All packets not matched by the IPv4 ACL will be processed by the next IPv4 ACP entry or implicitly discarded if no further IPv4 ACP entries exist.
pool *<pool name>*	Specifies the NAT pool to use for address mapping. If the destination IPv4 address does not fall within the global range of the specified pool, the packet will be processed by the next IPv4 ACP entry or implicitly discarded if no further IPv4 ACP entries exist.
no-alg	Optional. Allows packets matching the IPv4 ACP entry to traverse the firewall without being processed by the application-level gateways (ALGs). This parameter, along with the appropriate IPv4 ACL, prevents specific destinations from being processed by the ALGs.

Default Values

By default, all AOS security features are disabled and there are no configured IPv4 ACP entries.

Command History

Release 17.4	Command was introduced.

Functional Notes

AOS IPv4 ACPs are used to allow, discard, or manipulate (using NAT) data for each physical interface. Each IPv4 ACP consists of an action (**allow**, **discard**, **nat**) and a selector (ACL). When packets are received on an interface, the configured IPv4 ACPs are applied to determine whether the data will be processed or discarded.

*An implicit discard exists at the end of every IPv4 ACP. Specifying a **discard list** is unnecessary in most applications and should be used with caution. A **discard list** can adversely affect certain functions of a unit (virtual private network (VPN), routing protocols, etc.). Specifying an empty IPv4 ACL or a nonexistent IPv4 ACL in an IPv4 ACP will result in an implicit permit.*

Usage Examples

The following example enables NAT for traffic that matches the IPv4 ACL **OUTSIDE** and uses the NAT pool **POOL1** to map addresses:

(config)**#ip policy-class PUBLIC**
(config-policy-class)**#nat destination list OUTSIDE pool POOL1**

nat source list

Use the **nat source list** command to translate the source Internet Protocol version 4 (IPv4) address to a specified IPv4 address (or to the primary IPv4 address of the specified interface) and create an association in the firewall. The translation is applied only to those packets permitted by the specified IPv4 access control list (ACL), and entering the interface to which the IPv4 access control policy (ACP) is assigned. This function is commonly referred to as a "many-to-one NAT". All firewall associations are subject to the built-in firewall timers (refer to *ip policy-timeout on page 1439*). Variations of this command include:

nat source list <*ipv4 acl name*> **address** <*ipv4 address*> **overload**
nat source list <*ipv4 acl name*> **address** <*ipv4 address*> **overload no-alg**
nat source list <*ipv4 acl name*> **address** <*ipv4 address*> **overload no-alg policy** <*ipv4 acp name*>
nat source list <*ipv4 acl name*> **address** <*ipv4 address*> **overload policy** <*ipv4 acp name*>
nat source list <*ipv4 acl name*> **address vrf** <*ipv4 address*> <*vrf name*> **overload**
nat source list <*ipv4 acl name*> **address vrf** <*ipv4 address*> <*vrf name*> **overload no-alg**
nat source list <*ipv4 acl name*> **address vrf** <*ipv4 address*> <*vrf name*> **overload no-alg policy** <*ipv4 acp name*>
nat source list <*ipv4 acl name*> **address vrf** <*ipv4 address*> <*vrf name*> **overload policy** <*ipv4 acp name*>
nat source list <*ipv4 acl name*> **interface** <*interface*> **overload**
nat source list <*ipv4 acl name*> **interface** <*interface*> **overload no-alg**
nat source list <*ipv4 acl name*> **interface** <*interface*> **overload no-alg policy** <*ipv4 acp name*>
nat source list <*ipv4 acl name*> **interface** <*interface*> **overload policy** <*ipv4 acp name*>

Syntax Description

<*ipv4 acl name*>	Specifies the IPv4 ACL against which to check traffic before allowing packets to enter the interface. All packets not matched by the IPv4 ACL will be processed by the next IPv4 ACP entry or implicitly discarded if no further IPv4 ACP entries exist.
address <*ipv4 address*>	Specifies the IPv4 address from which the translated packets will be sourced. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
address vrf <*ipv4 address*> <*vrf name*>	Specifies the virtual routing and forwarding (VRF) instance corresponding to the specified post-NAT source address.
interface <*interface*>	Specifies the interface from which the translated packets will be sourced. The primary IPv4 address of an interface is used as the source IPv4 address for translated packets. Specify an interface in the format <*interface type* [*slot/port* | *slot/port.subinterface id* | *interface id* | *interface id.subinterface id*]>. For example, for an Ethernet subinterface, use **eth 0/1.1**; for a PPP interface, use **ppp 1**; and for an ATM subinterface, use **atm 1.1**. Type **nat source list** <*ipv4 acl name*> **interface ?** for a list of valid interfaces.

policy *<ipv4 acp name>*	Optional. Specifies the IPv4 ACP against which to match traffic. The firewall attempts to match the specified IPv4 ACP with the IPv4 ACP that is applied to the packet's egress interface as determined by the routing table or policy-based routing configuration. If there is a match, the firewall will process the packet. If there is no match, the firewall will process the packet based on the next IPv4 ACP entry or implicitly discard it if no further IPv4 ACP entries exist.
overload	Allows multiple source IPv4 addresses to be replaced with the single IPv4 address specified or the primary IPv4 address of the specified interface. This conceals private IPv4 addresses from acl nameoutside the local network. The **overload** command is not optional and must be used when using the **nat source list** command with a single address or interface. To perform static 1:1 NAT, use a network address translation (NAT) pool instead (refer to *nat source list <ipv4 acl name> pool <pool name> on page 4294*).
no-alg	Optional. Allows packets matching the IPv4 ACP entry to traverse the firewall without being processed by the application-level gateways (ALGs). This parameter, along with the appropriate IPv4 ACL, prevents specific sources from being processed by the ALGs. For example, this option can be used to prevent specific hosts from being uniform resource locator (URL) filtered by configuring an IPv4 ACP entry with the **no-alg** parameter that matches specific hosts followed by another IPv4 ACP entry that matches remaining hosts. The **no-alg** parameter can be placed before or after the **policy** *<acp name>* parameter.

Default Values

By default, all AOS security features are disabled and there are no configured IPv4 ACP entries.

Command History

Release 2.1	Command was introduced.
Release 16.1	Command was expanded to include the **no-alg** parameter.
Release 17.1	Command was expanded to include the **vrf** parameter.
Release A4.01	Command was expanded to include the Metro Ethernet Forum (MEF) Metro Ethernet interface and alter the syntax for the **address vrf** parameter.
Release A5.01	Command was expanded to include the Gigabit Ethernet interface.

Functional Notes

AOS IPv4 ACPs are used to allow, discard, or manipulate (using NAT) data for each physical interface. Each IPv4 ACP consists of an action (**allow**, **discard**, **nat**) and a selector (ACL). When packets are received on an interface, the configured IPv4 ACPs are applied to determine whether the data will be processed or discarded.

*An implicit discard exists at the end of every IPv4 ACP. Specifying a **discard list** is unnecessary in most applications and should be used with caution. A **discard list** can adversely affect certain functions of a unit (VPN, routing protocols, etc.). Specifying an empty IPv4 ACL or a nonexistent IPv4 ACL in an IPv4 ACP will result in an implicit permit.*

The optional **vrf** <*vrf name*> parameter specifies the VRF instance corresponding to the specified address. (If an interface is specified, the VRF of that interface is used.) The VRF does not have to be the same VRF from which the packet originated. VRF on an AOS product allows a single physical router to be partitioned into multiple virtual routers. Each router VRF instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the abovementioned commands without specifying a VRF indicates that the specified address corresponds to the default unnamed VRF.

Usage Examples

The following configuration enables NAT for traffic that matches the IPv4 ACL **MATCHALL** and changes the source address to **63.12.1.2**:

(config)**#ip policy-class UNTRUSTED**
(config-policy-class)**#nat source list MATCHALL address 63.12.1.2 overload**

nat source list *<ipv4 acl name>* pool *<pool name>*

Use the **nat source list pool** command to translate the source Internet Protocol version 4 (IPv4) address to an IPv4 address within the specified pool of addresses, translating a local private address to global public address. The translation is applied only to those packets permitted by the specified IPv4 access control list (ACL), and entering the interface to which the IPv4 access control policy (ACP) is assigned and whose source IPv4 address falls within the local range of addresses in the specified pool. All firewall associations are subject to the built-in firewall timers (refer to *ip policy-timeout on page 1439*). Variations of this command include:

nat source list *<ipv4 acl name>* **pool** *<pool name>*
nat source list *<ipv4 acl name>* **pool** *<pool name>* **no-alg**
nat source list *<ipv4 acl name>* **pool** *<pool name>* **no-alg policy** *<ipv4 acp name>*
nat source list *<ipv4 acl name>* **pool** *<pool name>* **policy** *<ipv4 acp name>*
nat source list *<ipv4 acl name>* **pool** *<pool name>* **policy** *<ipv4 acp name>* **no-alg**

Syntax Description

<ipv4 acl name>	Specifies the IPv4 ACL against which to check traffic before allowing packets to enter the interface. All packets not matched by the IPv4 ACL will be processed by the next IPv4 ACP entry or implicitly discarded if no further IPv4 ACP entries exist.
pool *<pool name>*	Specifies the network address translation (NAT) pool to use for address mapping. If the source IPv4 address does not fall within the local range of the specified pool, the packet will be processed by the next IPv4 ACP entry or implicitly discarded if no further IPv4 ACP entries exist.
policy *<ipv4 acp name>*	Optional. Specifies the IPv4 ACP against which to match traffic. The firewall attempts to match the specified IPv4 ACP with the IPv4 ACP that is applied to the packet's egress interface as determined by the routing table or policy-based routing configuration. If there is a match, the firewall will process the packet. If there is no match, the firewall will process the packet based on the next IPv4 ACP entry or implicitly discard it if no further IPv4 ACP entries exist.
no-alg	Optional. Allows packets matching the IPv4 ACP entry to traverse the firewall without being processed by the application-level gateways (ALGs). This parameter, along with the appropriate IPv4 ACL, prevents specific sources from being processed by the ALGs. For example, this option can be used to prevent specific hosts from being uniform resource locator (URL) filtered by configuring an IPv4 ACP entry with the **no-alg** parameter that matches specific hosts followed by another IPv4 ACP entry that matches remaining hosts. The **no-alg** parameter can be placed before or after the **policy** *<acp name>* parameter.

Default Values

By default, all AOS security features are disabled and there are no configured IPv4 ACP entries.

Command History

Release 17.4	Command was introduced.

Functional Notes

AOS IPv4 ACPs are used to allow, discard, or manipulate (using NAT) data for each physical interface. Each IPv4 ACP consists of an action (**allow**, **discard**, **nat**) and a selector (ACL). When packets are received on an interface, the configured IPv4 ACPs are applied to determine whether the data will be processed or discarded.

*An implicit discard exists at the end of every IPv4 ACP. Specifying a **discard list** is unnecessary in most applications and should be used with caution. A **discard list** can adversely affect certain functions of a unit (virtual private network (VPN), routing protocols, etc.). Specifying an empty IPv4 ACL or a nonexistent IPv4 ACL in an IPv4 ACP will result in an implicit permit.*

Usage Examples

The following example configures the IPv4 ACP **PRIVATE** using an undefined IPv4 ACL that matches all traffic, specifies the NAT pool **POOL1**, and specifies that the traffic matching this entry should be destined for the **PUBLIC** policy class:

(config)**#ip policy-class PRIVATE**
(config-policy-class)**#nat source list MATCHALL pool POOL1 policy PUBLIC**

IPv6 Access Control List Command Set

An Internet Protocol version 6 (IPv6) access control list (ACL) is an ordered list of entries used as packet selectors by an IPv6 access control policy (ACP) in the Adtran Operating System (AOS) command line interface (CLI). ACLs and ACPs work together to regulate IPv6 traffic through the routed network.

There are two types of IPv6 ACLs in AOS: **standard** and **extended**. A **standard** IPv6 ACL allows source IPv6 address packet patterns only. An **extended** IPv6 ACL may specify patterns using most fields in the IPv6 header and the Transmission Control Protocol (TCP) header, User Datagram Protocol (UDP) header, or Internet Control Message Protocol version 6 (ICMPv6) message type or code. This configuration command set details the configuration of both standard and extended IPv6 ACLs.

IPv4 ACLs are also supported by AOS, but are explained separately in this document. Refer to IPv4 Access Control List Command Set on page 4252 for more information on configuring IPv4 ACLs.

To create a **standard** IPv6 ACL and activate the Standard IPv6 ACL Configuration mode, enter the **ipv6 access-list standard** <*ipv6 acl name*> command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ipv6 access-list standard MATCHALLv6
(config-std6-nacl)#
```

To create an **extended** IPv6 ACL and activate the Extended IPv6 ACL Configuration mode, enter the **ipv6 access-list extended** <*ipv6 acl name*> command at the Global Configuration mode prompt. For example:

```
>enable
#configure terminal
(config)#ipv6 access-list extended MATCHALLv6
(config-ext6-nacl)#
```

*An IPv6 ACL will remain inactive until it is assigned to an **active** IPv6 ACP. For more information on configuring and activating IPv6 ACPs, refer to the IPv6 Access Control Policy Command Set on page 4326.*

Technology Review

IPv6 ACPs and ACLs regulate traffic through the routed network. When designing your traffic flow configuration, it is important to keep the following in mind:

- An IPv6 ACL serves as a packet selector, defining exactly which packets should take the given action.
- An IPv6 ACP defines the action to take on the packets selected by the ACL.
- An IPv6 ACL is inactive until it is assigned to an active IPv6 ACP.
- An IPv6 ACP is inactive until it is assigned to an interface.

IPv6 Access Control Policies

IPv6 ACPs are used to allow or discard data for each physical interface. Each IPv6 ACP consists of an action (**allow**, **discard**) and a selector (IPv6 ACL). In a sense, the IPv6 ACPs answer the question, “What should I do?” while the IPv6 ACLs answer the question, “On which packets?”

When IPv6 packets are received on an interface with an IPv6 ACP applied, the ACP is used to determine whether the data is processed or discarded. Both IPv6 ACLs and ACPs are order dependent. When a packet is evaluated, the matching engine begins with the first entry in the list and progresses through the entries until it finds a match. The first entry that matches is executed. The IPv6 ACP has an implicit **discard** at the end of the list. Typically, the most specific entries should be at the top and the most general at the bottom.

IPv6 Access Control Lists

IPv6 ACLs are used as packet selectors by IPv6 ACPs. They must be assigned to an IPv6 ACP in order to be active.

IPv6 ACPs must use an IPv6 ACL. You cannot apply an IPv4 ACL to an IPv6 ACP, or vice versa. In addition, all IPv6 ACLs and IPv6 ACPs must have a different name than any configured IPv4 ACLs or IPv4 ACPs.

IPv6 ACLs are composed of an ordered list of entries. Each entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** action is used to allow packets (meeting the specified pattern) to enter the router system. A **deny** action is used to disregard packets (that do not match the specified pattern) and proceed to the next entry on the ACP. In IPv4, packets either match a **permit** or a **deny** entry in the ACL. In IPv6, if no match is found between the packet and the match criteria, a **miss** entry is passed to the application using the ACL. Depending on the application, the **miss** can be processed differently. For example, with typical IPv6 traffic, access groups treat a **miss** as a **deny**, effectually giving a **deny any any** at the end of the IPv6 ACL. For IPv6 Neighbor Discovery (ND) protocol messages, however, access groups treat **miss** packets as a **permit,** resulting in a **permit** for ND before the end of the ACL.

The AOS provides two types of IPv6 ACLs: **standard** and **extended**. A **standard** IPv6 ACL allows source IPv6 address packet patterns only. An **extended** IPv6 ACL can specify patterns using most fields in the IPv6 header, as well as the TCP header, UDP header, or ICMPv6 message type or code.

Creating and Assigning IPv6 ACLs and ACPs

Creating IPv6 ACPs and ACLs to regulate traffic through the routed network is a four-step process:

Step 1:
Enable the security features of AOS using the **ipv6 firewall** command. Refer to the command *ipv6 firewall on page 1523* for more information.

Step 2:
Create an IPv6 ACP that uses a configured IPv6 ACL by issuing the **ipv6 policy-class** command. AOS IPv6 ACPs are used to allow or discard data for each physical interface. Each IPv6 ACP consists of an action (**allow**, **discard**) and a selector (IPv6 ACL). When IPv6 packets are received on an interface, the configured IPv6 ACPs are applied to determine whether the data will be processed or discarded.

Step 3:
Create an IPv6 ACL to permit or deny specified IPv6 traffic by using either the **ipv6 access-list extended** or **ipv6 access-list standard** command. Standard IPv6 ACLs match based on the source IPv6 address of the packet. Extended IPv6 ACLs match based on the source and destination of the packet. Refer to the command *ipv6 access-list extended <ipv6 acl name> on page 1500* or the command *ipv6 access-list standard <ipv6 acl name> on page 1502* for more information. Sources can be expressed in one of three ways:

1. Using the keyword **any** to match any IPv6 address.

2. Using **host** <*ipv6 address*> to specify a single host address.

3. Using the <*ipv6 prefix/prefix-length*> to specify a source IPv6 address to match.

Step 4:
Apply the created IPv6 ACP to an interface. To assign an IPv6 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ipv6 access-policy** <*ipv6 acp name*>. The following example assigns IPv6 ACP **UNTRUSTED** to the Ethernet 0/1 interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 access-policy UNTRUSTED**

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
exit on page 83
interface on page 84

The following are commands used to configure an **extended** IPv6 ACL. **Extended** IPv6 ACL configuration includes specifying an IPv6 ACL action, a protocol, a packet source, a source port, a packet destination, and a destination port. These commands are described in this section in alphabetical order.

deny <protocol> <source> <destination> on page 4300
deny [tcp | udp] <source> <source port> <destination> <destination port> <tcp flags> on page 4302
deny icmpv6 <source> <destination> on page 4306
permit <protocol> <source> <destination> on page 4310
permit [tcp | udp] <source> <source port> <destination> <destination port> <tcp flags> on page 4312
permit icmpv6 <source> <destination> on page 4316
remark <remark> on page 4320

The following are commands for configuring a **standard** IPv6 ACL. **Standard** IPv6 ACL configuration includes specifying an ACL action and a packet source. These commands are described in this section in alphabetical order.

deny *<protocol> <source> <destination>*

Use the **deny** command to configure the extended Internet Protocol version 6 (IPv6) access control list (ACL) to deny specified packets entry into the routing system. This command provides traffic matching based on the IPv6 header field. Use the **no** form of this command to remove the deny parameter from the IPv6 ACL. Variations of this command include:

deny *<protocol> <source> <destination>*
deny ipv6 *<source> <destination>* **fragments**

Syntax Description

<protocol>	Specifies the IPv6 data protocol **ahp**, **esp**, **gre**, or a specific protocol. Range is **0** to **255**. The keyword **ipv6** can optionally be used to match any IPv6 traffic. Extension header values are not allowed.
<source>	Specifies the source used for IPv6 packet matching. Sources can be expressed in one of three ways: 1. Using the keyword **any** to match any IPv6 address. 2. Using **host** *<ipv6 address>* to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**. 3. Using *<ipv6 prefix/prefix-length>* to specify a source address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
<destination>	Specifies the destination used for IPv6 packet matching. Destinations can be expressed in one of three ways: 1. Using the keyword **any** to match any IPv6 address. 2. Using **host** *<ipv6 address>* to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**. 3. Using *<ipv6 prefix/prefix-length>* to specify a destination address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
fragments	Optional. Indicates that the ACL entry is only matched by non-initial fragments. This parameter is only available using the **ipv6** protocol.

Default Values

By default, all AOS IPv6 security features are disabled, and there are no configured IPv6 ACLs.

Command History

Release 18.1	Command was introduced.
Release R11.10.2	Command was expanded to include the **fragments** parameter.

Functional Notes

IPv6 ACLs are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv6 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv6 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** ACL is used to match packets (meeting the specified pattern) and allow them to enter the router system or specify that the feature using the ACL should apply its action to this traffic. A **deny** ACL advances AOS to the next ACP entry, discards the traffic, or specifies that the feature using the ACL should not apply its action to this traffic. AOS provides two types of IPv6 ACLs: standard and extended. Standard IPv6 ACLs match based on the source of the packet. Extended IPv6 ACLs match based on the source and destination of the packet.

ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

IPv6 ACLs match non-initial fragments in the following manner:

- Non-initial fragments can match entries with the **fragments** keyword, provided the other Layer 3 information specified in the entry matches the packet.
- Non-initial fragments can match entries with the **ipv6** protocol specified, provided the other Layer 3 information specified in the entry matches the packet.
- Non-initial fragments are implicitly permitted by access groups if the fragments did not match an explicit entry in the ACL.

Usage Examples

The following example creates an entry in the **Untrustedv6** IPv6 ACL that denies IPv6 traffic matching source IPv6 prefix **2001:DB8:3F::/64** and any destination IPv6 address:

(config)**#ipv6 access-list extended Untrustedv6**
(config-ext6-nacl)**#deny ipv6** 2001:DB8:3F::/64 any

deny [tcp | udp] <*source*> <*source port*> <*destination*> <*destination port*> <*tcp flags*>

Use the **deny [tcp | udp]** command to configure the extended Internet Protocol version 6 (IPv6) access control list (ACL) to deny specified Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) packets entry into the routing system. This command provides traffic matching based on the IPv6 header field and the upper layer protocol flags (TCP or UDP). Use the **no** form of this command to remove the deny parameter from the IPv6 ACL. Variations of this command include:

deny tcp <*source*> <*destination*>
deny tcp <*source*> <*source port*> <*destination*>
deny tcp <*source*> <*source port*> <*destination*> <*destination port*>
deny tcp <*source*> <*source port*> <*destination*> <*destination port*> <*tcp flags*>
deny udp <*source*> <*destination*>
deny udp <*source*> <*source port*> <*destination*>
deny udp <*source*> <*source port*> <*destination*> <*destination port*>

Syntax Description

tcp	Specifies the IPv6 data protocol as TCP, indicating that TCP upper-layer protocol headers and fields are used for matching in this ACL entry.
udp	Specifies the IPv6 data protocol as UDP, indicating that UDP upper-layer protocol headers and fields are used for matching in this ACL entry.
<*source*>	Specifies the source used for IPv6 packet matching. Sources can be expressed in one of three ways: 1. Using the keyword **any** to match any IPv6 address. 2. Using **host** <*ipv6 address*> to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**. 3. Using <*ipv6 prefix/prefix-length*> to specify a source address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
<*source port*>	Optional. Specifies that traffic comparison is conducted on the source port for the associated protocol (TCP or UDP). When you specify a source port, you must enter a port operator and a port number or name. The following keywords and port numbers/names are supported for the <*source port*> field:

any	Matches any destination port.
eq <*port number/name*>	Matches only packets equal to specified port number.
gt <*port number/name*>	Matches only packets with a port number greater than the specified port number.
lt <*port number/name*>	Matches only packets with a port number less than the specified port number.

neq <*port number/name*>	Matches only packets that are not equal to the specified port number.
range <*beginning port number/name*> <*ending port number/name*>	Matches only packets that contain a port number in the specified range.
<*port number*>	Specifies the port number used by TCP or UDP to pass information to upper layers using the following syntax: <***0-65535***>. All ports below 1024 are considered well-known ports, and are controlled by the Internet Assigned Numbers Authority (IANA). All ports above 1024 are dynamically assigned ports that include registered ports for vendor-specific applications.
<*port name*>	The following UDP port numbers can be specified using the associated names:

biff (Port 512)**ntp** (Port 123)

bootpc (Port 68)	**pim-auto-rp** (Port 496)
bootps (Port 67)	**rip** (Port 520)
discard (Port 9)	**snmp** (Port 161)
dnsix (Port 195)	**snmptrap** (Port 162)
domain (Port 53)	**sunrpc** (Port 111)
echo (Port 7)	**syslog** (Port 514)
isakmp (Port 500)	**tacacs** (Port 49)
mobile-ip (Port 434)	**talk** (Port 517)
nameserver (Port 42)	**tftp** (Port 69)
netbios-dgm (Port 138)	**time** (Port 37)
netbios-ns (Port 137)	**who** (Port 513)
netbios-ss (Port 139)	**xdmcp** (Port 177)

The following TCP port numbers can be specified using the associated names:

bgp (Port 179)	**lpd** (Port 515)
chargen (Port 19)	**nntp** (Port 119)
cmd (Port 514)	**pim-auto-rp** (Port 496)
daytime (Port 13)	**pop2** (Port 109)
discard (Port 9)	**pop3** (Port 110)
domain (Port 53)	**smtp** (Port 25)
echo (Port 7)	**sunrpc** (Port 111)
exec (Port 512)	**tacacs** (Port 49)
finger (Port 79)	**talk** (Port 517)
ftp (Port 21)	**tftp** (Port 69)

gopher (Port 70)	**telnet** (Port 23)
hostname (Port 101)	**time** (Port 37)
ident (Port 113)	**uucp** (Port 540)
irc (Port 194)	**whois** (Port 43)
klogin (Port 543)	**www** (Port 80)
kshell (Port 544)	
login (Port 513)	

<destination> Specifies the destination used for IPv6 packet matching. Destinations can be expressed in one of three ways:

1. Using the keyword **any** to match any IPv6 address.
2. Using **host** *<ipv6 address>* to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
3. Using *<ipv6 prefix/prefix-length>* to specify a destination address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

<destination port> Optional. Specifies that traffic comparison is conducted on the destination port for the associated protocol (TCP or UDP).The same keywords and port numbers/names used for the *<source port>* field are valid for the *<destination port>* field. Refer to previously listed *<source port>* for more details.

<tcp flags> Optional. When used with the TCP protocol, this option defines which flag in the TCP flag to use for traffic matching. The following keywords are the supported TCP flags:

ack	Matches the TCP acknowledgement header flag.
fin	Matches the TCP finish header flag.
psh	Matches the TCP push header flag.
rst	Matches the TCP reset header flag.
syn	Matches the TCP synchronize header flag.
urg	Matches the TCP urgent pointer header flag.

Default Values

By default, all AOS IPv6 security features are disabled, and there are no configured IPv6 ACLs.

Command History

Release 18.1	Command was introduced.

Functional Notes

IPv6 ACLs are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv6 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv6 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** ACL is used to match packets (meeting the specified pattern) and allow them to enter the router system or specify that the feature using the ACL should apply its action to this traffic. A **deny** ACL advances AOS to the next ACP entry, discards the traffic, or specifies that the feature using the ACL should not apply its action to this traffic. AOS provides two types of IPv6 ACLs: standard and extended. Standard IPv6 ACLs match based on the source of the packet. Extended IPv6 ACLs match based on the source and destination of the packet.

ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Usage Examples

The following example creates an entry in the **Untrustedv6** IPv6 ACL that denies IPv6 traffic matching TCP source IPv6 prefix **2001:DB8:3F::/64** from port **1080** and any destination IPv6 address:

(config)**#ipv6 access-list extended Untrustedv6**
(config-ext6-nacl)**#deny tcp ipv6 2001:DB8:3F::/64 eq 1080 any**

deny icmpv6 <*source*> <*destination*>

Use the **deny icmpv6** command to configure the extended Internet Protocol version 6 (IPv6) access control list (ACL) to deny specified Internet Control Message Protocol version 6 (ICMPv6) packets entry into the routing system. This command provides traffic matching based on the packet's IPv6 header field and ICMPv6-specific fields. Use the **no** form of this command to remove the deny parameter from the IPv6 ACL. Variations of this command include:

deny icmpv6 <*source*> <*destination*>
deny icmpv6 <*source*> <*destination*> <*message name*>
deny icmpv6 <*source*> <*destination*> <*message type*> <*message code*>

Syntax Description

<*source*>

Specifies the source used for IPv6 packet matching. Sources can be expressed in one of three ways:

1. Using the keyword **any** to match any IPv6 address.
2. Using **host** <*ipv6 address*> to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
3. Using <*ipv6 prefix/prefix-length*> to specify a source address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

<*destination*>

Specifies the destination used for IPv6 packet matching. Destinations can be expressed in one of three ways:

1. Using the keyword **any** to match any IPv6 address.
2. Using **host** <*ipv6 address*> to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
3. Using <*ipv6 prefix/prefix-length*> to specify a destination address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

<*message name*>

Optional. Specifies the ICMP message type used for matching ICMPv6 packets. ICMP message names are specified using one of the following keywords:

beyond-scope	Indicates the destination is unreachable because it is beyond the scope of the source address.
dest-unreachable	Indicates the destination address is unreachable.
dhaad-reply	Indicates a home agent address discovery reply message.

dhaad-request	Indicates a home agent address discovery request message.
echo-reply	Indicates an echo reply message.
echo-request	Indicates an echo request message.
header	Indicates an erroneous header field has been encountered.
hop-limit	Indicates the hop limit has been exceeded in packet transit.
mld-query	Indicates a mulitcast listener discovery query message.
mld-reduction	Indicates a multicast listener discovery reduction message.
mld-report	Indicates a multicast listener discovery report message.
mp-advertisement	Indicates a mobile prefix advertisement message.
mp-solicitation	Indicates a mobile prefix solicitation message.
nd-na	Indicates a Neighbor Discovery neighbor advertisement message.
nd-ns	Indicates a Neighbor Discovery neighbor solicitation message.
next-header	Indicates an unrecognized next header type was encountered.
no-admin	Indicates the destination is unreachable because communication with the destination is administratively prohibited.
no-route	Indicates the destination is unreachable because there is no route to the destination.
packet-too-big	Indicates the packet is too large.
parameter-option	Indicates that an unrecognized IPv6 option was encountered.
parameter-problem	Indicates there is a parameter problem with the packet.
port-unreachable	Indicates the destination is unreachable because the port is unreachable.

reassembly-timeout	Indicates that the fragment reassembly time limit has been exceeded.
redirect	Indicates a redirect message.
renum-command	Indicates a router renumbering command.
renum-result	Indicates a router renumbering result.
renum-seq-number	Indicates a router sequence number reset.
router-advertisement	Indicates a router advertisement message.
router-renumbering	Indicates a router renumbering for all codes.
router-solicitation	Indicates an router solicitation message.
time-exceeded	Indicates the time limit has been exceeded.
unreachable	Indicates the destination is unreachable.

<message type>	Optional. Specifies the ICMP message type for matching ICMPv6 packets. When you specify an ICMP message type, you must also specify an ICMP message code. Message types range from **0** to **127** for error messages and from **128** to **255** for informational messages.
<message code>	Optional. Specifies the ICMP message code for matching ICMPv6 packets. You must specify the message code when you specify the ICMP message type. Message code range is **0** to **255**.

Default Values

By default, all AOS IPv6 security features are disabled, and there are no configured IPv6 ACLs.

Command History

Release 18.1	Command was introduced.

Functional Notes

IPv6 ACLs are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv6 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv6 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** ACL is used to match packets (meeting the specified pattern) and allow them to enter the router system or specify that the feature using the ACL should apply its action to this traffic. A **deny** ACL advances AOS to the next ACP entry, discards the traffic, or specifies that the feature using the ACL should not apply its action to this traffic. AOS provides two types of IPv6 ACLs: standard and extended. Standard IPv6 ACLs match based on the source of the packet. Extended IPv6 ACLs match based on the source and destination of the packet.

ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Usage Examples

The following example creates an extended IPv6 ACL named **Untrustedv6** IPv6 ACL that denies any IPv6 traffic from a source with the same prefix bits as **2001:DB8:3F::/64**, headed to a destination of **2001:DB8:85A3::8A2E:0370:7334**, and an ICMPv6 message type of **echo-request**:

(config)**#ipv6 access-list extended Untrustedv6**
(config-ext6-nacl)**#deny icmpv6 2001:DB8:3F::/64 2001:DB8:85A3::8A2E:0370:7334 echo-request**

permit *<protocol> <source> <destination>*

Use the **permit** command to configure the extended Internet Protocol version 6 (IPv6) access control list (ACL) to permit specified packets entry into the routing system. This command provides traffic matching based on the IPv6 header field. Use the **no** form of this command to remove the deny parameter from the IPv6 ACL. Variations of this command include:

permit *<protocol> <source> <destination>*
permit ipv6 *<source> <destination>* **fragments**

Syntax Description

<protocol>	Specifies the IPv6 data protocol **ahp**, **esp**, **gre**, or a specific protocol. The keyword **ipv6** can optionally be used to match any IPv6 traffic. Range is **0** to **255**. Extension header values are not allowed.
<source>	Specifies the source used for IPv6 packet matching. Sources can be expressed in one of three ways: 1. Using the keyword **any** to match any IPv6 address. 2. Using **host** *<ipv6 address>* to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**. 3. Using *<ipv6 prefix/prefix-length>* to specify a source address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
<destination>	Specifies the destination used for IPv6 packet matching. Destinations can be expressed in one of three ways: 1. Using the keyword **any** to match any IPv6 address. 2. Using **host** *<ipv6 address>* to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**. 3. Using *<ipv6 prefix/prefix-length>* to specify a destination address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
fragments	Optional. Indicates that the ACL entry is only matched by non-initial fragments. This parameter is only available using the **ipv6** protocol.

Default Values

By default, all AOS IPv6 security features are disabled, and there are no configured IPv6 ACLs.

Command History

Release 18.1	Command was introduced.
Release R11.10.2	Command was expanded to include the **fragments** parameter.

Functional Notes

IPv6 ACLs are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv6 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv6 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** ACL is used to match packets (meeting the specified pattern) and allow them to enter the router system or specify that the feature using the ACL should apply its action to this traffic. A **deny** ACL advances AOS to the next ACP entry, discards the traffic, or specifies that the feature using the ACL should not apply its action to this traffic. AOS provides two types of IPv6 ACLs: standard and extended. Standard IPv6 ACLs match based on the source of the packet. Extended IPv6 ACLs match based on the source and destination of the packet.

ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

IPv6 ACLs match non-initial fragments in the following manner:

- Non-initial fragments can match entries with the **fragments** keyword, provided the other Layer 3 information specified in the entry matches the packet.
- Non-initial fragments can match entries with the **ipv6** protocol specified, provided the other Layer 3 information specified in the entry matches the packet.
- Non-initial fragments are implicitly permitted by access groups if the fragments did not match an explicit entry in the ACL.

Usage Examples

The following example creates an entry in the **Untrustedv6** IPv6 ACL that permits IPv6 traffic matching source IPv6 prefix **2001:DB8:3F::/64** and any destination IPv6 address:

(config)**#ipv6 access-list extended Untrustedv6**
(config-ext6-nacl)**#permit ipv6** 2001:DB8:3F::/64 any

permit [tcp | udp] <*source*> <*source port*> <*destination*> <*destination port*> <*tcp flags*>

Use the **permit [tcp | udp]** command to configure the extended Internet Protocol version 6 (IPv6) access control list (ACL) to permit specified Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) packets entry into the routing system. This command provides traffic matching based on the IPv6 header field and the upper layer protocol flags (TCP or UDP). Use the **no** form of this command to remove the deny parameter from the IPv6 ACL. Variations of this command include:

permit tcp <*source*> <*destination*>
permit tcp <*source*> <*source port*> <*destination*>
permit tcp <*source*> <*source port*> <*destination*> <*destination port*>
permit tcp <*source*> <*source port*> <*destination*> <*destination port*> <*tcp flags*>
permit udp <*source*> <*destination*>
permit udp <*source*> <*source port*> <*destination*>
permit udp <*source*> <*source port*> <*destination*> <*destination port*>

Syntax Description

tcp	Specifies the IPv6 data protocol as TCP, indicating that TCP upper-layer protocol headers and fields are used for matching in this ACL entry.
udp	Specifies the IPv6 data protocol as UDP, indicating that UDP upper-layer protocol headers and fields are used for matching in this ACL entry.
<*source*>	Specifies the source used for IPv6 packet matching. Sources can be expressed in one of three ways: 1. Using the keyword **any** to match any IPv6 address. 2. Using **host** <*ipv6 address*> to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**. 3. Using <*ipv6 prefix/prefix-length*> to specify a source address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
<*source port*>	Optional. Specifies that traffic comparison is conducted on the source port for the associated protocol (TCP or UDP). When you specify a source port, you must enter a port operator and a port number or name. The following keywords and port numbers/names are supported for the <*source port*> field:

any	Matches any destination port.
eq <*port number/name*>	Matches only packets equal to specified port number.
gt <*port number/name*>	Matches only packets with a port number greater than the specified port number.
lt <*port number/name*>	Matches only packets with a port number less than the specified port number.

neq *<port number/name>* — Matches only packets that are not equal to the specified port number.

range *<beginning port number/name>* *<ending port number/name>* — Matches only packets that contain a port number in the specified range.

<port number> — Specifies the port number used by TCP or UDP to pass information to upper layers using the following syntax: <***0-65535***>. All ports below 1024 are considered well-known ports, and are controlled by the Internet Assigned Numbers Authority (IANA). All ports above 1024 are dynamically assigned ports that include registered ports for vendor-specific applications.

<port name> — The following UDP port numbers can be specified using the associated names:

biff (Port 512)	**ntp** (Port 123)
bootpc (Port 68)	**pim-auto-rp** (Port 496)
bootps (Port 67)	**rip** (Port 520)
discard (Port 9)	**snmp** (Port 161)
dnsix (Port 195)	**snmptrap** (Port 162)
domain (Port 53)	**sunrpc** (Port 111)
echo (Port 7)	**syslog** (Port 514)
isakmp (Port 500)	**tacacs** (Port 49)
mobile-ip (Port 434)	**talk** (Port 517)
nameserver (Port 42)	**tftp** (Port 69)
netbios-dgm (Port 138)	**time** (Port 37)
netbios-ns (Port 137)	**who** (Port 513)
netbios-ss (Port 139)	**xdmcp** (Port 177)

The following TCP port numbers can be specified using the associated names:

bgp (Port 179)	**lpd** (Port 515)
chargen (Port 19)	**nntp** (Port 119)
cmd (Port 514)	**pim-auto-rp** (Port 496)
daytime (Port 13)	**pop2** (Port 109)
discard (Port 9)	**pop3** (Port 110)
domain (Port 53)	**smtp** (Port 25)
echo (Port 7)	**sunrpc** (Port 111)
exec (Port 512)	**tacacs** (Port 49)
finger (Port 79)	**talk** (Port 517)
ftp (Port 21)	**tftp** (Port 69)

gopher (Port 70)	**telnet** (Port 23)
hostname (Port 101)	**time** (Port 37)
ident (Port 113)	**uucp** (Port 540)
irc (Port 194)	**whois** (Port 43)
klogin (Port 543)	**www** (Port 80)
kshell (Port 544)	
login (Port 513)	

<destination> Specifies the destination used for IPv6 packet matching. Destinations can be expressed in one of three ways:

1. Using the keyword **any** to match any IPv6 address.
2. Using **host** <*ipv6 address*> to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
3. Using <*ipv6 prefix/prefix-length*> to specify a destination address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

<destination port> Optional. Specifies that traffic comparison is conducted on the destination port for the associated protocol (TCP or UDP).The same keywords and port numbers/names used for the <*source port*> field are valid for the <*destination port*> field. Refer to previously listed <*source port*> for more details.

<tcp flags> Optional. When used with the TCP protocol, this option defines which flag in the TCP flag to use for traffic matching. The following keywords are the supported TCP flags:

ack	Matches the TCP acknowledgement header flag.
fin	Matches the TCP finish header flag.
psh	Matches the TCP push header flag.
rst	Matches the TCP reset header flag.
syn	Matches the TCP synchronize header flag.
urg	Matches the TCP urgent pointer header flag.

Default Values

By default, all AOS IPv6 security features are disabled, and there are no configured IPv6 ACLs.

Command History

Release 18.1	Command was introduced.

Functional Notes

IPv6 ACLs are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv6 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv6 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** ACL is used to match packets (meeting the specified pattern) and allow them to enter the router system or specify that the feature using the ACL should apply its action to this traffic. A **deny** ACL advances AOS to the next ACP entry, discards the traffic, or specifies that the feature using the ACL should not apply its action to this traffic. AOS provides two types of IPv6 ACLs: standard and extended. Standard IPv6 ACLs match based on the source of the packet. Extended IPv6 ACLs match based on the source and destination of the packet.

ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Usage Examples

The following example creates an entry in the **Untrustedv6** IPv6 ACL that permits IPv6 traffic matching TCP source IPv6 prefix **2001:DB8:3F::/64** from port **1080** and any destination IPv6 address:

(config)**#ipv6 access-list extended Untrustedv6**
(config-ext6-nacl)**#permit tcp ipv6 2001:DB8:3F::/64 eq 1080 any**

permit icmpv6 <*source*> <*destination*>

Use the **permit icmpv6** command to configure the extended Internet Protocol version 6 (IPv6) access control list (ACL) to permit specified Internet Control Message Protocol version 6 (ICMPv6) packets entry into the routing system. This command provides traffic matching based on the packet's IPv6 header field and ICMPv6 specific fields. Use the **no** form of this command to remove the deny parameter from the IPv6 ACL. Variations of this command include:

permit icmpv6 <*source*> <*destination*>
permit icmpv6 <*source*> <*destination*> <*message name*>
permit icmpv6 <*source*> <*destination*> <*message type*> <*message code*>

Syntax Description

<*source*>

Specifies the source used for IPv6 packet matching. Sources can be expressed in one of three ways:

1. Using the keyword **any** to match any IPv6 address.
2. Using **host** <*ipv6 address*> to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
3. Using <*ipv6 prefix/prefix-length*> to specify a source address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

<*destination*>

Specifies the destination used for IPv6 packet matching. Destinations can be expressed in one of three ways:

1. Using the keyword **any** to match any IPv6 address.
2. Using **host** <*ipv6 address*> to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
3. Using <*ipv6 prefix/prefix-length*> to specify a destination address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

<*icmp message name*>

Optional. Specifies the ICMP message type used for matching ICMPv6 packets. ICMP message names are specified using one of the following keywords:

beyond-scope	Indicates the destination is unreachable because it is beyond the scope of the source address.
dest-unreachable	Indicates the destination address is unreachable.
dhaad-reply	Indicates a home agent address discovery reply message.

dhaad-request	Indicates a home agent address discovery request message.
echo-reply	Indicates an echo reply message.
echo-request	Indicates an echo request message.
header	Indicates an erroneous header field has been encountered.
hop-limit	Indicates the hop limit has been exceeded in packet transit.
mld-query	Indicates a mulitcast listener discovery query message.
mld-reduction	Indicates a multicast listener discovery reduction message.
mld-report	Indicates a multicast listener discovery report message.
mp-advertisement	Indicates a mobile prefix advertisement message.
mp-solicitation	Indicates a mobile prefix solicitation message.
nd-na	Indicates a Neighbor Discovery neighbor advertisement message.
nd-ns	Indicates an Neighbor Discovery neighbor solicitation message.
next-header	Indicates an unrecognized next header type was encountered.
no-admin	Indicates the destination is unreachable because communication with the destination is administratively prohibited.
no-route	Indicates the destination is unreachable because there is no route to the destination.
packet-too-big	Indicates the packet is too large.
parameter-option	Indicates that an unrecognized IPv6 option was encountered.
parameter-problem	Indicates there is a parameter problem with the packet.
port-unreachable	Indicates the destination is unreachable because the port is unreachable.

reassembly-timeout	Indicates that the fragment reassembly time limit has been exceeded.
redirect	Indicates a redirect message.
renum-command	Indicates a router renumbering command.
renum-result	Indicates a router renumbering result.
renum-seq-number	Indicates a router sequence number reset.
router-advertisement	Indicates a router advertisement message.
router-renumbering	Indicates a router renumbering for all codes.
router-solicitation	Indicates an router solicitation message.
time-exceeded	Indicates the time limit has been exceeded.
unreachable	Indicates the destination is unreachable.

<message type> Optional. Specifies the ICMP message type for matching ICMPv6 packets. When you specify an ICMP message type, you must also specify an ICMP message code. Message types range from **0** to **127** for error messages and from **128** to **255** for informational messages.

<message code> Optional. Specifies the ICMP message code for matching ICMPv6 packets. You must specify the message code when you specify the ICMP message type. Message code range is **0** to **255**.

Default Values

By default, all AOS IPv6 security features are disabled, and there are no configured IPv6 ACLs.

Command History

Release 18.1	Command was introduced.

Functional Notes

IPv6 ACLs are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv6 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv6 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** ACL is used to match packets (meeting the specified pattern) and allow them to enter the router system or specify that the feature using the ACL should apply its action to this traffic. A **deny** ACL advances AOS to the next ACP entry, discards the traffic, or specifies that the feature using the ACL should not apply its action to this traffic. AOS provides two types of IPv6 ACLs: standard and extended. Standard IPv6 ACLs match based on the source of the packet. Extended IPv6 ACLs match based on the source and destination of the packet.

ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Usage Examples

The following example creates an extended IPv6 ACL named **Untrustedv6** that permits any IPv6 traffic from a source with the same prefix bits as **2001:DB8:3F::/64**, headed to a destination of **2001:DB8:85A3::8A2E:0370:7334**, and an ICMPv6 message type of **echo-request**:

(config)**#ipv6 access-list extended Untrustedv6**
(config-ext6-nacl)**#permit icmpv6 2001:DB8:3F::/64 2001:DB8:85A3::8A2E:0370:7334 echo-request**

remark *<remark>*

Use the **remark** command to associate a descriptive tag with an extended Internet Protocol version 6 (IPv6) access control list (ACL). Use the **no** form of this command to remove the descriptive tag.

Syntax Description

<remark>	Specifies a descriptive tag for the ACL. Tags can be up to **80** alphanumeric characters enclosed in quotation marks. For example, “This list blocks all outbound Web traffic.”

Default Values

By default, all AOS IPv6 security features are disabled, and there are no configured IPv6 ACLs.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example specifies a description for extended IPv6 ACL **matchall**:

(config)**#ipv6 access-list extended matchall**
(config-ext6-nacl)**#remark “Allows all ip traffic from remote location.”**

deny *<source>*

Use the **deny** command to configure the Internet Protocol version 6 (IPv6) standard access control list (ACL) to deny specified packets entry into the routing system. Use the **no** form of this command to remove the permit permission from the ACL.

Syntax Description

<source>	Specifies the source used for IPv6 packet matching. Sources can be expressed in one of three ways: 1. Using the keyword **any** to match any IPv6 address. 2. Using **host** *<ipv6 address>* to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**. 3. Using *<ipv6 prefix/prefix-length>* to specify a source address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

Default Values

By default, all AOS IPv6 security features are disabled, and there are no configured IPv6 ACLs.

Command History

Release 18.1	Command was introduced.

Functional Notes

IPv6 ACLs are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv6 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv6 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** ACL is used to match packets (meeting the specified pattern) and allow them to enter the router system or specify that the feature using the ACL should apply its action to this traffic. A **deny** ACL advances AOS to the next ACP entry, discards the traffic, or specifies that the feature using the ACL should not apply its action to this traffic. AOS provides two types of IPv6 ACLs: standard and extended. Standard IPv6 ACLs match based on the source of the packet. Extended IPv6 ACLs match based on the source and destination of the packet.

ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Usage Examples

The following example creates an IPv6 ACL **Untrusted** to deny all traffic from a source with the same prefix bits as **2001:DB8:3F::/48**:

(config)**#ipv6 access-list standard Untrusted**
(config-std6-nacl)**#deny 2001:DB8:3F::/48**

permit <*source*>

Use the **permit** command to configure the Internet Protocol version 6 (IPv6) standard access control list (ACL) to permit specified packets entry into the routing system. Use the **no** form of this command to remove the permit permission from the ACL.

Syntax Description

<*source*>	Specifies the source used for IPv6 packet matching. Sources can be expressed in one of three ways: 1. Using the keyword **any** to match any IPv6 address. 2. Using **host** <*ipv6 address*> to specify a single host address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**. 3. Using <*ipv6 prefix/prefix-length*> to specify a source address to match. IPv6 prefixes should be expressed in colon hexadecimal format (**X:X::X/<Z>**). For example, **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.

Default Values

By default, all AOS IPv6 security features are disabled, and there are no configured IPv6 ACLs.

Command History

Release 18.1	Command was introduced.

Functional Notes

IPv6 ACLs are used as packet selectors by different AOS features (firewall, virtual private network (VPN), quality of service (QoS)); by themselves they do nothing. IPv6 ACLs are composed of an ordered list of entries with an implicit **deny all** at the end of each list. An IPv6 ACL entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** ACL is used to match packets (meeting the specified pattern) and allow them to enter the router system or specify that the feature using the ACL should apply its action to this traffic. A **deny** ACL advances AOS to the next ACP entry, discards the traffic, or specifies that the feature using the ACL should not apply its action to this traffic. AOS provides two types of IPv6 ACLs: standard and extended. Standard IPv6 ACLs match based on the source of the packet. Extended IPv6 ACLs match based on the source and destination of the packet.

ACLs are performed in order from the top of the list down. Generally, the most specific entries should be at the top and the more general at the bottom.

Usage Examples

The following example creates an IPv6 ACL **Trusted** to permit all traffic from a source with the same prefix bits as **2001:DB8:3F::/48**:

(config)**#ipv6 access-list standard Trusted**
(config-std6-nacl)**#permit 2001:DB8:3F::/48**

remark *<remark>*

Use the **remark** command to associate a descriptive tag with a standard Internet Protocol version 6 (IPv6) access control list (ACL). Use the **no** form of this command to remove the descriptive tag.

Syntax Description

<remark>	Specifies a descriptive tag for the ACL. Tags can be up to **80** alphanumeric characters enclosed in quotation marks. For example, “This list blocks all outbound Web traffic.”

Default Values

By default, all AOS IPv6 security features are disabled, and there are no configured IPv6 ACLs.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example specifies a description for standard IPv6 ACL **matchall**:

(config)**#ipv6 access-list standard matchall**
(config-std6-nacl)**#remark “Allows all ip traffic from remote location.”**

IPv6 Access Control Policy Command Set

An Internet Protocol version 6 (IPv6) access control policy (ACP) defines a policy class containing IPv6 access control lists (ACLs) in the Adtran Operating System (AOS) command line interface (CLI). The ACP is a named policy with multiple action entries.

IPv4 ACPs are also supported by AOS, but are explained separately in this document. Refer to *IPv4 Access Control Policy Command Set on page 4278* for more information on configuring IPv4 ACPs.

To create an IPv6 ACP and activate the IPv6 Access Control Policy Configuration mode, enter the **ipv6 policy-class** <*ipv6 acp name*> command at the Global Configuration mode prompt. For example:

```
>enable
#config terminal
(config)#ipv6 policy-class PRIVATE
(config-policy6-class)#
```

> NOTE *Configured IPv6 ACPs will only be active if the **ipv6 firewall** command has been entered at the Global Configuration mode prompt to enable the AOS IPv6 security features. All configuration parameters are valid, but no security data processing will be attempted unless the security features are enabled.*

> CAUTION *Before applying an IPv6 ACP to an interface, verify your Telnet or secure shell (SSH) connection will not be affected by the policy. If an IPv6 ACP is applied to the interface you are connecting through and it does not allow Telnet or SSH traffic, your connection will be lost.*

Technology Review

IPv6 ACPs and ACLs regulate traffic through the routed network. When designing your traffic flow configuration, it is important to keep the following in mind:

- An IPv6 ACL serves as a packet selector, defining exactly which packets should take the given action.
- An IPv6 ACP defines the action to take on the packets selected by the ACL.
- An IPv6 ACL is inactive until it is assigned to an active IPv6 ACP.
- An IPv6 ACP is inactive until it is assigned to an interface.

IPv6 Access Control Policies

IPv6 ACPs are used to allow or discard data for each physical interface. Each IPv6 ACP consists of an action (**allow**, **discard**) and a selector (IPv6 ACL). In a sense, the IPv6 ACPs answer the question, “What should I do?” while the IPv6 ACLs answer the question, “On which packets?”

When IPv6 packets are received on an interface with an IPv6 ACP applied, the ACP is used to determine whether the data is processed or discarded. Both IPv6 ACLs and ACPs are order dependent. When a packet is evaluated, the matching engine begins with the first entry in the list and progresses through the entries until it finds a match. The first entry that matches is executed. The IPv6 ACP has an implicit **discard** at the end of the list. Typically, the most specific entries should be at the top and the most general at the bottom.

IPv6 Access Control Lists

IPv6 ACLs are used as packet selectors by IPv6 ACPs. They must be assigned to an IPv6 ACP in order to be active.

IPv6 ACPs must use an IPv6 ACL. You cannot apply an IPv4 ACL to an IPv6 ACP, or vice versa. In addition, all IPv6 ACLs and IPv6 ACPs must have a different name than any configured IPv4 ACLs or ACPs.

IPv6 ACLs are composed of an ordered list of entries. Each entry contains two parts: an action (**permit** or **deny**) and a packet pattern. A **permit** action is used to allow packets (meeting the specified pattern) to enter the router system. A **deny** action is used to disregard packets (that do not match the pattern) and proceed to the next entry on the ACP. In IPv4, packets either match a **permit** or a deny entry in the ACL. In IPv6, if no match is found between the packet and the match criteria, a **miss** entry is passed to the application using the ACL. Depending on the application, the **miss** can be processed differently. For example, with typical IPv6 traffic, access groups treat a **miss** as a **deny**, effectually giving a **deny any any** at the end of the IPv6 ACL. For IPv6 Neighbor Discovery (ND) messages, however, access groups treat **miss** packets as a **permit,** resulting in a **permit** for ND before the end of the ACL.

The AOS provides two types of IPv6 ACLs: **standard** and **extended**. A **standard** IPv6 ACL allows source IPv6 address packet patterns only. An **extended** IPv6 ACL may specify patterns using most fields in the IPv6 header and the Transmission Control Protocol (TCP) header, User Datagram Protocol (UDP) header, or Internet Control Message Protocol version 6 (ICMPv6) message type or code.

Creating and Assigning IPv6 ACLs and ACPs

Creating IPv6 ACPs and ACLs to regulate traffic through the routed network is a four-step process:

Step 1:
Enable the security features of AOS using the **ipv6 firewall** command. Refer to the command *ipv6 firewall on page 1523* for more information.

Step 2:
Create an IPv6 ACP that uses a configured IPv6 ACL by issuing the **ipv6 policy-class** command. Refer to the command *ipv6 policy-class <ipv6 acp name> on page 1549* for more information. AOS IPv6 ACPs are used to allow or discard data for each physical interface. Each IPv6 ACP consists of an action (**allow**, **discard**) and a selector (IPv6 ACL). When IPv6 packets are received on an interface, the configured IPv6 ACPs are applied to determine whether the data will be processed or discarded. Up to 20 IPv6 ACPs can be created.

Step 3:
Create an IPv6 ACL to permit or deny specified IPv6 traffic by using either the **ipv6 access-list extended** or **ipv6 access-list standard** command. Standard IPv6 ACLs match based on the source IPv6 address of the packet. Extended IPv6 ACLs match based on the source and destination of the packet. Refer to the command *ipv6 access-list extended <ipv6 acl name> on page 1500* or the command *ipv6 access-list standard <ipv6 acl name> on page 1502* for more information. Sources can be expressed in one of three ways:

1. Using the keyword **any** to match any IPv6 address.
2. Using **host** <*ipv6 address*> to specify a single host address.
3. Using the <*ipv6-prefix/prefix-length*> to specify a source IPv6 address to match.

Step 4:
Apply the created IPv6 ACP to an interface. To assign an IPv6 ACP to an interface, enter the interface configuration mode for the desired interface and enter **ipv6 access-policy** <*ipv6 acp name*>. The following example assigns IPv6 ACP **UNTRUSTED** to the Ethernet 0/1 interface:

(config)**#interface ethernet 0/1**
(config-eth 0/1)**#ipv6 access-policy UNTRUSTED**

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
exit on page 83
interface on page 84

All other commands for this command set are described in this section in alphabetical order.

allow list on page 4329
allow reverse list on page 4331
discard list on page 4333

allow list

Use the **allow list** command to specify an Internet Protocol version 6 (IPv6) access control list (ACL) to determine which packets are allowed to enter the interface to which the IPv6 access control policy (ACP) is assigned, and create a firewall association in the IPv6 firewall. All associations created by the **allow list** command are subject to the built-in firewall timers. Variations of this command include:

allow list <*ipv6 acl name*>
allow list <*ipv6 acl name*> **policy** <*ipv6 acp name*>
allow list <*ipv6 acl name*> **policy** <*ipv6 acp name*> **stateless**
allow list <*ipv6 acl name*> **self**
allow list <*ipv6 acl name*> **self stateless**
allow list <*ipv6 acl name*> **stateless**

Syntax Description

<*ipv6 acl name*>	Specifies the IPv6 ACL against which to check traffic before allowing packets to enter the interface. All packets not matched by the IPv6 ACL will be processed by the next IPv6 ACP entry or implicitly discarded if no further ACP entries exist.
policy <*ipv6 acp name*>	Optional. Specifies the destination IPv6 ACP against which to match traffic. The IPv6 firewall attempts to match the specified ACP with the ACP that is applied to the packet's egress interface as determined by the routing table. If there is a match, the firewall attempts to match the ACL next. If there is no match, the firewall will process the packet based on the next ACP entry or implicitly discard it if no further ACP entries exist.
self	Optional. Allows packets to pass that are permitted by the IPv6 ACL and destined for any local interface on the unit. These packets are terminated by the unit and are not routed or forwarded to other destinations. Using the **self** keyword is helpful when opening up remote administrative access to the unit (Telnet, secure shell (SSH), Internet Control Message Protocol (ICMP)).
stateless	Optional. Enables bypassing of built-in firewall timers. A stateless policy session will time out, but because it does not perform stateful attack checking, a new policy session for existing connections can be easily recreated. Use for trusted traffic or traffic that the firewall is incorrectly blocking as a perceived attack.

Default Values

By default, all AOS IPv6 security features are disabled and there are no configured IPv6 ACP entries.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example configures the IPv6 ACP name **UNTRUSTED** to allow any traffic that matches the IPv6 ACL named **INWEB** to enter the router system:

(config)**#ipv6 policy-class UNTRUSTED**
(config-policy6-class)**#allow list INWEB**

allow reverse list

Use the **allow reverse list** command to specify an Internet Protocol version 6 (IPv6) access control list (ACL) to determine which packets are allowed to enter the interface to which the IPv6 access control policy (ACP) is assigned, and create a firewall association in the IPv6 firewall. The **allow reverse list** command is identical in function to the **allow list** command with the exception of the **reverse** keyword. The **reverse** keyword instructs the firewall to use the source information as the destination information and vice versa when attempting matches against the specified IPv6 ACL. Variations of this command include:

allow reverse list *<ipv6 acl name>*
allow reverse list *<ipv6 acl name>* **policy** *<ipv6 acp name>*
allow reverse list *<ipv6 acl name>* **policy** *<ipv6 acp name>* **stateless**
allow reverse list *<ipv6 acl name>* **self**
allow reverse list *<ipv6 acl name>* **self stateless**
allow reverse list *<ipv6 acl name>* **stateless**

Syntax Description

<ipv6 acl name>	Specifies the IPv6 ACL against which to check traffic before allowing packets to enter the interface. All packets not matched by the ACL will be processed by the next IPv6 ACP entry or implicitly discarded if no further ACP entries exist.
policy *<ipv6 acp name>*	Optional. Specifies the destination IPv6 ACP against which to match traffic. The firewall attempts to match the specified ACP with the ACP that is applied to the packet's egress interface as determined by the routing table. If there is a match, the firewall attempts to match the ACL next. If there is no match, the firewall will process the packet based on the next ACP entry or implicitly discard it if no further ACP entries exist.
self	Optional. Allows packets to pass that are permitted by the IPv6 ACL and destined for any local interface on the unit. These packets are terminated by the unit and are not routed or forwarded to other destinations. Using the **self** keyword is helpful when opening up remote administrative access to the unit (Telnet, secure shell (SSH), Internet Control Message Protocol (ICMP)).
stateless	Optional. Enables bypassing of built-in firewall timers. A stateless policy session will time out, but because it does not perform stateful attack checking, a new policy session for existing connections can be easily recreated. Use for trusted traffic or traffic that the firewall is incorrectly blocking as a perceived attack.

Default Values

By default, all AOS IPv6 security features are disabled and there are no configured IPv6 ACP entries.

Command History

Release 18.1	Command was introduced.

Usage Examples

The following example configures the IPv6 ACP named **UNTRUSTED** to allow any traffic that matches the IPv6 ACL named **INWEB** (with source and destination information reversed) to enter the router system:

(config)**#ipv6 policy-class UNTRUSTED**
(config-policy6-class)**#allow reverse list INWEB**

discard list

Use the **discard list** command to specify an Internet Protocol version 6 (IPv6) access control list (ACL) to determine which packets are discarded after entering the interface to which the IPv6 access control policy (ACP) is assigned. Packets matched by the IPv6 ACL will be discarded, and no further IPv6 ACP entries will be inspected. All packets not matched by the IPv6 ACL will be processed by the next ACP entry or implicitly discarded if no further ACP entries exist. Variations of this command include:

discard list <*ipv6 acl name*>
discard list <*ipv6 acl name*> **policy** <*ipv6 acp name*>
discard list <*ipv6 acl name*> **self**

Syntax Description

<*ipv6 acl name*>	Specifies the IPv6 ACL against which to check traffic before discarding the packet. All packets not matched by the IPv6 ACL will be processed by the next IPv6 ACP entry or implicitly discarded if no further ACP entries exist.
policy <*ipv6 acp name*>	Optional. Specifies the destination IPv6 ACP against which to match traffic. The firewall attempts to match the specified ACP with the ACP that is applied to the packet's egress interface as determined by the routing table. If there is a match, the firewall attempts to match the ACL next. If there is no match, the firewall will process the packet based on the next IPv6 ACP entry or implicitly discard it if no further ACP entries exist.
self	Optional. Discards packets that are matched by the IPv6 ACL and destined for any local interface on the unit. These packets, had they been allowed, would be terminated by the unit and not routed or forwarded to other destinations.

Default Values

By default, all AOS IPv6 security features are disabled and there are no configured IPv6 ACP entries.

Command History

Release 18.1	Command was introduced.

Functional Notes

AOS IPv6 ACPs are used to allow or discard IPv6 data for each physical interface. Each IPv6 ACP consists of an action (**allow**, **discard**) and a selector (IPv6 ACL). When IPv6 packets are received on an interface, the configured ACPs are applied to determine whether the data will be processed or discarded.

*An implicit discard exists at the end of every ACP. Specifying a **discard list** is unnecessary in most applications and should be used with caution. Specifying an empty ACL or a nonexistent ACL in an ACP will result in an implicit permit.*

Usage Examples

The following example configures the IPv6 ACP named **UNTRUSTED** to discard any traffic that matches the IPv6 ACL named **INWEB**:

(config)**#ipv6 policy-class UNTRUSTED**
(config-policy6-class)**#discard list INWEB**

DHCP COMMAND SETS

This section includes the following command sets:

DHCPv4 Pool Command Set

The Dynamic Host Configuration Protocol version 4 (DHCPv4) server pool is created using the **ip dhcp pool** command from the Global Configuration mode prompt. This command creates the DHCPv4 server pool and enters the pool's configuration mode. The server pool is used to define the information to be assigned to clients by the DHCPv4 server. The pool chosen to serve a specific client's request is determined by the current pool selection algorithm. To create a DHCPv4 server pool, and enter the pool's configuration mode, enter the command as follows:

```
>enable
#configure terminal
(config)#ip dhcp pool MyPool
(config-dhcp)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83
interface on page 84
shutdown on page 93

All other commands for this command set are described in this section in alphabetical order.

bootfile <name> on page 4338
client-identifier <identifier> on page 4339
client-name <name> on page 4340
default-router on page 4341
dns-server on page 4342
domain-name <name> on page 4343
hardware-address on page 4344
host <ipv4 address> on page 4346
lease <days> on page 4347
nap on page 4348
netbios-name-server on page 4349
netbios-node-type on page 4350
network on page 4351
next-server <ipv4 address> on page 4352
next-server-file <name> on page 4353
ntp-server <ipv4 address> on page 4354
option on page 4355

bootfile *<name>*

Use the **bootfile** command to specify a fully qualified directory-path name to a file located on a Trivial File Transfer Protocol (TFTP) server on the network. Some network devices use the file (the path sent to the Dynamic Host Configuration Protocol version 4 (DHCPv4) client in the DHCPOFFER message) for initial configuration. Use the **no** form of this command to remove a configured boot file.

Syntax Description

<name>	Specifies a fully qualified directory-path name to the file located on the network. If the file is located in the root directory of the TFTP server, enter the file name only.

Default Values

By default, there is no specified boot file.

Command History

Release 2.1	Command was introduced.

Functional Notes

RFC 2131 provides specifications for DHCPv4 servers to supply clients with information that allows the clients to exchange packets with other hosts on the network. DHCPv4 clients that do not store the correct boot software on an internal flash drive can receive a boot file from a TFTP server. The AOS DHCPv4 server can provide these devices with the address of the network TFTP server and the configuration file name. For example, some IP phones use this functionality to download the feature and key activation file. Use the command *tftp-server <name> on page 4356* to specify the IP address of the network TFTP server.

RFC 2131 includes provisions to allow DHCPv4 servers to utilize the 128 octets designated for the boot file directory-path for expanding the DHCPv4 options field. RFC 1533 outlines the available DHCPv4 variables for the options field. This process must be negotiated between client and server during the DHCPDISCOVER process and should only take place if the client specifies a small maxDHCPv4message size in the DHCPDISCOVER message.

Usage Examples

The following example specifies the location of a TFTP server on the local area network (LAN) at **10.10.0.4** and a boot file of **myconfig.cfg** (located in the TFTP server root directory) for the DHCPv4 pool **IP_Phones**:

(config)**#ip dhcp pool IP_Phones**
(config-dhcp)**#tftp sever 10.10.0.4**
(config-dhcp)**#bootfile myconfig.cfg**

client-identifier *<identifier>*

Use the **client-identifier** command to specify a unique identifier (in dotted hexadecimal notation) for a Dynamic Host Configuration Protocol version 4 (DHCPv4) client. Use the **no** form of this command to remove a configured client identifier.

Syntax Description

<identifier>	Specifies a client identifier using 7 to 28 hexadecimal characters with colon delimiters. Refer to the *Functional Notes* below for more information.

Default Values

No default values are necessary for this command.

Command History

Release 2.1	Command was introduced.

Functional Notes

DHCPv4 clients use client identifiers in place of hardware addresses. To create the client identifier, begin with the two-digit numerical code representing the media type and append the client's medium access control (MAC) address. For example, a Microsoft client with an Ethernet (01) MAC address d2:17:04:91:11:50 uses a client identifier of 01:d2:17:04:91:11:50.

Usage Examples

The following example specifies the client identifier for a Microsoft client with an Ethernet MAC address of **d217.0491.1150**:

(config)**#ip dhcp pool Microsoft_Clients**
(config-dhcp)**#client-identifier 01:d2:17:04:91:11:50**

client-name <*name*>

Use the **client-name** command to specify the name of a Dynamic Host Configuration Protocol version 4 (DHCPv4) client. Use the **no** form of this command to remove the configured client name.

Syntax Description

<*name*>	Identifies the DHCPv4 client (example is **client1**) using an alphanumeric string (up to 32 characters in length).

The specified client name should not contain the domain name.

Default Values

By default, there are no specified client names.

Command History

Release 2.1	Command was introduced.

Usage Examples

The following example specifies a client name of **myclient**:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#client-name myclient**

default-router

Use the **default-router** command to specify the default primary and secondary routers to use for the Dynamic Host Configuration Protocol version 4 (DHCPv4) client. Use the **no** form of this command to remove the configured router. Variations of this command include:

default-router *<ipv4 address>*
default-router *<ipv4 address> <secondary>*

Syntax Description

<ipv4 address>	Specifies the IPv4 address of the preferred router on the client's subnet.
<secondary>	Optional. Specifies the IPv4 address of the second preferred router on the client's subnet. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, there are no specified default routers.

Command History

Release 2.1	Command was introduced.

Functional Notes

When specifying a router to use as the primary/secondary preferred router, verify that the listed router is on the same subnet as the DHCPv4 client. AOS allows a designation for two routers, listed in order of precedence.

Usage Examples

The following example configures a default router with address **192.22.4.253** and a secondary router with address **192.22.4.254**:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#default-router 192.22.4.253 192.22.4.254**

dns-server

Use the **dns-server** command to specify the default Internet Protocol version 4 (IPv4) domain naming system (DNS) servers (up to four servers) to use for the Dynamic Host Configuration Protocol version 4 (DHCPv4) client. Use the **no** form of this command to remove the configured IPv4 DNS server. Variations of this command include:

dns-server <*ipv4 address*>
dns-server <*ipv4 address*> <*second*>
dns-server <*ipv4 address*> <*second*> <*third*>
dns-server <*ipv4 address*> <*second*> <*third*> <*fourth*>

Syntax Description

<*ipv4 address*>	Specifies the IPv4 address of the preferred DNS server on the network.
<*second*>	Optional. Specifies the IPv4 address of the second preferred DNS server on the network.
<*third*>	Optional. Specifies the IPv4 address of the third preferred DNS server on the network.
<*fourth*>	Optional. Specifies the IPv4 address of the fourth preferred DNS server on the network.
	IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, there are no specified default DNS servers.

Command History

Release 2.1	Command was introduced.
Release 4.1	Command was expanded to include the Internet key exchange (IKE) client configuration pool.
Release 17.3	Command was expanded to include a third and fourth IPv4 DNS server listing.

Usage Examples

The following example specifies a default IPv4 DNS server with address **192.72.3.254** and a secondary DNS server with address **192.100.4.253**:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#dns-server 192.72.3.254 192.100.4.253**

domain-name <*name*>

Use the **domain-name** command to specify the domain name for the Dynamic Host Configuration Protocol version 4 (DHCPv4) client. Use the **no** form of this command to remove the configured domain name.

Syntax Description

<*name*>	Identifies the DHCPv4 client (e.g., **adtran.com**) using an alphanumeric string (up to **32** characters in length).

Default Values

By default, there are no specified domain names.

Command History

Release 2.1	Command was introduced.

Usage Examples

The following example specifies a domain name of **adtran.com**:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#domain-name adtran.com**

hardware-address

Use the **hardware-address** command to specify the name of a Dynamic Host Configuration Protocol version 4 (DHCPv4) client. Use the **no** form of this command to remove the configured client name. Variations of this command include:

hardware-address <*mac address*>
hardware-address <*mac address*> <*type*>
hardware-address <*mac address*> **ethernet**
hardware-address <*mac address*> **ieee802**

Syntax Description

<*mac address*>	Specifies a valid 48-bit medium access control (MAC) address. MAC addresses should be expressed in the following format xx:xx:xx:xx:xx:xx (for example, **00:A0:C8:00:00:01**).	
<*type*>	Optional. Specifies one of the hardware types listed in RFC 1700. Valid range is **1** to **21**.	
	The valid hardware types are as follows:	
	1	10 Mb Ethernet
	2	Experimental 3 Mb Ethernet
	3	Amateur Radio AX.25
	4	Proteon ProNET Token Ring
	5	Chaos
	6	IEEE 802 Networks
	7	ARCNET
	8	Hyperchannel
	9	Lanstar
	10	Autonet Short Address
	11	LocalTalk
	12	LocalNet (IBM PCNet or SYTEK LocalNet)
	13	Ultra link
	14	SMDS
	15	Frame Relay
	16	Asynchronous Transfer Mode (ATM)
	17	High Level Data Link Control (HDLC)
	18	Fibre Channel
	19	Asynchronous Transfer Mode
	20	Serial Line
	21	Asynchronous Transfer Mode
ethernet	Optional. Specifies standard Ethernet networks.	
ieee802	Optional. Specifies IEEE 802 standard networks.	

Default Values

By default, the hardware address type is set to **10 Mbps Ethernet** (**1**).

Command History

Release 2.1	Command was introduced.

Usage Examples

The following example specifies an Ethernet client with a MAC address of **ae:11:54:60:99:10**:

```
(config)#ip dhcp pool MyPool
(config-dhcp)#hardware-address ae:11:54:60:99:10 ethernet
```

host *<ipv4 address>*

Use the **host** command to specify the Internet Protocol version 4 (IPv4) address and subnet mask for a manual binding to a Dynamic Host Configuration Protocol version 4 (DHCPv4) client. Use the **no** form of this command to remove the configured client address. Variations of this command include:

host <*ipv4 address*>
host <*ipv4 address*> <*subnet mask*>

Syntax Description

<*ipv4 address*>	Specifies the IPv4 address for a manual binding to a DHCPv4 client. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*subnet mask*>	Optional. Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**). If the subnet mask is left unspecified, the DHCPv4 server examines its address pools to obtain an appropriate mask. If no valid mask is found in the address pools, the DHCPv4 server uses the Class A, B, or C natural mask.

Default Values

By default, there are no specified host addresses.

Command History

Release 2.1	Command was introduced.

Usage Examples

The following examples show two different ways to specify a client with IPv4 address **12.200.5.99** and a 21-bit subnet mask:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#host 12.200.5.99 255.255.248.0**

or

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#host 12.200.5.99 /21**

lease *<days>*

Use the **lease** command to specify the duration of the lease for an Internet Protocol version 4 (IPv4) address assigned to a Dynamic Host Configuration Protocol version 4 (DHCPv4) client. Use the **no** form of this command to return to the default lease value. Variations of this command include:

lease *<days>*
lease *<days>* *<hours>*
lease *<days>* *<hours>* *<minutes>*

Syntax Description

<days>	Specifies the duration of the IPv4 address lease in days.
<hours>	Optional. Specifies the number of hours in a lease. You may only enter a value in the hours field if the days field is specified.
<minutes>	Optional. Specifies the number of minutes in a lease. You may only enter a value in the minutes field if the days and hours fields are specified.

Default Values

By default, an IPv4 address lease is **one** day.

Command History

Release 2.1	Command was introduced.

Usage Examples

The following example specifies a lease of **2** days:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#lease 2**

The following example specifies a lease of **1 hour**:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#lease 0 1**

The following example specifies a lease of **30 minutes**:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#lease 0 0 30**

nap

Use the **nap** command to enable network access protection (NAP) advertisements for the Dynamic Host Configuration Protocol version 4 (DHCPv4) server pools of AOS units that are operating as DHCPv4 servers. Use the **no** form of this command to disable NAP advertisements on the server pool.

Syntax Descriptions

No subcommands.

Default Values

By default, NAP advertisements are disabled on DHCPv4 server pools.

Command History

Release 17.8	Command was introduced.

Functional Notes

This command is used if your AOS unit is functioning as a DHCPv4 server and you want DHCPv4 server pools to advertise that they are NAP compatible because you are using desktop auditing. Desktop auditing is an AOS feature that collects NAP information through NAP messages sent in DHCPv4 messages between clients connected to the network and the network server.

Desktop auditing is configured by enabling the feature (using the command *desktop-auditing dhcp on page 1257*) and by configuring filters to limit the output of the collected NAP information. Information is limited by specifying local desktop auditing policies. The configuration of these policies is outlined in *Desktop Auditing Local Policy Command Set on page 4395*. For more information about desktop auditing, refer to the *Configuring Desktop Auditing in AOS* configuration guide available online at https://supportcommunity.adtran.com.

Usage Examples

The following example enables NAP advertisements on the DHCPv4 server pool **MyPool**:

```
(config)#ip dhcp pool MyPool
(config-dhcp)#nap
```

netbios-name-server

Use the **netbios-name-server** command to specify the primary and secondary network basic input/output system (NetBIOS) Windows Internet Naming Service (WINS) name servers available for use by the Dynamic Host Configuration Protocol version 4 (DHCPv4) clients. Use the **no** form of this command to remove a configured NetBIOS name server. Variations of this command include:

netbios-name-server <*ipv4 address*>
netbios-name-server <*ipv4 address*> <*secondary*>

Syntax Description

<*ipv4 address*>	Specifies the IPv4 address of the preferred NetBIOS WINS name server on the network.
<*secondary*>	Optional. Specifies the IPv4 address of the second preferred NetBIOS WINS name server on the network. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, there are no configured NetBIOS WINS name servers.

Command History

Release 2.1	Command was introduced.

Usage Examples

The following example specifies a primary NetBIOS WINS name server with an IPv4 address of **172.45.6.99** and a secondary with an IPv4 address of **172.45.8.15**:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#netbios-name-server 172.45.6.99 172.45.8.15**

netbios-node-type

Use the **netbios-node-type** command to specify the type of network basic input/output system (NetBIOS) node used with Dynamic Host Configuration Protocol version 4 (DHCPv4) clients. Use the **no** form of this command to remove a configured NetBIOS node type. Variations of this command include:

netbios-node-type <*value*>
netbios-node-type b-node
netbios-node-type h-node
netbios-node-type m-node
netbios-node-type p-node

Syntax Description

<*value*>	Specifies the NetBIOS node type using the numerical value. Refer to the node types below for the corresponding numerical values.
b-node	Specifies the broadcast node. Numeric value is **1**.
h-node	Specifies the hybrid node (recommended). Numeric value is **8**.
m-node	Specifies the mixed node. Numeric value is **4**.
p-node	Specifies the peer-to-peer node. Numeric value is **2**.

Default Values

By default, the **netbios-node-type** is set to **h-node** (hybrid node, numeric value **8**).

Command History

Release 2.1	Command was introduced.

Usage Examples

The following example specifies a client's NetBIOS node type as **h-node**:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#netbios-node-type h-node**

Alternately, the following also specifies the client's NetBIOS node type as **h-node**:

(config-dhcp)**#netbios-node-type 8**

network

Use the **network** command to specify the subnet number and mask for an AOS Dynamic Host Configuration Protocol version 4 (DHCPv4) server address pool. Use the **no** form of this command to remove a configured subnet. Variations of this command include:

network <*ipv4 address*>
network <*ipv4 address*> <*subnet mask*>

Syntax Description

<*ipv4 address*>	Specifies the IPv4 address of the DHCPv4 address pool. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).
<*subnet mask*>	Optional. Specifies the subnet mask that corresponds to a range of IPv4 addresses (network) or a specific host. Subnet masks can be expressed in dotted decimal notation (for example, **255.255.255.0**) or as a prefix length (for example, **/24**). If the subnet mask is left unspecified, the DHCPv4 server uses the Class A, B, or C natural mask.

Default Values

By default, there are no configured DHCPv4 address pools.

Command History

Release 2.1	Command was introduced.

Usage Examples

The following examples show two different ways to configure an address pool subnet of **192.34.0.0** with a 16-bit subnet mask:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#network 192.34.0.0 255.255.0.0**

or

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#network 192.34.0.0 /16**

next-server *<ipv4 address>*

Use the **next-server** command to specify the Internet Protocol version 4 (IPv4) address presented in the server IPv4 address (SIADDR) field in the Bootstrap Protocol (BOOTP) header of the DHCPOFFER message. The next-server is generally the Trivial File Transfer Protocol (TFTP) server address that holds a boot file for the Dynamic Host Configuration Protocol version 4 (DHCPv4) client. Use the **no** form of this command to remove a configured next server.

Syntax Description

<ipv4 address>	Specifies the IPv4 address presented in the SIADDR field in the BOOTP header of the DHCPOFFER message.

Default Values

By default, no next server is defined.

Command History

Release 18.1	Command was introduced.

Functional Notes

This command specifies a different element of a DHCPOFFER message than that which is specified using the **tftp-server** command.

Usage Examples

The following example specifies the IPv4 address presented in the SIADDR field of the BOOTP header of the DHCPv4 offer packet:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#next-server 192.168.1.1**

next-server-file *<name>*

Use the **next-server-file** command to specify the file name presented in the boot file name field in the Bootstrap Protocol (BOOTP) header of the DHCPOFFER message. This file name is generally located on the next-server, the address of which is specified by the server Internet Protocol version 4 (IPv4) address (SIADDR) field presented in the BOOTP header. Use the **no** form of this command to remove a configured next server file.

Syntax Description

<file name>	Specifies the name of the file presented in the BOOTP header.

Default Values

By default, no next server file is configured.

Command History

Release 18.1	Command was introduced.

Functional Notes

This command specifies a different element of a DHCPOFFER message than that which is specified using the **bootfile** command.

Usage Examples

The following example specifies **test.cfg** as the file presented in the BOOTP header:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#next-server-file test.cfg**

ntp-server *<ipv4 address>*

Use the **ntp-server** command to specify the name of the Network Time Protocol (NTP) server published to the Dynamic Host Control Protocol version 4 (DHCPv4) client. Use the **no** form of this command to remove a defined NTP server.

Syntax Description

<ipv4 address>	Specifies the IPv4 address of the NTP server. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no NTP server is defined.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example specifies the IPv4 address of the NTP server:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#ntp-server 192.168.1.1**

option

Use the **option** command to describe a generic Dynamic Host Configuration Protocol version 4 (DHCPv4) option to be published to the client. The user can specify any number of generic options to be published to the client. Use the **no** form of this command to return to the default value. Variations of this command include:

option <*number*> **ascii** <*string*>
option <*number*> **hex** <*hexbytes*>
option <*number*> **ip** <*ipv4 address*>

Syntax Description

<*number*>	Specifies the value of the generic DHCPv4 option published to the client. Range is **0** to **255**.
ascii <*string*>	Specifies the DHCPv4 option information in simple text (ASCII) with a string of up to **256** characters.
hex <*hexbytes*>	Specifies the DHCPv4 option information as a hexadecimal number of up to **128** digits. This option requires an even number of digits.
ip <*ipv4 address*>	Specifies the DHCPv4 option information as an IPv4 address. IPv4 addresses should be expressed in dotted decimal notation (for example, **10.10.10.1**).

Default Values

By default, no DHCPv4 options are configured.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example publishes DHCPv4 options to the client:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#option 100 ascii ascii_value**
(config-dhcp)**#option 101 hex AB458E80**
(config-dhcp)**#option 102 ip 192.168.1.1**

tftp-server *<name>*

Use the **tftp-server** command to specify the Internet Protocol version 4 (IPv4) address or IPv4 domain naming system (DNS) name of the Trivial File Transfer Protocol (TFTP) server published to the client. Use the **no** form of this command to remove a defined TFTP server.

Syntax Description

<name>	Specifies the IPv4 DNS name or dotted decimal notation IPv4 address of the server.

Default Values

By default, no TFTP server is defined.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example specifies the IPv4 address of the TFTP server:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#tftp-server 192.168.1.1**

The following example specifies the DNS name of the TFTP server:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#tftp-server MyServer.adtran.com**

timezone-offset <*value*>

Use the **timezone-offset** command to specify the time zone adjustment (in hours) published to the Dynamic Host Control Protocol version 4 (DHCPv4) client. Use the **no** form of this command to remove a time zone offset.

Syntax Description

<*value*>	Specifies the time zone adjustment (in hours) published to the client. Use an integer from **-12** to **12** hours.

Default Values

No default values are necessary for this command.

Command History

Release 9.1	Command was introduced.

Usage Examples

The following example sets the time zone adjustment for the client to **-3** hours. For example, if the server time is configured for Eastern time and the client is configured for Pacific time, you can set the client time zone adjustment to -3 hours:

(config)**#ip dhcp pool MyPool**
(config-dhcp)**#timezone-offset -3**

vrf *<name>*

Use the **vrf** command to associate a Dynamic Host Configuration Protocol version 4 (DHCPv4) address pool with a specific virtual routing and forwarding (VRF) instance. An address pool can only be assigned to one VRF instance, but a VRF instance can have multiple address pools providing addresses for it. Use the **no** form of this command to remove the association with the named VRF instance and assign the address pool to the default (unnamed) VRF instance.

Keep in mind that associating a DHCPv4 address pool with a nondefault VRF instance will clear all previously configured settings for the address pool.

Syntax Description

<name>	Specifies the name of the VRF instance to associate with the DHCPv4 address pool.

Default Values

By default, DHCPv4 address pools are associated with the default unnamed VRF instance.

Command History

Release 17.1	Command was introduced.
Release 18.3	Command was added to Border Gateway Protocol (BGP) and Dynamic Host Control Protocol (DHCP) version 4 (DHCPv4) and version 6 (DHCPv6).
Release R11.2.0	Command was added to network monitoring

Functional Notes

VRF instances must be created first before a DHCPv4 address pool can be assigned. An address pool can only be assigned to one VRF instance, but multiple address pools can be assigned to the same VRF instance.

VRF instances on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the abovementioned commands without specifying a VRF instance will only affect the default unnamed VRF instance.

Usage Examples

The following example creates a DHCPv4 address pool named **PRIVATE** and assigns it to the VRF instance named **RED**:

(config)**#ip dhcp pool PRIVATE**
(config-dhcp)**#vrf RED**
WARNING!!! All settings for this pool have been removed
(config-dhcp)**#network 10.22.199.0 255.255.255.0**

DHCPv6 Pool Command Set

The Dynamic Host Configuration Protocol version 6 (DHCPv6) server pool is created using the **ipv6 dhcp pool** command from the Global Configuration mode prompt. This command creates the DHCPv6 server pool and enters the pool's configuration mode. The server pool is used to define the information to be assigned to clients by the DHCPv6 server. The pool chosen to serve a specific client's request is determined by the current pool selection algorithm, just as in DHCPv4. To create a DHCPv6 server pool, and enter the pool's configuration mode, enter the command as follows:

```
>enable
#configure terminal
(config)#ipv6 dhcp pool MyPool
(config-dhcpv6)#
```

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76
do on page 81
end on page 82
exit on page 83

All other commands for this command set are described in this section in alphabetical order.

address prefix

Use the **address prefix** command to specify an Internet Protocol version 6 (IPv6) address prefix from which the Dynamic Host Control Protocol version 6 (DHCPv6) server assigns addresses to requesting clients served by this server pool. Use the **no** form of this command to remove the IPv6 address prefix. Variations of this command include:

address prefix <*ipv6 prefix/prefix-length*>
address prefix <*ipv6 prefix/prefix-length*> **lifetime** <*valid lifetime*> <*preferred lifetime*>
address prefix <*ipv6 prefix/prefix-length*> **lifetime** <*valid lifetime*> **infinite**
address prefix <*ipv6 prefix/prefix-length*> **lifetime infinite** <*preferred lifetime*>
address prefix <*ipv6 prefix/prefix-length*> **lifetime infinite infinite**
address prefix <*prefix name*> <*ipv6 prefix/prefix-length*>
address prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime** <*valid lifetime*> <*preferred lifetime*>
address prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime** <*valid lifetime*> **infinite**
address prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime infinite** <*preferred lifetime*>
address prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime infinite infinite**
address prefix named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*>
address prefix named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime** <*valid lifetime*> <*preferred lifetime*>
address prefix named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime** <*valid lifetime*> **infinite**
address prefix named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime infinite** <*preferred lifetime*>
address prefix named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime infinite infinite**

Syntax Description

<*ipv6 prefix/prefix-length*>	Specifies the numerical value and length of the IPv6 address prefix. The prefix value is specified in colon hexadecimal format (**X:X::X/<Z>**), for example: **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
<*prefix name*>	Specifies the name of the variable that holds the service provider assigned value for the IPv6 address prefix. The IPv6 prefix cannot be a link-local address.
named-prefix	Optional. Specifies that the address is constructed using the value defined in the named prefix. If a named prefix is used, the lifetime values are determined by the named prefix's configuration and do not need to be specified with this command.
lifetime	Optional. Specifies the lifetime of the IPv6 address prefix in the DHCPv6 server pool.
<*valid lifetime*>	Specifies the value of the valid lifetime for the IPv6 address prefix. This value must be longer than the preferred lifetime value. Valid lifetime range is **0** to **4294967295** seconds, with a default value of **2592000** seconds.
<*preferred lifetime*>	Specifies the preferred lifetime for the IPv6 address prefix. This value must be shorter than the valid lifetime value. Valid preferred lifetime range is **0** to **4294967295** seconds, with a default value of **604800** seconds.

infinite	Specifies that the prefix does not age.

Default Values

By default, no IPv6 address prefix are specified or sent to the DHCPv6 client. By default, when using a named prefix with this command, the default lifetime values are those assigned by the delegating DHCPv6 server.

Command History

Release R10.1.0	Command was introduced.
Release R10.9.0	Command was expanded to include the **named-prefix** parameter.

Functional Notes

This command can be entered multiple times, once for each link IPv6 address. Up to 50 IPv6 prefixes can be entered.

Usage Examples

The following example specifies an IPv6 address prefix of **2001:DB8:3F::/64** is assigned to requesting DHCPv6 clients by the server pool. This IPv6 address prefix is configured with **infinite** valid and preferred lifetimes.

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#address prefix 2001:DB8:3F::/64 infinite infinite**

bootfile *<url>*

Use the **bootfile** command to specify a boot file uniform resource locator (URL) that will be supplied to requesting Dynamic Host Control Protocol version 6 (DHCPv6) clients served by this DHCPv6 server pool. The URL is conveyed in the Bootfile URL option 59, and the requesting client can use the URL to load a boot file. Use the **no** form of this command to remove the URL from the DHCPv6 pool.

Syntax Description

<url>	Specifies the transfer protocol, the location, and the name of the boot file to be transferred to the DHCPv6 client. URLs are specified in a valid string of up to **512** characters in the following format: **protocol://path/filename.ext**.

Default Values

By default, no boot file URL is specified or sent to requesting DHCPv6 clients.

Command History

Release 18.3	Command was introduced.

Functional Notes

DHCPv6 is the Internet Protocol version 6 (IPv6) version of DHCPv4 (which works with IPv4). In DHCPv4, the Trivial File Transfer Protocol (TFTP) protocol is used, in conjunction with a name in a directory path, to specify which boot file should be used by requesting DHCP clients. In DHCPv6, however, a URL is used to specify a file location and transfer protocol for the boot file used by DHCPv6 clients.

Usage Examples

The following example specifies the URL **FTP://hostname/ftpshared/folder/filename1.ext** for requesting DHCPv6 clients:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#bootfile FTP://hostname/ftpshared/folder/filename1.ext**

client-identifier

Use the **client-identifier** command to specify the Dynamic Host Control Protocol version 6 (DHCPv6) client ID (DUID) that represents a single client and, together with the identity association identifier (IAID), identifies a single interface on a single DHCPv6 client. Use the **no** form of this command to remove the DUID from the DHCPv6 server pool. Variations of this command include:

client-identifier <*client DUID*>
client-identifier <*client DUID*> <*IAID*>

Syntax Description

<*client DUID*>	Specifies the DUID of the client to be matched. The DUID is expressed as a hexadecimal value.
<*IAID*>	Optional. Specifies a hexadecimal value that represents the IAID expected in the DHCPv6 client request. This option is useful if the client has more than one interface requesting DHCPv6 information, and specific information is required for each interface.

Default Values

By default, no DHCPv6 DUID is specified.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

The value specified when using this command is used to allow a single device, or interface, to match the DHCPv6 server pool and is used as part of the automatic pool selection algorithm that matches DHCPv6 client requests to the best server pool from which to assign information to the client. When specifying this command, you should remember that a specified DUID can be present in one DHCPv6 server pool only. You can, however, create multiple DUIDs by using multiple instances of this command. Each ID is created and deleted individually. Up to 50 IDs can be created on a single DHCPv6 server pool.

Usage Examples

The following example creates the client ID (the DUID) **F2A4C9** for the requesting DHCPv6 client:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#client-identifier F2A4C9**

dns-server *<ipv6 address>*

Use the **dns-server** command to specify the Internet Protocol version 6 (IPv6) address of a domain naming system (DNS) server supplied to Dynamic Host Control Protocol version 6 (DHCPv6) requesting clients for this DHCPv6 server pool. Use the **no** version of this command to remove the DNS server address from the pool. If the **no** version of this command is entered without specifying an IPv6 address, all DNS server addresses are removed from the pool.

Syntax Description

<ipv6 address>	Specifies the IPv6 address of the DNS server for requesting DHCPv6 clients. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **20012:DB8:1::1**. Up to **50** DNS server addresses can be entered.

Default Values

By default, no DNS server address is specified or sent to the requesting DHCPv6 client.

Command History

Release 18.3	Command was introduced.

Functional Notes

Multiple DNS server addresses can be entered by using multiple instances of this command. Each address is added or deleted individually. Up to **50** DNS server addresses can be entered. These addresses are assigned in the order they are entered. If the **no** version of this command is entered without specifying an IPv6 address, all DNS server addresses are removed from the DHCPv6 pool.

Usage Examples

The following example adds a DNS server address to the DHCPv6 server pool:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#dns-server 2001:DB8:1::1**

domain-name <*name*>

Use the **domain-name** command to specify a domain name suffix to be supplied to requesting Dynamic Host Control Protocol version 6 (DHCPv6) clients served by this DHCPv6 server pool. Use the **no** version of this command to remove the domain name from the pool. If the **no** version of this command is entered without specifying a domain name, all domain names are removed from the pool.

Syntax Description

<*name*>	Specifies the domain name suffix supplied to requesting DHCPv6 clients. Domain names are specified in ASCII text of up to **245** characters, and are typically a domain name suffix the client uses to fully quality host names.

Default Values

By default, no domain names are specified or sent to the requesting DHCPv6 client.

Command History

Release 18.3	Command was introduced.

Functional Notes

Multiple domain names can be entered using multiple instances of this command. Each name is added or deleted individually. Up to **50** domain names can be entered. These names are assigned in the order they are entered. If the **no** version of this command is entered without specifying a domain name, all domain names are removed from the pool.

Usage Examples

The following example adds the domain name **Name1** to the DHCPv6 pool for requesting DHCPv6 clients:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#doman-name Name1**

host client-identifier

Use the **host client-identifier** command to create a Dynamic Host Control Protocol version 6 (DHCPv6) host entry within the DHCPv6 server pool. This command creates a host entry in the server pool, and enters the DHCPv6 Host Configuration mode. The command also specifies the manual binding of a set of information to a single client as identified by a DHCPv6 client ID (DUID). Use the **no** form of this command to remove the DUID from the server pool. Variations of this command include:

host client-identifier <*client DUID*>
host client-identifier <*client DUID*> <*IAID*>

Syntax Description

<*client DUID*>	Specifies the DUID of the client to be matched as a DHCPv6 host. The DUID is expressed as a hexadecimal value.
<*IAID*>	Optional. Specifies a hexadecimal value that represents the IAID expected in the DHCPv6 client request.

Default Values

By default, no host DUID is specified.

Command History

Release R10.1.0	Command was introduced.

Functional Notes

The value specified by this command is used to allow a single device, or interface, to match the DHCPv6 server pool and is used as part of the automatic pool selection algorithm that matches DHCPv6 client requests to the best pool from which to assign information to the client.

Using this command also enters the DHCPv6 Host Configuration mode. From the Host Configuration mode, you can specify Internet Protocol version 6 (IPv6) address and hostname bindings for a single DHCPv6 client. For more information about the DHCPv6 Host Configuration mode, refer to *DHCPv6 Server Pool Host Command Set on page 4383*.

Usage Examples

The following example creates a DHCPv6 host DUID of **F2A4C9** and enters the DHCPv6 Host Configuration mode:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#host client-identifier F2A4C9**
(config-dhcpv6-host)#

import

Use the **import** command to instruct the Dynamic Host Control Protocol version 6 (DHCPv6) server to import the values of certain information from the global information pool when serving a DHCPv6 client request. These parameters are served to DHCPv6 clients using this server pool as if their values had been configured locally in the pool. Use the **no** form of this command to disable the importation of the specified information. If no parameters are specified when the **no** version of this command is issued, then all imported parameters are removed from the pool's configuration. Variations of this command include:

import dns-server
import domain-name
import ntp
import timezone

Syntax Description

dns-server	Specifies that domain naming system (DNS) server options are imported.
domain-name	Specifies that domain name options are imported.
ntp	Specifies that Network Time Protocol (NTP) options are imported.
timezone	Specifies that time zone database information is imported.

Default Values

By default, no information is imported into the DHCPv6 server pool.

Command History

Release 18.3	Command was introduced.

Functional Notes

The parameters imported from the global information pool are served to DHCPv6 clients using this server pool as if their values had been configured locally in the pool. If the imported values do not exist in the global information pool, the respective value in the importing pool behaves as if it is not configured. Once a value exists in the global configuration, the respective value in the importing pool is initialized and can be used. These options can also be configured locally using the commands *client-identifier on page 4364*, *domain-name <name> on page 4366*, *ntp address <ipv6 address> on page 4371*, *ntp domain-name <name> on page 4372*, and *timezone on page 4379*.

This command can be issued multiple times to import a separate parameter each time. If no parameters are specified when the **no** version of the command is issued, then all imported parameters are removed from the DHCPv6 pool's configuration.

Usage Examples

The following examples enables the importation of DNS server information to the DHCPv6 server pool:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#import dns-server**

information refresh

Use the **information refresh** command to enable the Dynamic Host Control Protocol version 6 (DHCPv6) server to send the information refresh value to requesting clients served by this DHCPv6 pool when using the stateless exchange option for configuration information. This command also specifies the information refresh rate. Use the **no** form of this command to return the refresh rate to the default value. Variations of this command include:

information refresh infinite
information refresh <*days*>
information refresh <*days*> <*hours*>
information refresh <*days*> <*hours*> <*minutes*>

Syntax Description

infinite	Specifies that there is an infinite refresh time.
<*days*>	Specifies the number of days to wait before refreshing the assigned information. Valid range is **0** to **365** days.
<*hours*>	Optional. Specifies the number of hours to wait before refreshing the assigned information. Valid range is **0** to **23** hours.
<*minutes*>	Optional. Specifies the number of minutes to wait before refreshing the assigned information. Valid range is **0** to **59** minutes.

Default Values

By default, no information refresh time is set and the DHCPv6 client should refresh every **24** hours.

Command History

Release 18.3	Command was introduced.

Usage Examples

The following example changes the information refresh rate for clients using stateless DHCPv6 to acquire configuration information to every **4** days:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#information refresh 4**

The following example changes the information refresh rate for clients using stateless DHCPv6 to acquire configuration information every **6** days and **3** hours:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#information refresh 6 3**

The following example changes the information refresh rate for clients using stateless DHCPv6 to acquire configuration information every **20** days, **12** hours, and **30** minutes:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#information refresh 20 12 30**

link-address *<ipv6 prefix/prefix-length>*

Use the **link-address** command to specify an Internet Protocol version 6 (IPv6) prefix that the Dynamic Host Control Protocol version 6 (DHCPv6) sever can use to match a received interface or relay-forwarded client request to the server pool. Use the **no** version of this command to remove the link address form the server pool. If the **no** version of this command is entered without specifying an IPv6 prefix, all link address prefixes are removed from the pool.

Syntax Description

<ipv6 prefix/prefix-length>	Specifies the IPv6 prefix to use for matching a client request or received interface to the server pool. The prefix value is specified in colon hexadecimal format (**X:X::X/<Z>**), for example: **2001:DB8:3F::/64**.

Default Values

By default, no link addresses are specified in the DHCPv6 pool.

Command History

Release 18.3	Command was introduced.

Functional Notes

The IPv6 prefix value is only used as part of the automatic DHCPv6 pool selection that matches client requests to the pool from which to assign information to the client. The prefix is typically the prefix of the DHCPv6 relay agent's interface.

Multiple IPv6 prefixes can be entered using multiple instances of this command. Each prefix is added or deleted individually. Up to **50** IPv6 prefixes can be entered. If the **no** version of this command is entered without specifying a prefix, all link address prefixes are removed from the pool.

Usage Examples

The following example adds an IPv6 link address prefix to the DHCPv6 pool:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#link-address 2001:DB8:3F::/64**

ntp address *<ipv6 address>*

Use the **ntp address** command to specify the unicast Internet Protocol version 6 (IPv6) address, or a multicast group address, of a Network Time Protocol (NTP) server to be supplied to requesting Dynamic Host Control Protocol version 6 (DHCPv6) clients served by this DHCPv6 pool. Use the **no** form of this command to remove the server address from the pool. If no NTP server address is specified when using the **no** form of this command, all NTP server addresses are removed from the pool.

Syntax Description

<ipv6 address>	Specifies the unicast or multicast IPv6 address of the NTP server to be supplied to requesting DHCPv6 clients that use this DHCPv6 pool. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.

Default Values

By default, no NTP information is specified or sent to the DHCPv6 client.

Command History

Release 18.3	Command was introduced.

Functional Notes

Multiple NTP server addresses can be entered using multiple instances of this command. Each address is added or deleted individually. Up to **50** addresses can be entered. These addresses are assigned in the order they are entered. If the **no** version of this command is entered without specifying an address, all NTP server addresses are removed from the pool.

Usage Examples

The following example adds an NTP server address to the DHCPv6 pool:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#ntp address 2001:DB8:1::1**

ntp domain-name *<name>*

Use the **ntp domain-name** command to specify the domain name of a Network Time Protocol (NTP) server to be supplied to requesting Dynamic Host Control Protocol version 6 (DHCPv6) clients by this server pool. Use the **no** form of this command to remove the server domain name from the pool. If no server domain name is specified when using the **no** form of this command, all NTP server domain names are removed from the pool.

Syntax Description

<name>	Specifies the fully qualified domain name of an IPv6 NTP server.

Default Values

By default, no NTP information is specified or sent to the DHCPv6 client.

Command History

Release 18.3	Command was introduced.

Functional Notes

Multiple NTP domain names can be entered using multiple instances of this command. Each name is added or deleted individually. Up to **50** domain names can be entered. These names are assigned in the order they are entered. If the **no** version of this command is entered without specifying a domain name, all domain names are removed from the pool.

Usage Examples

The following example adds an NTP server domain name to the DHCPv6 pool:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#ntp domain-name Name1**

option

Use the **option** command to specify a generic Dynamic Host Control Protocol version 6 (DHCPv6) option to assign to clients using this DHCPv6 pool. Use the **no** form of this command to remove the option from the DHCPv6 pool. Variations of this command include:

option <*number*> **address** <*ipv6 address*>
option <*number*> **ascii** <*string*>
option <*number*> **hex** <*hexbytes*>

Syntax Description

<*number*>	Specifies the DHCPv6 option number. Valid range is **0** to **65535**.
address <*ipv6 address*>	Specifies the option value as an IPv6 address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
ascii <*string*>	Specifies the option in simple text (ASCII) with a string of up to **256** characters.
hex <*hexbytes*>	Specifies the option value as a hexadecimal number with up to **512** digits.

Default Values

By default, no DHCPv6 options are configured.

Command History

Release 18.3	Command was introduced.

Usage Examples

The following example specifies a generic DHCPv6 option for clients using this pool:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#option 35 address 2001:DB8:1::1**

prefix-delegation

Use the **prefix-delegation** command to enable Internet Protocol version 6 (IPv6) address prefix delegation from the Dynamic Host Control Protocol version 6 (DHCPv6) server that assigns addresses to requesting clients served by this server pool. Use the **no** form of this command to disable IPv6 address prefix delegation. Variations of this command include:

prefix-delegation <*ipv6 prefix/prefix-length*>
prefix-delegation <*ipv6 prefix/prefix-length*> **lifetime** <*valid lifetime*> <*preferred lifetime*>
prefix-delegation <*ipv6 prefix/prefix-length*> **lifetime** <*valid lifetime*> **infinite**
prefix-delegation <*ipv6 prefix/prefix-length*> **lifetime infinite** <*preferred lifetime*>
prefix-delegation <*ipv6 prefix/prefix-length*> **lifetime infinite infinite**
prefix-delegation named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*>
prefix-delegation named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime** <*valid lifetime*> <*preferred lifetime*>
prefix-delegation named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime** <*valid lifetime*> **infinite**
prefix-delegation named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime infinite** <*preferred lifetime*>
prefix-delegation named-prefix <*prefix name*> <*ipv6 prefix/prefix-length*> **lifetime infinite infinite**

Syntax Description

<*ipv6 prefix/prefix-length*>	Specifies the numerical value and length of the IPv6 address prefix. The prefix value is specified in colon hexadecimal format (**X:X::X/<Z>**), for example: **2001:DB8:3F::/64**. The prefix length (**<Z>**) is an integer with a value between **0** and **128**.
named-prefix <*prefix name*>	Optional. Specifies that the address is constructed using the value defined in the named prefix and the name of the variable that holds the service provider assigned value for the IPv6 address prefix. The IPv6 prefix cannot be a link-local address. If a named prefix is used, the lifetime values are determined by the named prefix's configuration and do not need to be specified with this command.
lifetime	Optional. Specifies the lifetime of the IPv6 address prefix in the DHCPv6 server pool.
<*valid lifetime*>	Specifies the value of the valid lifetime for the IPv6 address prefix. This value must be greater than the preferred lifetime value. Valid lifetime range is **0** to **4294967295** seconds, with a default value of **2592000** seconds.
<*preferred lifetime*>	Specifies the preferred lifetime for the IPv6 address prefix. This value must be lesse than the valid lifetime value. Valid preferred lifetime range is **0** to **4294967295** seconds, with a default value of **604800** seconds.
infinite	Specifies that the prefix does not age.

Default Values

By default, no IPv6 address prefixes are specified or sent to the DHCPv6 client. By default, when using a named prefix with this command, the default lifetime values are those assigned by the delegating DHCPv6 server.

Command History

Release R11.1.0	Command was introduced.

Usage Examples

The following example enables IPv6 address prefix delegation for requesting DHCPv6 clients served by the server pool. This IPv6 address prefix is configured with **infinite** valid and preferred lifetimes.

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#prefix-delegation 2001:DB8:3F::/64 infinite infinite**

sip address *<ipv6 address>*

Use the **sip address** command to specify the Internet Protocol version 6 (IPv6) address of a Session Initiation Protocol (SIP) server that is supplied to requesting Dynamic Host Control Protocol version 6 (DHCPv6) clients served by this pool. Use the **no** form of this command to remove the SIP server address from the pool. If no SIP server address is specified when using the **no** form of this command, then all SIP server addresses are removed from the pool.

Syntax Description

<ipv6 address>	Specifies the SIP server address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.

Default Values

By default, no SIP server is specified or sent to the requesting DHCPv6 client.

Command History

Release 18.3	Command was introduced.

Functional Notes

Multiple server addresses can be entered using multiple instances of this command. Each address is added or deleted individually. Up to **50** addresses can be entered. These addresses are assigned in the order they are entered. If the **no** version of this command is entered without specifying an address, all SIP server addresses are removed from the pool.

Usage Examples

The following example adds a SIP server address to the DHCPv6 pool:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#sip address 2001:DB8:1::1**

sip domain-name <*name*>

Use the **sip domain-name** command to specify a Session Initiation Protocol (SIP) server domain name to be supplied to requesting Dynamic Host Control Protocol version 6 (DHCPv6) clients served by this DHCPv6 pool. Use the **no** form of this command to remove the server domain name from the pool. If no server domain name is specified when using the **no** form of this command, then all SIP server domain names are removed from the pool.

Syntax Description

<*name*>	The fully qualified domain name (FQDN) of an IPv6 SIP server, entered in ASCII text of up to **256** characters.

Default Values

By default, no SIP server information is specified or sent to DHCPv6 clients.

Command History

Release 18.3	Command was introduced.

Functional Notes

Typically, the SIP server domain name is the domain name of the SIP outbound proxy server for the DHCPv6 client to use.

Multiple domain names can be entered using multiple instances of this command. Each name is added or deleted individually. Up to **50** domain names can be entered. These names are assigned in the order they are entered. If the **no** version of this command is entered without specifying a domain name, all domain names are removed from the pool.

Usage Examples

The following example adds a SIP server domain name to the DHCPv6 pool:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#sip domain-name Name1**

sntp-server *<ipv6 address>*

Use the **sntp-server** command to specify the unicast Internet Protocol version 6 (IPv6) address of a Simple Network Time Protocol (SNTP) server to be supplied to requesting Dynamic Host Control Protocol version 6 (DHCPv6) clients served by this pool. Use the **no** form of this command to remove the server address from the pool. If no server address is specified when using the **no** form of this command, all SNTP server addresses are removed from the pool.

Syntax Description

<ipv6 address>	Specifies the IPv6 address of the SNTP server. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.

Default Values

By default, no SNTP information is specified or sent to the DHCPv6 client.

Command History

Release 18.3	Command was introduced.

Functional Notes

Multiple SNTP server addresses can be entered using multiple instances of this command. Each address is added or deleted individually. Up to **50** addresses can be entered. These addresses are assigned in the order they are entered. If the **no** version of this command is entered without specifying an address, all addresses are removed from the pool.

Usage Examples

The following example adds an SNTP server to the DHCPv6 pool:

(config)**#ipv6 dhcp pool MyPool1**
(config-dhcpv6)**#sntp-server 2001:DB8:1::1**

timezone

Use the **timezone** command to specify the time zone information that is supplied to requesting Dynamic Host Control Protocol version 6 (DHCPv6) clients served by this DHCPv6 pool. Use the **no** form of this command to remove the time zone information. Variations of this command include:

timezone <*timezone*>
timezone <*tzdb string*>
timezone posix <*string*>

Syntax Description

<*timezone*>	Specifies the time zone using a predefined value. Enter **timezone ?** to display the available time zones and their associated cities.
<*tzdb string*>	Specifies a time zone string in standard time zone (TZ) database format (as defined in RFC 4833). TZ database strings are limited to **256** characters.
posix <*string*>	Specifies a time zone in POSIX form, using the following format: **EST5EDT4,M3.2.0/02:00,M11.1.0/02:00**.

Default Values

By default, no time zone information is specified.

Command History

Release 18.3	Command was introduced.

Usage Examples

The following example specifies a time zone for requesting DHCPv6 clients using TZ database format:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#timezone America\Chicago**

vendor-specific <*number*>

Use the **vendor-specific** command to specify a specific vendor option for the Dynamic Host Control Protocol version 6 (DHCPv6) pool and to enter the vendor-specific configuration mode. Use the **no** form of this command to remove the vendor-specific options or suboptions from the pool. Variations of this command include:

vendor-specific <*number*>

Additional subcommands are available once you have entered the vendor-specific DHCPv6 Pool Configuration mode:

suboption <*number*> **address** <*ipv6 address*>
suboption <*number*> **ascii** <*string*>
suboption <*number*> **hex** <*hexbytes*>

Syntax Description

vendor-specific <*number*>	Specifies the enterprise identifier of the vendor information you are entering. Valid range is **1** to **4294967295**.
suboption <*number*>	Specifies the vendor-specific option number for the suboption. Valid range is **0** to **65535**.
address <*ipv6 address*>	Specifies that the suboption value is an IPv6 address. IPv6 addresses should be expressed in colon hexadecimal format (**X:X:X:X::X**). For example, **2001:DB8:1::1**.
ascii <*string*>	Specifies that the suboption is expressed as a simple text ASCII string of up to **256** characters.
hex <*hexbytes*>	Specifies that the suboption is expressed as a hexadecimal number of up to **512** digits.

Default Values

By default, no vendor-specific options or suboptions are configured.

Command History

Release 18.3	Command was introduced.

Usage Examples

The following example configures a vendor-specific DHCPv6 pool entry, and configures a suboption for that entry:

(config)**#ipv6 dhcp pool MyPool**
(config-dhcpv6)**#vendor-specific 6**
(config-dhcpv6-vs)**#suboption 7 address 2001:DB8:1::1**

vrf *<name>*

Use the **vrf** command to associate a Dynamic Host Configuration Protocol version 6 (DHCPv4) server address pool with a specific virtual routing and forwarding (VRF) instance. An address pool can only be assigned to one VRF instance, but a VRF instance can have multiple address pools providing addresses for it. Use the **no** form of this command to remove the association with the named VRF instance and assign the address pool to the default (unnamed) VRF instance.

Keep in mind that associating a DHCPv6 address pool with a nondefault VRF instance will clear all previously configured settings for the address pool.

Syntax Description

<name>	Specifies the name of the VRF instance to associate with the DHCPv6 address pool.

Default Values

By default, DHCPv6 address pools are associated with the default unnamed VRF instance.

Command History

Release 17.1	Command was introduced.
Release 18.3	Command was added to Border Gateway Protocol (BGP) and Dynamic Host Control Protocol (DHCP) version 4 (DHCPv4) and version 6 (DHCPv6).
Release R11.2.0	Command was added to network monitoring.

Functional Notes

VRF instances must be created first before a DHCPv6 address pool can be assigned. An address pool can only be assigned to one VRF instance, but multiple address pools can be assigned to the same VRF instance.

VRF instances on AOS products allows a single physical router to be partitioned into multiple virtual routers. Each router instance has its own route table and interface assignments. Beginning with Release 16.1, all AOS routers supporting multiple VRF instances (multi-VRF) have an unnamed default VRF instance regardless of whether multi-VRF is configured. Therefore, executing the abovementioned commands without specifying a VRF instance will only affect the default unnamed VRF instance.

Usage Examples

The following example creates a DHCPv6 address pool named **PRIVATE** and assigns it to the VRF instance named **RED**:

(config)**#ipv6 dhcp pool PRIVATE**
(config-dhcpv6)**#vrf RED**
WARNING!!! All settings for this pool have been removed
(config-dhcpv6)**#network 10.22.199.0 255.255.255.0**

DHCPv6 Server Pool Host Command Set

In Dynamic Host Control Protocol version 6 (DHCPv6), you can create a DHCPv6 host entry within a DHCPv6 server pool by issuing the **host client-identifier** command from the DHCPv6 Server Pool Configuration mode. This command creates a host entry in the server pool and enters the DHCPv6 Server Pool Host Configuration mode. From this mode, you can specify an Internet Protocol version 6 (IPv6) address and additional host name bindings for a single DHCPv6 client.

To create a DHCPv6 host entry within a DHCPv6 server pool, enter the **host client-identifier** command from the DHCPv6 Server Pool Configuration mode as follows:

```
(config)#ipv6 dhcp pool MYPOOL
(config-dhcpv6)#host client-identifier F2A4C9
(config-dhcpv6-host)#
```

For more information about configuring DHCPv6, and DHCPv6 server pools, refer to the configuration guide *Configuring DHCPv6 in AOS* available online at http://supportforums.adtran.com and the *DHCPv6 Pool Command Set on page 4360* of this guide.

The following commands are common to multiple command sets and are covered in a centralized section of this guide. For more information, refer to the sections listed below:

cross-connect on page 76

All other commands for this command set are described in this section in alphabetical order.

address <ipv6 address> lifetime on page 4384
host client-identifier on page 4386
